Purpose: Aims of this longitudinal study were to determine whether and to what extent a disease-specific health status questionnaire correlates with generic health status questionnaires at 4 different time points in patients with advanced COPD; and to determine the correlation between the changes in these questionnaires during 1-year follow-up.

Methods: Demographic and clinical characteristics were assessed in 105 outpatients with advanced COPD. Disease-specific health status (Saint George’s Respiratory Questionnaire, SGRQ) and generic health status (EuroQol-5-Dimensions, EQ-SD) were measured at baseline. Agreement in direction of change was assessed.

Results: Eighty patients (80.0%) were included for analysis (61.9% male, age 65.7±9.2 yrs, FEV1 34.2 (13.7%) pred) SGRQ total score and EQ-SD index score, AqQol total score and SF-36 PCS score were moderately to strongly correlated (r = 0.49 ± 0.00). The correlation of the changes between SGRQ and EQ-SD, AqQol and SF-36 PCS and SF-36 Mental Component Summary measure (SF-36 MCS) score were weak or absent (r = 0.13 ± 0.27). The direction of changes in SGRQ agreed slightly with the direction of changes in EQ-SD, AqQol and SF-36 PCS score (Cohen’s Kappa = 0.11 ± 0.18, p<0.05).

Conclusions: Disease specific health status questionnaires and generic health status questionnaires should be used together to gain complete insight in health status and changes in health status over time in patients with advanced COPD.

P1466
Psychiatric comorbidity in COPD and its determinants
Mohammed Zidan 1, Rasha Daabis 1, Heba Essam 2, 1Chest Diseases Department, Alexandria Faculty of Medicine, Alexandria, Egypt; 2Psychiatry and Neurology Department, Alexandria Faculty of Medicine, Alexandria, Egypt

Background: Depression and anxiety are prevalent in patients with chronic obstructive pulmonary disease (COPD); however, their etiology and relationship to the clinical features of COPD are not well understood.

Objectives: To evaluate the prevalence of psychiatric comorbidity (depression and anxiety) in COPD patients and to examine possible associations with demographic and clinical characteristics as well as health-related quality of life of these patients.

Design and methods: A total of 100 clinically stable COPD patients answered the St. George’s Respiratory Questionnaire (SGRQ) (assessing HRQoL), the Hos-
pital Anxiety and Depression Scale (HADS), Modified Medical Research Council (MMRC) Dyspnea Scale. Socio-demographic information, lung function, and other clinical data were collected.

Results: The prevalence of depression was found to be 40%, while that of anxiety was 29%. Patients living alone, having a longer duration of COPD diagnosis, lower BMI and more severe disease (as measured by FEV1% of predicted) had more depressive and anxious symptoms. The significant independent predictors of both anxiety and depression were higher MMRC score and worse quality of life.

Conclusion: We found that patients with COPD had high prevalence of depressive and anxious symptoms. Clinical and physiologic measures were less important determinants of psychiatric comorbidities in COPD than dyspnea and quality-of-life.

Therefore, screening and treatment of these psychiatric comorbidities in patients with COPD may lead to significant improvements in patients’ quality of life.

P1465
Impact of a pulmonary rehabilitation program on psychopathology of patients diagnosed with COPD

Athanasios Tselios1,2, Dismissios Bratis1,2, Argyro Pachi1, Emilia Theodorakopoulou2, Silvia Dimiri1, Georgios Moussas1, Nikolaos Sialakas1, Nikolaos Tzanakos1,2,3

1Psychiatric Department, “Sotiria” General Hospital of Chest Diseases, Athens, Greece; 2Pulmonary Rehabilitation Centre, “Sotiria” General Hospital of Chest Diseases, Athens, Greece; 3Department of Thoracic Medicine, University of Crete Medical School, Heraklion, Crete, Greece

Introduction: Psychological comorbidities such as anxiety and depression are common in COPD. Recent studies suggest a decrease in both anxiety and depression in patients with COPD after participating in a rehabilitation program. However, there is insufficient literature on changes in general psychopathology after RP.

Aims and objectives: To examine the changes in general psychopathology of patients with COPD after participating in a rehabilitation program.

Methods: The participants were patients (80 men and 21 women) with pure COPD who attended a three-month RP. The patients' psychopathology was assessed at the start and by the end of the PR, using the Symptom Checklist-90-R (SCL-90-R), which is a self-report questionnaire widely used in both normal and distressed populations. In order to determine COPD severity a spirometric evaluation before and after bronchodilatation was performed.

Results: Means of anxiety and of FEV1% of predicted were 64.15±8.13 and 43.51±21.53, respectively. Statistically significant changes (Paired t test) were observed at the end of the PR on the following scales: somatisation (0.70 VS 0.45, p<0.01), obsessive-compulsive (0.75 VS 0.48, p<0.01), interpersonal sensitivity (0.44 VS 0.35, p<0.05), depression (0.81 VS 0.48, p<0.01), anxiety (0.63 VS 0.35, p<0.05), hostility (0.53 VS 0.31, p<0.01), phobic anxiety (0.33 VS 0.17, p<0.01), paranoid ideation (0.43 VS 0.33, p<0.05). However, there was no statistical difference regarding the psychosomatic scale (0.15 VS 0.13, p>0.05).

Conclusions: A pulmonary rehabilitation program may improve psychopathological symptoms, particularly those of the neurotic spectrum, of COPD patients.

P1468
Health status and coping skills of carers of patients receiving home oxygen therapy for respiratory diseases

Peter Frith1, Ruth Sladek, Mary Lasue1, Paul Caffarella2, Richard Woodman1, Tanya Eftf2, Tina Jones1, Debra Rowlett2, Paddy Phillips1

1Faculty of Health Sciences, Flinders University, Bedford Park, SA, Australia; 2Respiratory Medicine, Repatriation General Hospital, Daw Park, SA, Australia

Introduction: Carer burden is well-documented for a range of chronic diseases. Burdens for those who care for people with chronic respiratory diseases (CRD) requiring home oxygen therapy (HOT) have not been reported but would be expected to have a similarly high burden.

Methods: Consecutive patient-carer dyads were enrolled over three years from 3 metropolitan hospitals if the patient was receiving HOT for a CRD. Baseline demographic observations and validated questionnaires were collected for Carers: health-related quality of life with Short Form-36 (SF36); Self-Esteem (SE) and Mastery (MS) Scales; Anticipated & Received Social Support (ARSS) and Carer Overload (CO) Scales, and Experiences and Impacts of Fatigue Scale (ICFS).

Results: All measures were completed by all 197 carers enrolled. Score results are expressed as mean, SD. Most (68.5%) were female and married (88.3%).

Their mean age (67.12 yrs) was significantly lower than their patient (74.5±6 yrs) (p<0.001). Carer SF-36 dimension scores were similar to normative values for age and gender. They had high SE (43.05±8) and MS (60.9%), had no perceived overload (7.9; 2.5), and were not unduly fatigued.

Conclusions: In this population, patients receiving HOT have carers (mostly marital partners) who generally perceive little undue burden, either physically or emotionally.

Funded by an Australian NHMRC Project Grant.

P1469
Coping styles in patients with COPD before and after pulmonary rehabilitation

Ana-Stinikova1, Daisy J.A. Janssen2, Frits M.E. Franssen2, Martijn A. Spruit2, Emiel F.M. Wouters1,2,3, SUNDAY, SEPTEMBER 2ND 2012

1Department of Respiratory Medicine, Maastricht University Medical Centre+ (MUMC+), Maastricht, Netherlands; 2Program Development Centre, CHO+, Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 3CAPRI, Maastricht University, Maastricht, Netherlands

Background: Pulmonary rehabilitation (PR) improves physical and psychological symptoms in COPD patients. To date, it remains unknown whether coping styles change following comprehensive PR. This study assessed retrospectively coping styles in COPD patients before and after PR programme.

Methods: Coping styles were assessed in 303 COPD patients (53.1% men) before and after 36 PR sessions using the Utrecht Coping List (UCL). Additionally, lung function, St. George’s Respiratory Questionnaire (SGRQ), Hospital Anxiety and Depression Scale (HADS-A and HADS-D) and six-minute walking distance (6MWD) were recorded.

Results: Mean age was 62.4±8.4 yrs; FEV1; 47.9±19.5% pred; SGRQ total score 56.2±15.4 pts; 6MWD 441.6±112.2 m; HADS-A 7.4±4.2 pts and HADS-D 7.1±4.1 pts. Mean change scores following PR were SGRQ total score -6.3±12.9 pts; HADS-A -1.7±3.6 pts; HADS-D -1.6±3.7 pts (all p<0.001) and 6MWD 28.9±51.2 m (p>0.05). The level of active confronting coping style increased (p<0.05), while the levels of avoidance (p<0.05), passive reaction pattern and reassurring thoughts coping styles decreased following PR (both p<0.001). Palliative reaction, seeking social support and expressing emotions coping styles did not change (p>0.05).

Conclusions: Comprehensive PR results in significant change in coping styles of COPD patients. Further studies are needed to evaluate the outcome of interventions actively targeting coping style domains.

P1470
An evaluation of the needs of carers of people with COPD

Paul Caffarella1,2, Tanya Eftf1,2, Peter Frith1,2,3, Respiratory Medicine, Repatriation General Hospital, Adelaide, SA, Australia; 1Health Sciences, Medicine, Flinders University, Adelaide, SA, Australia

Introduction: Many COPD patients are dependent on carers. Whilst the role of caring can be very demanding, surprisingly little is known about the needs of carers of COPD patients and hence this was the main aim of this study.

Methods: 21 patient-carer dyads recruited from databases at Repatriation General Hospital completed questionnaires and carers attended focus group meetings.

Results: Carers (mean age 71.1, SD 9.8) completed the Short-Form 36 (SF36); Physical Component Score (PCS) 41.1, SD 11.4; Mental Component Score (MCS) 44.9, SD 9.2), and Hospital Anxiety and Depression scale (HADS: Anxiety 8.9, SD 3.3; Depression 5.1, SD 3.3). Patients (mean age 75.2, SD 7.6) completed the Chronic Respiratory Questionnaire (Dyspnoea 3.5, SD 1.2; Fatigue 3.5, SD 1.5; Emotional 4.3, SD 1.3; Mastery 4.5, SD 1.4, SF36 PCS 25.7, SD 7; MCS 47.1, SD 11.9) and HADS (Anxiety 7.5, SD 3.4; Depression 6.5, SD 4). The thematic analysis of focus group transcripts indicated that carers emphasised physical and emotional impacts of their duties and identified social and work-related handicap as consequences. Carers believed that physical and/or emotional problems (either theirs or their patient’s) as well as a lack of knowledge were significant barriers to their role. A lack of inclusion in patient treatment plans, particularly following hospital discharge, was also noted. Respite support, peer debriefing, counselling and respiratory disease education were identified as areas that would assist carers with their role.

Discussion: Carer burden, handicap, lack of inclusion and knowledge were identified as issues that remain under-supported. The findings suggest the potential value of carer recognition, support and upsilling in COPD treatment planning.
P1471 A self-management programme of activity coping and education (SPACE) for COPD: Patients perspective
Lindsay Apps1, Samantha Harrison1, Jo Williams1, Mick Steiner1, Mike Morgan1, Sally Singh1, NBR CLAIRC-LNR Pulmonary Rehabilitation Research Group, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; Health & Life Sciences, Coventry University, Coventry, United Kingdom

Introduction: We have developed a self-management programme ‘SPACE for COPD’ and as part of it’s wider evaluation a nested qualitative study was conducted exploring patient’s perspectives of self-management before and after completing the programme.

Method: Semi-structured interviews were carried out with participants randomised to ‘SPACE for COPD’ prior to starting SPACE and 6 weeks later. Interviews were transcribed verbatim and thematic analysis was performed by NVivo (Version 8). A third researcher analysed a sub-group of interviews to ensure agreement over themes.

Results: Four main themes describe patient’s beliefs and expectations prior to starting ‘SPACE for COPD’ - role of self-management, barriers to exercise, facilitators to exercise, role of healthcare professionals. Patients had differing perspectives of self-management and were focussed on maintaining current activity levels. All desired more knowledge about COPD. Analysis of follow-up interviews identified themes - changing perceptions, the impact of SPACE for COPD, barriers to exercise, facilitators to exercise, the manual as a motivator. The experience of using SPACE was positive and many described the motivating effect of the manual. Education was an important component of the intervention and self-management skills were demonstrated. At baseline patients anticipating positive results had been encouraged to initiate exercise and at follow-up positive results had been observed, this further reinforced exercise behaviour. Barriers to exercise identified at baseline remained at follow-up.

Conclusion: ‘SPACE for COPD’ has enabled patients to learn more about their condition and become more active.

P1472 Do illness beliefs predict depression and quality of life after pulmonary rehabilitation?
Natalie Zöckler1, Winfried Rief1, Nikolai Sterzel1, Kerstin Küh1, Klaus Kemm1, Department of Clinical Psychology, Philipps University of Marburg, Germany; 2Department of Pneumonous, Schön Klinik Berchtesgaden Land, Schönau am Königsee, Germany

Introduction: Several studies have demonstrated the relevance of illness beliefs for health-related outcomes in chronic diseases. Patients form beliefs about possible causes, controllability and consequences. These illness beliefs are linked to anxiety, depression, coping strategies. Aim: Aim of this study was to examine the role of subjective illness beliefs in chronic obstructive pulmonary disease (COPD) patients on later depression and health-related quality of life after pulmonary rehabilitation (PR).

Methods: 96 COPD inpatients (GOLD II/III; 56 female; M=61.3 yrs±7.8) were tested for measures such as exercise capacity (6MWD) and forced expiratory volume in one second (FEV1% pred.) before and after PR. Additionally, assessment of illness beliefs (Illness Perception Questionnaire-Revised (IPQ-R)), health-related quality of life (HRQL;SF36) and depressive symptoms (Hospital Anxiety and Depression Scale (HADS)) before and after rehabilitation were collected. Results: Biomedical variables showed a significant improvement after PR: 6MWD ±66.5m; p<0.01 (admission 294.11±636m and FEVI ±4.67±8.43% pred.; p<0.05 (baseline FEVI 33.52±12.53% pred.). Results of hierarchical multiple regression analyses, after controlling for demographic variables and illness severity, indicated that COPD-patients’ beliefs about their illness before PR predicted depressive symptoms (β=0.46; p<0.001) and health-related quality of life (β=0.29; p<0.05) after treatment.

Conclusion: Patients’ illness beliefs before PR strongly influence later health-related quality of life. COPD-patients may benefit from interventions aimed at changing maladaptive illness beliefs to improve outcome of treatment.

P1473 Evolution of functional capacity and health status 2 years after a pulmonary rehabilitation programme
Vanessa Matias1, Dalila Ferreira1, Ana Martins1, Isabel Matias2, Flávia Simões1, Pátima Rodrigues1, Unidade de Reabilitação Respiratória, Hospital Pulido Valda-Centro Hospitalar Lisboa Norte, Lisboa, Portugal; 2Serviço de Pneumologia, Hospital de Faro, EPE, Faro, Portugal

Background: Pulmonary rehabilitation programs (PRP) have been shown to improve exercise capacity and health status and to reduce dyspnoea and healthcare resource use, in patients (pts) with chronic lung disease. These benefits have been shown to last for up to 9 months, however appear to decline by 12 months. Aim: Evaluate functional exercise capacity and health status after PRP in pts followed in “respiratory failure day hospital”.

Methods: Retrospective study of pts integrated in a PRP. After PRP, pts who kept a physically active lifestyle (at least 3 walks of 30 minutes/week) were included in the active group (AG). The others were considered as control group (CG). Were evaluated demographic characteristics, pulmonary pathology, six-minute walk test (6MWT) and St’s George’s respiratory questionnaire (SGRQ).

Results: Thirty-two pts were included. 24 in the AG and 8 in the CG. 81% of the pts had chronic obstructive pulmonary disease, with mean FEV1 of 42%. Immediately after PRP, there was a significant improvement in the 6MWD and SGRQ global score, in both groups. After completing PRP, there was a decline in the mean 6MWD when evaluated at 6 months, 1 and 2 years as well as in SGRQ score. However, after 2 years, the AG continued to show an average improvement of 15m in the 6MWD and at least 4 points in SGRQ comparing with pre-PRP, although in the CG, there was a clinically significant decline in 6MWD (-34m) and SGRQ score (13 points).

Conclusion: Despite the progressive decrease of benefits after completing PRP in the AG, these are still significantly positive 2 years after training, which does not happen in the CG. Active lifestyle seems to contribute to maintain the benefits of PRP.

P1474 Health-related quality of life in hypercapnic COPD patients during an admission for acute exacerbation
Francesk Struk1,2, Hubert Kerstjens1,3, Gerrie Bladder1, Nicolle Cobben2, Marianne Zijnen1, Jeroen Aan1, Peter Wijkstra3,4, 1Department of Pulmonary Diseases/Home Mechanical Ventilation, University of Groningen, Groningen, Netherlands; 2Department of Pulmonary Diseases/Home Mechanical Ventilation, Maastricht University Medical Center, Maastricht, Netherlands; 3Department of Intensive Care/Home Mechanical Ventilation, Erasmus MC, University Medical Center, Rotterdam, Netherlands; 4Department of Pulmonary Diseases, Ambia Hospital, Breda, Netherlands;

GRIAC Research Institute, University of Groningen, University Medical Center Groningen, Netherlands

Introduction: Little is known about Health Related Quality of Life (HR-QoL) during an admission in COPD patients with chronic hypercapnic respiratory failure (CHRF) after an episode of ventilation for acute exacerbation. The Maugeri Respiratory Failure (MRF-28) and Severe Respiratory Insufficiency (SRI) questionnaires were specifically developed for patients with stable CHRF.

Methods: Hospitalized patients still hypercapnic > 48 hours after ending mechanical (invasive or non invasive) ventilation filled in the SRI, MRF-28 and Chronic Respiratory Questionnaire (CRQ), Groninger Activity Restriction Scale (GARS) and Hospital Anxiety and Depression Scale (HADS). Concurrent validity was evaluated by comparing both questionnaires with the CQ. Construct validity was determined by assessing correlations between the different domains of the MRF-28, SRI, CQ and both generic physical and psychological questionnaires measured during admission.

Results: N=163 COPD patients (67 men; age 63 yrs; FEV1 0.67L±0.26L). Total scores and all domains of MRF-28 and SRI correlated (p<0.01) with the CQ and with its respective domains. Physical domains of all 3 questionnaires correlated strongly with the GARS (r=0.77, 0.74 and 0.52, respectively) and psychological domains of the SRI and CRQ with the HADS (r=0.79 and 0.76).

Conclusions: This study shows that SRI and MRF-28 are valid questionnaires in hospitalized patients with CHRF who are still hypercapnic 48 hours after ending mechanical ventilation for an acute COPD exacerbation. As the SRI is more elaborate with also a psychological domain we recommend this questionnaire in this specific group of severe COPD patients.

P1475 Health related quality of life and family burden in ALS patients. Differences over time
Eleni Perantonis1, Dimitra Siopi2, Kalliopi Christoforatou1, Andreas Kosmas2, Evaggelia Serasli1, Vasileios Michailidis2, Venetia Tsara1, 12nd Pulmonary Clinical, GH G Papamikou, Thessaloniki, Greece

The aim of this study was to investigate the health related Quality of Life (HR-QoL) in ALS patients and the burden on their families over time.

Methods/Patients: The SF-36 was used for HR-QOL estimation in 15 ALS patients and the Family Burden Questionnaire for assessment of objective and subjective burden as well as adaptation strategies in 15 caregivers, with a 6 months interval. Demographic characteristics of all subjects and patients ALSFS were recorded.

Results: Patients were aged (64.4±11.4 years) with ALSFS 77.6±8.4. All SF-36 domains had low scores except for pain and no statistical difference was observed after 6 months. Moderate/severe burden was objectively recognized by 42.8% of caregivers in employment, 60% in social activities, 40% in finances and 64.3% in household management, although the subjective burden was lower in most domains. After 6 months the objective and subjective burden was almost consistent. A significant negative correlation was observed between caregivers’ subjective burden in social activities, employment, patient’s physical function (r=0.596, p<0.019) and social function=r=-0.905, p<0.013) respectively. Caregivers’ adaptation strategies changed over time in passivity (50% vs. 33.3%), ambivalence (66% vs. 60%), guilt (66.7% vs. 80%), resignation (16.7% vs. 26.7%), hopefulness (33.3 vs. 53.3%) and in reorientation of their life (33% vs. 26.7%). Hopefulness was significantly correlated with patients’ social function (r=0.684, p<0.001).

Conclusion: ALS patients had low QOL. Families experienced a considerable
amount of burden in all examined domains but also rather negative feelings which seem to replenish over time and re-organize their life to support the patient.

156. Lung transplantation: studies in candidates and recipients

P1476 Results of a phase 2b multi-center trial of ALN-RSV01 in respiratory syncytial virus (RSV)-infected lung transplant patients
Amy Simon1, Verena Karsten1, Jeff Cehelsky1, Shaly Shah1, Jared Gollob1, Rachel Abele1, Sarah Gossweiler1, John DeVincenzo2, Selim Arcay1, Michael Musk3, Ute Sommerwerk4, Jens Gottlieb4, 5 Research and Development, Ablynx Pharmaceuticals, Cambridge, MA, United States; 2Thoracic Medicine, St. Vincent’s Hospital, Darlinghurst, Australia; 3Pulmonary and Critical Care, University of Colorado Hospital, Denver, United States; 4Pediatics and Infectious Disease, University of Tennessee Health Science Center, Memphis, United States; 5Pulmonary, Columbia University Medical Center, New York, United States; 6Respiratory Medicine, Westdeutsches Langencentrum am Uniersitesklinikum, Essen, Germany; 7Respiratory Medicine, Medizinische Hochschule, Hannover, Germany

ALN-RSV01 is a small interfering RNA targeting RSV replication. A Phase 2a randomized controlled trial in 25 RSV-infected lung transplant patients undergoing nebulized ALN-RSV01 or PBO daily for 3 days was previously conducted in which ALN-RSV01 led to a significant decrease in new or progressive bronchiolitis obliterans syndrome (BOS) at Day 90 (p=0.027). We have now performed a Phase 2b multi-center, randomized, double-blind, PBO controlled trial in 87 RSV-infected lung transplant patients to examine the impact of ALN-RSV01 on the incidence of new or progressive BOS at Day 180. RSV positive patients were randomized (1:1) to receive nebulized ALN-RSV01 or PBO daily for 5 days, alongside the institution’s standard-of-care. Patients were prospectively stratified for: 1) days from symptom onset to treatment; and 2) pre-infection BOS grade. Of the 39 patients enrolled, 21 were RSV positive, of which 45 were randomized to receive ALN-RSV01 and 42 to receive PBO (intent-to-treat (ITT) population). Ten patients were without confirmed RSV by central laboratory testing, thus a total of 77 patients (ALN-RSV01, n=44; PBO, n=33) comprised the ITT population. Baseline viral load was balanced between both treatments. ALN-RSV01 was generally safe and well tolerated. There was a decrease in new or progressive BOS at Day 180 in ALN-RSV01-treated patients compared to PBO in the ITT population (13.6% vs. 30.3%, p=0.056), which was statistically significant by prospectively defined Last Observation Carried Forward (p=0.028) and Per-Protocol (p=0.025) analyses. ALN-RSV01 had a treatment effect of 54.6% in all of the pre-specified populations.

P1477 The impact of desensitization therapy prior to lung transplantation
Suneesh Nair1, Rahul Hassain2, Hammad Qureshi3, Harsh Seetharamraj4, Kyle Dawson5, Pawel Kolodziejski6, Amit Parulekar7, 1Dept. of Pulmonary and Critical Care, Baylor College of Medicine, Houston, TX, United States; 2Medicist J.C. Walter Jr. Transplant Center, The Methodist Hospital, Houston, TX, United States

Introduction: Limited data exists on the impact of allosensitization on wait time and waitlist mortality in lung transplantation. No published data exists on the impact of desensitization therapy in lung transplant patients.

Aim: Determine the impact of desensitization therapy on wait time and waitlist mortality.

Methods: We performed a retrospective cohort study based on chart review of all patients listed for lung transplant between 1/1/2007 and 12/31/2010 at The Methodist Hospital. Groups were compared by Chi square test. P-values of 0.05 were considered statistically significant.

Result: Excluding retransplant listings, 299 patients were listed for lung transplant. 30(10%) had panel reactive antibody (PRA) <25%, while 269 (90%) had PRA ≥25%. Median wait time was significantly longer in those with PRA ≥25% (181 days vs. 45 days, p<0.0001). Waitlist mortality was also significantly higher in those with PRA ≥25% (26.7% vs. 8.6%, p=0.0001). Of the patients with PRA ≥25%, 16 (53.3%) underwent desensitization with intravenous immunoglobulin and plasma exchange +/- rituximab. Of the patients undergoing desensitization therapy, 10 (62.5%) were transplanted, 4 died waiting (25%), and 2 (12.5%) are still waiting. Of the patients with PRA ≥25% that did not receive desensitization therapy, 7 (50%) were transplanted, 4 (28.6%) died waiting, and 3 (21.4%) are still waiting.

Conclusion: PRA ≥25% was associated with a longer wait time and higher waitlist mortality. Desensitization therapy did not improve waitlist time or waitlist mortality when compared to allosensitized patients that did not undergo desensitization. Study is limited by being a retrospective, single center study with low numbers of patients.

P1478 Multiple breath washout in bronchiolitis obliterans syndrome following paediatric lung transplantation
Paul Robinson1, Helen Spencer2, Paul Auora3, 1Department of Respiratory Medicine, The Children’s Hospital at Westmead, Sydney, NSW, Australia; 2Department of Cardiothoracic Transplantation, Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom

Aim: Bronchiolitis obliterans syndrome (BOS) is a significant cause of morbidity and mortality following lung transplantation. Lung Clearance Index (LCI) measured by multiple breath washout (MBW) detects early structural lung damage in other paediatric obstructive lung disease. The aim was to determine the pattern of LCI values in children with BOS.

Methods: Retrospective analysis of MBW and spirometry data from subjects transplanted between 2002-2010 (date of annual MBW testing introduction). BOS staging was defined using published “all age” reference equations. LCI in BOS 0, 0p and 1 were compared.

Results: 50(56%) subjects had MBW performed (n=162): mean (SD range) 3.1 (1.85-1.13) times over a mean (SD range) follow up 1069 (613; 196-2613) days. Abnormal LCI values (>1.75) were common post-transplant (63/144 tests, 55%). LCI was increased in subjects with BOS. All those with persistent LCI >10 (n=8) died from severe BOS. Two distinct BOS patterns were seen: gradual vs very rapid FEV1 decline. Despite infrequent testing, earlier LCI signal was seen in some (1/8) but not all 8 subjects (e.g. not those with rapid FEV1 decline).

Conclusion: LCI is frequently abnormal post lung transplantation. LCI is significantly elevated in BOS, and appears to increase with BOS severity. An early signal of subsequent outcome may exist but optimal frequency of testing is yet to be determined.

P1479 Assessment of the restrictive allograft syndrome in patients after lung transplantation
Vasiliki Bessi1, Bjorn E. Kleibriek1, Gerhard Weinreich1, Markus Kamler2, Helmut Teschl1, Ute Sommerwerk1, 1Department of Pneumology, Ruhrrlandklinik, West German Heart Center, University Hospital Essen, Germany; 2Department of Thoracic and Cardiovascular Surgery, West German Heart Center, University Hospital Essen, Germany

Background: Chronic lung allograft dysfunction (CLAD) is the leading cause of long term mortality after lung transplantation. The rare but constant finding of fibrotic changes has led to the hypothesis that bronchiolitis obliterans syndrome (BOS) is not the only manifestation of chronic rejection after lung transplantation.

Aims: The purpose of our study was to evaluate the recently reported criteria for the diagnosis of Restrictive Allograft Syndrome (RAS) in our post-lung transplantation patient population.

Methods: We retrospectively analyzed the lung function tests from 162 patients after lung transplantation from 2000 to 2011 with a conditional survival of 180 days. Established criteria for BOS were used for the definition of CLAD. RAS was defined as a detectable, irreversible decline of more than 10% of the best post-transplant total lung capacity (TLC). CT-scans were evaluated for the detection of possible causes for the TLC-decline.

Results: In our study 68 (42%) patients were diagnosed with CLAD, and 22 (14%) of these patients met the criteria for RAS after exclusion of 13 patients with other causes for a TLC-decline. Mean post-transplant survival was 2873 ± 318 days. Abnormal LCI values (≥1.5) were detected in 50/56 (89%) subjects had MBW performed (n=162): mean (SD: range) 3.1 (1.85-1.13) times over a mean (SD range) follow up 1069 (613: 196-2613) days. Abnormal LCI values (>1.75) were common post-transplant (63/144 tests, 55%). LCI was increased in subjects with BOS. All those with persistent LCI >10 (n=8) died from severe BOS. Two distinct BOS patterns were seen: gradual vs very rapid FEV1 decline. Despite infrequent testing, earlier LCI signal was seen in some (1/8) but not all 8 subjects (e.g. not those with rapid FEV1 decline).

Conclusion: LCI is frequently abnormal post lung transplantation. LCI is significantly elevated in BOS, and appears to increase with BOS severity. An early signal of subsequent outcome may exist but optimal frequency of testing is yet to be determined.
vival after lung transplantation and reduces health related quality of life (HRQOL). **Aims:** The study was performed to find parameters correlating with low exercise capacity of patients with advanced CLAD. **Methods:** In this single-center prospective study, all patients with advanced CLAD (FEV1 <50% baseline) in our out-patient clinic were screened between 1.7.2011 and 15.11.2011 by exercise capacity, HRQOL (using SF 36, St. George, HADS), body composition, blood gas analysis, pulmonary function testing, respiratory muscle function and chest x-ray. The patients with low exercise capacity (LEC-CLAD) were defined as 6MWT < 50% predicted or use of oxygen or wheelchair/rollator. Results: 319 of 785 patients (40%) had LEC-CLAD and 53 had the diagnosis of advanced CLAD. A single patient refused consent to this study. 52 patients were included. 19 needed oxygen or had a 6 min walk test (6 MWT) fewer than 50% predicted (LEC-CLAD). Patients with LEC-CLAD demonstrated lower forced vital capacity (FEV1 <50%) in terms of acute rejection (AR), lymphocytic bronchiolitis (LB), infections, BOS and survival. All 193 patients transplanted for emphysema between 1993-2011 and surviving more than 60 days post transplant, were included (53 SLTs(x singly) and 140 SLTS(double)). AB, LB and BOS are diagnosed according to the ISHLT criteria. Multivariate analyzes were done using SAS software. Patients with LEC-CLAD demonstrated a decrease in activity and social function. **Conclusion:** Advanced CLAD is an inhomogeneity cohort of patients showing different exercise tolerance of reduced lung function. We were able to demonstrate pronounced hypventilation in patients with worse toleration and pathologic respiratory muscle function.

Lung transplantation (LTx) is an accepted therapeutic option for patient with end-stage emphysema. These emphysema patients can be subdivided in blue blowers and pink puffers, although most patients have characteristics of both groups. BMI is an important tool in distinguishing these subgroups. A low BMI is associated with a poor nutritional status which may predict a poor outcome after LTx. We aimed to investigate the outcome of emphysema patients with a low pre-transplant BMI (<20) in terms of acute rejection (AR), lymphocytic bronchiolitis (LB), infections, BOS and survival. We observed: 193 patients transplanted for emphysema between 1993-2011 and surviving more than 60 days post transplant, were included (53 SLTs(x singly) and 140 SLTS(double)). AB, LB and BOS are diagnosed according to the ISHLT criteria. Multivariate analyzes were done using SAS software. Patients with a lower BMI (<20) had a significant better 10-years survival compared to patients with a BMI between 18-20 for the total population (p=0.01) (figure). Prevalence of BOS was significantly lower within the lower BMI group, independent from other covariates (table). There is a statistical association between the prevalence of BOS, infection and LB (table).

We conclude from this single centre observation that emphysema patients with a BMI below 20 have a better outcome in terms of BOS and mortality and this should therefore no longer be regarded as contra-indication for LTx.

P1482 Systemic oxygenation affects post-transplantation edema formation and pulmonary artery hypertension in an ex vivo animal model Sara Klein, Stefan Dhein, Luisa Bauer, Franziska Schlegel, Sven Lehmann, Markus Barten, Friedrich-Wilhelm Mohr, Hartmuth Bittner. Heart Center Leipzig, Clinic for Cardiac Surgery, Leipzig, Germany

**Introduction:** By using an ex vivo model of isolated perfused and ventilated rabbit lungs we investigated the influence of systemic oxygenation on pulmonary function during simulated transplantation. **Methods:** Lungs of New Zealand White rabbits were flush-perfused with Perfadex® Solution, followed by an ischemic storage for 4h on ice. Thereafter ventilation and reperfusion for 2h were continued to simulate a transplantation situation (oxygenated group, pulmonary artery pO2=120mmHg). In another series the perfusate inflow was gassed with nitrogen to simulate the typical situation with deoxygenated pulmonary artery blood and not reanastomized private vessels(deoxygenated group, pulmonary artery pO2=50mmHg). Hemodynamic and ventilatory parameters were continuously detected. **Results:** After 2h reperfusion time the oxygenated group showed a significant lower PAP and lung weight compared to the deoxygenated group (p<0.05). PAP and lung weight steadily increased after reestablishment of lung perfusion (PAP 8.78±0.89 to 11.5±1.06cmH2O; lung weight 22.1±1.32 to 35.4±4.23g). This development was significantly influenced by the intravascular pO2 (P ≤ 0.05 to 8.02±0.63cmH2O; lung weight 17.9±1.54 to 21.6±2.29g; p<0.05). **Conclusions:** Oxygenation of the lung perfusate during simulated transplantation attenuates post transplant edema formation and decreases pulmonary arterial hyperpenterosion. This suggests that systemic oxygenation may delay the surgical situation, revascularisation of bronchial arteries after lung transplantation might initiate effective impacts in the early phase after lung transplantation.

P1483 Extracorporeal life support (ECLS) as a bridge to lung transplantation (LTx) | David Ruttens, Toufan Bahrami1, Anna Reed2, Mohamed Amrani1, Prashant Mohite1, Ajay Moza1, Heike Krueger1, Martin Carby2, Andre Simon1. 1Department or Cardiothoracic Transplantation and Mechanical Circulatory Support, Harefield Hospital, Royal Brompton and Harefield NHS Foundation Trust, Harefield, Middlesex, United Kingdom; 2Department of Respiratory Medicine, Harefield Hospital, Royal Brompton and Harefield NHS Foundation Trust, Harefield, Middlesex, United Kingdom

**Purpose:** Death on the waiting list remains high in patients awaiting LTx. ECLS as a bridge may increase patient’s survival. We present our initial experience. **Materials and methods:** Between Feb. 2010 and Dec. 2011 100 patients underwent LTx at our institution. 7 (7%) recipients were supported with ECLS prior to LTx. Outcome, donor and recipient parameters were analysed. **Results:** Donor age was 24(20-47) (median [interquartile range]); gender – F/M: 5/2, cause of death: intrinsic hamorrhage 3, hypoxic brain injury 2, bacterial meningitis 2; duration of donor mechanical ventilation was 2(2;2) days; PaO2/FiO2 ratio: 63.6±58.15;69.45±1.5Kpa. One patient died during the support.

**Results:** ECLS as a bridge to LTx is a feasible option of treatment providing good early results. Longer weaning from mechanical ventilation, hospital and ICU LOS after transplantation should be expected.

P1484 Superior lung preservation with a polyethylene glycol based solution in a porcine lung transplant model | Anne Olland1, Arne Neynck1, Malika Benhamede1, Thomas Boogmans2, Albreka Stana1, Karin Elbay2, Shaharyar Wouters1, Geert Verleden1, Izzie Namer1, Dirk Van Raemdonck2,3. 1Laboratory for Experimental Thoracic Surgery, Catholic University Leuven, Leuven, Belgium; 2CNRS UMR 7237, UMR 7177, Strasbourg University, Strasbourg, France; 3Laboratory for Pneumology, University Hospital Gasthuisberg, Leuven, Belgium. *Biophysics and Nuclear Medicine Department, University Hospital, Strasbourg, France; 3Thoracic Surgery Department, University Hospital Gasthuisberg, Leuven, Belgium; 4Anesthesiology Department, University Hospital Gasthuisberg, Leuven, Belgium

**Objectives:** Scot15® is a low-K+ preservation solution including polyethylene glycol (PEG) as a colloid for protection of vascular endothelium during cold ischemia. PEG was previously demonstrated to have “immunomodulation” properties. The aim of this study was to assess whether these properties would be beneficial in a pig lung transplant model.

**Material:** Domestic pig donor lungs were flushed either with Scot15®[S;n=6] or Perfadex®[P;n=6] and stored on ice for 22 hours. The left lung was transplanted in a recipient animal observed during 6 hours after reperfusion. Pulmonary vascular resistance (PVR) and partial arterial oxygen tension (PaO2) were measured hourly. Lung biopsies were taken for HRMAS detection of the respective colloid in the lungs. Bronchoalveolar lavage (BAL) was taken to assess neutrophilic alveolar recruitment. At the end of reperfusion, wet to dry weight ratio (W/D) was measured as a marker of lung edema.

**Results:** HRMAS showed presence of PEG in the lungs in [S] before and during storage (8.78±0.43 to 8.02±0.63cmH2O; lung weight 17.9±1.54 to 21.6±2.29g; p<0.05).

**Conclusions:** Scot15® as a colloid for protection of vascular endothelium during cold ischemia.
The prevalence of SDB is high in lung transplant recipients, and sleep was associated with symptoms of sleepiness as measured by ESS. Interestingly, neither the occurrence of SDB nor the quality of body mass index was associated with less inflammatory reaction in lung grafts preserved with Scot15®.

**Patients and Methods:** Between March 2011 and February 2012 we included 28 clinically stable lung transplant recipients (16 men, time range after LTX 6±8.3 years, BMI: 26±8.3 kg/m² and FEV1 69±12 and 43±8 vessels/mm²), suggesting a role for denervation of the lung in the impairment of exercise capacity after bilateral lung transplantation.

**Results:** Age and body mass index (BMI) of men and women were similar (age: 56±9 years vs. 54±9 years, BMI: 26±3 kg/m² vs. 25±6 kg/m², n=30). The prevalence of acute rejection was observed by logistic regression analysis, even after adjustment for FEV1 and gender in multivariate analysis we found a statistically significant correlation between the exercise capacity and HCVR.

Conclusion: There is a remarkable difference in ventilatory response to carbon dioxide between male and female bilateral lung transplant recipients, suggesting a role for denervation of the lung in the impairment of exercise capacity after bilateral lung transplantation.

**Background:** Only few studies reported findings on CO2 rebreathing in long-term bilateral lung transplant recipients. Bilateral lung transplantation causes denervation of the donor lung. This might have an impact on control of breathing as measured by the hypercapnic ventilatory response (HCVR). The influence of gender on HCVR and the relation to exercise capacity is unknown yet.

**Objectives:** To study HCVR and the relation to exercise capacity after bilateral lung transplantation.

**Methods and patients:** Minute ventilation, respiratory rate and HCVR were studied in 24 bilateral lung transplant recipients (12 male). HCVR was measured according to the Read protocol. Exercise testing was performed to evaluate the maximum level of workload. This was expressed as percentage of the corresponding reference value.

**Results:** Age and body mass index (BMI) of men and women were similar (age: 56±9 years vs. 54±9 years, BMI: 26±3 kg/m² vs. 25±6 kg/m², n=30). The prevalence of acute rejection was observed by logistic regression analysis, even after adjustment for FEV1 and gender in multivariate analysis we found a statistically significant correlation between the exercise capacity and HCVR.

Conclusion: There is a remarkable difference in ventilatory response to carbon dioxide between male and female bilateral lung transplant recipients, suggesting a role for denervation of the lung in the impairment of exercise capacity after bilateral lung transplantation.
Progressive and irreversible fibroproliferative process leads to BOS. The presence of mesenchymal cells, the primary source of fibrotic cells, has been described in BAL fluid of LTR as predictive of BOS onset (Badri et al, 2011). CD44 cell surface glycoprotein has been found increasingly expressed by graft infiltrating lymphocytes, macrophages and AR fibroblasts with active OB. CD44 has been associated to an invasive fibroblast phenotype. Inhibition of mTOR, responsible of cell over-proliferation has been found effective in treating fibrotic process. Aim of this work is to assay CD44 expression in fibroblastoid cells derived from colony-forming units (CFU) of mesenchymal cells isolated from BAL of LTR patients with BOS. BOS 0p, 1 and 2 to evaluate its implication in fibrotic process. In addition, in the same cells expression of the active form of mTOR has been assayed to specifically target pharmacological treatment.

Results: BOS 1 and 2 patients showed moderate to strong expression of both CD44 and mTOR in 80% and weak in 20% BOS 0p subjects displayed moderate to high expression in 5% cells, weak signal in 60% and no detection in 35% cells. We also found that cells isolated from BOS 0p had a significantly \( p < 0.01 \), ANOVA lower proliferation rate compared to other cultured fibroblastoid cells. Conclusion: These results open new perspectives in the identification of a specific fibroblastoid phenotype linked to BOS grades and to target a therapeutic treatment.

P1491

Oxidized-polymers of Z-AT are associated with exaggerated pulmonary inflammation post lung transplantation

Sam Alam1, Karthik Santhanakrishnan2, Jas Parmar2, Ravi Mahadeva1.

Aim of this work is to assay CD44 expression in fibroblastoid cells derived from colony-forming units (CFU) of mesenchymal cells isolated from BAL of LTR patients with BOS. BOS 0p, 1 and 2 to evaluate its implication in fibrotic process. In addition, in the same cells expression of the active form of mTOR has been assayed to specifically target pharmacological treatment.

Results: BOS 1 and 2 patients showed moderate to strong expression of both CD44 and mTOR in 80% and weak in 20% BOS 0p subjects displayed moderate to high expression in 5% cells, weak signal in 60% and no detection in 35% cells. We also found that cells isolated from BOS 0p had a significantly \( p < 0.01 \), ANOVA lower proliferation rate compared to other cultured fibroblastoid cells. Conclusion: These results open new perspectives in the identification of a specific fibroblastoid phenotype linked to BOS grades and to target a therapeutic treatment.

P1492

Characterization and hypertocyte-like differentiation of mesenchymal stem cells derived from adipose tissue of immunodeficient mice

Samir Alam, Veronika Klaassen, Jana Hübler, Nieder Mollen, Bruno Christ.

Aims and objectives: To isolate CDSCs from mouse adipose tissue and verify their potential for differentiation to explore their use for alleviating the shortage of liver transplantation donors to treat AATD.

Methods: MSCs were isolated from immunodeficient mice and cultured to 90% confluency. After DNA demethylation, a differentiation medium was applied and cellular morphology was assessed by microscopy after 0, 7, 14 and 21 days. Flow cytometry was used to detect mesenchymal (CD13, CD29, CD44, CD105) and haematopoietic (CD34, CD45) cell surface markers to estimate the percentage of differentiated cells. Gene expression of the hypertocyte-specific markers transferrin, albumin, CR1, CD26 and CYP3A1 was measured by semi-quantitative reverse transcription polymerase chain reaction.

Results: During differentiation, the morphology of MSCs changed from a spindle shape into a more polygonal aspect. Mesenchymal markers were expressed at each time point, whereas haematopoietic markers were hardly detectable after 21 days. The relative gene expression of the hepatic markers was increased at each time point.

Conclusion: MSCs derived from mouse adipose tissue may differentiate into hypertocyte-like cells in vitro. Conversely, human MSCs derived from mesenchymal tissue of a syngeneic mouse model of AATD can now be analysed.

P1493

Creatine supplementation attenuates systemic and pulmonary effects of acute lung injury induced by pulmonary ischemia-reperfusion in rats

Julho University, Sao Paulo, SP, Brazil; 1Thoracic Surgery (LIM 61), University of Sao Paulo, School of Medicine, Sao Paulo, SP, Brazil; 2Pathology (LIM 05), University of Sao Paulo, School of Medicine, Sao Paulo, SP, Brazil; 3Post-graduation Program in Biophotonics Applied to Health Sciences, Nove de Julho University, Sao Paulo, SP, Brazil.

Creatine supplementation (CS) prevents prothrombin and therapeutic effects for some muscular, cardiovascular and neurological disorders. In case of temporary ischemia, CS improves the capacity to generate ATP reducing cell damage. Ischemia and reperfusion (IR) injury is partially attributed to decreased intracellular ATP turnover, but also to increased oxidative stress and reduced IGF-1. Thus, this study evaluated the effects of 5 days of CS prior 90 minutes ischemia of left pulmonary artery followed by 120 minutes of reperfusion in 40 male Wistar rats divided in 4 groups: Sham-operated, CS+Isham, Ischemia/Reperfusion, Creat+Isham/Reperfusion. Lung mechanics, exhaled nitric oxide, cellularity in systemic circulation and in bronchoalveolar lavage (BAL), neutrophils and edema in lung tissue, total proteins in BAL, the levels of IL-\( \beta \)-ta, IL-4, IL-6, IL-17, KC, MCP-1 and TNF-alpha in serum and in bronchoalveolar lavage were evaluated by ELISA, as well as the expression of IGF-1, iNOS and caspase-3 in lung tissue. Compared with IR group, CS supplementation (CS+IR group) resulted in a reduction of exhaled nitric oxide (p<0.05), tissue damping (GTIS) and tissue elastance (HTIS) (p<0.05), total cells and neutrophils number in systemic circulation, in BAL and also in lung tissue (p<0.01), BAL levels of total proteins (p<0.05) and edema index in lung tissue (p<0.05), and systemic and pulmonary IL-\( \beta \)-ta (p<0.05). In addition, CS resulted in increased expression of IGF-1 in lung tissue. CS presents protective effects for the development of pulmonary and systemic manifestations of acute lung injury caused by pulmonary IR.

P1494

The development of pulmonary hypertension after first episode of acute pulmonary embolism and related risk factors

Shuai Zhang1, Shengzuo Zhai1, Yuanhua Yang1, Tugun Kuang1, Chen Wang2, 3.

Respiratory and Critical Care Medicine Department, Beijing Institute of Respiratory Medicine, Beijing, China; 2Respiratory and Critical Care Medicine Department, Beijing Hospital, Beijing, China.

Background: Part of patients with acute pulmonary embolism(PE) will develop into pulmonary hypertension(PE) including chronic pulmonary thromboembolic hypertension(CTEPH). Related risk factors need to be addressed to guide clinical practice.

Objectives: To investigate the incidence of PH after PE and related risk factors.

Methods: Consecutive patients diagnosed as acute PE admitted to our institute from 2006 to 2010 were included. All the patients were followed till Dec 2011. During the follow-up, patients with PH showed in echocardiogram, defined as an increased systolic pulmonary artery pressure (PAP) over 50mmHg, received right heart catheterization to confirm the diagnosis of CTEPH.
Results: 612 patients were included and the median follow-up period was 36 months. All-cause mortality was 17.3%. 15 patients developed into PH and 10 were diagnosed as CTEPH. The 1-, 2- and 5-year cumulative incidences of PH were 1.0% (95% CI: 0.2%-1.8%), 1.3% (95% CI: 0.3%-2.3%) and 3.5% (95% CI: 1.5%-5.5%) respectively. Patients with varicose vein of lower limbs (HR 5.480, 95% CI 2.795-10.793) and existence of PH at the beginning (HR 10.743, 95% CI 2.315-49.852) had higher risk in developing into PH.

Conclusion: CTEPH is a serious complication in a significant number of PE cases. History of varicose vein of lower limbs and estimated sPAP over 50mmHg at the first episode of PE seem to predict the risk of CTEPH in long-term follow-up.

P1495
Measurement of gas transfer components using nitric oxide in post pulmonary endartecctomy (PEA) chronic thromboembolic hypertension (CTEPH) patients
Louise Harlow1, Katrina Oates, Robert MacKenzie-Ross, Joana Pepka-Zaba.
Respiratory Physiology, Papworth Hospital NHS Foundation Trust, Cambridge, United Kingdom

Introduction: Reduced TLCO is frequently observed in CTEPH patients. Previous work has used single breath for NO to differentiate the diffusing membrane capacity (Dm) and capillary blood volume (Vc); the components of TLCO. It has been suggested, that TLNO is a more accurate reflection of Dm, due to greater affinity for haemoglobin and independence from Vc. This study uses new technology to measure Dm and Vc, using NO, in a cohort of post PEA CTEPH patients. The aim of the study is to compare the relative contribution of Dm and Vc to the reduction in TLCO.

Methods: We studied 24 CTEPH patients (14 male, 10 female, mean age 56±15) post PEA. Full lung function were performed and TLNO and Dm were measured using single breath for NO and CO on a PFTpro system (Viasys). Vc was calculated using the equation 1(DLCO=1(Dm×[(CO×Vc)]/NO)×Vc). Patients with co-existing parenchymal lung disease were excluded from the study. Correlations between variables were looked at using Pearson’s.

Results: Both Dm and Vc demonstrated a significant correlation with TLCO. Vc is more affected than the alveolar component Dm. The new technology offers a simple patient friendly procedure allowing measurements of Dm and Vc. This has the potential for improving our understanding of the different components of gas transfer. Further work is warranted in this area.

P1496
Circulating microRNA signature and its novel involvement in pathogenesis of chronic thromboembolic pulmonary hypertension
Lixuan Guo1,2,4, Jun Cai2, Lei Wang1,2,4, Lifeng Li1,2,4, Jie Liu2,4, Yuanhui Yang1,2,4, Baosen Pang1,4, Zhenguo Zhai1,4, Yan Liu4,5, Song Gu4,5, Chen Wang1,3,4, Jun Wang1,2,4, Jiefei Li1,2,4, Jie Liu2,4, Benjamin Planquette1,2, Amandine Vial1,2, Antoine Roux1,2, Joseph Emmerich1,3,4, Guy Meyer1,2,3, Olivier Sanchez1,2, 1Université Paris Descartes, Sorbonne Paris Cité, Paris, France; 2Service de Pneumologie et Soins Intensifs, Hôpital Européen Georges Pompidou, Paris, France; 3INSERM U 765, Faculté de Pharmacie, Paris, France; 4Service de Médecine Vasculaire, Hôpital Européen Georges Pompidou, Paris, France

Chronic thromboembolic pulmonary hypertension (CTEPH) is a progressive disease characterized by multiple etiology and mechanism. Circulating miRNA is partially derived from cells affected by disease and therefore can serve as potential biomarker and reflect the pathogenesis of this disease. In present study, we compared miRNA expression in plasma from 10 CTEPH patients and 10 healthy control subjects by microarray, and fourteen miRNAs were indentified to be differentially expressed.

Selectively, five of the differentially expressed miRNAs were further validated in an independent 40 pairs of subjects by stem-loop qRT-PCR, among which let-7b and miR-22 were downregulated to about 25% in CTEPH patients. Endothelin-1 (ET-1) and transforming growth factor beta receptor 1 (TGFBR1) was the direct targets of let-7b by reporter assay, and plasma ET-1 level was reversely correlated to let-7b. TGFBR1 was further required for induction of ET-1 in endothelial cells.

P1497
Persistent lung perfusion defect is a risk factor for recurrent venous thromboembolism after pulmonary embolectomy
Alexis Ferré1,2, Benjamin Planquette1,2,3, Armandine Vial1,2, Antoine Roux1,2, Joseph Emmerich1,3,4, Guy Meyer1,2,3, Olivier Sanchez1,2, 1Université Paris Descartes, Sorbonne Paris Cité, Paris, France; 2Service de Pneumologie et Soins Intensifs, Hôpital Européen Georges Pompidou, Paris, France; 3INSERM U 765, Faculté de Pharmacie, Paris, France; 4Service de Médecine Vasculaire, Hôpital Européen Georges Pompidou, Paris, France

Introduction: Up to 50% of patients with pulmonary embolism (PE) still have lung perfusion defects after 6 months of anticoagulant treatment, but little is known about the risk of recurrence in patients with persistent perfusion defect after an acute PE.

Aim of the study: To assess the risk of recurrent venous thromboembolism (VTE) in patients with persistent lung perfusion defects after a first episode of PE.

Patients and methods: Consecutive patients given at least 3 months of anticoagulant for an objectively proven first episode of acute PE were included. Ventilation/perfusion (V/Q) lung scan was performed 6 to 12 months after the diagnosis of PE. Objectively proven recurrent deep vein thrombosis (DVT) and PE were registered during follow-up. Persistent perfusion defects were defined as a pulmonary vascular obstruction > 10% on the V/Q lung scan.

Results: 318 patients (mean age 58±13 years) with an acute PE were included. 63 (19.8%, 95% CI, 15.4-24.2%) had persistent perfusion defects. During follow-up (median duration: 51 months [25th 75th percentiles: 27 - 73 months]), 71 patients (22%) had a recurrent episode of VTE. In multivariate analysis, persistent defect (HR 2.22; 95% CI, 1.3-3.75; p = 0.0048), unprovoked PE (HR 3.48; 95% CI, 1.96-6.19; p = 0.0001), persistent risk factor for VTE (HR 2.64; 95% CI 1.08-6.48; p = 0.03001) and age (60 to 75 years; HR 1.88; 95% CI, 1.0-3.61; p = 0.0112) were identified as independent risk factors for recurrent VTE whereas prolonged anticoagulation was a protecting factor (HR 0.19; 95% CI, 0.07-0.54; p = 0.0001).

Conclusion: Persistent perfusion defect is an independent risk factor for recurrent VTE after a first episode of PE.
Involvement of the pulmonary micro-vasculature in chronic thromboembolic pulmonary hypertension (CTEPH)

Conclusion: Other significant.

P1498

Two inventive protocols are useful to reduce the artifacts in rPA.

Introduction: Pulmonary endarterectomy (PEA) is the treatment of choice for patients with CTEPH. However, a limited subset of CTEPH-patients present with persistent PH after PEA.

Aims: To assess microvascular lesions and clinical characteristics in CTEPH-patients with persistent PH after PEA.

Methods: We analyzed lung histology available from 8/10 patients with persistent PH after PEA and compared them with 10 randomly selected CTEPH-patients with successful PEA.

Results: Histopathology from 8 persistent PH patients revealed thrombotic lesions, intimal fibrosis and medial hypertrophy in peripheral small muscular pulmonary arteries of all analyzed lungs. 7/8 persistent PH patients displayed moderate pulmonary venous involvement, including intimal fibrosis of small pre-septal venules, foci of capillary multiplication, and hemosiderosis. All cases presented hypertrophy of bronchial systemic arteries. Hemodynamic data, exercise testing and medical history exhibited non-significant but by-trend discriminating values between the persistent PH and the successful PEA group for PVR (119±154 dynes s cm^-5 versus 825±98 dynes s cm^-5), DCO (63±6% versus 75±4%), 6-minute walking distance (6MWD) (272±64m versus 415±33m), history of vascular implants (6/10 versus 0/10), and presence of subpleural septa on chest scanner (6/10 versus 2/10).

Conclusion: We report conspicuous remodeling of the pre- and post-capillary microvasculature in CTEPH-patients with persistent PH after PEA. Group-related discrepancies of PVR, DCO, 6MWD, vascular implant-history, and one radio logic criterion were observed in CTEPH patients with persistent PH, as compared with CTEPH-patients with successful PEA.

P1499

Inventive protocols of CT pulmonary angiography (CTPA) avoid artifacts in pulmonary embolism (PE).

Methods: Aims: To investigate the incidence of recurrent VTE in patients with first episode acute pulmonary embolism(PE) and related risk factors

Patients and methods: 24 consecutive patients suspected PE underwent CTPAs using a 64-detector MDCT. Each protocol was started with a 3 ml/sec-injection of 100ml of CM (300mg/Iml) via vein in upper limb. Three protocols followed the above CM injection, protocol-1 (P-1) with immediate exposure, protocol-2 (P-2) with exposure after 10 sec.-delayed, and protocol-3 (P-3) with exposure after injection of 30ml saline (3ml/sec). We observed artifacts regarding rPA, subclavian veins, calciﬁcation, and motion. Then an artifact-observed score (AOS) was given 0 to 4 as artifact grade.

Results: Each average of AOS in rPA was 1.80 in P-1, 0.25 in P-2, and 0.13 in P-3. The AOS in P-1 was higher than the others, in P-2 (p=0.04) and in P-3 (p=0.001). Each average of AOS in subclavian veins and motion artifact did not differ from P-1 to P-3. The CM-density of all regions of interest in P-1 were higher than the others significantly.

Conclusion: Invasive protocols are useful to reduce the artifacts in rPA.

They may improve detectability of thrombi in rPA in CTPA.

P1500

Sleep-disordered breathing in acute pulmonary embolism: A dangerous comorbidity?

Department of Cardiology, Respiratory Medicine and Intensive Care, Klinikum Augsburg, Ludwigs-Maximilians-University Munich, Augsburg, Germany.

Background: Sleep-disordered breathing (SDB) is a common comorbidity in patients with acute pulmonary embolism (PE) but its prognostic relevance in PE is unclear. Therefore, we conducted a prospective cohort study to clarify if the presence of SDB is associated with an adverse outcome in acute PE.

Methods: 106 consecutive PE patients were prospectively evaluated by portable monitoring (PM). Nocturnal polysomnography was performed in all subjects who have been diagnosed by PM to have an apnoea-hypopnoea index (AHI) > 15 or evidence of increased daytime sleepiness. All-cause mortality was registered after a mean observation period of 12 months.

Results: Neither central sleep apnoea nor periodic breathing were observed. Mild obstructive sleep apnoea (OSA) was diagnosed in 35.8% of patients. 12.3% of subjects suffered from moderate to severe OSA (AHI > 15/h). The incidence of sleep apnoea among study participants was significantly higher in patients with moderate to severe OSA compared to subjects with an AHI > 15/h (8.3% vs. 2.4%, p = 0.003).

Conclusion: OSA is a common comorbidity to PE and might be associated with an increased mortality in survivors of acute PE.

P1501

Red cell distribution width (RDW): A new predictor for chronic thromboembolic pulmonary hypertension

Yasum Abl1, Savas Ozan1, Asher Korkmaz2, Yilmaz Bulbul1, Tefik Ozl1, Yasin Abul1, Yamin Abul1, Mahmut Buyuktekin3, Inge Juskowski4, Detlev Ganten5,6,7, Peter Dorfmüller5,6,7, Marcin Suber1,6,7, Gérald Simonneau1,6,7, Philippe Dartevelle2,6,7, Sophie Maitre3,6, Jean-François Paul4, Vincent de Montpréville5, Elie Fadel2,6,7, Martin Schwaibmair.

Introduction: Our aim is to investigate whether RDW might be a predictor of CTEPH in pulmonary embolism patients or not. This study is a retrospective cohort study. A total of 203 consecutive patients with acute PE were included. Minimum follow-up period was 10 months. We collected each patient's baseline characteristics including RDW, Troponin-T and CRP. Receiver operating characteristic (ROC) analysis was performed to determine the optimal RDW cut-off levels to predict CTEPH. CTEPH frequency in PE patients (n=203) was 7.9% (n=16). RDW was higher in CTEPH patients than the patients without CTEPH (17.0±4.46; 14.6±1.82) (p=0.015). The optimal cutoff value of RDW for predicting CTEPH was 14.65. The area under the curve of RDW for prediction of CTEPH was 0.735 (CI: 0.600-0.869). In cases with RDW levels>14.65, the specificity and sensitivity for CTEPH were 62% and 75%, respectively. Negative predictive value of RDW at cutoff 14.65 for CTEPH was 96.7%. At multivariate regression analysis, RDW, hazard ratio: 1.58 (95% confidence interval: 1.09-2.30) was a predictor of CTEPH (p=0.016). High RDW levels was an independent predictor of CTEPH in PE patients. Therefore, RDW levels may provide a potential market to predict CTEPH in PE patients.

P1502

The incidence of venous thromboembolism recurrence in patients after first episode acute pulmonary embolism and related risk factors.

Shuai Zhang1,2, Zhenguo Zhai1,2, Yanhui Yang1,2, Tongzeng Huang1,2, Wanniu Xie1, Chen Wang1,2,3, Shifeng Chen1.1, Respiratory and Critical Care Medicine Department, Beijing Institute of Respiratory Medicine, Beijing, China; 2Respiratory and Critical Care Medicine Department, Beijing Hospital, Beijing, China.

Background: Early identification of recurrent venous thromboembolism(VTE) in patients with first episode acute pulmonary embolism(PE) and related risk factors is important in clinical practice.

Methods: Consecutive patients with acute PE from 2006 to 2010 were enrolled. Baseline clinical data was collected and patients were followed up for years. The primary endpoint is symptomatic recurrent VTE and the second endpoint is death.

Results: 612 patients were included. The median follow-up period was 36 months and all-cause mortality was 17.3%. The 1-, 2- and 5-year cumulative recurrent incidences were 3.9%(95%CIs: 2.3%-5.5%), 6.9%(95%CIs: 4.9%-8.9%) and 13.5%(95%CIs: 10.2%-16.8%) respectively. Patients with uncomplicated PE (HR: 3.52, 95%CI: 1.81-6.84), concurrent deep venous thrombosis(DVT) (HR 5.39, 95%CI: 1.83-15.84) or varicose vein of lower limbs(HR 4.286, 95%CI: 2.210-8.313) had higher risk in recurrence. Conversely, patients with longer duration of anticoagulation(HR 0.971, 95%CI: 0.952-0.991) suffered less.

Conclusions: VTE recurrence is relatively common. Unprovoked PE, concurrent...
DVT and history of varicose vein of lower limbs seem to increase the risk of recurrence. Longer duration of anticoagulation seems to protect patients from recurrent VTE.

**P1503**

Circulating endothelial cell levels decrease after vasodilator therapy and are a biomarker of clinical worsening in refractory pulmonary hypertension in children

Marilyne Levy1, Damien Bonnet1, Laetitia Mauge1, Clement d’Audigier1, David Celeramajer1, Pascale Gaussen2, David Smadja1, 1Pediatric Cardiology, Necker Hospital, Universite Paris Descartes, Paris, France; 2Hospital for Sick Children, London, UK

**Background:** Pulmonary vasodilators in general and prostacyclin therapy in particular have improved the outcome of patients with pulmonary arterial hypertension (PAH). Endothelial dysfunction is a key feature of PAH and we previously described that circulating endothelial cells (CECs) could be used as a biomarker of endothelial dysfunction in PAH. We now hypothesized that PAH-specific vasodilator therapy might decrease CEC numbers.

**Methods:** CECs were quantified by immunomagnetic separation with antiCD146 coated beads in peripheral blood from children with idiopathic PAH (iPAH, n = 30) or PAH secondary to congenital heart disease (PAH-CHD, n = 30): before, after treatment and during follow up.

**Results:** Oral treatment with endothelin antagonists and/or PDE5 inhibitors significantly reduced CEC counts in children. In 10 children with refractory PAH despite oral combination therapy, subcutaneous (SC) treprostinil was added and we observed a significant decrease in CEC counts during the first month of such treatment. CECs were quantified during a 6 to 36 month follow-up after initiation of SC treprostinil and we found that CEC counts changed over time, with rising counts always preceding clinical deterioration.

**Conclusions:** CECs might be useful as a biomarker during follow-up of PAH treatment in pediatric iPAH and PAH-CHD, to assess response to treatment and to anticipate clinical worsening.

**P1505**

Atrial flutter and fibrillation in patients with chronic pulmonary hypertension

Karen Olsson1, Nils Nickel1, Jorn Tongers2, Marius Hoepner1, 1Department of Respiratory Medicine, Hannover Medical School, Hannover, Germany; 2Department of Cardiology, Hannover Medical School, Hannover, Germany

**Background:** Atrial flutter and atrial fibrillation are frequently observed in patients with pulmonary hypertension but their clinical implications remain unclear.

**Objectives:** Aim of the study was to determine the prevalence and clinical impact of supraventricular tachyarrhythmias (SVTs) in patients with pulmonary hypertension.

**Methods:** In a 5-year, prospective study, we assessed the incidence of new-onset SVTs as well as risk factors, clinical consequences, management, and impact on survival in patients with pulmonary arterial hypertension (PAH, n=157) or inoperable chronic thromboembolic pulmonary hypertension (CTEPH, n=82).

**Results:** New onset SVTs were detected in 48/239 (20%) patients with a cumulative 5-year incidence of new-onset SVTs of 25.1% (95% confidence interval, 13.8-35.4%). Atrial flutter and atrial fibrillation were equally frequent. Stable sinus rhythm was re-established in 21/24 (88%) of patients initially presenting with atrial flutter and in 16/24 (67%) of patients with atrial fibrillation. Development of SVTs was associated with more severe hemodynamic impairment. New-onset SVTs were an independent risk factor of death (p=0.04, simple Cox regression analysis) with a significantly higher mortality in patients with persistent atrial fibrillation compared to patients in whom sinus rhythm was restored (estimated survival at 1, 2 and 3 years 64%, 55%, and 27% versus 97%, 80%, and 57%, respectively; p=0.01, log-rank analysis).

**Conclusions:** SVTs develop in a considerable number of patients with PAH or inoperable CTEPH and often cause clinical deterioration and right heart failure. Mortality is high when sinus rhythm cannot be restored.
P1508
Prognostic risk factors of disease worsening in patients with functional class II pulmonary arterial hypertension

Gerald Simonneau1, Nazzareno Galí2, Marius M. Hoeper3,4, Andjela Kusic-Pajic4,5, Jean-Christophe Lemarie2, Lewis J. Rubin6, Service de Pneumologie, Hôpital Universitaire de Bicêtre, Université Paris-Sud, Le Kremlin Bicêtre, France; 2Institute of Cardiology, University of Bologna, Italy; 3Department of Respiratory Medicine, Hannover Medical School, Hannover, Germany; 4Clinical Development, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; 5Efi-Stat, Effi-Stat, Paris, France; 6Division of Pulmonary & Critical Care Medicine, University of California, San Diego, United States

Introduction: The open-label extension (OLE) phase of the EARLY trial provides a unique opportunity to analyse long-term data from WHO functional class II pulmonary arterial hypertension (PAH) patients. Here we investigated prognostic factors associated with PAH worsening.

Methods: PAH worsening was defined as initiation of parenteral prostanoids, atrial septostomy, lung transplantation or death. Data on these 4 parameters, collected annually until study end regardless of OLE participation or treatment discontinuation, for all 185 patients originally randomized to placebo or bosentan were included in this analysis. OLE continued until at least 50% of patients had the opportunity to be treated with bosentan for at least 5 years. Cox regression analysis, univariate (significance set at P<0.1 cut-off) and multivariate (backward selection set at P<0.1 cut-off, including all variables having a P-value <0.1 in the univariate analysis), were employed to determine prognostic factors of PAH worsening.

Results: In the univariate analysis, significant prognostic factors for a low risk of PAH worsening were time since PAH diagnosis >16 months, 6-minute walk distance >437.0 m and mixed venous oxygen saturation >68%. High values in NT-proBNP and PAH associated with connective tissue disease versus idiopathic, heritable or HIV-associated PAH were significant risk factors for PAH worsening. Apart from time since diagnosis, these factors were confirmed as significant in the multivariate analysis.

Conclusions: This analysis provides firm evidence of risk factors significantly associated with PAH worsening in patients at a functionally early stage of the disease.

P1510
Potential pharmacological interactions between oral pulmonary arterial hypertension (PAH) therapies and new oral anticoagulants

Jean-Christophe Lega1, Marc Hambert1,2,3, Patrick Missset1,2,3, Thrombosis Research Group (EA3055), University of Saint-Etienne, France; 2CIC-CIE3, INSERM, Saint-Etienne, France; 3Department of Therapeutic Medicine, CHU Saint-Etienne, Hôpital Nord, Saint-Etienne, France; 4Clinical Pharmacology Unit, CHU Saint-Etienne, Hôpital Nord, Saint-Etienne, France; 5Faculté de Médecine, Univ Papa-Sud, Kremlin-Bicêtre, France; 6Service de Pneumologie et Réanimation Respiratoire, Centre National de Référence de l’Hypertension Pulmonaire Sévère, AP-HP, Hôpital Antoine Béclère, Clamart, France; 7U999, Hypertension Artérielle Pulmonaire: Physiopathologie et Innovation Thérapeutique, INSERM, Le Plessis-Robinson, France; 8Department of Internal and Vascular Medicine, Hôpital Lyon Sud, Hospices Civils de Lyon, Université Claude Bernard Lyon 1, France

Background: Anticoagulation with vitamin-K antagonists is currently recommended in PAH. We aimed to search for potential pharmacological interactions between new oral anticoagulants (NOA) and oral PAH therapies.

Methods: We reviewed the potential pharmacokinetic and pharmacodynamics drug-drug interactions (DDI), in particularly regarding metabolism and drug transport, port, with bosentan (B), ambrisentan (A), sildenafil (S), tadalafil (T) and NOA (rivaroxaban, apixaban, dabigatran).

Results: B is metabolized mainly by hepatic cytochrome P450 (CYP) 3A4, A by uridine 5’-diphosphate glucuronitransferase and to a lesser extent, by CYP3A4 and CYP2C19. The organic anion transport proteins for B and P-glycoprotein for are both probably involved in the transports of these drugs. B, but not A, induces CYP3A4, which is involved in the metabolism of anti-Xa NOA rivaroxaban (30%) and apixaban (50%). Concomitant use of B may reduce their biological efficacy. S and T are also mainly metabolized by CYP3A4, but act as slight CYP3A4 inhibitors. The risk for clinically significant DDI seems low between S or T and anti-Xa NOA. However, in case of PAH-combination therapy, the risk for a decreased concentration might be amplified for anti-Xa NOA. Conversely, an increased risk of myocardial infarction recently evoked with dabigatran, an anti-IIa drug not metabolised by CYP, should preclude its use in PAH.

Conclusion: DDI may occur in PAH patients receiving NOA and PAH therapies, and potentially amplified in case of combination therapy. In the absence of robust clinical and pharmacological data, NOA are not recommended in PAH.
To study pulmonary hemodynamics and the prevalence of porto pulmonary hypertension (POPH) in cirrhotic patients

Sachin Kumar1, Praveen Kumar Sharma2, Manoj Kumar Sharma2, Ashish Kumar2, Shiv Kumar Sarin1, 2 Pulmonary Medicine, Institute of Liver & Biliary Sciences, New Delhi, Delhi, India; 2 Hepatology, Institute of Liver & Biliary Sciences, New Delhi, Delhi, India

Background: Pulmonary hypertension (PH) (mean pulmonary artery (MPA) pressure \(\geq 25\) mm Hg at rest) associated with cirrhosis have variable etiologies and prognostic implications.

Aim: To study pulmonary hemodynamics and determine the prevalence of porto pulmonary hypertension (POPH) in cirrhotic patients.

Method: Retrospective study comprised 1492 patients with cirrhosis seen at a tertiary teaching hospital from July 2001 to March 2011 undergoing invasive haemodynamic measurements during hepatic venous pressure gradient (HVPG) study. The data on etiology of cirrhosis, medical history and Child-Pugh classification of liver disease also collected.

Result: 1492 patients (M:F, 1177:315, Child A:B:C, 378:360:754) mean age 45.4 ± 13.2 37 (2.48%) had confirmed PH and 7 (0.47%) patients satisfied the criteria of POPH. Out of 37 PH patients, precapillary PH was present in 7 (POPH group) while postcapillary PH was present in 30 (2.0%) and was passive in 27 patients. Cardiac dysfunction (n=17), spirometric evidence of COPD (n=10 including 4 overlap with cardiac disease), unknown (n=4) and serological evidence of connective tissue disorders (n=3) were also present in postcapillary PH patients. Only 3 out of 30 patients had reactive postcapillary PH (Transpulmonary gradient (TPG) >12mm Hg). Higher MPA and TPG significantly associated with POPH.

Conclusion: The prevalence of POPH in cirrhosis was 0.47%. Presence of PH in cirrhotic should alert the physician to search for more common causes other than POPH, may be more amenable to treatment, making them eligible and also reducing the risk associated with untreated PH, especially in patients being considered for liver transplantation.
202. Early detection of lung cancer

Interval lung cancers not detected on screening chest x-rays: How are they different?
Paul A. kraus1, christine cole Johnson2, Martin tammemagi1,2, pamela m. marcus3, Carl j. zylak4, David l. spitzny4, William hockings5, Martin oken6, John commins3, Lawrence ragard7, ping hu4, Christine berg4, philip prorek4, 1Division of Pulmonary and Critical Care, Henry ford Health System, detroit, mi, United States; 2Department of Public Health Sciences, henry ford Health System, detroit, MI, United States; 3Department of Public Health Sciences, Henry Ford Health System, Detroit, MI, United States; 4Division of Cancer Prevention, National Cancer Institute/National Institute of Health, Bethesda, MD, United States; 5Department of Radiology, henry ford Health System, detroit, MI, United States; 6Department of Clinical Oncology, Marshfield Clinic, Marshfield, WI, United States; 7Division of Environmental Health Sciences, School of Public Health, University of Minnesota, Minneapolis, MN, United States; 8L & O Subcommittee Support, Information Management Services, Inc., Rockville, MD, United States; 9Research Support, Westat, Rockville, MD, United States; 10Community Health Sciences, Brock University, St. Catharines, on, Canada

Background: The Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial provides us an opportunity to describe interval lung cancers not detected by screening chest x-ray (cXr) compared to screen-detected cancers. Methods: Participants were randomized to cXr at baseline and annually for two (never smokers) or three (ever smokers) more years. Putative interval cancers were those with a negative cXr screen but with a diagnosis of lung cancer within 12 months. Screen-detected cancers were those with a positive cXr and diagnosis within 12 months. Potential interval cancers were reviewed to determine whether lung cancer was missed and probably present during the initial interpretation or whether the lesion was a “true interval” cancer. Results: 7745 participants were randomized to the intervention arm with 70,633 screened. Of 5,227 positive screens from any screening round, 298 resulted in screen-detected lung cancers; 152 had potential interval cancers with 128 cXr available for re-review. Cancer was probably present in 45/128 (35.2%) at time of screening; 83 (64.8%) were “true interval” cancers. Compared to screen-detected cancers, true interval cancers were more common among males, persons with <12 years education and those with a history of smoking. True interval lung cancers were more often adenocarcinoma (57% vs. 16.7%), more often small cell (27.7% vs. 7.4%), and less often adenocarcinoma, 25.3% vs. 56.4% (p<0.0001), and less likely to be in the right upper lobe, 16.9% vs. 36.2% (p<0.001). Conclusion: True interval lung cancers differ from cXr-screen-detected cancers with regard to demographic variables, stage, cell type and location.

1637

The effect of route of presentation on lung cancer outcome
Laura Succo1, Elaine Swanson2, Sue Gauthier3, James Ramsay1, 1Respiratory Medicine, Laton and Dunstable NHS Trust, Laton, Bedfordshire, United Kingdom; 2Clinical Audit, Laton and Dunstable foundation Trust, Laton, Bedfordshire, United Kingdom

Background: Lung cancer is the commonest cause of cancer death in the UK, with one year survival lagging behind the rest of Europe. Early lung cancer diagnosis is imperative in achieving the highest chance of curative therapy. Recent Public Health Campaigns have highlighted importance of early lung cancer detection and early presentation to primary care, allowing onward referral. The Laton and Dunstable Hospital is situated north of london, covering a population of 320,000. Observations show when patients present as an emergency, instead of through outpatient referral, disease is at a later stage and limited treatment, if any, available. Aims: To compare stage of lung cancer, treatment intent and survival, between patients referred from primary care and emergency inpatient presentations. Methods: 2010 lucada data from Laton and Dunstable NHS Trust were analysed, including 144 patients. 63 primary care referrals, and 81 inpatient presentations. Performance status, stage, survival and treatment were compared using the chi-squared contingency test. Results: Patients referred through outpatients had a significantly better performance score (p<0.001) and an earlier stage disease (p=0.0085) compared to those diagnosed following emergency admission. Survival data (at time of analysis), revealed a greater likelihood of death within the inpatient population (p<0.001). A trend existed for more active treatment in outpatient referrals, although this failed to reach statistical significance. Conclusions: Our data shows outpatient diagnosis is associated with better performance scores, earlier cancer stage and prolonged survival. Early symptom recognition, with early referral is vital in improving life expectancy from lung cancer.

1638

The results of the prevalence screen in Lung SEARCH: A UK based screening trial for lung cancer based on sputum cytology and cytometry, by the Lung SEARCH screening group
Stephen Sturm, Respiratory Medicine, Royal Brompton Hospital, London, United Kingdom

Lung SEARCH is a screening trial in 9 UK centres of 1658 subjects with a ≥20 pack-year smoking history, mild or moderate chronic obstructive pulmonary disease (COPD). Randomisation was to a control group who had no active intervention, but an exit chest x-ray (cXr) at the end of 5 years; or a surveillance group who provide sputum samples annually for 5 years, for cytological and cytometrical analysis, and if normal for the duration of the study, an exit cXr. Samples showing abnormalities would undergo annual low-dose computed tomography (CT) and autofluorescent fiberoptic bronchoscopy (AFB) for the remaining years of the five. Our aim is to identify more early stage cancers in the surveillance arm (<50%) than the control (<10%) and literature on COPD suggested we would need 37 cancers in each study group. We entered 785 subjects into the surveillance, and 783 in the control arms. The two groups were well matched with 52% of men in both groups, 56% and 44% in each group were current or ex-smokers, and their mean ages were 63 years. 75% in each group had moderate COPD and 25% were mild.

Results: Of the 785 subjects in the surveillance arm, 92% provided a sputum sample. Of these only 132 of 742 were inadequate for analysis. 352 (37%) were normal, 128 (17%) were abnormal: 16 were high grade and 112 low grade.

Background: National Lung Screening Trial (NSLT) reported screening with low-dose CT could reduce mortality from lung cancer. Breath analysis such as biomarker discovery could detect volatile organic compounds (VOC).

Objectives: To detect specific VOC peaks in lung cancer then compare lung cancer and healthy subjects.

Methods: IMS coupled to a multi-capillary column (MCC/IMS) (BioScout: B&S Analytik, Dortmund, Germany) with a 95MBq β-radiation source was used to detect VOC peaks. For the Japanese market, regulations restrict 63Ni β-radiation sources to under 100MBq. Exhaled breath samples were collected at quiet breathing in 30 patients with lung cancer and 13 healthy volunteers. Peaks were characterized using Visual Now 2.2 software (B&S Analytik, Dortmund, Germany).

Results: Patients included 17 adenocarcinoma, 3 squamous cell carcinoma, 6 small cell carcinoma and 4 unclassified carcinoma. Forty-seven VOC peaks were detected and 10 VOC peaks showed significant differences between lung cancer and healthy volunteers (p<0.05).

Conclusions: IMS using 95MBq β-radiation source is a feasible screening test in the detection of lung cancer. In the future, IMS may detect histological types of lung cancer and molecular mutation.
Cancer-associated oncogenic BARD1 isoforms: From biomarker expression studies to development of a blood test for early detection of lung cancer

Imagard Irving-Finger1,2,3, Pierre-Alain André1,2, Maxim Frygun1,4, Balazs Hegedus5, Francisco Piantedosi6, Geoff Laurent5, Andrea Bianco7, 1Department of Gynecology-Obstetrics, Geneva University, Geneva, Switzerland; 2School of Medicine, The University of Queensland, Brisbane, QLD, Australia; 3Department of Medicine, The University of Queensland, Brisbane, QLD, Australia.

We have reported that exhaled volatile organic compound (eVOC) profile of lung cancer (LC) subjects differed from healthy ever smokers (HS).

Aim: To find if eVOC profile of LC subgroups (1) peripheral tumours and (2) early stage disease differ from HS.

Method: LC (n=53) and HS (n=177) subjects provided a breath sample after tidal breathing through an inspiratory port filter for 5 mins. It was analysed with a 32 sensor Cyranose 320 (Smiths Detection). Tumours were staged (7th ed TNM system), and defined as peripheral if located in the outer 1/3 of lung fields on axial CT images. LC subgroups were: Stages I/II (n=27), III/IV (n=25), central (n=32) and peripheral tumours (n=21).

Results: The eVOC profile distinguished between LC and HS with a cross validation (CVV) accuracy of 79%, (p<0.0001). eVOC profile CVV accuracy was 77% when analysing central, peripheral and HS cases. A principal component vector was significantly different between early (I/II) stage LC and HS (p=0.035).

Conclusions: These data indicate the ability of exhaled breath VOC profiles to distinguish early stage and peripheral lung cancer cases from healthy ever smokers, and therefore support its potential as a non-invasive screening tool for early detection of lung cancer.

Hyaluronan: A novel sputum marker for the screening and diagnosis of lung cancer patients

Marina Perez Ranger1, Vanessa Karen de Sá1, João Roberto Maciel Martins2, Kwun Fong1,2, Rayleen Bowman1,2, Paul Zimmerman1,2, Paul Zhang1,2, Tereza Takagaki1, Helena Nader2, Vera Luzia Capelozi1, Kwun Fong1,2, Paula Strudin Claudio School of Medicine of University of Sao Paulo, Sao Paulo, Brazil; 3Molecular Biology and Biochemistry, Federal University of Sao Paulo, SP, Brazil; 4Molecular Oncology Research Center, Barretos Cancer Hospital, Barretos, Brazil

Introduction: Hyaluronic Acid (HA) is elevated in several cancers, but there is no data regarding its concentration in the sputum of lung cancer patients. In this study, we examined the HA concentrations in the sputum and its impact on the screening and diagnosis of lung cancer patients.

Methods: HA was examined in sputum samples of 90 lung cancer patients, 25 COPD patients and 15 healthy controls. All the patients and healthy controls selected underwent a sputum induction. Sputum samples were incubated with area at 60°C and afterwards incubated with a proteolytic enzyme. The levels of HA were measured by a noncompetitive ELISA-like fluorometric assay.

Results: A significant difference in concentration pattern of HA in the sputum was found among lung cancer, COPD and healthy individuals (p<0.001; Fig. 1A). ROC curve between lung cancer and healthy volunteers furnished an area of 0.821 (0.727–0.915). Assuming a cut off value of 31.44ng/mg, the specificity was 100% and the sensitivity was 51% (Fig. 1B). ROC curve to distinguish COPD patients from lung cancer patients showed an area of 0.698 (0.600–0.797) and the cut off

An electronic nose in the discrimination of patients with lung cancer and controls

Maris Bukovskis1,2,3, Gunta Strazda1,2,3, Uldis Kopēka1,2, Normunds Jurka1,2, Liga Balode1,2, Ilmaris Tuvans1,2, Tumors and Allergology, Paula Strudins Clinical University Hospital, Riga, Latvia; 2Institute of Experimental and Clinical Medicine, University of Latvia, Riga, Latvia; 3Department of Pathology Faculty of Medicine, University of Latvia, Riga, Latvia.

Background: Lung cancer is a leading cause of death in men suffering from oncological diseases. Exhaled breath contains hundreds of volatile organic compounds (VOCs) that could serve as biomarkers of lung disease. Electronic nose can distinguish VOC patterns by mixture pattern recognition.

Objective: We hypothesized that an electronic nose can discriminate exhaled air of patients with lung cancer from healthy controls.

Methods: 25 patients with clinically and histologically verified lung cancer and 45 controls were included in a study with sampling of exhaled breath. Subjects inspired VOC-filtered air by tidal breathing for 5 minutes, and a single expiratory sample was collected into polyethylene terephthalate bag that was sampled by electronic nose (Cyranose 320) within 5 minutes. Smellprints were analyzed by multilayer feedforward neural network analysis (MLRA). Optimal detector parameter combination for diagnosis of lung cancer was calculated by MLRA backward stepwise method. Sensitivity, specificity, PPV and NPV of the method were calculated.

Results: Optimal detector parameters for discrimination of lung cancer were maximum of detectors number 6, 13. and 23. and area under curve of detectors 2, 6, 24 and 29. 22 out of 25 or 88.0% of lung cancer cases were predicted correctly by MLRA. Sensitivity of the method was 88.0%, specificity 91.1%, PPV 84.6% and NPV 93.2%.

Conclusions: The electronic nose appears to be able to discriminate exhaled breath from subjects with lung cancer and healthy controls. Analysis of exhaled breath could be used as the lung cancer screening method in the future.

Acknowledgements
Study was sponsored by ERAF activity Nb. 2.1.1.1.0. Project Nb. 2010/0303/2DYP/2.1.1.1.0/10/APEVIA043.
The 2011 Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines recommend a combined assessment for measuring the impact of COPD which considers current symptoms and future exacerbation risk (A: low risk, less symptoms; B: low risk, more symptoms; C: high risk, less symptoms; D: high risk, more symptoms). Two symptom cut-points are proposed: COPD Assessment Test (CAT) score ≥10 and modified Medical Research Council Dyspnoea (mMRC) score ≥2.

This analysis examined health status scores split by these cut-points, using CAT and mMRC data together with SGRQ and SF-12 Physical Function (PF) scores, in a primary care population from the Health Related Quality of Life in European COPD Study.

Data from 1817 patients (mean [SD] FEV1 1.6 [0.6] L; age 64.9 [9.6] years; males 67.6%) were included. COPD Study.

Conclusions: The mMRC cut-point of ≥2 classified a high proportion of these patients as having low symptoms, despite having moderately high SGRQ scores and poor SF-12 PC scores. The distribution of the individuals according to the two stratification systems differs considerably. With regard to prediction of exacerbations, the A-D GOLD 2011 classification performs well.

Conclusions: The results presented suggest a promising role of HA quantification in the sputum as a novel screening and diagnostic marker for differentiating normal and other type of fibrotic pulmonary problems from lung cancer patients.
followed by spirometry and exacerbation history to determine exacerbation risk (Fig 1). We examined this guidance in the London COPD cohort. 106 patients completed daily symptom diary cards for ≥1 year and the CAT at least once when stable. All exacerbations received additional systemic and/or inhaled therapy. Mean age was 72.6 years (SD 8.3), FEV1 1.1L (0.5), and FEV1 predicted 48.5% (16.4).

Using CAT and GOLD grade to assess exacerbation risk yielded significantly more high risk patients (category C&D) than when exacerbation history was used (56.6% vs. 33.0%, p=0.001). After combined assessment using both GOLD grade and exacerbation history, few patients were included in the high risk, less symptoms category C: 8.5% (9/106) using CAT and 10.4% (11/106) using mMRC. In a specialist outpatient setting, few patients fulfill criteria for inclusion in the high risk, less symptoms category C. Furthermore, the method chosen to assess exacerbation risk had a large influence on risk stratification. Additional work is required to examine the utility of this aspect of GOLD guidance in primary care to screen for exacerbation risk.

1648 Combined assessment according to the new GOLD guidelines and its relation to outcome in COPD

Daiana Stolz1, Kostantinos Costakis2, Francesco Biasi3, Brasilava Milenkovic4, Wim Boersma5, Joachim Aerts6, Renaud Louis7, Tobias Welte8, Alicia Lacoona9, Cristina Pract10, Andreas Scherr1, Janko Rakic1, Marilena Pappalettter1a, Gernot Rohde10, Antoni Torres11, Sabine Hertel12, Alicia Lacoma9, Cristina Prat9, Andreas Scherr1, Janko Rakic1, Sven Giersdorf12, Michael Tamm1.

Background: The new GOLD guidelines recommend pharmacological and non-pharmacological management of COPD to be individualized based on the assessment of symptoms and exacerbation risk (A=low risk, less symptoms; B=low risk, more symptoms; C=high risk, less symptoms; D=high risk, more symptoms). We hypothesize that functional parameters and the risk of future events differ among patients categorized by the combined assessment according to the guidelines.

Methods: We prospectively evaluated 638 patients with stable COPD for exacerbation and death from any cause. Median observation time was 24 weeks, >10 PY and GOLD II-IV seeking care in pulmonary tertiary hospitals in 8 European countries and included in the PROMISE cohort. The outcome variables were exacerbation and death from any cause. Median observation time was 24 months.

Results: There were 1152 exacerbations, 225 severe exacerbations and 63 deaths among 586 patients classified as A=50 (7.6%), B=184 (28.8%), C=27 (4.2%), and D=325 (50.9%). Health-related QoL, as assessed by all domains of the SGRQ (p<0.0001) and most but not all domains of the SF-36, circulating pro-dromalmeulin (p=0.0287), 6 MWD (p=0.0001), exacerbations rate (p<0.0001), severe exacerbation rate (p<0.0001) and mortality (p<0.0001) differ significantly among the 4 groups. Mortality was highest in the group D (12%) followed by groups A (10%), B (6%). Remarkably, mortality was lowest in group C (0%).

Conclusion: The combined assessment according to the new GOLD guidelines is only partially associated with quality of life and the risk of future events in COPD.

1649 Differences in the recommended initial therapy of COPD according to GOLD guidelines 2006 and 2011

Ivan Vysnyvetsky1, Yuriy Mostovoy2, Olexiy Onyshchenko1. 1Internal Medicine and General Practice - Family Medicine, Donetzk National Medical University, Donetsk, Ukraine; 2Proephrethic Therapy, National Pirogov Memorial Medical University, Vinnytsia, Ukraine.

Background: The last GOLD Guideline revision was released in late 2011. We hypothesized that newer GOLD guidelines would frequently lead to a different initial treatment choice. Aims and objectives: To demonstrate the magnitude of difference in recommended initial treatments in COPD patients based on past and recent GOLD revisions. Methods: We retrospectively analyzed 52 patients with first diagnosed stable COPD. Spirometry, COPD Assessment Test and evaluation of exacerbations were done. Patients were allocated to the most appropriate treatment according to GOLD 2006 and 2011 management scheme. Results: According to GOLD 2006 criteria 32 (61.5%), 18 (34.6%) and 2 (3.8%) patients were stage II, III and IV, respectively. Forty (76.9%) patients should be prescribed monotherapy with LABA or ICS/LABA therapy. According to GOLD 2011 6 (11.5%), 19 (36.5%), 2 (3.8%) and 25 (48.1%) patients were Group A, B, C and D, respectively. Thus, 6 (11.5%) patients would not be prescribed long-acting bronchodilators (BD) as initial therapy, 20 (38.5%) patients required monotherapy with long-acting BD and 26 (50.0%) required therapy with ICS/LABA. In accordance with GOLD 2011 treatment scheme, initial therapy was required to be changed in 21 (40.4%) patients (13 (40.6%) stage II and 8 (40.0%) stage III/IV). In 6 (11.5%) cases we had to administer more "light" therapy (with short-acting BD instead of long-acting BD), and 14 (26.9%) patient required more intensive treatment, usually LABA/ICS instead of monotherapy. Conclusions: In significant proportion of COPD patients GOLD 2011 treatment scheme leads to another, generally more intensive, initial treatment.

1650 GOLD assessment of COPD patients: Impact of symptoms assessment choice

Hana Mullerova1, Nicholas Locatone2, Paul Jones3. 1Worldwide Epidemiology, GlaxoSmithKline R&D, Uxbridge, United Kingdom; 2Clinical Statistics, GlaxoSmithKline R&D, Research Triangle Park, NC, United States; 3Clinical Science, St. George’s University, London, United Kingdom.

Background: The 2011 GOLD guidelines recommend combined COPD assessment using symptoms (modified Medical Research Council Dyspnoea [mMRC] ≥2 or COPD Assessment Test [CAT] ≥10) combined with a history of exacerbations in the past 12mo (0.1) vs ≥2 and spirometric classification GOLD III vs IIIV. Four groups are identified: A: low symptoms + low risk; B: high symptoms + low risk; C: low symptoms + high risk; D: high symptoms + high risk.

Objectives: Characterize the 4 groups using the ECLIPSE (Evaluation of COPD Longitudinally to Identify Predictive Surrogate Endpoints) cohort.

Methods: 2028 COPD patients. FEV1<80%, pred, baseline mMRC, SGRQ and previous 12mo history of exacerbations. SGRQ score ≥25 was used to replace the CAT ≥10, using a validated conversion (Jones: BMCPulmMed 2011).

Results: The 4 groups were comparable on age and gender, but had different characteristics. Size of patient groups classified by mMRC were A: 23%, B: 14%, C: 3%, D: 60%. Compared to the SGRQ, patients classified as "low symptoms" (GOLD A & C) using mMRC had worse health status, more fatigue and lower exercise capacity (6MDW). Categories mMRC ≥2 produced groups of similar size to those classified by GOLD A: 9%, B: 28%, C: 4%, D: 59%. The kappa of agreement for group membership defined by SGRQ and mMRC increased from 0.2 (mMRC ≤1 vs ≥2) to 0.5 (mMRC 0 vs ≥1).

Conclusions: The new assessment permits classification of COPD patients beyond airflow obstruction. GOLD recommends either CAT ≥10 or mMRC ≥2 as the symptomatic cut-point, but this analysis suggests that mMRC ≥1 will classify patients more closely to using the CAT. Clinicaltrials.gov NCT00292552; GSK study SC0104960.
The small differences in classification of patients using CAT or MRC similar health status to those classified by CAT but are not directly equivalent. In influence treatment in only a very small proportion of patients.

Data suggest that CS instillation favors gas diffusion by increasing alveolar surface area, despite a large inhomogeneity in alveolar distension, likely reflecting local differences in surfactant distribution and/or alveolar compliance.

The mMRC cut-point of identifies a group of low symptom patients who have similar health status to those classified by CAT but are not directly equivalent. The small differences in classification of patients using CAT or MRC ≥1 may influence treatment in only a very small proportion of patients.

204. Modern clinical physiology: imaging structure and evaluating function

1652 In-vivo microscopy of the effect of surfactant on alveolar morphology

Caterina Salito1, Andrea Aliverti1, Enrico Mazzucca2, Barbara Uva3, Giuseppe Miserocchi4, Department of Bioengineering, Politecnico of Milan, Milano, Italy; 2Department of Experimental Medicine, University of Milano Bicocca, Monza, Italy

Changes in alveolar morphology induced by intra-tracheal delivery of CUROSurf (CS, Chiesi) were evaluated after opening a pleural window allowing in-vivo microscopic imaging (x300) of sub-pleural alveoli (fig 1a) revealing in physiological, non surfactant deprived conditions, a remarkable degree of geometrical inhomogeneity. Data were collected in 7 male anesthetized, tracheotomized and mechanically ventilated brown Norway rats (fig 1c, closed symbols). No changes in alveolar geometry were observed in animals not receiving CS (open circles).

Surfactant instillation, on average, caused an increase in alveolar area (fig 1b, closed circles), peaking at about 10% after 10 minutes and returning towards baseline after 20 minutes. The large standard deviation reflects the variability in caliper following CS instillation as shown for individual alveoli in one representative animal (fig 1c, closed symbols). No changes in alveolar geometry were observed in animals not receiving CS (open circles).

Conclusions: This is the first comparison of S3v with direct measurements of ventilation heterogeneity confirming the contribution of this parameter to the increase in S3v during bronchoconstriction.

1653 Comparison of changes in the expiratory capnogram waveform and regional ventilation distribution measured by synchrotron imaging during acute bronchoconstriction in brown Norway rat

Mathieu Guilbart1, Lisa Porr2, Loic Degugniliers3, Barna Babik4, Franck Robs5, Françoise Rogerieux3, François Marchal3, Bruno Chemet4, Sam Bayat3. 1Department of Physics, University of Helsinki, Finland; 2EA4285 UMR1, University of Picardie Jules Verne Medical Faculty, Amiens, France; 3Department of Anesthesiology and Intensive Therapy, University of Szeged, Hungary; 4EA 3450, Laboratoire de Physiologie, Faculté de Médecine, Université Henri Poincaré, Vandoeuvre les Nancy, France; 5Pediatric Cardiology and Respiratory Medicine, Amiens University Hospital, Amiens, France

Rationale: Although the increase in the phase III slope of the volumetric expiratory capnogram (S3v) is attributed to ventilation heterogeneity in patients, the relation between S3v and direct measurements of ventilation distribution has not been studied.

Methods: Rats divided into 2 groups: ovalbumin-sensitized (OVA) and exposed to air or to NO2, 10 ppm, 6h/d, 5d/wk for 4 weeks underwent K-edge subtraction synchrotron imaging, to measure regional ventilation (sV*), the area of well-ventilation regions (VAA) and ventilation heterogeneity (CV of sV*) at baseline and during intravenous infusion of methacholine (MCH, 15 μg/kg/min (γ)). S3v was computed using a rapid CO2 analyzer.

Results: S3v and CV of sV* increased during MCH infusion and the 2 parameters were correlated (R=0.78, p<0.001).

Conclusions: The increase in the phase III slope of the expiratory capnogram waveform and regional ventilation distribution measured by synchrotron imaging during acute bronchoconstriction in brown Norway rat.
tions can cause the interruption of femoral venous flow (Qfv). The purpose of this study was to determine the values of Pab, airflow, volume and time at which Qfv ceases and restarts within the respiratory cycle time (Ttot).

In 4 healthy subjects (age 45±2.1 yr) lying in semirecumbent position airflow was measured during quiet breathing (QB) by a pneumotachograph. Pab by gastric pressure measurements using catheter-balloon-transducer system and Qfv by an echo-Doppler probe. Qfv contour was extracted from the images recorded by the echo-Doppler. The values of Pab, airflow, volume above FRC (ΔV) and times t1 and t2 at which Qfv stopped and restarted (where femoral venous velocity could no longer be detected and became measurable again) within Ttot were calculated (see figure for a representative case).

t1 and t2 occurred respectively during inspiration and expiration when airflow averaged 0.4±0.04 and -0.39±0.10 L/sec. No significant difference between Pab at t1 (3±1.2±2.3 cmH2O) and t2 (2.8±2.0 cmH2O) was found. ΔV was 0.3±0.6±0.09 at t1 and 0.4±0.1±0.0 L at t2 (p<0.05). The fraction of Ttot in which Qfv was negligible, defined as (t2−t1)/Ttot averaged 0.3±0.07.

These data suggest that diaphragm and Pab variations produced by diaphragm contraction have a profound modulatory within-breadth effect on venous return from the lower limb and this modulation is dependent on Pab dynamics.

1656
Pulmonary edema is frequently triggered by marathon running

Gerald Zvezdicka1, Eric Milne2, Massimo Pistolesi3, Federico Lavorini3, Joseph Rienzi4, Kaleen Lav1, Allison Strahl5
1Human Physics Laboratory, Marywood University, Scranton, PA, United States; 2Radiological Sciences, University of California, Irvine, CA, United States; 3Section of Respiratory Medicine, University of Florence, Italy; 4Department of Radiology, Regional Hospital of Scranton, PA, United States

Despite the mounting evidence that pulmonary edema can be triggered by strenuous exercise, (Acta Physiol 2007, 189: 305-17) it is still widely debated (J Appl Physiol 2010, 109: 1276-80). The purpose of this study was therefore to determine if pulmonary edema is triggered by marathon running and, if so, to examine its incidence and severity. Twenty-seven runners completed the 2011 Steamtown Marathon, in Scranton, PA, United States, beginning at an elevation of 452 meters above sea level (8° C, 90% RH) and ending with a net elevation drop of 291 meters at the finish (21°C, 51% RH). All runners finished between 142 and 289 minutes. Posteroanterior (PA) and lateral (LA) radiographs were taken one day before the race, then at 19 (SD 8), 55 (13), and 98 (15) min post-marathon finish, the delay ensuring that any post-exercise increase in capillary blood volume would return to normal. Two experienced chest image readers (EM, MP) independently interpreted the images. They were blinded as to the times at which the images were taken. The PA/LA radiographs were viewed together as a set at each time-point and were scored on eight different radiological characteristics.

When summed together, the scores could range from 0 (no edema) to 32 (severe interstitial edema). Mean edema scores from all subjects increased from 1.5 units pre-exercise to 4.1, 3.7, and 2.8 units at 19, 55, and 98 minutes post-exercise, respectively (p<0.01). Nine runners (33%) had an average increase in the edema score (average of the 19 min post-score minus the average of the pre-score) >7.1 units (5-fold increase), which still remained high at 55 min post-exercise. In conclusion, pulmonary edema is triggered in 33% of marathon finishers.

1657
Regional hyperinflation in COPD patients: Correlation between lobar hyperinflation and internal flow redistribution

Wilfried De Backer1, Samir Vinchurkar1, Vin Mys1, Cedric Van Holsbeke2, Jan De Backer1,2 *Respiratory Medicine, University Hospital, Edegem, Belgium; 2Respiratory, FluxiDA.net, Kontich, Belgium

Background: Diagnosis of COPD patients is mainly based on lung function tests. Severe COPD patients often develop dynamic and static hyperinflation. However, few studies have addressed the association of hyperinflation and internal flow redistribution. This study describes the relation between regional hyperinflation and flow distribution in COPD patients.

Methods: Lobar volume levels in COPD patients (n=39). (FEV1)= 42.1±2.1 (n=141) (pried) were determined using functional imaging based on CT data (De Backer J. et al, Radiology 2010; 257(3):854-862). Lobar flow distribution was obtained by calculating the relative difference in the TLC and FRC volumes on the lobar level. The flow distribution towards the different lobes was compared to the imaged based volumes of the corresponding lobes.

Results: Statistically significant correlations (R²= 0.4, p< 0.04) were observed between lobar flow distribution and lobar volume-hyperinflation with more flow going to more hyperinflated areas.

Conclusion: Internal flow is redistributed towards the hyperinflated zones which means that also inhaled medication would mainly go to the hyperinflated areas leaving other areas flow partially untreated and this may further enhance the observed flow redistribution.

1658
Residual lung volume is associated with increased left ventricular mass

Benjamin Small1,2, David Blumenke1, Eric Hoffman1, Robert Basner1, Steven Kawan1, Martin Prince2, Antonine Gomez2, Daichi Shimb01, Chia-Ying Liu1, Joao Lima3, Erin Micbors4, Ravi Kallan5, Daniel Rabnitzivi6, Steven Shek1,2, R. Graham Batt1,2,1, Medicine, Columbia University, New York, NY, United States; 2Medicine, McGill University, Montreal, QC, Canada; 3Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD, United States; 4Radiology, University of Iowa Carver College of Medicine, Iowa City, IA, United States; 5Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States; 6Radiology, Columbia University, New York, NY, United States; 7Medicine, UCLA David Geffen School of Medicine, Los Angeles, CA, United States; 8Radiology, Johns Hopkins University, Baltimore, MD, United States; 9Medicine, Johns Hopkins University, Baltimore, MD, United States; 10Medicine, Northwestern University, Chicago, IL, United States; 11Radiology, Columbia University, New York, NY, United States; 12Epidemiology, Columbia University Mailman School of Public Health, New York, NY, United States

Increased left ventricular (LV) mass and chronic obstructive pulmonary disease (COPD) predict cardiovascular (CV) events, but their relationship is poorly understood. We hypothesized that residual volume would be associated with increased LV mass.

We recruited participants ages 50-79 years with ≥10 pack-year smoking history that were free of clinically apparent CV disease. LV mass was estimated by cardiac magnetic resonance. Body plethysmography and pre- and post-bronchodilator spirometry were performed according to ATS/ERS guidelines. Percent emphysema-like lung was estimated on full-lung CT. Anthropometry, medication use, blood pressure (BP), fasting glucose and lipid levels were measured in a standardized fashion. COPD was defined according to GOLD criteria. Multiple linear regression was used to adjust for age, sex, race/ethnicity, height, weight, body surface area term, smoking status, pack-yers, systolic BP, BP meds, fasting glucose, diabetes meds, low density lipoprotein, lipid lowering meds, and percent emphysema. Of 419 participants completing all study components, 65% had COPD (24% mild, 29% moderate, and 12% severe/very severe). Mean LV mass was 122±34 grams.
Residual lung volume was independently associated with increased LV mass in the fully adjusted model (p < 0.001). The magnitude of association for residual volume was similar on a SD basis to that of systolic BP (8.7 gm/95%CI 4.5–13 gm per 714 ml increase in residual volume versus 6.9 gm/95%CI 3.5–10 gm per 16 mmHg increase in systolic BP, respectively).

Residual volume is associated with increased LV mass. Further understanding of this relationship may improve cardiovascular risk assessment and represent a novel therapeutic target.

1659

Evidence of impaired spontaneous baroreceptor sensitivity in patients with COPD as a potential link to cardiovascular morbidity and mortality

Sherwin Asghar, Victoria Wieser, Robab Beytray-Kohansal, Irene Firlinger, Otto Burghuber, Arschang Valipour. Department of Respiratory and Critical Care Medicine, Ludwig-Boltzmann-Institute for COPD and Respiratory Epidemiology, Otto-Wagner Hospital, Vienna, Austria

Objectives: Recent studies suggest reduced cardiac filling pressures in patients with COPD due to hyperinflation. A reduction in cardiac preload may result in unloading of baroreceptors. We thus investigated spontaneous baroreceptor sensitivity, an independent predictor of cardiovascular morbidity and mortality, in patients with COPD and controls.

Methods: 33 patients with severe airflow obstruction but free from clinical cardiovascular disease (age 64±7 yrs, BMI 23±4 kg/m², FEV1 27±7%, TLC 140±19%) and 12 age, gender, and body-weight matched controls without airflow obstruction were studied. Spontaneous baroreceptor activity was measured using the sequence method during resting conditions. The baroreceptor effectiveness index was calculated from the total number of baroreceptor sequences divided by the total number of systolic blood pressure ramps.

Results: The mean slope of spontaneous baroreceptor sequences (7±±4±7 msec/mmHg vs. 13±±5±6 msec/mmHg, p < 0.01) and the baroreceptor effectiveness index (71±±54±9 vs. 103±±34±4, p < 0.05) were significantly lower in patients with COPD than controls. There was a significant inverse relationship between the slope of baroreceptor sensitivity (r = -0.302, p < 0.05) and baroreceptor effectiveness index (r = -0.391, p < 0.01) with RV/TLC ratio. There were no such associations with airflow obstruction.

Conclusions: Our findings indicate a link between hyperinflation and baroreceptor function in patients with COPD.

205. “Snoring and scoring”: subjective and objective measures of sleep-disordered breathing

1660

The Epworth sleepiness score should not be used to screen out patients with suspected sleep-breathing disorders

Sara Neale, Adrian H. Kendrick. Department of Respiratory Medicine, University Hospitals, Bristol, United Kingdom

The Epworth Sleepiness Score (ESS) is used to assess the level of daytime sleepiness as perceived by the patient. In some centres and in primary care, the ESS is used to reduce the number of referrals for suspected sleep-breathing disorders (SBD), where an ESS is within normal range (ESS 0–10), to be a reliable subjective measure of symptom improvement. However, there was poor correlation between ESS & hypersomnolence.

Reference:

1662

Sleep-breathing disorders (SBD) – Sleepiness, fatigue, quality of life (QoL) and depression

Adrian H. Kendrick, Sara Neale. Department of Respiratory Medicine, University Hospitals, Bristol, United Kingdom

Patients with SBD may present with sleepiness, fatigue, and often cannot separate them. SBD affects QoL and depression may occur.

Aim: To determine sleepiness, fatigue, depression and QoL in relation to the severity of SBD.

Methods: 150 consecutively referred patients had 2 nights of home oximetry (Minolta 300i). Oximetry data was analysed by experienced Physiologists (Down-load 2001, Stowood Scientific,UK) for 4% dips/hr and an Δindex cut-off of ≥0.6. Data is given as median (range). The highest dips/hr and Δindex was used in the analysis from either night.

Results: 130 patients had usable data; 39F and 91M, aged 50 yrs (19-79), ESS - 11.5 (1–23), MFI-20 - 4.8 (0.3-119) and 6.2 (0.1-118), and Δindex - 0.57 (0.2-5.6) and 0.63 (0.2-10.9) on the 2 nights respectively. There was no correlation between ESS and oximetry indices.

Distribution of patients based on Epopwth score:

<table>
<thead>
<tr>
<th>ESS</th>
<th>≤10</th>
<th>11–15</th>
<th>&gt;15</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;5% 4% dips/hr</td>
<td>25</td>
<td>14</td>
<td>13</td>
</tr>
<tr>
<td>5–18% 4% dips/hr</td>
<td>13</td>
<td>14</td>
<td>15</td>
</tr>
<tr>
<td>15–30% 4% dips/hr</td>

<td>15</td>
<td>16</td>
</tr>
<tr>
<td>Δindex &lt;0.6</td>
<td>34</td>
<td>23</td>
<td>20</td>
</tr>
</tbody>
</table>

25/130 (19%) had a normal 4% dips/hr and 20/130 (15%) had a normal Δindex in with a normal ESS of ≤10. 27/130 (21%) had a normal 4% dips/hr with an ESS >10.

Conclusion: The ESS, within limitations, is a guide as to whether daytime sleepiness is present. It should not be used to reduce referrals for assessment of suspected SBD, as part of a screening assessment using oximetry and a good clinical history. The reasons why patients have a high ESS in the absence of a significant SBD requires further investigation.

1661

Clinical audit of the Quebec Sleep Questionnaire in a routine sleep apnoea service

James Stockley, Theresa McCauley, Liam O’Reilly, Josie Hunt, Brendan Cooper. Lung Function & Sleep Department, Queen Elizabeth Hospital Birmingham, United Kingdom

Introduction: We reviewed 2 years of our obstructive sleep apnoea & hypopnoea syndrome (OSASH) service. The Quebec Sleep Questionnaire (QSQ) was used as a subjective measure of improvement with CPAP. We aimed to see if QSQ reflected symptomatic improvement in treated patients.

Methods: Referrals underwent history & baseline overnight oximetry (Pulsox 300e, Minolta, Japan). If positive for OSASH, they underwent an auto-titration and, if beneficial, a trial of CPAP. Of 783 patients, only 155 completed QSQ before & after the CPAP trial. QSQ includes 5 areas; Q1: hypersomnolence, Q2: diurnal symptoms, Q3: nocturnal symptoms, Q4: emotions, Q5: social interactions. An increased score indicated improved symptoms. We compared objective & subjective improvements with CPAP.

Results: Patients exhibited witnessed apnoeas (68%), snoring (90%), excessive daytime sleepiness (76%) with 56% showing all 3 symptoms. Differences in SpO2 dip rate, Epworth Score (ESS) & QSO pre- & post-CPAP trial are shown in Table 1. Surprisingly, there was poor correlation between hypersomnolence (Q1) & ESS.

QSQ scores (Q1-Q5), Diprate and ESS pre- & post-two week CPAP trial

P < 0.05 p < 0.05 p < 0.05 p < 0.05 p < 0.05 p < 0.05

Data is presented as mean (SD) with T-Test comparisons of Baseline to End of Trial.

Conclusion: QSQ correlates with subjective improvements in OSASH & appears to be a reliable subjective measure of symptom improvement. However, there was poor correlation between ESS & hypersomnolence.

282s

MONDAY, SEPTEMBER 3RD 2012
Conclusions: We observed high levels of fatigue and sleepiness and poor QoL. Patients with mild SBD had high levels of fatigue, depression and sleepiness, whereas patients with moderate SBD had a lower percentage of patients. It is essential to account for fatigue and QoL and to investigate negative studies further.

Screening for obstructive sleep apnoea (OSA) in patients attending a respiratory function laboratory

Aims: Some sleep laboratories use two SpO2 channels to better detect artefact. This study aimed to examine the agreement between two SpO2 monitors used concurrently on the same polysomnography (PSG).

Methods: 117 PSGs were audited for this study. The PSGs included channels from an integrated SpO2 monitor (Nonin) and an external device from another manufacturer (Masimo). The mean SpO2 and the desaturation index (DI) for both oximeters were compared. Comparisons were made using Bland Altman analysis, with limits of agreement (LOA) of 1.96 standard deviations, and confidence intervals (CI) of 95%.

Results: Bland Altman analysis indicated a bias of +1.7% (CI +1.4%, +2.0%), showing a systematic offset towards Masimo. The LOA were -1.2% (CI -1.7%, 0.7%) to 4.5% (CI 4.0%, 5.0%), indicating a variation of ±2.8%. Bland Altman analysis of the DI indicates a -38.5% (CI: -28.0%, -49.1%) smaller DI for the integrated sensor as compared to the external sensor.

Conclusions: When used to assess mean SpO2 there is a variation of ±2.9%, this may not be clinically acceptable. Additionally the external sensors produced systematically higher readings than integrated sensor. Therefore the outcome of an assessment of hypoxia is device dependent, if only one of these devices is used. There is poor agreement between devices with regards to the desaturation index. The integrated sensor detected 38.5% less desaturations compared with the external sensor. This systematic bias suggests that an assessment of sleep disordered breathing is device dependant.

Screening for obstructive sleep apnoea (OSA) in patients attending a hypertension clinic with features of the metabolic syndrome

Aim: To see if OSA is a common finding in patients with Metabolic Syndrome.

Background: Metabolic Syndrome has been described as a constellation of risk factors for cardiovascular disease (CVD). The WHO places the incidence at 21% of the population. OSA syndrome occurs in 2-4% of males and females. Both conditions represent a significant burden to the health service in terms of diagnosis, treatment and management. Volunteers agreed to undergo a home cardiopulmonary sleep study and interview with questionnaires including the Epworth score. Studies were manually scored to determine the Apnoea Hypopnoea Index.

Results: 35 volunteers were recruited. This yielded 32 studies (10 female) that were analysed. Mean age: 50 yrs (Range 26 – 73), mean BMI: 37.5 (±5.8). Significance of OSA (AHI>5) was found in 7 females (80%) and 20 male (88%) subjects, 86% overall.

Conclusion: OSA is prevalent in this group of patients and was not the primary reason for attendance. Epworth Score alone was a poor predictor of sleep breathing disorder in those with mild to moderate AHI. OSA is a risk factor for CVD and so we suggest that there should be routine screening for OSA in this particular patient group.

Pulse oximetry to assess sleep disordered breathing (SDB)

Aim: To determine the use of pulse oximetry in the assessment of SDB using 4 indices and the value of using 2 nights of assessment

Methods: 50 consecutively referred patients had 2 nights of oximetry at home (Minolta 300i). Data was analysed (Download 2001; Stowood Scientific, UK), by experienced Physiologists and artefact removed. The 4% and 3% dip/hr, cumulative %time at SpO2 < 90% (CT%, Olson et al, J Sleep Res 1999;8:51-55) and Aindex<0.6 (Levy et al, Chest 1996:109;395-99) were obtained for each night.

Results: 132 patients gave usable data, 39F and 93M, aged 50 yrs (19–79).

The median (range) differences between the two nights (N1 – N2) for the group were: 4% dip/hr: -0.78 (-29.5 to 19.9), 3% dip/hr: -1.2 (-15.6 to 20.2), CT%: -0.12 (-21.9 to 29.7) and Aindex: -0.04 (-10.4 to 1.2). Using a combination of these indices, 26/132 (20%) were negative for all 4, 66 (50%) positive for all 4, 10 for any 3, 12 for any 2 and 18 for any one.

Conclusions: To use pulse oximetry

1) requires analysis by experienced practitioners to ensure accuracy of data; 2) requires two nights, resulting in a > 25% increase in a positive diagnosis from the second night; 3) with a combination of the 4 indices, all of which have good sensitivity and specificity for SDB, gives an indication of the likelihood of SDB being present. Using a combination of any 3 or all 4 accounts for 77% of the patients assessed.

Forensic oximetry: Is it possible to confirm that the same patient has worn an oximeter on 2 nights?

Introduction: We suspected a patient had performed home oximetry on their partner as they did not wish to receive treatment or be stopped from driving due to their obstructive sleep apnoea syndrome (OSAHS). We wanted to see if it was possible to recognise a pulse rate “fingerprint” in patients who had performed consecutive sleep studies. We wanted to determine the normal variation in pulse rate (PR) on 2 nights in the same subject. The mean PR or the SD of the PR should be close enough to tell that the same patient is using the device.

Method: We reviewed mean and standard deviation (SD) of the pulse rates recorded during routine overnight oximetry and a multi-channel study in 37 patients [17F:20M Mean (SD); Age 50.8 (13.9) yrs] with suspected OSAHS. 16.4 (8.4) >4 dips per hour 37% of patients had confirmed OSAHS.

Results: The results (Table 1) show that mean difference in heart rate was 3.5 bpm (±1.7) and that statistically there was no little difference between the 2 nights. However, analysis by Bland & Altman (Fig 1) shows that the variation in pulse rate was 9-12%.

*Values shown as Mean (SD). No significant difference were found between Nights 1 & 2.

Discussion: The variation in pulse rate between any two oximetry studies is on average 10% or between ±7 bpm difference in the mean PR. However, 3 out of 37 patients had greater variation than this.

Conclusion: It is not possible on an individual basis to confirm if the same patient has performed an oximetry study. We have shown the expected normal range in PR for the same patient.

Cheest wall mechanics during induction of anesthesia

Background: It has been reported that anesthesia may be associated to variation in chest wall (CW) mechanics. We have developed a CW scanning system (CWS) based on self-mixing laser interferometers that allows the measurement of relative displacement. If this approach is combined with Forced Oscillation Technique (FOT) it allows to infer CW mechanics.

Methods: Five patients were studied during anesthesia induction at different stages, while they were submitted to a sinusoidal pressure forcing at the mouth with components at 5, 11 and 19 Hz. At each step FRC (GE, Engstrom CareStation) and CW mechanics (phase displacement among these points and the pressure stimulus) were estimated by spectral technique.

Results: Figure 1 shows results at 11 Hz. At all steps rib cage and abdomen the pressure stimulus travels faster in the rib cage than in the abdomen, likely because of the high inert of the latter. FRC presents a minimum during sedation, then it increased during pressure support and it reaches physiological values after the inhalation of sevoflurane.

283s
in the vastus lateralis of seventeen COPD patients, ten with low fat free mass index (FFMI, COPD1) (FEV1, 33±4.3%pred, FFMI 15±0.2 kg m⁻²), seven with preserved FFMI (COPD2) (FEV1, 47±7.3%pred, FFMI 19±0.6 kg m⁻²) and compared with nine age and gender-matched healthy sedentary subjects (C) (FEV1, 96±4.0%pred, FFMI 20±0.9 kg m⁻²). Mitochondrial density was reduced in COPD1 in comparison to COPD2 (1.8±2.0±0.5% and 2.7±2.4±0.4% respectively, p<0.05). In comparison to C, only COPD1 showed a reduction in mitochondrial mean linear diameter (0.15±0.0μm and 0.13±0.0 μm respectively, p<0.05) reflecting a reduction in mitochondrial size.

Mitochondrial density correlated with parameters of lung function, muscle function, exercise capacity and exacerbation frequency. Only exacerbations frequency remained independently related to mitochondrial density in a multiple regression analysis.

We conclude that peripheral muscle of COPD1 patients have a reduced mitochondrial density that is likely to contribute to a decreased oxidative capacity of the muscle.

Supported by Chief Scientist Office (CSO) Scotland 06/110/05 and The British Lung Foundation (Trevor Clay, Te0709). SG was supported by an ERS long term research fellowship.

Blunted muscle angiogenic response after exercise training in COPD patients

Elena Grou 1, Christian Prentif 2, Adriana Andriaou 1, Emilie Rouffet 1, Philippe de Riga 1, Nicolas Molinari 1, David Laoudj-Chenvesse 1, Jacques Mercier 1, Olivier Breton 2, Maurice Hayot 1, 1Department of Clinical Rehabilitation, INSERM U1046, CHRU Montpellier 1 and II, Montpellier, France. Metropolis, 2Pulmonary Rehabilitation, Pulmonary Rehabilitation Center “La Solane”, Fontalvage Group, Ottessa, France, Metropolis. 3Pulmonary Rehabilitation, Pulmonary Rehabilitation Center “La Solane”, Fontalvage Group, Lotde, France, Metropolis. 4Angiogenesis Research Group, York University, Faculty of Health, Toronto, ON, Canada; 5Department of Medical Information, CHRU Montpellier, UMR 729 MISTEA, University of Montpellier I, Montpellier, France. Metropolis.

In chronic obstructive pulmonary disease (COPD) patients, the skeletal muscle impairment reduces the exercise capacity. Systemic factors (i.e. oxidative stress, low grade inflammation ...) have been incriminated. Then, as for the muscle oxidative fibers, the muscle angiogenic-adaptive response to training could also be blunted in COPD, like in other chronic conditions. Therefore, we aim to characterise the muscle functional response, myofiber remodeling and angi-adaptations to training in COPD patients and sedentary healthy subjects (SHS). 21 COPD patients and 23 SHS completed a 6-week rehabilitation program based on individualized moderate-intensity endurance and resistance training. Histomorphological muscle analysis and measurements of pro-angiogenic vascular endothelial factor-A (VEGF-A) and antiangiogenic thrombospondin-1 (TSP-1) were conducted before and after training.

Both COPD patients and SHS improved their peak oxygen consumption (respectively, +0.96±2.4 and +2.9±2.6 ml/kg/min, p<0.001) and muscle endurance (respectively, +6.5% and +10.8%, p<0.001), although improvements were lower in COPD patients (group-time interaction: p<0.05 and p=0.06 respectively). Whereas the capillary-to-fiber ratio (C/F) and the angiogenic-adaptive VEGF-A/TSP-1 ratio increased in COPD patients and SHS (C/F: p<0.01, VEGF-A/TSP-1: p<0.05), the improvement in C/F was significantly reduced in COPD patients vs. SHS (p<0.05), and no fiber type switch occurred in patients. Absolute changes in C/F and in VO_2max were correlated (r=0.51, p<0.05). The angiogenic response may have driven the functional improvements. In addition to a lack of fiber switch, the angiogenic response to training was blunted in COPD patients.

1671
Effects of a 3-week inpatient pulmonary rehabilitation (PR) on muscle remodelling in patients with emphysema

Ina Heinzellmann 1, Sebastian Gehlert 2, Axel Clever 1, Christian Wingels 2, Bernd Szepanski 1, Bloch Wilhelm 1, Kenn Klaus 1, 1Department of Pulmonary Medicine, Schoen Klinik/Berchtesgadener Land, Schoenau am Koenigssee, Germany; 2Department for Molecular and Cellular Sports Medicine, German Sport University, Cologne, Germany.

Rationale: Exercise training of at least 10 weeks duration induces significant changes in myofiber size, capillarization and distribution in patients with emphysema. Up to date it is unknown which changes in muscle structure can be achieved by a German inpatient PR with a standard duration of 3 weeks.

Methods: Ten patients with emphysema (age: 57±5y; BMI: 24±3kg/m²; FEV1: 31±9%pred.) were included in this prospective trial. All patients performed an incremental cycle test to determine the peak work rate (PWR). The PR included daily supervised exercise training sessions (strength- and endurance training). Pre and post PR, biopsies from vastus lateralis muscle were taken.

Results: PWR improved significantly during PR (+17%M [95% CI, 6.3 to 22.7]% p<0.01). We observed a significant increase in the capillary to fibre ratio in fibre types I and IIa respectively (+0.5% [95% CI, 0.1 to 1.0]% p=0.03; +1.0% [95% CI, 0.6 to 1.4]% p<0.01) in skeletal muscle. We found a significant negative correlation between FEV1 pred. and the change in capillary to fibre I ratio (r=-0.633, p<0.05).
A non-significant but notable increase in the quantity of fibre type I (+6.5%), IIa (+2.2%) and IIx (+2.6%) was detected. Hybrid fibres decreased during PR (type IIa: -1.3% [95% CI. -2.21 to -0.39] p<0.01, type IIx: -5.2%, p<0.09).

**Conclusions:** These preliminary data show that an inpatient 3-week PR is able to exert relevant adaptations in peripheral muscle of COPD patients. This includes an increase in capillarization and an augmented type I myofiber distribution. To confirm these first results, further patients will be investigated.

### 1672 Changes in fatigue index during an 8 week quadriceps resistance training programme for patients with COPD & healthy controls

**Linzy Houchen**<sup>1</sup>, Samantha Harrison<sup>1</sup>, Carolyn Sandiland<sup>1</sup>, Manoj Monen<sup>1</sup>, Mike Morgan<sup>1</sup>, Sally Singh<sup>2</sup>, Mick Steiner<sup>1</sup><sup>,</sup> <sup>2</sup>**Pulmonary Rehabilitation Research Group, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; 3Faculty of Health and Life Sciences, Coventry University, Coventry, United Kingdom**

**Introduction:** Fatigue index (FI) measures the reduction in muscle force during muscle testing/training & can be altered by resistance training (RT). FI is seldom reported in patients with COPD. In isokinetic testing 2 variables are of interest: peak torque (PT) & total work (TWor).

**Aims:** To evaluate changes in FI for PT & TWor during 3-weeks of RT in patients & healthy controls.

**Methods:** 70 patients (mean ± SD age 68.6 [9.1]yr, FEV₁:44.8[15.2%] pt, 42 men & 22 controls [age 66.6 [5.1]yr, FEV₁:103.4[15.9%] pt, 12 men] completed quadriceps RT for 8weeks. RT was 5x30 knee extensions; 3times/week on a cybex dynamometer (speed=180°/sec). PT (Newton-metres:Nm) & TWor (Joules:J) were recorded for each set & FI was calculated as: set5/set1x100 for the right leg (weekly average). A high FI:less fatigue.

**Results:** There were no significant differences between/within-groups for PT FI over 8 weeks (FI approx 90% in both groups for all weeks). TWor FI in the COPD group did not significantly change over 8weeks. Control subjects displayed improvements in TWor FI & the difference in FI at week8 was significant compared to baseline & week4. However there were no significant differences between the 2 groups for TWor FI (Fig. 1).

**Figure 1**

**Conclusions:** Healthy controls experienced less fatigue in TWor as RT progressed. This did not occur in the COPD group & may be related to muscle dysfunction. TWor seems a more sensitive measure than PT.

### 1673 Effects of home-based pulmonary rehabilitation on the time spent in active- and passive-walking in elderly patients with COPD

Atsuveshi Kawagoshi<sup>1</sup>, Noritaka Kiyokawa<sup>1</sup>, Keiyo Sugawara<sup>1</sup>, Hitomi Takashahi<sup>1</sup>, Takeshi Kashihara<sup>1</sup>, Misunobu Homma<sup>1</sup>, Shinichi Sakata<sup>1</sup>, Masahito Satake<sup>1</sup>, Takanobu Shioya<sup>2</sup>, <sup>2</sup>**Physical Therapy, Akita University Graduate School of Medicine, Akita, Japan; 2Rehabilitation, Higashi Inaniwa Clinic, Akita, Japan; 3Rehabilitation, Akita City General Hospital, Akita, Japan; 4Pulmonary Medicine, Akita City General Hospital, Akita, Japan; 5Kumamoto technology and Industry foundation, Industry-University Cooperation and Promotion, Kumamashitohigun, Kumamoto Prefecture, Japan**

**Purpose:** The objective of this study was to evaluate the effect of home-based pulmonary rehabilitation (PR) including a chair-walking exercise and lower muscle training on daily active- and passive-walking time in elderly patients with COPD.

**Methods:** We assessed walking time according to the walking speed using a newly developed triaxial accelerometer (A-MES activity monitor, Kumamoto, Japan), which could measure the time spent in walking, standing, sitting and lying separately and also could discriminate active walking (>2 km/hour) from passive walking (<2 km/hour). Twenty elderly patients with COPD (Age:76±7 years; FEV₁:56±18.7% pred) were evaluated using this activity monitor for 3 consecutive days before and after PR. The home-based PR program included a chair-walking exercise, lower muscle training, stretching of body trunk, respiratory muscle training and education of self management. Pulmonary function, exercise capacity (6-min walking distance; 6MWD), quadriceps muscle force (QF), and health-related QOL (CRQ) were evaluated before and after PR.

**Results:** Active-walking time increased (pre PR: 27±23 vs. post PR: 52±31 min/day) and lying time decreased (pre PR: 53±18 vs. post PR: 36±18 min/day) significantly after PR. Frequency of standing increased (pre PR: 8±42 vs post PR: 117±63 times/day) significantly after PR. The degree of improvement of active-walking time after PR correlated with 6MWD and QF.

**Conclusions:** These data suggested that home-based PR consisting of a chair-walking exercise and lower muscle training was effective in improving active-walking time in elderly patients with COPD.

### 1674 The effect of post operative physical training on activity after curative surgery for non small cell lung cancer (NSCLC) – RCT

Gill Arbun<sup>1</sup>, Bellen Valladares<sup>2</sup>, Claire Speed<sup>1</sup>, Abdel Douni<sup>1</sup>, Nicholas Hart<sup>1</sup>, Nick Hopkinson<sup>1</sup>, Sally Singh<sup>1</sup>, Rachel Garrod<sup>1</sup>, <sup>1</sup>**School of Rehabilitation, Faculty of Health and Social Care Sciences, St George’s University of London; 2Therapy Department, Kings College Hospital NHS Foundation Trust, London; 3Health and Social Care Research, Kings College London; 4Respiratory & Critical Care Medicine, Guy’s & St Thomas’ NHS Foundation Trust, London; 5National Heart and Lung Institute, Royal Brompton Hospital, London, 6Cardiac and Pulmonary Rehabilitation, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom**

**Background:** In England and Wales the incidence of lung cancer is around 0.05%, with surgery the preferred curative intent. Strategies addressing quality of life (QoL) and activity post op are lacking.

**Aims and objectives:** To evaluate the effect of in-patient, cycle training, provided post op for NSCLC on physical activity at 4 weeks post op.

**Methods:** This RCT recruited patients undergoing curative lung resection. The control group received usual care. The active group additionally received daily cycle training a home walking programme with diary. Outcomes, measured pre, 5 days and 4 weeks post op, activity monitor data, muscle strength, exercise tolerance and QoL, (SF36). ANCOVA was used to test for differences between groups.

**Results:** 131 patients (72 female), mean age 67.5 (SD: 10.97) years, FEV₁ 2.4 (1.13) l, median ISWT to 290 [IQR: 190-440] were randomised. 63 (48%) had evidence of spirometric obstruction (OB). Physical activity was not significantly different between groups nor in those with OB. There were no significant differences in any secondary outcomes for the groups as a whole. However, in those with OB, physical and mental component scores for the SF36 were 11.7 (p = 0.04) and 19.6 (p=0.01) higher in the active group compared to controls at 4 weeks post op and muscle strength was significantly different between groups in favour of active (p = 0.04).

**Conclusions:** Compared with a control group, a cycle and home walking programme prevented decline in QoL and quadriceps muscle strength seen at 4 weeks post op in people with OB. These data support the need for further exercise interventions aimed at patients with OB undergoing surgery for NSCLC.

### 1675 Atherosclerosis in subjects with COPD is independently determined by the degree of airflow limitation

Lowie Vanfleteren<sup>1</sup>, Frits Fransen<sup>1</sup>, Martin Spruijt<sup>1</sup>, Miriam Groenen<sup>1</sup>, Emiel Wouters<sup>1</sup>, <sup>1</sup>**Program Development Center, CIBO+, Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 2Respiratory Medicine, MUMC, Maasstricht University Medical Center, Maastercht, Netherlands**

**Background:** Subjects with COPD have an increased cardiovascular risk that may be related to shared risk factors. To date, it is not clear whether this is a consequence of the severity of COPD itself.

**Objective:** We aimed to determine independent predictors of the presence of atherosclerosis in patients with COPD and establish whether and to what extent the degree of airflow obstruction is independently predictive for the degree of atherosclerosis in a model including all traditional cardiovascular risk factors.

**Method:** Pulmonary function, blood gases, packyears, body composition (BMI, FMFM), lipids, glucose, hsCRP, renal function (eGFR) and blood pressure were determined in 197 patients (mean±SD: age: 64±7 year, 60% male, FEV₁:51±17% pred., BMI: 26.2±5.2 kg/m²) with stable COPD prior to pulmonary rehabilitation. Carotid-wall intima-media thickness (c-IMT) was assessed in all patients (mean±SD: 0.93±0.18 mm) as an ultrasonographic surrogate measure of atherosclerosis. Independent predictors of an increased c-IMT were assessed using multivariate backward linear regression.

**Results:**

207. COPD: risk factors, biomarkers and diagnosis

1676 
Respiratory health at the extremes of the ageing population: Initial results of the UK Newcastle 85+ study
Theresa Small1, Joanna Collerton2, Karen Davies2, Mohammed Yadegarfar2, Thomas Kirkwood1, Paul Corrie1, Andrew Fisher1, Sir William Lethch, Freeman Hospital, Newcastle upon Tyne, United Kingdom; 1Institute for Ageing and Health, Newcastle University, Newcastle upon Tyne, United Kingdom; 2Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom

People aged 85+ years are demographically the fastest growing age group worldwide, increasing the burden on healthcare resources. In the Newcastle 85+ study subjects born in 1921, recruited from the Newcastle area, underwent domiciliary health assessment, including respiratory history, symptoms, spirometry and review of general practitioner (GP) records for pre-existing disease. 319 (Male: 52%, Female: 48%) took part, regardless of current health status.

Significant occupational exposure to heavy industry was reported by 42% men and 11% women. 31% men and 52% women were current or ex-regular smokers. Review of GP records showed 18% men and 16% women had a diagnosis of Chronic Obstructive Pulmonary Disease (COPD); 7% men and 13% women a diagnosis of Asthma; and 10% men and 7% women had other primary respiratory diagnoses. 92% performed reproducible spirometry. 28% males had normal spirometry, 13% restrictive and 59% obstructive spirometry (Mild 36%; Moderate 46%; Severe 15% and very severe 3%). In the females, 33% had normal spirometry, 16% restrictive and 51% obstructive spirometry (Mild 44%; Moderate 43%; Severe 11% and very severe 2%). The MRC Dyspnoea score was ≥2 in 38% men and 40% women. This study presents data on a large population of very elderly people. It shows a high prevalence of diagnosed airways diseases with 25% men and 29% women having asthma or COPD. Obstructive spirometry was reported in 59% men and 50% women with significant disability shown by MRC-dyspnoea score. These initial results suggest that respiratory compromise could have a significant impact on health care services in the coming years.

1677 
Passive smoking and COPD – More dangerous than believed
Stig Hagstad1, Tamara Schikowski2, Linda Ekerljung1, Anders Bjerg1, Anne Lindberg2,3, Eva Renlund1,2, Bo Lundback2,1. Krefting Research Centre, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden; 2.The OLIN Studies, Norrbottens Läns Landsting, Luleå, Sweden; 3.Department of Public Health and Clinical Medicine, University of Umeå, Sweden

Background: Passive smoking has been identified as a risk factor for cardiovascular diseases, asthma, lung cancer and with detrimental effects on lung function, but the relationship between passive smoking and COPD is not fully established.

Aim: To study environmental tobacco smoke (ETS) as a risk factor for COPD in never-smokers.

Methods: Data from three cross-sectional studies from the Swedish OLIN database were pooled. Only never-smokers were included in the analyses, and 2118 never-smokers had completed structured interviews and lung function tests of acceptable quality. COPD was defined according to the GOLD criteria. Risk analysis was performed by using multiple logistic regression analysis.

Results: Exposure to ETS at home was associated with COPD (OR 1.5, 95% CI 1.0-2.2). ETS at current or past workplace was also associated with COPD. The relationship was more pronounced in subjects who reported exposure to ETS at both past and current workplace (OR 2.4, 95% CI 1.5-4.0). Current exposure to ETS at home in combination with ETS at both current and previous workplace was strongly related to COPD (OR 3.6, 95% CI 1.6-8.5). There was a strong relationship between increasing amount of exposure to ETS in various settings and the prevalence of COPD, especially among women. Interestingly, of the 14 women aged ≥65 years who had reported current exposure to ETS at home and at both previous and current workplace, 7 had COPD.

Conclusion: ETS was found to be an independent risk factor for COPD. This relationship was stronger in women and the association was stronger with increasing degree of exposure.

Rationale: Smoking is the strongest COPD risk factor, however it has been recognised that a substantial proportion of COPD cases arises in non-smokers. Many studies suggest that obesity is more prevalent in patients with COPD, but it has not been elucidated whether this is also true for never-smokers. Aim of the current study was to assess the effect of change in BMI on incidence and persistence of COPD in never smoking women.

Methods: The current study used pooled data from the population based SAPAL-Dina and SALIA cohorts. Weight status was defined based on BMI at baseline and change in BMI. Pre-bronchodilator ratio of forced expiratory volume in one second over forced vital capacity (FEVI/FVC) was measured in both studies at baseline and follow-up. COPD was diagnosed according to the GOLD criteria or having FEVI/FVC<70% of normal limit of normal and percent predicted FEVI<80%.

Mixed regression models with random intercept for study area were used to assess the association between BMI change and COPD prevalence and incidence in non smoking women after adjustment for selected confounders.

Results: Lung function data and information on potential confounders were available in 962 women. The majority of women were never smokers (62.5%). The average BMI between baseline and follow-up ranged between 15.48-5.38 kg/m². The incidence of COPD according to the GOLD criteria stage 1 was 3.2% and the incidence in the combined stage 2 and higher was 2.52%. The odds of developing COPD in stage 2 increased by a factor of 1.1 for each unit increment in BMI. Menopausal status did not influence this association.

Conclusion: The results of our analysis suggest that a change in BMI influences the development of COPD in never-smoking women.

1679 
COPD – Prevalence and risk study from rural north India
Mukhmdut Singh, Anup K. Mukherjee, Surendra K. Ahluwalia, Anu Bhardwaj, Shiveta Saini. Community Medicine, MMMSR, Mullana, Haryana, India

Background: The increasing impact of Chronic Obstructive Pulmonary Disease (COPD) on health care resources is now being recognised as a major public health problem and is projected to be the third leading cause of death worldwide by 2020.

Aims and objectives: To estimate the prevalence and assess the risk factors for COPD in adults using spirometry (GOLD criteria).

Methods: A community-based, cross-sectional, multiphasic survey was conducted on 2112 adults, age ≥35 years. COPD was diagnosed using fixed ratio post bronchodilator FEV1/FVC<70% on spirometric evaluation conducted on participants who screened positive using clinical (by validated respiratory questionnaire) or PEF criteria.

Results: The overall prevalence of COPD was 8% (10.8% in males and 5.1% in females). The prevalence of COPD was 15.3% in the ever smokers and were at 3.54 times higher risk (95% CI 2.6-4.9) compared to non smokers. The exposure to high risk occupation showed an increased risk for development of COPD [OR 3.983, 95% CI 2.8-5.5] than the non exposed individuals. Among females, the prevalence was highest for the heavy kitchen smoke exposure (8.2%). On logistic regression the factors related with COPD were age >65 years [OR 1.079-95% CI 0.641-1.095], exposure to high risk occupation [OR 2.395 95% CI 1.485-3.861] and smoking [OR 2.263 95% CI 1.467-3.492]. Other factors as exposure to passive tobacco smoke, education, socio-economic status did play a role independently, however no significant higher risk was observed using multivariate statistical model.

Conclusion: Ageing, smoking, occupation and biomass smoke exposure certainly explain the web of causation on the background of other risk factors as passive smoking, education and socioeconomic status.

1680 
Association between serum levels of clara cell secretory protein and lung function in adults from ECRHS
Marta Raya1,2, Lluisa Tares1, Iris Lavi1, Esther Barreiro3, Jan-Paul Zock1, Anna Ferrer1, Nerea Munozaren2, Rachel Nad2, Francine Kaufmann3, Josep M. Anto1, Stefano Granata1,1 Centro de Recerca en Epidemiologia Ambiental CREAL, Parc de Recerca Biomèdica de Barcelona - PRBB, Barcelona, Spain; 2Respiratory and Environmental Epidemiology Team CESP, Centre for Research in Epidemiology and Population Health UMR U1019, INSERM, University Paris Sud, Villejuif, France; 3Unit of Epidemiology and Health Information, IMIM-Hospital del Mar, Parc de Salut Mar, UFG, CIBERES, Barcelona, Spain; 4Hospital General de Almansa, Complejo Hospitalario Universitario de Albacete, Spain; 5Ousuam Saida, Bizkaiko Lurralde Zuzendarren, Public Health of Bizkaia, Department of Health, Basque Government, Bilbao, Basque Country, Spain

The 16-kD Clara cell secretory protein (CC16) has anti-inflammatory properties and protective effects from oxidative stress on the respiratory tract and has been

Conclusion: In addition to traditional cardiovascular risk factors, such as obesity, older age, higher blood pressure and higher fasting triglycerides, atherosclerosis (c-IMT) is independently predicted by increasing airflow limitation in patients with COPD.
proposed as a biological marker of pulmonary health. Whether CC16 is associated with lung function and airflow limitation in the general population remains proposed as a biological marker of pulmonary health. Whether CC16 is associated with lung function and airflow limitation in the general population remains unclear.

We used data from the population-based Austrian BOLD study. Parameters (FEV1% and FVC% predicted and FEV1/FVC), airflow limitation (AL) defined by GOLD criteria (FEV1/FVC <0.70) were considered. All the analyses were adjusted for center, sex, age, smoking, pack-years, body mass index (BMI), and height. Mean CC16 level was 5.8 (sd=2.9), ranging from 0.4 to 19 g/l. CC16 <5 g/l was associated with lower lung function and moderate/severe airflow limitation in the general population.

This association was stronger in asthmatics (2.6% increase (95% CI 0.6-4.5) in FEV1/FVC) as compared to non-asthmatics (0.6% CI 0.1-1.0) (p for interaction 0.01). CC16 levels were lower in subjects with moderate/severe AL (4.1 μg/l) compared to multifactorial multivariate regression=0.04), but not in those with mild AL (5.7 μg/l, p=0.3) compared to subjects with no AL (5.9 μg/l). This study shows that reduced CC16 levels are associated with lower lung function and moderate/severe airflow limitation in the general population.

Funded by Spanish FIS ISCIII PS09/01354 and ERS fellowship 123-2011.

**1681 Screening of citizens with suspicion of COPD in eight municipalities in Denmark**

Jens Dollerup1, Torben Jakobsen2, Henriette Fischer3, Ulla Hemmingsen4, Susanne Ollendorff5, Jeanette Madsen 6, Maj-Britt Gulstad 7, Henrik Borggren8, Birgitte Kivis8, Peter Bo Poulsen1,1 Medical & Access, Pfizer Denmark; Ballerup, Denmark; 2Department of Health Prevention and Promotion, Municipality of Ebeltoft, Ebeltoft, Denmark; 3Healthcare Center Struer, Municipality of Struer, Struer, Denmark; 4Health Secretariat, Municipality of Vordingborg, Vordingborg, Denmark; 5Department of Health Prevention and Promotion, Municipality of Vejle, Vejle, Denmark; 6Department of Health, Municipality of Gråborg, Helsingør, Denmark; 7Department of Health, Municipality of Jægerspris, Brovst, Denmark; 8Social Centre, Municipality of Solrød, Solrød, Denmark; 9Department of Health Prevention and Promotion, Municipality of Frederikshavn, Frederikshavn, Denmark.

**Background:** Around 430,000 Danes suffer from chronic obstructive pulmonary disease (COPD) with one-third diagnosed today. Danish National Board of Health (NBH) recommends early detection of COPD, focusing on smokers/ex-smokers (or high-risk occupation) above 35 years with ≥ 1 respiratory symptom. Municipalities have been suggested to be responsible for early detection. A pilot study found early detection in municipalities to be feasible and reliable in terms of citizens ending up with the final diagnosis of COPD at their GP.

**Aim and objective:** To investigate the success of screening for COPD in eight Danish municipalities.

**Methods:** Eight municipalities (430,000 inhabitants) offered spirometry to citizens (self-referral) with no previous COPD diagnosis fulfilling the NBH criteria. Citizens with airway obstruction (fixed ratio: FEV1/FVC <0.70) were requested to visit their GP for diagnosis. Data, including spirometry and smoking habits, were recorded in a secure database.

**Results:** 950 citizens in the risk group of COPD were included (55% females, 58 years, 45% smokers, 30 pack-years, 1-2 lung symptoms, MRC 1.6). Of the sample 34% (323) (22-44% in different municipalities) had indication of airway obstruction. Screening spirometry suggested 86% had mild to moderate COPD. With evidence from the pilot study: 85% detected by municipality screening end up diagnosed with COPD at their GP. This suggests that 29% (275) of the patients in the present sample were COPD patients. After screening 65% of smokers were interested in quitting smoking.

**Conclusions:** Early detection of COPD at the municipality level seems to be worthwhile and successful. Together with the GP-level this might identify undiagnosed COPD patients.

**1682 Is spirometry properly used to diagnose COPD? Results from the population-based BOLD study in Salzburg, Austria**

Benedikt Lampevent1, Andrea Mahrtger1, Bernhard Kaiser2, Joan Soriano2, Michaela Zeitler,3 Department of Pulmonary Medicine, University Salzburg, Austria; 1Program of Epidemiology & Clinical Research, Fundacion CIBER-CARDIO, Banyuls, Spain

**Background & objective:** Current guidelines recommend post-bronchodilator spirometry to confirm a diagnosis of COPD. We investigated whether a self-reported diagnosis of COPD was associated with prior spirometry and, whether a correct diagnosis of COPD was made reliably when spirometry was reported.

**Methods:** We used data from the population-based Austrian BOLD study. Participants were aged >40 years, and completed the BOLD questionnaire and post-bronchodilator spirometry.

Reported COPD diagnosis and reported prior lung function test were based on the BOLD questionnaire. Non-reversible airways obstruction (AO) was defined as post-bronchodilator FEV1/FVC <0.7. A correct diagnosis of COPD was defined, when subjects reported a prior COPD diagnosis and demonstrated non-reversible airways obstruction on post-bronchodilator spirometry.

**Results:** 68 (5.4%) of 1258 participants reported a prior physician’s diagnosis of COPD. Among those only 25.0% (1768) reported a lung function test within the past 12 months, and 67.6% (46/68) at any time in the past. The likelihood for a correct COPD GOLD stage I+ diagnosis was similar among subjects reporting (likelihood ratio 2.07 [95% CI, 0.89 – 5.00 CI]) and subjects not reporting (likelihood ratio 2.78 [95% CI, 1.58 – 4.87]) a lung function during the last 12 months. Similar likelihood ratios were seen when GOLD stage II+ was investigated and, when lung function was reported at any time in the past.

**Conclusion:** One third of subjects with a reported diagnosis of COPD never had a lung function test. When spirometry was reported, this did not increase the likelihood for a correct COPD diagnosis.

**1683 Inhaled corticosteroids and the risk of pneumonia in Medicare patients with COPD**

Julia Thornton Snieder1, Yesenia Luna1, Ken Wong2, Jie Zhang2, Susan Chen1, Dana Golomb1*, Patrick Gless.1 Research, Precision Health Economics, Los Angeles, CA, United States; 2Health Economics & Outcomes Research, Novartis Pharmaceuticals, East Hanover, NJ, United States; 3School of Policy, Planning and Development, University of Southern California, Los Angeles, CA, United States; 4School of Pharmacy, University of Southern California, Los Angeles, CA, United States.

**Background:** A growing number of studies have found a positive association between the use of inhaled corticosteroids (ICS) in chronic obstructive pulmonary disease (COPD) and the risk of pneumonia.

**Objective:** To determine the relationship between ICS use and risk of pneumonia among Medicare patients with COPD.

**Methods:** We performed a nested case control analysis to study the relationship between ICS use and risk of pneumonia in a cohort of Medicare Advantage members with COPD. We designated a case to be a member’s first inpatient or outpatient episode of pneumonia. Cases were matched to controls of the same age and sex who entered the COPD cohort at the same time but had not yet contracted pneumonia by the case’s event date. We estimated the association between ICS use and pneumonia using logistic regression analysis. Adjusted models controlled for age, sex, race, use of other COPD medication classes, markers of COPD severity, receipt of the pneumococcal vaccine, and comorbidities.

**Results:** Out of a COPD cohort of 83,455 members, we identified 13,778 episodes of pneumonia, which were matched to 36,767 controls. Adjusting for covariates, we found that having used any ICS during the past year is associated with an increased risk of a pneumonia episode (OR 1.16, 95% CI: 1.14-1.18). In alternative specifications, we found the risk of pneumonia is highest for current ICS users (OR 1.26, 95% CI: 1.16-1.36) and current high-dose users (OR 1.55, 95% CI: 1.25-1.92), compared to non-users.

**Conclusion:** Our study confirms the finding of previous studies that ICS use – especially current use and high-dose use – is associated with increased risk of pneumonia.

**208. Novelties in clinical management of thoracic diseases: from diaphragm paralysis to pleura**

Matthew Kaufman, Andrew Elkwood, Michael Rose, Tushar Patel, Russell Ashinoff. The Institute for Advanced Reconstruction, Jersey Shore University Medical Center, Showsbury, NJ, United States.

Diaphragm paralysis may cause symptomatic respiratory disturbances, and often occurs as a result of iatrogenic or traumatic phrenic nerve injury. Treatment options have been limited to placement of the diaphragm, however it is likely that most patients receive no therapeutic intervention regardless of the severity of symptoms. Although nerve transplantation is efficacious for various peripheral nerve injuries, it has only begun to be established for analogous conditions involving the phrenic nerve. Thirty consecutive patients presenting with chronic, symptomatic phrenic nerve injuries following surgery, traumatic manipulation, trauma or anesthetic blocks were screened for eligibility. Interventional evaluation, including radiographic and electrophysiologic assessments. Inclusion criteria consisted of patients who failed to improve.
during six months of conservative management, in whom a clear etiology for phrenic nerve injury could be elicited and confirmed with pre-operative evaluation. Measures of post-operative improvement included: pulmonary function testing, chest fluoroscopy, and a standardized quality-of-life survey.

Reversal of diaphragm paralysis was clearly demonstrated in 77% of patients (2/3) following nerve transplantation. In four patients (13%) there was no clinical or radiographic evidence of diaphragm function after 18 months, whereas in the remaining three patients (10%) it was too early to determine if surgical intervention was successful. There were no pulmonary or cardiac complications.

Nerve transplantation may reverse phrenic nerve injury and should be considered as an effective treatment option in the management of symmetric diaphragm paralysis.

Conclusion: The data suggest that NF eliminated significant acid liquid reflux. An abnormal airway pH with a mean Ryan score of 175.28 (range 17.5-573.46) of 3.47 (range 0.5-11.7), normal of 15 (68%) of these patients had an abnormal airway pH study with a mean upright normal of 39 (range 25-66), normal of 14.72. Out of the 7 with normal DeMeester 5 had substituted the study population. All of these patients continued to have troublesome cough in impaction of gaseous reflux in the pharynx and upper airways rather than acid reflux.

Proadrenomedullin improves the prognostic property of the BODE index. We prospectively evaluated 638 patients with stable COPD for improvement in COPD. We hypothesize that systemic biomarkers might additionally improve categorization and outcome prediction in COPD. There were 63 deaths among the 638 patients (9.9%). 32 (51%) of the deaths were attributed mainly to COPD. Patients with higher proadrenomedullin (p < 0.0001 both) were significantly associated with 2 year survival. The C-index for the prediction of mortality in COPD was 0.72 (0.68-0.76, p = 0.001). The addition of proadrenomedullin to the BODE index improved its performance significantly (C-index 0.743, p = 0.00020). In combination with proadrenomedullin, the BMI (B), the degree of airflow obstruction (O) and dyspnea (D) domains by itself (e.g. without exercise capacity) performed similarly to the BODE index (C-index 0.772).

Conclusion: Proadrenomedullin improves the performance of the BODE index at predicting the risk of death from any cause among patients with COPD.

1687 Is the bacterium T. whipplei cause of the disease in a subgroup of patients with presumed sarcoidosis?

Aim: To assess pharyngeal gaseous pH in patients who failed to respond to NF, a recognised treatment option for patients who fail medical treatment. Unfortunately some patients continue to be symptomatic even after NF.

Methods: Retrospective case review of 22 patients who remained symptomatic post NF at Castle Hill Hospital, UK. All subjects had pre-NF oesophageal manometry, a 24 hour ambulatory PH monitoring and a post-NF airway pH measurement, using Restech DP-H pH measurement system. Some of these patients continued to have troublesome cough evidenced by a high pH Cough Hypersensitivity Score with a mean score of 28 (range 25-46), normal < 12.

Results: Total of 22 patients (18 female) with a mean age of 44±18.72 years, underwent a subtotal paraesophageal hysterection and a normal Ryan score of 145 (range 17.2-573.46), normal < 9.41. All of the 7 patients who had 24 hour oesophageal pH monitoring had a normal DeMeester score with a mean of 3.47 (range 0.5-11.7). Out of the 7 patients with a normal DeMeester score 5 had an abnormal airway pH with a mean Ryan score of 175.28s (range 17.5-573.46).

Conclusion: The data suggest that NF eliminated significant acid liquid reflux. A significant proportion of patients continued to have airway gaseous reflux as evidenced by a positive Ryan score. This implies that the aetiology of chronic cough lies in impaction of gaseous reflux in the pharynx and upper airways rather than acid reflux detected on conventional testing.

1688 Sarcoidosis relapses in corticosteroid treated patients

Assessing the frequency of relapses and the disease characteristics associated with relapses in corticosteroid treated sarcoidosis patients.

Aim: Assessing the frequency of relapses and the disease characteristics associated with relapses in corticosteroid treated sarcoidosis patients. Sarcoid relapses were defined as 125 patients with biopsy-proven sarcoidosis treated with corticosteroids for 6-18 months after diagnosis were evaluated. Number and type of relapses were noted during the follow-up period. The clinical and laboratory parameters were compared in patients with a relapse of the disease versus (vs) patients without relapses.

Results: 38 patients (30%) had a sarcoid relapse, 2-4 months after the treatment stop (mean interval 11±6.13 months). The manifestations were clinical in 36 patients (similar symptoms as at diagnosis), radiological in 34 and functional in 26 (decreased diffusion capacity in 22 patients, pulmonary volumes in 13 and flows in 15). The relapses were seen in 7 patients with complete remission after the first treatment, 30 with partial remission and 1 with stationary evolution. The patients with relapses had more frequent interstitial lung disease at diagnosis compared to patients without relapses (88 vs 59%, p = 0.007), more frequent duration <1 year of the first treatment (42 vs 10%, p = 0.007), more severe diffusion capacity impairment (26 vs 10%, p = 0.044) or absence of complete remission after the first treatment (81 vs 45%, p = 0.003). No other significant differences were seen in clinical or laboratory parameters.

Conclusions: Almost one third of the sarcoidosis patients in which corticosteroid treatment was necessary at diagnosis had a disease relapse during the follow-up period. Disease severity at diagnosis or at the end of the first corticosteroid treatment and the short duration of the treatment were associated with the occurrence of a relapse.

Occurrence of hypersensitivity to beryllium among patients with diagnosed sarcoidosis. Initial results
Lukasz Kasprzak1, Krzysztof Sladek1, Jerzy Soja1, Hanna Platecka2, Marek Sanak1, 1Division of Thoracoscopy and Bronchoscopy, Jagiellonian University, Cracow, Poland; 2Division of Molecular Biology and Clinical Genetics, Jagiellonian University, Cracow, Poland

Introduction: Sarcoidosis is a form of interstitial lung disease of unknown cause. In this disease the formations of granulomas are diagnosed also among individuals with berylliosis – an occupational disease clinically similar to sarcoidosis, but associated with hypersensitivity to beryllium.

Aim of study: Our objective is to determine the frequency of hypersensitivity to beryllium in individuals with diagnosed sarcoidosis and to attempt to work out diagnostic methods of berylliosis.

Methodology: Individuals selected for the research were diagnosed with sarcoidosis. All individuals were screened using a modified beryllium lymphocyte proliferation test (BeLPT). The method involved isolating blood lymphocytes, staining them with fluorescent marker (CFSE) and exposing them to beryllium sulfate (of various concentration) or mitogen (positive control). The number of dividing cells (CFSE dilution) was marked after 5 days of incubation with flow cytometry. Individuals suspected of positive proliferation test result and those suspected of the risk for beryllium compounds exposure will be examined by patch tests with beryllium sulfate.

Results: 30 individuals with sarcoidosis have been tested. 5 of them (14.3%) exhibited increased lymphocyte proliferation index.

Conclusions: The study attempts to present a new diagnostic method of identifying hypersensitivity to beryllium. Presently, neither reliable in vitro tests for berylliosis have been standardised nor routinely carried out. Our method requires validation against patients with berylliosis, testing the method in control group and comparison of BeLPT-CFSE methods with a standard thymidine test.

1690
Pentraxin-3: A novel biomarker for the differentiation of parapneumonic effusion and malignant pleural effusion
Savas Ozsu1, Yasin Abul1, Ahmet Mentese1, Hayryne Bektas1, Aysegul Uzun2, Tevfik Ozlu1, 1Department of Chest, Karadeniz Technical University Faculty of Medicine, Trabzon, Turkey; 2Department of Biochemistry, Karadeniz Technical University Faculty of Medicine, Trabzon, Turkey

Pentraxin-3 (PTX-3) is a new marker of inflammation. Pentraxins like C-reactive protein are key components of the innate immune system. Diagnostic value of PTX-3 in parapneumonic pleural effusion (PPPE) and malignant pleural effusion (MPE) has not been examined before.

The concentrations of pleural fluid PTX-3 were measured in a total of 61 patients: 20 with PPPE and 41 with MPE. A diagnosis PPPE was based upon the presence of an effusion in patients with clinical and radiological evidence of acute pneumonia. A malignant pleural effusion (PE) was defined by pleural biopsy or the presence of malignant cells on PE cytology. The area under the curve (AUC) quantified the overall diagnostic accuracy of the tests.

The study demonstrated that PTX-3 concentration was higher in pleural fluid of PPPE patients compared with MPE patients (31.8 ng/mL vs 6.9 ng/mL, respectively, p<0.001). Pleural effusion PTX-3 for PPPE at the cut-off concentration of 8.5 ng/mL was 80% and 64%, respectively.

Measuring PTX-3 concentrations in pleural fluid may be helpful in distinguishing pleural effusion due to a PPPE or MPE aetiology.

209. Pulmonary circulation and functional lung imaging

P1692
Simultaneous imaging of lung structure and function with triple nuclear MRI
J. M. Wild1, Helen Marshall2, Graham Norquay1, Peggy Xu1, Juan Parra-Robles3, 1Academic Radiology, University of Sheffield, United Kingdom

Rationale: In this work, we re-engineer a standard clinical MRI scanner to allow spatially registered human lung imaging from three different nuclei simultaneously with 1H anatomical images and hyperpolarized 3He and 129Xe lung ventilation images.

Methods: This is achieved by the use of geometrically nested, decoupled radio-frequency (RF) coil hardware resonating at the respective resonant frequencies. Multi-nuclear RF transmission and reception is achieved by rapid switching (<10 ms) between the signals from the respective nuclei. The technique is demonstrated with simultaneous imaging of 3He, 129Xe and 1H in the lungs of healthy normal’s following an inhalation of a 1 litre bag of gas containing 300 ml of 3He and 400 ml of 1H.

Main results: See Fig. 1. Images of 1H, 3He (red), and 129Xe (blue) acquired from a healthy volunteer in the same breath containing 300 ml of 129Xe and 300 ml of 3He; the anatomical 1H image shows excellent spatial registration with the 3He and 129Xe ventilation images as demonstrated by the overlaid fused image (purple).

Figure 1

Conclusions: The precise temporal and spatial registration of these images is impossible to achieve in separate breath-hold scans. This new system opens up the possibility of simultaneous capture of regional lung function by exploiting the different properties of 3He and 129Xe gases (eg different diffusivities) with lung structure and anatomy from the 1H MRI without reliance on ionizing radiation.

PET imaging with [11C]PBR28 and [18F]FDG distinguishes macrophage from neutrophil lung inflammation
Delphine Chen1, Eugene Agapow2, Kiran Solingaparam1, Jacqueline Engle1, Elizabeth Griffin1, Steven Brody2, Jason Woods2, Robert Mach1, Richard Pierce2, Michael Holtzman1, 1Multinuclear Institute of Radiology, Washington University School of Medicine, St. Louis, MO, United States; 2Internal Medicine/Division of Pulmonary and Critical Care Medicine, Washington University School of Medicine, St. Louis, MO, United States.

Introduction: Noninvasive methods for quantifying macrophage and neutrophil activation and recruitment in chronic obstructive pulmonary disease (COPD) would be highly useful in assessing the efficacy of anti-inflammatory therapies.

Objective: To test whether positron emission tomography (PET) imaging with [11C]PBR28 and [18F]fluorodeoxyglucose ([18F]FDG) could distinguish macrophage-dominant from neutrophilic inflammation in a mouse model of COPD.

Methods: C57BL/6J mice inoculated with PBS or Sendai virus were imaged by microPET (Inveon or Focus 220, Siemens/CTI) with both [11C]PBR28 and [18F]FDG at Days 3 and 84 post-inoculation (p.i.). Regions of interest placed over the lungs determined the % injected dose per cc (%ID/cc) at 60 min. Lung sections were stained for TSPO ([11C]PBR28 ligand), Ly6G (neutrophil marker) and CD68 (macrophage marker).

Results: Only [18F]FDG uptake increased significantly during acute illness at p.i. Day 3. Both [11C]PBR28 and [18F]FDG uptake increased significantly during chronic disease at p.i. Day 84. The [11C]PBR28/[18F]FDG ratio, calculated for each mouse, was different between infected (1.9 ± 0.5) and uninfected mice (2.0 ± 0.9) at Day 3. This ratio increased significantly at p.i. Day 84 (3.1 ± 0.9) in infected mice compared to controls (1.7 ± 0.5). Lung sections showed macrophages with intense TSPO staining at p.i. Day 84.

Conclusion: PET imaging with [11C]PBR28 and [18F]FDG quantitatively distinguishes macrophage-dominant from neutrophilic inflammation in a mouse model of COPD. This approach may be useful for monitoring the pulmonary macrophage burden in humans with COPD, thereby guiding emerging targeted anti-inflammatory therapies.

3He MRI in young adults with congenital diaphragmatic hernia: Alveolar size differences between lungs
Maaike Snel1, Helen Marshall1, Hanneke Jissevijn1, Juan Parra-Robles2, Piet Wielopolska1, Elis van der Wiel1, Andrew Swift2, Shmita Rajaram2, Dick Tibboel1, Harm Tiddens2, Jim Wild1.

Methods and Measurements
3He MRI was used to image regional ventilation and to compute apparent diffusion coefficients (ADC) for ipsilateral (left) and contralateral lung separately. Volumes were gated CINE MR and phase contrast imaging sequences were acquired in all patients. During follow-up of 42 months, 16 patients died. Cardiac volumes and function and survival in patients with pulmonary hypertension due to COPD were assessed using univariate and multivariate regression or Kaplan-Meier analysis.

Results: Low SV measured by phase contrast MRI predicted mortality independently of demographic, haemodynamic, lung function and embolus severity data (p=0.029). LVEF predicted mortality from univariate analysis (p=0.017), but did not reach significance at multivariate analysis (p=0.573). According to Kaplan-Meier survival curves, outcome was less favourable for patients with an inframedian SV index < 40 mL/m² (log rank: p=0.007), and worse outcome was associated with a LVEF <61%.

Right ventricular end-diastolic and systolic volume and left ventricular end-diastolic and end-systolic did not significantly predict mortality at Cox proportional hazards regression or Kaplan-Meier analysis.
Conclusions: Low SV is a strong predictor of adverse outcome in patients with PH-COPD. Static ventricular volumes did not aid the prediction of adverse outcome.

P1607
Quantitative estimation of lung perfusion scintigraphy in patients with chronic thromboembolic pulmonary hypertension and idiopathic pulmonary arterial hypertension
Olga Arkhipova, Tamila Martyukov, Ludmila Samoileenko, Vladimir Sereginko, Irina Chazova. Department of Systemic Hypertension, Russian Cardiology Research-and-Production Complex, Moscow, Russian Federation

Aim: To estimate lung perfusion in patients with chronic thromboembolic pulmonary hypertension (CTEPH) and idiopathic pulmonary arterial hypertension (IPAH) by perfusion scintigraphy with technetium-99m macroaggregated albumin.

Methods: The study included 54 pts with pulmonary arterial hypertension: 21pts (12 f/9m) with CTEPH and 33 pts with IPAH. Patients were comparable on age (45.7±12.5/37.5±10.5), WHO FC, systolic pulmonary artery pressure and distance in the 6 minute walking test. A 111-MBq dose of 99mTc-labeled macroaggregated albumin (99mTc-MAA) was injected into a cubital vein with the patient in a horizontal position. Just after, lung scanning was performed using a gamma-camera system Philips SKY LIGHT. Calculated including 99mTc-MAA in the upper, mean, lower zones of each lung and relation of the upper share to the lower was considered (U/L). Results:

<table>
<thead>
<tr>
<th>Zone</th>
<th>CTEPH</th>
<th>IPAH</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zone V esta No. 1, %</td>
<td>41.3±6.8</td>
<td>40±3.2</td>
</tr>
<tr>
<td>Left Lung</td>
<td>36.2±5.0</td>
<td>37.5±5.0</td>
</tr>
<tr>
<td>Right Lung</td>
<td>7.0±3.2</td>
<td>6.5±3.2</td>
</tr>
</tbody>
</table>

Conclusions: Decrease of perfusion in the upper zone and decrease of U/L was revealed only in patients with IPAH. On the contrary CTEPH was characterized by increased in U/L. This finding may be helpful for differential diagnostics of pulmonary hypertension.

P1608
New insights into functional consequences of pulmonary embolism by cardiac MRI
Dirk Frechen1, Stefan Krüger1, Ingo Paetsch2, Sebastian Kozerke2, Bernhard Schnackenburg1, Michael Frick1, Nikolaus Marx1, Cesima Jahne1.
1Internal Medicine I, University Hospital, Aachen, Germany; 2Institute for Biomedical Engineering, University of Zurich and Swiss Federal Institute of Technology, Zurich, Switzerland; 3Research Laboratories, Philips, Hamburg, Germany

Introduction: The objective of the present study was to evaluate a magnetic resonance imaging (MRI) algorithm which facilitates morphological diagnosis of pulmonary embolism (PE), right ventricular function and pulmonary perfusion (PP) in same examination.

Methods: 12 patients with documented PE on multidetector computed tomography (MDCT) and 14 healthy probands served in controls underwent multicomponent cardiovascular MRI. Diagnosis of PE was based on embolus visualization in MDCT. First, cine MRI was done employing multiple standard views. Second, high resolution, contrast-enhanced dynamic imaging of PP was performed. Third, a three-dimensional MRI angiography was acquired. Quantitative analysis of PP was derived from the signal intensity curve.

Results: In patients with PE compared to controls, RV ejection fraction was significantly lower (47±1±10.4% vs. 57±2±2.9%, p=0.002). Diagnosis of PE on a patient basis was 100% concordant between MDCT and MRI. PP in MRI of areas affected by PE compared to normal lung areas showed a lower relative peak enhancement (17±1±157% vs. 54±2±13%, p<0.001), maximum peak enhancement (31±1±198% vs. 691±264%, p<0.001), wash-in rate (58±2±72a.u. vs. 184±77a.u., p<0.001), AUC (32±1±2269 vs. 7215±3199, p<0.001) and a longer time-to-peak enhancement (17.5±1±6.9s vs. 9.5±1±3s, p<0.001).

Conclusions: Multicomponent cardiovascular MRI facilitated characterization of pulmonary arterial supply, RV function and PP during a single session examination and may serve as a profound basis for rapid clinical decision and for determination of therapeutic options in patients suspected of pulmonary embolism.

P1609
Cardiac magnetic resonance imaging versus echocardiography for assessment of cardiac involvement in pulmonary sarcoidosis
Teresa Fund1, Stefan Pfaffenberger1, Karin Vobank2, Beatrice Marzuf2, Julia Mascherbauer1, Thomas Binder1, 1Dept. of Internal Medicine II, Division of Cardiology, Medical University of Vienna, Austria; 2Dept. of Internal Medicine II, Division of Pulmonology, Medical University of Vienna, Austria

Study objectives: Data on the prevalence of cardiac involvement in sarcoidosis patients vary depending on the patient population and diagnostic modality studied. We aimed to compare cardiac involvement diagnosed by cardiac magnetic resonance imaging (CMR) with standard echocardiography and speckle tracking echocardiography for detection of cardiac sarcoidosis in patients with pulmonary sarcoidosis.

Methods: 41 patients (mean 47 years) with biopsy-proven pulmonary sarcoidosis underwent echocardiography and CMR imaging. Cardiac involvement was diagnosed if a positive late gadolinium enhancement (LE) pattern not typical for coronary artery disease on CMR was found. LE was compared to regional wall motion abnormalities on standard echocardiography and to global longitudinal peak systolic strain (GLPSS) on speckle tracking echocardiography. NT-proBNP was evaluated.

Results: (p<0.001) 40 (97.6%) patients showed a positive LE on CMR (14 (34%) patients showed a positive LE on CMR (p<0.001). Four (10,5%) patients with positive LE showed a reduced GLPSS compared to 3 (7,9%) patients without LE (p=0.245). Mean NT-proBNP was higher in patients with positive LE (127 pg/ml), when compared to subjects without LE (87 pg/ml).

Conclusion: Cardiac involvement in pulmonary sarcoidosis patients was detected in more cases by CMR than by standard echocardiography. Speckle tracking echocardiography was also more sensitive than standard echocardiography. However, cardiac involvement in a caucasian population was rare compared to previously published data based on a predominantly afro-american population.

P1700
Comparison of dynamic contrast-enhanced MRI tracer-kinetic modeling in the lungs of smokers vs non-smokers
David Luke, Penny Hubbard, Geoff Parker, Josephine Naish. Imaging Science and Biomedical Imaging, The University of Manchester, United Kingdom

Previous analysis [1] of dynamic contrast-enhanced (DCE) MRI data in smokers vs non-smokers using the extended Kety model revealed increased K trans in smokers. By fitting the indicator dilution theory (IDT) and adiabatic approximation to the tissue homogeneity (AATH) models we hypothesise that we can decouple the contribution from perfusion and permeability to K trans to yield enhanced information on lung function and changes due to smoking. Figure 1 summarises the results obtained from the three models used in the smoker study.

Conclusions: LV is a strong predictor of adverse outcome in patients with PH-COPD. Static ventricular volumes did not aid the prediction of adverse outcome.
K$_{trans}$ showed a significant difference between smokers and non-smokers from both the extended Kety (p=0.032) and AATH (p=0.038) models. The AATH model implies that the increase in K$_{trans}$ is due to an increase in the permeability of the capillaries (p=0.030), rather than an increase in blood flow. Both the extended Kety (p=0.026) and AATH (p=0.025) models show a significant increase in the extracellular/extravascular space (EES) in smokers compared to non-smokers. In conclusion, the use of all three tracer-kinetic models indicate a coherent picture, supporting the hypothesis that increases in K$_{trans}$ observed in smokers compared to non-smokers are related to increased capillary permeability rather than increased blood flow.

**Simultaneous imaging of lung structure and function with triple nuclear MRI**

Jim Wild, Helen Marshall, Xuxin Xu, Graham Norquay, Juan Parra-Robles

Academic Radiology, University of Sheffield, United Kingdom

Hybrid medical imaging scanners (e.g. PET-CT) allow imaging with different detection modalities at the same time, providing complementary anatomical and functional information within the same physiological time course. Here, we re-engineer a standard clinical MRI scanner for the simultaneous acquisition of lung MR images from three different nuclei (1H, 3He and 129Xe) in a single breath-hold. The temporal and spatial registration of these images is impossible to achieve in separate breath-hold scans. This new system opens up the possibility of simultaneous capture of regional lung function from the 3He and 129Xe gases and lung structure from the 1H MRI without reliance on ionising radiation.

Figure 1 shows images of 3He, 1H and 129Xe acquired from a healthy volunteer in the same breath-hold; the anatomical 1H images show excellent spatial registration with the 3He and 129Xe ventilation images.

The method has multiple potential applications, allowing side-by-side quantitative analysis of early signs of impaired lung function from the 3He and 129Xe images and anatomical signs of disease from 1H MRI. For a variety of lung diseases, registration of ventilation MRI to anatomical 1H MRI would allow subsequent image registration to the radiological gold standard for anatomy, CT, which serves as the clinical gold standard in diseases such as emphysema.

### P1702

**Physiological modelling of dynamic contrast-enhanced MRI in COPD**

Penny Hubbard1, Geoff Parker1, Dave Singh2, Jørgen Vestbo3, Lars Olsson1, Lars Wigtrom1, Simon Young1, Eva Bondesson2, Josephine Naish2, 1Imaging Sciences Research Group/The Biomedical Imaging Institute, The University of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; 2Medicines Evaluation Unit, South Manchester University Hospital Trust, Manchester, United Kingdom; 3Biomedical Imaging Institute, The University of Manchester, Manchester, United Kingdom; 4R&D, AstraZeneca, Alderley Park, Macclesfield, United Kingdom

We present the results of a dynamic contrast-enhanced (DCE-)MRI study in subjects with COPD and age-matched healthy subjects. The pharmacokinetic model applied allows for extravasation of the contrast agent and can therefore be used to probe pulmonary capillary permeability.

Significant differences were not observed between healthy and moderate COPD groups in any of the DCE-MRI parameters. Significantly lower v$_p$ and K$_{trans}$ were observed in severe COPD compared with healthy and in v$_p$ compared with moderate COPD (Fig. 1). v$_p$ (extra-vascular/extra-cellular space) can be related to inflammation and shows an non-significant increase in moderate COPD.

<table>
<thead>
<tr>
<th>Group mean and standard deviation of physiological DCE-MRI parameters</th>
<th>Healthy</th>
<th>Moderate</th>
<th>Severe</th>
</tr>

<td>0.32±0.09</td>
<td>0.25±0.05</td>
</tr>
</tbody>
</table>

K$_{trans}$ is related to perfusion and/or capillary permeability and decreases significantly in severe COPD. v$_p$ (vascular space) also decreases with disease severity and, when considered in combination with decreased K$_{trans}$, is suggestive of reduced perfusion in the region analysed. This sensitivity to disease severity shows that DCE-MRI may provide a novel window on the progression of COPD.

### P1703

**Regional measures of 3D lung mechanics using magnetic resonance imaging**

Alexandra R. Morgan1,2, Geoff J.M. Parker1,2,3, Tim F. Cootes1,2, Marietta L.J. Scott1, Josephine H. Naish1,2, 1Imaging Science, School of Cancer and Enabling Sciences, Manchester Academic Health Sciences Centre, University of Manchester, Greater Manchester, United Kingdom; 2Biomedical Imaging Institute, The University of Manchester, Greater Manchester, United Kingdom; 3BiOxyDyn, BiOxyDyn Limited, Manchester, United Kingdom; 4AstraZeneca R&D, Alderley Park, Macclesfield, United Kingdom

Lung disease, such as emphysema and fibrosis, can result in changes in pulmonary mechanical properties that are not easily identified on a regional level using current methods. A recently reported method, using 2D structural proton MRI in conjunction with post-processing and image registration, to provide measures of local lung motion and relative regional tissue compliance demonstrated differences between healthy and diseased lungs. This technique has been extended to 3D, to overcome the limitations of the 2D method.

Multi-slice structural lung MR images were acquired in 2 healthy volunteers during breath-hold at end-expiration and end-inspiration. 3D lung volumes were segmented, and an automatic mesh-based image registration used to identify correspondence points in the lung between the two respiratory extremes. Vector field maps of local lung motion show an increasing magnitude of motion from apex to diaphragm, as expected in healthy lungs, with motion in the anterior-posterior as well as in the foot-head direction (Figure 1). These methods provide potentially useful information on local lung mechanics in diagnosis of disease, and may be used to calculate regional lung compliance.

P1704 Modelling of hyperpolarized gas diffusion in lungs of COPD patients and healthy volunteers using a fractional dynamics approach

Juan Parra-Robles, Helen Marshall, Jim M. Wild

Aim: To study the ventilation-perfusion ratio (V/Q), apex-base gradient of ventilation (UL-V/L) and perfusion (UL/Q) and alveolar-capillary permeability (ACP) in bronchial asthma (BA) patients on the basis of scintigraphy data.

Materials and methods: 30 people aged 18-60 took part in the study: patients diagnosed with moderate BA. The study was performed with 20 healthy non-smokers (SH). Three scintigraphic studies were performed by means of Omega 500 gamma camera (Technicare, USA-Germany). The subject of the research was an examination of ACP in the right (RL) and left (LL) lungs in the process of radiopharmaceutical derivation, static conditions, during the 1st, 10th and 30th minute after 99mTc-DTPA inhalation.

Results: BA patients: V/Q in both RL and LL was not higher than 1.0 and amounted to 0.96 (0.92-1.04) in the RL and 0.98 (0.95-1.01) in the LL. These parameters did not differ from those of healthy volunteers (p=0.72 and p=0.65). UL-V/L amounted to 0.55 (0.33-0.77) in the RL and 0.57 (0.45-0.69) in the LL. It was lower than that of healthy people (p=0.03 and 0.04). UL/Q amounted to 0.82 (0.68-0.98) in the RL and 1.1 (0.84-1.36) in the LL. This parameter was higher than that of healthy people (p=0.004, p=0.02). ACP in the RL amounted to 10.19% (6.49-14.19%) and 27.21% (22.99-31.41%) during the 10th and 30th minutes of the study, respectively; it was increased during the 30th minute of the study (p=0.001). ACP in the LL amounted to 9.68% (8.49-10.87%) and 27.87 (24.26-31.48%) during the 10th and 30th minutes of the study, respectively; it was increased during the 30th minute of the study (p=0.002).

Conclusions: The study findings may serve as additional scintigraphic criteria for bronchial asthma diagnostics.

P1705 Quantitative CT-estimation of total and regional lung inflation in patients with bronchial asthma (BA)

Andrew V. Pim1, Juliya M. Perelman1, Anatoly V. Lensin1, 1 Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveschensk, Russian Federation; 2 Laboratory of Boeijing Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveschensk, Russian Federation

Background: Functional abnormalities are often the first and the only symptoms in BA. Spirometry do not allow lung inflation estimation.

Aim: To estimate the potential of CT in identification of total and regional lung hyperinflation in BA patients.

Methods: 70 BA patients were examined compared with 20 healthy persons. The method of two stage multispiral CT by Actisum 16 ( Toshiba ) with the further 3D-reconstruction and volumetry (850 HU and lower) was used. The quantitative densitometric estimation at axial scanning in fixed upper, middle and lower lung zones was also done. Bronchodilatation test with salbutamol inhalation was used. Results: The lung dysfunction was registered in 66 patients. By 3D-volumetry, lung inflation at maximal expiration against inspiration in mild BA was 3.8±2.46% (in healthy people - 3.0±0.55%, p<0.001), in moderate BA - 16.2±5.27% (p<0.05 to mild BA) and in severe BA - 30±6.47% (p=0.05 to moderate BA). By densitometry the mean inspiration to expiration ratio of density in mild BA was 80±13.14% (in healthy people - 76.74±5.37%, p<0.01), in moderate BA - 85±5.48% (p=0.05 to mild BA), in severe BA - 91.5±4.19% (p=0.05 to moderate BA) and 103±5.06% of total inflation patients with mild BA had a decrease of "air traps" volume: before the test the expiration to inspiration ratio of lung

P1706 Synchrontron imaging of regional ventilation/perfusion-ratio after methylcholine provocation in rabbit

Lisa Perlla1, Mathieu Guylart1, Sara Strengell2, Pelka Suorti2

Aim: To assess the feasibility of quasi-simultaneous KES imaging of V and VB during inhalation and regional volume (VB) distributions during isoflurane infusion. In this study we assessed the feasibility of quasi-simultaneous KES imaging of V and VB.

Methods: Experiments were performed in anaesthetized and ventilated New Zealand rabbits (n=5). Images of V and VB were obtained at baseline and after infused MCh (125 mg/ml). Heterogeneity of both parameters was estimated as the coefficient of variation (CV) between pixels.

Results: Images of V, VB and their ratio (V/ VB) are shown in one rabbit at baseline and after MCh challenge (Figure). MCh inhalation produced clustered areas of poor ventilation; mean V decreased to 75.7±24.2 % and VB to 69.4±12.7% of baseline. The CV of V increased to 334±186%, CV of VB to 140±216%, and CV of V/ VB ratio to 193±50% of baseline. Values are m±SD, *significant change vs. baseline (p<0.05, Students paired t-test).

P1707 Scintigraphic parameters in bronchial asthma patients

Tatyana Ageeva1, Nikolay Kevzakov2, Anna Dubrdolav1, 1 Propedeutics of Internal Diseases Department, Siberian State Medical University, Tomsk, Russian Federation; 2 Radionuclide Diagnostics Laboratory, Cardiology Research Institute of Siberian Department of Russian Academy of Medical Sciences, Tomsk, Russian Federation

Aim: Study the ventilation-perfusion ratio (V/Q), apex-base gradient of ventilation (UL-V/L) and perfusion (UL/Q) and alveolar-capillary permeability (ACP) in bronchial asthma (BA) patients on the basis of scintigraphy data.

Methods and materials: 30 people aged 18-60 took part in the study: patients diagnosed with moderate BA. The study was performed with 20 healthy non-smokers (SH). Three scintigraphic studies were performed by means of Omega 500 gamma camera (Technicare, USA-Germany). The subject of the research was an examination of ACP in the right (RL) and left (LL) lungs in the process of radiopharmaceutical derivation, static conditions, during the 1st, 10th and 30th minute after 99mTc-DTPA inhalation.

Results: BA patients: V/Q in both RL and LL was not higher than 1.0 and amounted to 0.96 (0.92-1.04) in the RL and 0.98 (0.95-1.01) in the LL. These parameters did not differ from those of healthy volunteers (p=0.72 and p=0.65). UL-V/L amounted to 0.55 (0.33-0.77) in the RL and 0.57 (0.45-0.69) in the LL. It was lower than that of healthy people (p=0.03 and 0.04). UL/Q amounted to 0.82 (0.68-0.98) in the RL and 1.1 (0.84-1.36) in the LL. This parameter was higher than that of healthy people (p=0.004, p=0.02). ACP in the RL amounted to 10.19% (6.49-14.19%) and 27.21% (22.99-31.41%) during the 10th and 30th minutes of the study, respectively; it was increased during the 30th minute of the study (p=0.001). ACP in the LL amounted to 9.68% (8.49-10.87%) and 27.87 (24.26-31.48%) during the 10th and 30th minutes of the study, respectively; it was increased during the 30th minute of the study (p=0.002).

Conclusions: The study findings may serve as additional scintigraphic criteria for bronchial asthma diagnostics.

P1708 Modelling of hyperpolarized gas diffusion in lungs of COPD patients and healthy volunteers using a fractional dynamics approach

Juan Parra-Robles, Helen Marshall, Jim M. Wild

Aim: To investigate the ventilation-perfusion ratio (V/Q), apex-base gradient of ventilation (UL-V/L) and perfusion (UL/Q) and alveolar-capillary permeability (ACP) in bronchial asthma (BA) patients on the basis of scintigraphy data.

Materials and methods: 30 people aged 18-60 took part in the study: patients diagnosed with moderate BA. The study was performed with 20 healthy non-smokers (SH). Three scintigraphic studies were performed by means of Omega 500 gamma camera (Technicare, USA-Germany). The subject of the research was an examination of ACP in the right (RL) and left (LL) lungs in the process of radiopharmaceutical derivation, static conditions, during the 1st, 10th and 30th minute after 99mTc-DTPA inhalation.

Results: BA patients: V/Q in both RL and LL was not higher than 1.0 and amounted to 0.96 (0.92-1.04) in the RL and 0.98 (0.95-1.01) in the LL. These parameters did not differ from those of healthy volunteers (p=0.72 and p=0.65). UL-V/L amounted to 0.55 (0.33-0.77) in the RL and 0.57 (0.45-0.69) in the LL. It was lower than that of healthy people (p=0.03 and 0.04). UL/Q amounted to 0.82 (0.68-0.98) in the RL and 1.1 (0.84-1.36) in the LL. This parameter was higher than that of healthy people (p=0.004, p=0.02). ACP in the RL amounted to 10.19% (6.49-14.19%) and 27.21% (22.99-31.41%) during the 10th and 30th minutes of the study, respectively; it was increased during the 30th minute of the study (p=0.001). ACP in the LL amounted to 9.68% (8.49-10.87%) and 27.87 (24.26-31.48%) during the 10th and 30th minutes of the study, respectively; it was increased during the 30th minute of the study (p=0.002).

Conclusions: The study findings may serve as additional scintigraphic criteria for bronchial asthma diagnostics.
inflation was 7.3%, after the test - 2.3%; the quantity of voxels before the test was 3727 at inspiration, 276 at expiration (after the test - 4772 and 110, respectively). Conclusion: By 3D-volume and densitometric analysis the conclusions about the lung inflation abnormality and the volume of “air traps” in BA patients can be drawn, which considerably supplements the spirometry.

P1709 MRI-informed electrical impedance tomography from phantom to thorax
Rose Line1, John Davidson2, Josephine Nash1, Paul Wrigley2, Alexandra Morgan1, Ron Kikinis1, Hugh McCann2, Geoff Parker1
1 Imaging Science, University of Manchester, United Kingdom; 2 School of Electrical and Electronic Engineering, University of Manchester, United Kingdom; Surgical Planning Laboratory, Brigham and Women’s Hospital, Boston, MA, United States

Electrical impedance tomography (EIT) has the potential to provide non-invasive, high temporal resolution, long term lung function monitoring. We present an instrument capable of volumetric data acquisition applied to a male torso, show an MRI-informed reconstruction, and correspondence of EIT measurements with high resolution MRI.

EIT data were acquired using two planes of 16 electrodes on the Manchester EIT system, a BS EN 60601-1:2006 compliant system, followed by MRI acquired using a fast field echo on a 1.5 T Philips Achieva. The data were coalignaged using the open source medical image platform 3D-Slicer. Figure 1(a)-(c) shows an MRI axial slice of the torso, coalignaged with EIT, and EIT alone.

The system acquired volume data using 32 electrodes in two planes. The EIT was reconstructed using a torso boundary-only model derived from the MRI. This should produce a more faithful reconstruction than a generic model, allowing investigation of sensitivity of EIT measurements using increasingly precise models. At 100 fps, the EIT provides excellent temporal resolution. For example, it shows different temporal sequences of lung ventilation (dorsal versus ventral) within the breathing cycle for an upright subject as compared with supine. Current analyses of EIT data for lung function monitoring use sub-cycle statistics and time difference (minimum) 3-fold increase in frame rate provided by EIT will improve these methods substantially.

210. Current trends in home mechanical ventilation

P1710 Home mechanical ventilation and respiratory rehabilitation: Influence in respiratory functional test and exercise capacity
Eduardo Marquez-Martín, Pilar Cepajo, Jose Luis Lopez-Campos, Ana Rodriguez, Borja Valencia, Emilia Barrot, Francisco Ortega.
Medical-Surgical Unit of Respiratory Diseases, Virgen del Rocío University Hospital, Seville, Spain

Our aim is to assess the impact on respiratory function and exercise capacity of a respiratory rehabilitation program (RR) compared with a program of home mechanical ventilation (HMV) and the summation of both interventions.

Methods: 45 COPD patients with severe functional impairment and in situations of hypercapnic respiratory failure were prospectively randomized to 3 groups: RR (12 weeks in 40-minute sessions that included strength training and resistance), HMV (12 weeks BiPAP mode) and RR-HMV (combination of the two interventions). The patients underwent different components of BODE index, quality of live (CRDQ) and IP. C Reactive Protein (CRP), Tumor Necrosis Factor α (TNF-α), Interleukin-6 (IL-6), IL-8 and Surfactan D Protein (SDP).

Results: HMV group improved BODE index significantly by decreasing median 2 points (p = 0.003). Also get statistically significant improvement in quality of life index CRDQ (in total and its four components) IP improved significantly by decreasing TNF-α and IL-8. RR group obtained the same results in BODE index, and CRDQ. IP significantly improved by lowering CRP IL-8, SDP and C3. RR-HMV group improves BODE index significantly when going from 3 to 5.3 (p = 0.001). CRDQ in total and components of hypoxemia, fatigue, fear, and social control. Significantly improved IP by lowering CRP. TND-α, SDP and prealbumin.

Conclusions: HMV and the RR produced improvement in the BODE index and quality of life as well as when the two interventions are given together without finding differences when applied independently. The combination of both intervention control more IP than each other separately.

P1712 Home non-invasive ventilation (HNV) improves survival in hypercapnic patients with cystic fibrosis
Sergey Adevse, Gulnara Baimakanova, Stanislav Krasovsky, Victor Samoilenko, Elena Amelina, Alexander Chuchalin.
Clinical Department, Pulmonology Research Institute, Moscow, Russian Federation

Background: The clinical benefits of home non-invasive positive pressure ventilation (HNV) have not been well established in adult patients with cystic fibrosis (CT).

Objective: The purpose of this matched case-control study was to compare the effects of HNV and long-term oxygen therapy (LTOT) on survival of adult CF patients with chronic hypercapnic respiratory failure (CHRF).

Methods: Twelve patients receiving HNV were matched with 12 patients receiving LTOT regarding age, FEV1, PaCO2 and BMI.

Results: There were no differences between groups of patients in demographic, clinical and functional characteristics (HNV patients: 24.9 ± 4.8 years, BMI 16.1 ± 3.3 kg/m2, FEV1 15.3 ± 3.4%, PaCO2 59.8 ± 7.7 mmHg; and LTOT patients: 23.9 ± 4.0 years, BMI 15.8 ± 4.2 kg/m2, FEV1 16.1 ± 4.4%, PaCO2 61.4 ± 7.9 mm Hg). HNV settings were: ST mode, IPAP 20.1 ± 4.2 cm H2O, EPAP 4.6 ± 0.7 cm H2O (nasal mask – 4, oronasal mask – 8). Compared with LTOT, HNV significantly reduced breathing rate (p = 0.036), PaCO2 (p = 0.038) and number of exacerbations (p = 0.028). Survival was significantly better in HNV group in comparison with LTOT group (survival time 12.5 [95%CI 0.6-16.4] months vs 6.0 [95%CI 0.7-7.3] months; log-rank test, p = 0.024).

Conclusions: The survival of adult CF patients receiving HNV was better than that of patients treated with LTOT alone. We suggest HNV is a first-line treatment for adult patients with CHRF.

P1713 Meta-analysis on nocturnal non-invasive positive pressure ventilation for stable COPD: an update
Fransien Struijk1, Yves Lacasse2, Huib Kerstjens1, Peter Wijkstra1,3
1 Department of Pulmonary Diseases/Home Mechanical Ventilation, University of Groningen, University Medical Center Groningen, Netherlands; 2 Centre de Pneumologie, Institute Universitaire de Cardiologie et de Pneumologie de Quebec (Hospital Laval), Quebec, Canada; 3 GRIAC Research institute, University of Groningen, University Medical Center Groningen, Netherlands

Introduction: Nocturnal non-invasive positive pressure ventilation (NIPPV) might be beneficial in stable hypercapnic patients with COPD. However, evidence remains conflicting.

Aim: To determine the effect of NIPPV in patients with stable hypercapnic COPD. Methods: This meta-analysis gathered individual patient data from randomized controlled trials (RCTs) comparing NIPPV plus standard therapy with standard therapy alone. The current analyses are limited to gas exchange parameters.

Results: Our older Cochrane review and 3 new studies were identified, totaling
in PaCO2 and increase in PaO2 in stable hypercapnic COPD patients after 3 months with the newer studies, this update now finds a significant decrease (n=118; CI=0.24; 3.45 mmHg) but no significant changes after 12 months of NIPPV (mean difference= -3.56 (95% CI=-4.93;-2.18 mmHg)) and PaO2 (1.84 (95% 5 short-term and 2 long-term RCTs. After 3 months (n=162; age 66 yrs; FEV1 decreased from 88% to 51% of all patients treated in favor of pulmonary diseases and hypoventilation syndromes (from 3 to 12%). The change in BODE index is correlated with Oxygen Desaturation during sleep. Conclusion: NIV is largely used to treat patients with obesity-associated hypventilation treated with long-term non-invasive ventilation. Methods: A Cohort of OH patients initiated on NIV between March 2003 and July 2008. Anthropometry, diurnal and nocturnal respiratory parameters, comorbidities, medications, conditions of NIV initiation and NIV compliance were used as co-variates. Survival curves were estimated by the Kaplan-Meier method. Univariate and multivariate Cox models allowed estimating predictive factors of mortality. Conclusion: In 107 patients (56% women, mean follow-up of 43±14 months) NIV was initiated in acute conditions in 36%. The 1, 2, 3-year survival rates were 99, 85, 82% respectively. In univariate analysis, death was associated with older age (>63 yrs), low FEV1 (<60% pred value), male gender, concomitant COPD, obesity, diabetes and neuromuscular disease. In multivariate analysis, combination of cardiovascular agents was the only factor associated with a higher risk of death (HR=5.3; 95% CI: 1.18; 23.9). In contrast, female gender was associated with a lower risk. Conclusion: Cardiovascular comorbidities represent the main factor predicting mortality in NIV-treated OH patients. In this population, NIV should be used among a combination of treatment modalities allowing a reduction in cardiovascular risk.

P1716
Co-morbidities and cardiovascular medications are the best predictors of mortality in patients with obesity-associated hypventilation treated with long-term non-invasive ventilation.

Jean-Christian Borel1,3, Benoît Burel2, Renaud Tamisier1,2, Sonia Dias-Domingos1,2, Patrick Levy1,2, Jean-Louis Pepin1,2, 1HP2 Laboratory, Hypoxia: Pathophysiology, INSERM U 1042, Joseph Fourier University, La Tronche, France; 2Locomotion, Rehabilitation and Physiology Department, Grenoble University Hospital, Grenoble Cedex 09, France; 3Research and Development Department, AGRRadom, Meylan, France

Rationale: NIV is largely used to treat patients with obesity-associated hypventilation (OH). The impact of comorbidities, their medications and NIV compliance on survival of these patients remain unexplored.

Methods: We included 214 patients (55.6% women, mean age 63.8 years ± 13.3). 50% required hospital readmission and the median time to readmission was 170 weeks (144.1 to 195.8). Readmission was not related to the presence of comorbidities neither the initial results of HMV and appear related to poor quality of life. Predictors of readmission were also worse PaO2 control and PaCO2 control, greater number of previous admissions and poorer lung function. The multivariate model identified as independent predictors of readmission: Poor quality of life (HR 2.3-3.3, p<0.017), previous admissions, previous respiratory failure and a poor quality of life. Predictors of readmission were also worse PaO2 control and PaCO2 control, greater number of previous admissions and poorer lung function. The multivariate model identified as independent predictors of readmission: Poor adherence to NIV (OR 1.7; CI 95% 1.1 - 2.6), PaCO2 control (OR: 1.03, 95% CI I to 1.06) and the level of dyspnea at follow up (OR:2.3,95%CI:1.5-3.3).

Conclusions: 1. In our experience, a high percentage of patients on HMV required hospital readmission. 2. - Readmissions does not appear to be directly related to comorbidities neither the initial results of HMV and appear related to poor treatment adherence and severity of respiratory failure.

P1717
Predictors of readmission in patients on home mechanical ventilation (HMV)

Objectives: There are few studies that examine which factors determine the readmission of patients on HMV. Our objective was to study the variables related to this fact to determine which aspects should be monitored more closely.

Methods: Prospective observational study over a period of 10 years. We collected clinical variables during hospitalization and data related to treatment adherence and the date of hospital readmission. Bivariate analysis and a Cox multivariate model were performed

Results: We included 214 patients (55.6% women, mean age 63.8 years ± 13.3). 50% required hospital readmission and the median time to readmission was 170 weeks (144.1 to 195.8). Readmission was not related to the presence of comorbidities, morbidity, situation at the start of ventilation (chronic respiratory vs. acute respiratory failure) or main diagnosis that led to the start of HMV. During follow-up readmission was associated with poor adherence to HMV (46.7% vs 29.9%, p = 0.017), previous admissions, previous respiratory failure and a poor quality of life. Predictors of readmission were also worse PaO2 control and PaCO2 control, greater number of previous admissions and poorer lung function. The multivariate model identified as independent predictors of readmission: Poor adherence to HMV (OR 1.7; CI 95% 1.1 - 2.6), PaCO2 control (OR: 1.03, 95% CI I to 1.06) and the level of dyspnea at follow up (OR:2.3,95%CI:1.5-3.3).

Conclusions: 1- In our experience, a high percentage of patients on HMV required hospital readmission. 2- - Readmissions does not appear to be directly related to comorbidities neither the initial results of HMV and appear related to poor treatment adherence and severity of respiratory failure.

P1715
NIV (non invasive ventilation) improves Bode index in stable COPD with CHRF (chronic hypercapnic respiratory failure)

Andriani Zikiri, Chando Pastaka, Vasso Toulaki, Andrew Dimoulis, Konstantinos Georgioulanis, Maria Patent, George Sestanides. Pulmonary Department, University Hospital of Thessaly, Larissa, Greece

Introduction: The BODE index, a simple multidimensional grading system, is used to predict the risk of death from any cause and from respiratory causes among patients with COPD. The use of NIV in exacerbation of COPD is suggested. On the other hand there are not any guidelines for the use of NIV in patients with stable COPD.

Purpose: To investigate any improvement in patients with COPD and CHRF using NIV at home, in relation with BOE index and the factors that predict the improvement.

Material and methods: Patients with COPD and CHRF (in stable condition) with LTOT were included. Patients underwent a polysomnography study to exclude OSA (AHI<10). The patients used NIV at home for a year. BODE index and its components (FEV1, MRC, BMI, 6MW) were estimated at baseline (0 month) and 6 and 12 months after use. In addition, BODE index change on the 6th month was correlated with initial parameters (AHI, OD, min saturation, mean saturation at sleep, PO2, PCO2, BODE index (lnmonth), FVC, FEV1/FVC, age).

Results: There is a statistically significant change of BODE index after 6 months and after 12 months of using NIV. There is a correlation between BODE index change and oxygen desaturation (OD) (polysomnography study).

Conclusion: NIV improves BODE index in stable COPD and CHRF. The change in BODE index is correlated with Oxygen Desaturation during sleep.

P1714
The evolution of home mechanical ventilation in Poland between 2000 – 2010

Jacek Nasłonowski1, Marian Wachulska1, Wojciech Trzniadel1, Wendi Andrzejewski1, Marek Migdal1, Beata Drazuga1, Andrzej Pytel1, Robert Suchanke1, Małgorzata Czajkowska-Malinowska3, Tomasz Mączyński2, Ryszard Chazan1, 1Department of Internal Medicine, Pneumology and Allergology, Medical University of Warsaw, Poland; 2Home Mechanical Ventilation Center, Pulmmed, Bydgoszcz, Poland; 3Home Mechanical Ventilation Center, Ventamed, Zielona Gora, Poland; 4Home Mechanical Ventilation Center, Hospice for Children and Adults, Łódź, Poland; 5Home Mechanical Ventilation Center, The Children's Memorial Health Institute, Warsaw, Poland; 6Home Mechanical Ventilation Center, Beta-Med, Katowice, Poland; 7Home Mechanical Ventilation Center, HELP, Poznan, Poland; 8Home Mechanical Ventilation Center, Kujawsko-Pomorskie Pulmonology Centre, Bydgoszcz, Poland; 9Home Mechanical Ventilation Center, St. Vincent Medical Center, Warsaw, Poland

In the last decades the methods and indications for home mechanical ventilation (HMV) have changed significantly mainly due to technological development and an increasing number of patients with chronic pulmonary disorders. Data about HMV comes from developed countries. However, the shift was not as marked as in more developed countries. Prevalence of ICU is the principal location where HMV was initiated. However, its role diminished from 6 to 23% and the date of hospital readmission. Bivariate analysis and a Cox multivariate model were performed to comorbidities neither the initial results of HMV and appear related to poor quality of life. Predictors of readmission were also worse PaO2 control and PaCO2 control, greater number of previous admissions and poorer lung function. The multivariate model identified as independent predictors of readmission: Poor quality of life (HR 2.3-3.3, p<0.017), previous admissions, previous respiratory failure and a poor quality of life. Predictors of readmission were also worse PaO2 control and PaCO2 control, greater number of previous admissions and poorer lung function. The multivariate model identified as independent predictors of readmission: Poor adherence to NIV (OR 1.7; CI 95% 1.1 - 2.6), PaCO2 control (OR: 1.03, 95% CI I to 1.06) and the level of dyspnea at follow up (OR:2.3,95%CI:1.5-3.3).

Conclusions: 1- In our experience, a high percentage of patients on HMV required hospital readmission. 2- - Readmissions does not appear to be directly related to comorbidities neither the initial results of HMV and appear related to poor treatment adherence and severity of respiratory failure.
P1718
Effect of an automatic triggering and cycling system on patient-ventilator synchrony during noninvasive ventilation in a mechanical lung model

Lídia Melo, Renata Vasconcelos, Raquel Sales, Carla Magalhães, Mirzana Almeida, Juliana Silveira, Marcelo Holanda. Laboratório da Respiração - Respbak, Universidade Federal do Ceará, Fortaleza, CE, Brazil; Pós Graduação em Ciências Médicas, Universidade Federal do Ceará, Fortaleza, CE, Brazil.

Evaluate the effect of an automatic triggering and cycling system on patient-ventilator synchrony during NIV in a mechanical lung model. Bench study, one ICU ventilator (Esprit®) and one NIV ventilator (Trilogy®) were tested. The lung simulator ASL 5000 (Ingmar) was set with obstructive model: compliance 60 mL/cmH2O, resistance 20 cmH2O/L/s, and restrictive: compliance 30 mL/cmH2O and resistance 8 cmH2O/L/s, both with respiratory rate 15 bpm and ventilatory demand of 60 L/min. A facial mask was adapted to a head manikin, with an air leak of 10 L/min. The Esprit® was adjusted in the NIV mode and the Trilogy® in the S/T mode; PAP 10 cmH2O and EPAP 4 cmH2O, triggering and cycling were set automatically (AutoTrak®) or flow triggering (3 L/min) with expiratory cycling 25% (conventional) in both ventilators. Inspiratory and expiratory delay, inspiratory work and patient-ventilator asynchrony were analyzed. Auto-triggering was observed in the restrictive model in the Esprit® with conventional adjustments, but the phenomenon was abolished with the automatic settings. Little difference was observed between the systems, suggesting that both methods were equivalent with respect to inspiratory and expiratory delay and work.

P1719
The acute effects of postural change and non-invasive ventilation breathing on the regional distribution of lung ventilation: A electrical impedance tomography study

Nathalia Parente de Sousa1, Liliana Silveira Marinho1, Luana Torres Monteiro1, Aline Menezes Sampaio1, Vasco Pinheiro Diógenes Bastos1, Andréa da Nóbrega Alcântara Holanda1. Laboratory Respiration, Department of Medicine, Federal University of Ceará, Fortaleza, Brazil; 2Laboratory of Medical Investigation, University of São Paulo, Brazil.

Introduction: The combined effects of postural changes and the use of noninvasive positive pressure ventilation (NIV) on the regional distribution of lung ventilation (RLDV) is still underexplored. The electrical impedance tomography (EIT) has emerged as a consistent technique for the dynamic evaluation of RLDV. Objectives: To evaluate the RLDV in healthy subjects during spontaneous respiration (SR) and during NIV breathing in different body positions. Methodology: The RLDV was assessed by EIT (32 electrodes) in 10 healthy subjects (5 men), during 10 minutes of SR, or with CPAP of 10 cmH2O and with BiPAP of 15 cmH2O in four body positions (dorsal (D), ventral (V), right lateral (RL) and left lateral (LL)). Results: The figure below shows the % of RLDV in the four quadrants of the lungs.

During SR, the RLDV was higher in the gravity dependent quadrants, mainly in the lateral decubitus, except for the V position. NIV breathing (CPAP and BiPAP) did not alter the pattern of RLDV as compared to SR.

Conclusions: EIT can clearly demonstrate that, with the exception of prone positioning, the dependent regions of the lungs are better ventilated both during SR or CPAP and BiPAP breathing.
of physical impairment and respiratory failure. PPV may accelerate the delayed gastric emptying, possibly by esophago-gastric air inflation.

P1722 Unplanned respiratory crises requiring ventilation in Duchenne muscular dystrophy (DMD) patients can be reduced by timely respiratory review and care co-ordination at the age of transition

Emily Ballard1, Natalie Grey1, Heinz Jungbluth2, Elizabeth Wraige2, Stam Kapetanakis1, Craig Davidson1, Nicholas Hart1,4, 1The Lane Fox

The introduction of home mechanical ventilation (HMV) in DMD is associated with increased life expectancy. In 2009, we introduced a transitional care co-ordinator role with the hypothesis that we would reduce the number of unplanned respiratory crises with early intervention. We have prospectively gathered data for all 75 patients with DMD under review in 2009.

*This patient did not require long term NIV; data expressed as absolute values.

Analysis of these data was focused on the primary respiratory crisis admission requiring ventilatory support. Within 3 years we identified 19 patients who required initiation of HMV, all known to the respiratory team prior to initiation and only (15.8%) were as a result of an emergency admission. Of the 19 patients initiated on HMV, 16 were elective with a mean length of stay of 4.7 days (2-9) days. 1 patient was admitted directly from clinic as an emergency, requiring invasive ventilation but without tracheostomy formation. Of the two patients who required tracheostomy formation, one did not require NIV post discharge from hospital. The data supports that with timely intervention and coordination you can reduce the need for emergency intituation of ventilation through respiratory crisis.

P1723 Introduction of domiciliary mechanical insufflation-exsufflation can reduce the incidence of crisis admissions in patients with Duchenne muscular dystrophy (DMD)

Emily Ballard1, Natalie Grey1, Heinz Jungbluth2, Elizabeth Wraige2, Stam Kapetanakis1, Craig Davidson1, Nicholas Hart1,4, 1The Lane Fox

Although trials are ongoing, there is limited evidence to support the use of mechanical insufflations-exsufflation as a method of secretion clearance to prevent chest infections in patients with DMD. However our local unit practice is to provide a machine to DMD patients that are established on non-invasive ventilation with a peak expiratory cough flow < than 160 litres per min despite maximal physiotherapy adjuncts with either: (1) > 2 episodes of chest sepsis per year requiring antibiotics and hospital admission (2) 1 episode of severe chest sepsis requiring invasive ventilation. The aim of the use of the cough assist machine is to reduce the frequency of hospital admissions and length of stay (LOS). We reviewed the prospective data from our DMD patient cohort over a 7 year period in which 32 patients had been initiated with a machine. We reviewed the data for 12 months pre and post base in order to establish the effect on admission frequency and LOS.

</tbody>
</table>

Data are expressed as absolute value (range). *Significant using Wilcoxon signed ranks test.

These data have showed a significant reduction in both hospital admission frequency and LOS for those patients using a domiciliary cough assist machine. These are the first data to add support to the use of domiciliary cough assist machines in DMD patients with an ineffective cough and previous episodes of chest sepsis already established on NIV.

P1724 Neuropsychological functioning after CPAP treatment in obstructive sleep apnea: A meta-analysis

Justine Aaronson1, Wynne Kylstra1, Winni Hofmann2, Ben Schmud2, 1Research & Development, Helsemure, Wijk aan Zee, Netherlands; 2Psychology, University of Amsterdam, Netherlands

Introduction: The generally held clinical view is that treatment with continuous positive airway pressure (CPAP) substantially improves cognition in patients with obstructive sleep apnea (OSA). The cognitive domains in which recovery is found as well as the extent of recovery differs widely between studies, however.

Objective: A meta-analysis was conducted to quantify the magnitude of the overall effect of CPAP treatment in OSA on neuropsychological functioning

Methods: A comprehensive literature search of clinical trials published from January 1990 to June 2011 was performed. The inclusion criteria were: randomized controlled trial, diagnosis OSA by polysomnography, apnea-hypopnea index, duration and compliance of CPAP treatment, one or more standardized neuropsychological tests. Mean-weighted effect sizes of CPAP treatment for 7 cognitive domains were calculated.

Results: 12 studies encompassing 516 OSA patients were included. A small significant effect on attention was observed in favour of CPAP treatment (d=0.2). For the other cognitive domains the effect sizes did not reach significance. Improvement on measures of sleepiness was modest (d=0.30-0.40) and comparable to a prior meta-analysis.

Conclusion: This meta-analysis shows that effect of CPAP treatment on cognition is small and limited to the attention domain. These findings indicate that, contrary to the general assumption, only slight improvement of cognitive functioning after CPAP treatment can be expected.

P1725 Inaccuracy of built-in ventilator softwares (BIVS) in monitoring apnea-hypopnea index (AHI) in patients treated by home non invasive ventilation (NIV)

Julie Teule1, Frédéric Damagnes2, Ha Tran1, 1Pediatric Sleep Center, Center for Reference of CCHS, Robert Debré Hospital, Paris, France; 2ADEP Assistance, Suresnes, France; 3Univ Paris Diderot, Paris, France

Home ventilators are often equipped with BIVS able of recording various parameters over many months. AHI is one of the parameter most frequently used by clinicians to monitor efficiency of ventilation applied to patients with Obstructive Sleep Apneas (OSA). However, the reliability of algorithms used by BIVS to detect apnea (A) or hypopnea (H) has yet to be determined.

Patients & methods: We studied 55 patients with severe OSA (4M, 1F, 10.5 years, range 2.5-15 years) and treated by NIV (4 CPAP, 1 BiPAP). An overnight respiratory polygraphy (RP) was performed while the patient was on NIV at home. All RP were analyzed as usually recommended by one of us (J.T.) blinded to BIVS data. We compared A and H detected by BIVS versus those detected by RP.

Results: BIVS detected 169 A-H that were related to movements in 56% and no visible event using RP in 25% of cases.

Table 1

<table>
<thead>
<tr>
<th>Nb of events (%)</th>
<th>Movements-RP</th>
<th>No event-RP</th>
<th>A-RP</th>
<th>H-RP</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>A-H-VS</td>
<td>149 (100%)</td>
<td>95 (66%)</td>
<td>43 (25%)</td>
<td>31 (18%)</td>
</tr>
</tbody>
</table>

Among the 88 A-H detected by RP, only 35% were recognized by BIVS.

Table 2

<table>
<thead>
<tr>
<th>Nb of events (%)</th>
<th>No event-VS</th>
<th>A-VS</th>
<th>H-VS</th>
</tr>
</thead>
<tbody>
<tr>
<td>A-RP</td>
<td>19 (100%)</td>
<td>8 (42%)</td>
<td>2 (11%)</td>
</tr>
<tr>

<td>69 (100%)</td>
<td>49 (71%)</td>
<td>1 (1%)</td>
</tr>
<tr>
<td>A-H-RP</td>
<td>88 (100%)</td>
<td>57 (65%)</td>
<td>31 (35%)</td>
</tr>
</tbody>
</table>

Conclusion: The majority of A-H detected by BIVS was related to patient movements, whereas BIVS was unable to detect A-H seen in RP. These preliminary data support that AHI provided by BIVS is largely inaccurate in patients during NIV and should not be used to adjust NIV. Polysomnographies are required to monitor efficiency of NIV.
P1726
The inter-observer reliability of using a new non-invasive technique to identify patient ventilator asynchrony (PVA) during non-invasive ventilation (NIV) for respiratory muscle unloading resulting in patient discomfort and reduced adherence. We hypothesised that non-invasive measurements with pre-defined PVA criteria would be reliably correlated between 2 independent observers.

Methods: 5 patients initiated on NIV were assessed for PVA using respiratory inductance plethysmography (RIP), 2nd intercostal space parasternal electromyo-gramy (EMGpara) and mask pressures (Pmasks). Two independent observers each recorded PVA from the overnight traces examining each breath from a 2 minute period for each 10 minute epoch over an hour.

Results: A total of 1347 breaths were analysed by each observer. Correlation between two independent observers

<table>

</tr>
</tbody>
</table>

Conclusion: PVA can be reliably identified using the above technique. The predominant PVA was ineffective effort. This analysis could be automated to provide a simple approach to assessing PVA.

P1727
How well do questionnaires capture symptomatic relief and well-being over time with NIV in motor neuron disease?

Hikari Ando1, Biswajit Chakrabarti2, Carolyn Young3, Rosanna Cousins4, Everard Thornton5, Robert Angus5, 1Health Sciences, Liverpool Hope University, Liverpool, United Kingdom; 2Chest Centre, Aintree University Hospitals NHS Foundation Trust, Liverpool, United Kingdom; 3Neurology and Neurosurgery, The Walton Centre NHS Foundation Trust, Liverpool, United Kingdom; 4School of Psychology, University of Liverpool, United Kingdom

Benefits of non-invasive ventilation (NIV) in motor neuron disease (MND/ALS) have been explored using quantitative health measurements with little examination of subjective experience. This study explored whether current quantitative tools commonly used in MND adequately capture the effects of NIV. 6 patients (all male, mean age 67) from an original cohort of 35 were available for the present study having survived a year on NIV. Both questionnaires and semi-structured interviews were completed at 3 occasions: pre-NIV (Point A), 4-months (Point B) and 10-months post-NIV (Point C). The scales used were ALSFRS-R (physical functioning), ALSAQ-40 (ALS specific health status), MNDRS (dyspnoea), BDI (depression), BHS (hopelessness), HADS (depression and anxiety) and ESS (sleepiness). During the interviews, experience of NIV, physical changes and their impact on daily life were explored. All interviews were assessed using thematic analysis. Quantitative scores were compared using analysis of variance. Changes were seen from points A to C in ALSFRS-R 33 ± 27 (p=0.021), ALSAQ subscale for communication 46 ± 29 (p=0.018), BHS 3.67 ± 1.80 (p=0.03) and ESS 9.50 ± 2.8 (p=0.046). The scores of ALSFRS-R denote worsening functional status, while the other scales indicate improvement. Qualitatively, 4 symptoms were discriminated as problematic and were improved by NIV: energy level, quality of night sleep, daytime sleepiness and breathlessness. The results show the multidimensional range of symptoms that relate to hypoventilation in MND and how the routinely employed scales may fail to capture significant symptomatology or the impact of NIV on such symptoms.

P1728
Chronic pulmonary diseases and the epidemiology of invasive pneumococcal infection

Malin Inghammar1, Gunnar Engström1, Bengt Jüngenberg1, Claes-Goran Löfdahl2, Arne Egesten3, 1Section for Infection Medicine, Department of Clinical Sciences, Lund University, Lund, Sweden; 2Section for Respiratory Medicine & Allergology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden; 3Cardiovascular Epidemiology Research Group, Department of Clinical Sciences Malmö, Lund University, Lund, Sweden

Chronic pulmonary disease is an established risk factor for acquiring invasive pneumococcal disease (IPD), but estimates have in most cases been based on studies with aggregated denominators data on comorbidities and have not been large enough to allow detailed analyses on less prevalent pulmonary diseases. There have also been conflicting results whether or not an underlying pulmonary disease increases the risk of death from IPD. We examined the association between COPD, asthma, pulmonary fibrosis, sarcoidosis and pneumoconiosis and IPD, and the impact of these diseases on mortality from IPD.

IPD cases ≥ 18 years of age, 1990-2007, were identified via computerized databases. The associations between IPD and prior pulmonary diseases were assessed using conditional logistic regression, comparing IPD cases to 10 control subjects randomly selected from the general population (matched for sex, year of birth and county of residence). Adjustments were made for other chronic diseases, educational level and socio-economic position. Information on these was obtained through record linkage with other national databases.

4,085 cases of IPD were identified. COPD was associated with increased risk of IPD, (adjusted OR [aOR]: 4.7 [95% CI 4.0-5.6], as well as asthma (aOR: 2.2 [95% CI 1.6-2.8]) and pulmonary fibrosis (aOR: 5.3 [95% CI 2.8-10.0]), whereas sarcoidosis and pneumoconiosis were not independently associated with increased risk of IPD. In hospital mortality and 28-days mortality was not increased for patients suffering from the pulmonary diseases studied. Several but not all pulmonary diseases increase the risk of IPD although this seems not to be a risk factor for increased case-fatality rate.

P1729
Comparison of clinical characteristics between healthcare-associated pneumonia and community-acquired pneumonia in patients admitted into secondary hospitals

Hong Mo Kang1, Jee-Hong Yoo2, Jong Hoo Lee3, Yee Hyung Kim2, Myung Jae Park1, Chicon Woong Choi2, 1Pulmonary and Critical Care Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea; 2Pulmonary and Critical Care Medicine, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; 3Pulmonary and Critical Care Medicine, Jeju National University Hospital, Jeju, Republic of Korea

Background: To evaluate the clinical characteristics of HCAP patients admitted into secondary hospitals in Korea.

Methods: This study was retrospectively conducted between March 2009 and January 2011.

Results: Among 303 patients, 31.7% had HCAP. 42 (43.7%) resided in a long-term care facility, 36 (37.5%) were hospitalized in an acute care hospital for ≥ 2 days within 90 days. The rates of patients with CURB-65 ≥ 3 (22.9% vs. 9.1%) and PSI IV or more (82.2% vs. 34.7%) were higher in the HCAP group. Drug resistant pathogens were more frequently detected in the HCAP group (23.9% vs. 0.4%; p<0.001). Despite lower overall survival rate (p<0.001), multivariable analyses failed to show that HCAP was a prognostic factor for mortality.
Institute, Herston, QLD, Australia; 3Respiratory Medicine, Royal Children's Hospital, Queensland Children's Medical Research Institute, Brisbane, Australia; 4Institute of Medical Microbiology, University of Wuerzburg, Bochum, Germany; Dipartimento di Medicina Clinica e Prevenzione, Università di Milano-Bicocca, San Gerardo Hospital, Monza, Milan, Italy; Pneumology, Hospital La Fe de Valencia, Spain Infectious Disease, Hospital Clinic, IDIBAPS, Barcelona, Spain; Thoraxzentrum Ruhrgebiet, Klinikum für Pneumologie und Infektiologie, Thoraxzentrum Ruhrgebiet, Klinikum für Pneumologie und Infektiologie, EKV Herne und Augusta-Kranken-Anstalt, Bochum, Germany; Dipartimento di Medicina Clinica e Prevenzione, University of Milan-Bicocca, San Gerardo Hospital, Monza, Milan, Italy; Pneumology, Hospital La Fe de Valencia, Spain Infectious Disease, Hospital Clinic, IDIBAPS, Barcelona, Spain; Respiratory Medicine Section, Departamento Toracico-Pulmonare e Cardiocircolatorio, University of Milan, IRCCS Fondazione Ca' Granda Ospedale Maggiore, Milan, Italy

Background: Community-acquired pneumonia (CAP) is currently undergoing re-evaluation. The aim of the study was to determine the influence of age and comorbidity on microbial patterns in elderly patients with community-acquired pneumonia (CAP).

Methods: In a prospective observational study of adult patients with CAP, excluding those residing in nursing homes, we compared patients aged 65 - 74 years, 75 - 84 years and 85 years or older for potential differences in clinical presentation, comorbidities, severity on admission, microbial investigations, aetiologies, antimicrobial treatment, and outcomes.

Findings: We studied a total of 2149 patients. The number of patients in each age group was as follows: 759 (35.3%) patients aged 65-74 years, 941 (43.7%) aged 75-84 years, and 449 (20.8%) patients aged 85 years or older. At least one comorbidity was present in 1710 (79.6%) patients. Strepococcus pneumoniae was the most frequent pathogen in all age groups, regardless of comorbidity. Pathogens such as S. aureus (including MRSA), enterobacteriaceae, and P. aeruginosa were present in 15% and were found almost exclusively in patients with comorbidities. Increasing CAP severity on admission and mortality by decreasing ICU admission rates and use of mechanical ventilation suggested an increasing frequency of treatment restrictions across age groups.

Interpretation: Age did not significantly affect pathogen patterns. Potential multidrug-resistant (MDR) pathogens were not frequent and were found almost exclusively in patients with comorbidities. Excess mortality in the elderly was not related to aetiology but to age and disability.

P1732

Impact of age and comorbidity on presentation, aetiology and outcome in patients with community-acquired pneumonia

Cata Cilliron1, Eva Polverino, Santiago Ewig, Stefano Alberiti, Albert Gabarras, Ruthi Moreno, Josep Mena, Francesco Blasi, Antoni Torres.

Background: The ATS/IDSA guidelines for community-acquired pneumonia (CAP) were published in 2005. Both the bacteriological incidence and CAP risk factors have been described in recently published studies. Many of these CAP patients had risk factors for CAP and most of them had a comorbid illness. The objective of this study was to determine the influence of age and comorbidity on CAP presentation, aetiology and outcome in elderly people.

Methods: A total of 2149 patients were included in this prospective study: 759 patients aged 65 - 74 years, 941 patients aged 75 - 84 years, and 449 patients aged 85 years or older. A comparison of the main clinical and demographic characteristics was performed using a logistic regression model.

Findings: The main clinical and demographic characteristics were similar among the age subgroups. Only age, presence of comorbidities, and mortality were significantly different between the age groups.

Interpretation: Age and comorbidity are important factors in the presentation, aetiology and outcome of CAP. Further studies are needed to determine the impact of age and comorbidity on the treatment and prevention of CAP in elderly people.
important in addition to potentially drug-resistant pathogens (P. aeruginosa and S. aureus), and oral streptococci were more important than previously reported in patients with HCAP.

P1734

Effect of excluding ICU-admission on clinical outcomes in a randomized control trial addressing the effect of corticosteroids in patients hospitalized with CAP

Background: The effect of corticosteroids in patients hospitalized with CAP has not been thoroughly evaluated. In 2010, Snijders performed a multicenter cohort study and reported a higher rate of late failures in the prednisolone group. The objectives of this study were to evaluate the effect of excluding patients admitted to the ICU in a prospective randomized controlled trial.

Design: Randomized, placebo-controlled, double-blind trial.

Setting: Pulmonary Diseases, Medical Centre Alkmaar, Alkmaar, Netherlands; 
3 Internal Medicine and Pulmonary Diseases and Tuberculosis, University Medical Center, Groningen, Netherlands.

Methods: A prospective multicenter cohort study was performed in 13 hospitals. Severe sepsis was diagnosed using Drensmizov criteria (Chest 2006;129:968-978). 4,137 patients were included: 1,171 (28.3%) without severe sepsis, 1,394 (33.7%) with non severe sepsis and 1,572 (38%) with severe sepsis: 521 (33.1%) of these had early (≥48 hours) and 1,051 (62%) late onset. There were no gender differences in early vs. late onset. Early sepsis was associated to elderly patients (≥65 years: 72.2% vs. 65.2%; p=0.006). Statistical differences in clinical presentation and comorbid conditions are depicted in Table 1. Early/severe sepsis showed higher CURB65 scores than late sepsis (49.6% of patients vs. 41.5% with score 3).

Results: A prospective multicenter cohort study was performed in 13 hospitals. Severe sepsis was diagnosed using Drensmizov criteria (Chest 2006;129:968-978). 4,137 patients were included: 1,171 (28.3%) without severe sepsis, 1,394 (33.7%) with non severe sepsis and 1,572 (38%) with severe sepsis: 521 (33.1%) of these had early (≥48 hours) and 1,051 (62%) late onset. There were no gender differences in early vs. late onset. Early sepsis was associated to elderly patients (≥65 years: 72.2% vs. 65.2%; p=0.006). Statistical differences in clinical presentation and comorbid conditions are depicted in Table 1. Early/severe sepsis showed higher CURB65 scores than late sepsis (49.6% of patients vs. 41.5% with score 3).

Conclusions: This study showed that excluding ICU-patients prednisolone did have an impact on LOS and TTCS with an increased rate of late failures.

P1735

Characterization of community acquired pneumonia (CAP) with severe sepsis at diagnosis

Background: Early severe sepsis in CAP presents with greater severity while late onset does with large radiographic involvement. Diabetics, elderly patients and those with cerebrovascular disease are more prone to develop rapid onset severe sepsis in CAP.

Methods: We analyzed the degree of HRF measured as PaO2/FiO2 ≥250 in a group of patients with SCAP (PSI IV-V) who scored the item hypoxemia in PSI score (PaO2 <60 mmHg, >10 ps). Factors that determined a greater degree of HRF and its influence in the outcome (complications and mortality) were analyzed.

Results: From a cohort of 1,314 pneumonias, 364 (27.7%) were hypoxemic SCAP (PSI IV-V and PaO2/FiO2 <250) rated higher in PSI score [123.9 (23.4) vs 116.3 (20.2); p=0.01]. Multivariate analysis showed that PaO2/FiO2 ≤250 group (17.1% vs 4.1%; p=0.01), and a longer hospital stay (13.4 (14.7) vs 10.2 (6.5) days; p=0.014). Mortality was significantly higher in PaO2/FiO2 ≤250 group (17.1% vs 4.1%; p<0.01). The degree of HRF could negatively impact in the outcome (complications and mortality) of CAP.3-Our data suggest that the assessment of hypoxemia in SCAP should be considered as semi-quantitative data due to its prognostic implications.

P1737

Cardiac diseases in patients with community acquired pneumonia (CAP)

Background: Community Acquired Pneumonia (CAP) and cardiac diseases are mutually aggravating conditions. There is a surge of interest in the association of major cardiac diseases and CAP and this study was done to contribute to the world’s literature from the Indian sub-continent.

Materials and methods: In this retrospective analysis of patients admitted with CAP between January 2011 and January 2012 at a tertiary care referral centre we looked for associated cardiac diseases.

300s
Results: Of the total patients included in the analysis (n=73), 34.24% (25) had an associated cardiac disease. There were 45 instances of cardiac problems. 19.17% (14) had pulmonary hypertension, 16.44% (12) had CCF/Acute LVF, 13.69% (10) had ischemic heart disease, 4.1% (3) had Rheumatic heart diseases, 2.76% (2) had arrhythmias and there was 1 instance each of Infective endocarditis, acute pulmonary thromboembolism, congenital heart disease and MI (1.36%). 14.36% (out of 25) patients who had cardiac diseases required ICU care while 9 (18.75%) out of 48 patients who did not have cardiac conditions required ICU care(p=0.001). 6 out of 25 patients had new onset cardiac problems. Two patients in the cardiac disease group and 1 patient in the non cardiac disease group, one patient died.

Conclusions: There is a high degree of correlation between pre existing cardiac disease and CAP as also between CAP and new onset cardiac diseases especially CAD.

P1738

The role of procoagulant activity in patients with community acquired pneumonia

Andrea Matveychuk, Masri Numan, Alexander Guber, Baruch Chen, David Shtrir,
Pulmonary Department, Meir Medical Center, Kfar Saba, Israel Internal Medicine E Department, Meir Medical Center, Kfar Saba, Israel

Community acquired pneumonia (CAP) is still one of the most important causes of morbidity and mortality. In severe cases, parapneumonic effusions or empyema may develop. In these patients, the increased vascular permeability, mediated by several cytokines, allows migration of inflammatory cells, an increased fluid accumulation and bacterial invasion into pleural space. The activation of the fibrinolytic system produces D-dimer and follow by increased other procoagulant markers like thrombin anti thrombin (TAT), fragment 1.2. Moreover, serum levels of AT-III, D-D and CRP at admission appear to be useful biomarkers for assessing the severity of CAP. Our study included patients with CAP Blood D-dimer, TAT and Fragment 1,2 levels were measured by Enzyme Linked Fluorescent assay 24 and 48 hours after admission. The results were correlated with the clinical, laboratory, and radiologic findings (PORT and ARDS II). A total of 50 patients with pleural effusion were included in the study. Eleven patients (18%) developed pleural effusion. Only D-dimer levels increased 48 hours following admission compared to the 24 hours levels (1939±1234 vs 1812±1192 ng/ml). Fragment 1 and TAT levels decreased after 48 hours. D-dimer at 24 hours was correlated with the age, platelet counts and PORT score. F 1.2 and TAT at 24 hours were correlated with recent of neuprophils. PT at 24 hours was correlated with WBC count. After 48 hours, D-dimer was correlated only with age. F1.2 and TAT had no correlations with clinical parameters after 48 hours. The 24 hours D-dimer predicts severity of CAP. Other coagulation markers and serial monitoring of blood coagulation markers have a limited role in predicting CAP.

P1739

Pancreatic stone protein predicts positive sputum bacteriology in exacerbations of COPD

Andrew Scherr,1 Rolf Graf,2 Martha Bain,3 Miriam Christ-Cram,4
Bead Mihalko,4 Lajouania1, Michael Tamm1, Danaa Stodt,2 Clinic of Pneumology, Pneumology University, Basel, Switzerland; 2Pneumatics Research Laboratory, University Hospital, Zurich, Switzerland; 3Clinic of Endocrinology, University Hospital Basel, Switzerland; 4Internal Medicine, Hospital of Aarau, Argovia, Switzerland; 1LASCCO SA Geneva, LASCCO, Geneva, Switzerland

Background: Pancreatic Stone Protein(Regenerating protein) (PSP/Reg) is increased in bacterial inflammatory processes. PSP/Reg might therefore be also useful as a predictor of bacterial infection in COPD. Methods: 200 consecutive patients presenting to the emergency department due to acute exacerbation of COPD were prospectively assessed. Patients were evaluated based on clinical, laboratory and lung-functional parameters at admission (exacerbation) and after short term follow-up (14-21 days). PSP/Reg serum values were measured by a new developed enzyme linked immunosorbent assay (ELISA). Results: PSP/Reg levels were elevated in subjects with COPD exacerbation (23.8 ng/ml 95% CI [17.1-32.7]) when compared to those with stable disease (19.1 ng/ml 95% CI [14.1-30.4]) and healthy controls (14.0 ng/ml 95% CI [12.0-19.0], p<0.01). Higher of CAP were observed in exacerbation with positive (26.1 ng/ml 95% CI [19.2-38.1]) as compared to those with negative sputum bacteriology (20.8 ng/ml [15.6-27.2], p<0.01). Multivariate regression analysis revealed PSP/Reg as an independent predictor of positive sputum bacteriology. A combination of PSP/Reg cut-off of ≥ 33.9 ng/ml and presence of discolored sputum had a specificity of 97% to identify patients with pathogen bacteria on sputum culture. In contrast, PSP/Reg levels <18.4 ng/ml and normal sputum color ruled widely out positive bacterial sputum culture (sensitivity 92%). In survival analysis, high PSP/Reg levels at cut-off of 33.9 ng/ml were associated with increased 2-year mortality. Conclusions: PSP/Reg might represent a promising new biomarker to identify bacterial etiology of COPD exacerbation in future.
Results: A total of 110 patients (68 F) had a diagnosis of bronchiectasis with a median(range) age of 62(17-87) years and median(range) age of 65(12%-133%). Investigations carried out are shown in table 1 & underlying etiology in table 2.

P1743 Bacterial aetiology in the Danish pleural empyema project

Christian N. Møyer,1 Karin Armbruster,2 Bo Broberg3, Alice Friis-Moller4, Ram D. Dessau,5 Ina S. Petersen,6 Michael Pedersen,6 Thomas Ringbæk,6 Michael Kempa,7 Department of Internal Medicine, Roskilde Hospital, Roskilde, Denmark; 2Danish Pleural Emphyema Project Group, Region of Copenhagen and Region of Zealand, Roskilde, Denmark.

Recent publications identified the aetiology of pleural empyemas with results varying according to antimicrobials given before sampling. Objectives: Our aim was to identify the microbiological aetiology in pleural empyema by standard methods and later evaluate, if DNA-amplification methods may supplement culture results by detecting further clinically relevant microorganisms.

Methods: From 2008-2011 in the Danish Pleural Emphyema Project, the respiratory medical departments from 8 Danish hospitals participated. Cases were prospectively identified clinically and pleural fluid samples were collected for standard microbiological analysis (microscopy and culture). Further samples were collected and kept in storage at minus 80 degrees Celsius for later PCR analyses. Cases judged as non-infectious were excluded. Clinical data were collected regarding symptoms, pre-admission treatment, clinical findings, risk factors, co-morbidity, blood test results, radiology, treatment, and outcome.

Results: A total of 434 episodes of pleural empyema were identified. In 242 cases (56%), the cultured were either negative (n=198) or no pleural samples were successfully taken (n=44). Among the 192 cases with proven aetiology, mixed infections were identified in 47 cases (24%), 34 Streptococcus pneumoniae (18%), 53 non-pneumoniae streptococci (28%), 16 Staphylococcus aureus (8.3%), 15 enterobacteriaceae (7.8%), 15 anaerobes (7.8%), and 5 Enterococcus species (2.6%).

Conclusions: 56% of the cases were culture negative by standard methods. Future studies are planned to implement DNA-methods optimised for mixed infections for identification of the micro-organisms. This may expand the identified spectrum of detected micro-organisms and improve the treatment.

P1744 Predictors of rehospitalization after admission for community-acquired pneumonia

Eric Mertens1,2,3, Mary Jo Pugh1, Marcos Restrepo2,4, Antonio Anzueto4,5.

1Medicine, VA North Texas Health Care System, Dallas, TX, United States; 2Medicine, South Texas Veterans Health Care System, San Antonio, TX, United States.

The aim of our study was to examine variations in rates of rehospitalization, and predictors of rehospitalization, for patients hospitalized with community-acquired pneumonia (CAP) in the United States Department of Veterans Affairs (VA) health care system.

We conducted a retrospective national cohort study over 5 years including patients >65 years of age hospitalized with CAP. Our primary outcome was all-cause rehospitalization within 90-days. Our primary analysis was a multilevel regression model, adjusting for admitting hospital, and included 38 variables encompassing demographics, pneumonia severity, antibiotics received, prior outpatient medications, pre-existing comorbid conditions, and prior outpatient utilization (e.g., emergency department, primary care) the year prior to the pneumonia admission.

We identified 50,119 patients with CAP of which 21.8% required rehospitalization within 90-days. Hospital rates varied from 14.3% to 32.3%. In the regression model, factors significantly associated with increased rehospitalization included alcohol abuse (odds ratio 3.07, 95% confidence interval 1.23-7.61), number of prior outpatient pulmonary medications (1.10, 1.01-1.19), and number of prior emergency department visits (1.1, 1.04-1.14).

A large number of patients required rehospitalization after admission for CAP, and rates varied widely. Only a few factors were significantly associated with rehospitalization and these factors were not related to the pneumonia hospitalization. Additional research is needed to determine which rehospitalizations after pneumonia are preventable and ways to prospectively identify hospitalized CAP patients at risk for rehospitalization.

P1745 Comparison of PSI, A-DROP, CURB-65, CRB-65, and SOAR indices in hospitalized patients with community acquired pneumonia

Cemile Cetinkaya, Aysin Sakar Coskun, Yavuz Hayvanci, Turgha Goktalay, Pinar Celik, Arzu Yorgancio glu. Chest Disease, Celal Bayar University Medical Faculty, Manisa, Turkey.

We evaluated the relation between PSI, A-DROP, CURB-65, CRB-65, and SOAR indices and investigate the importance of these indices in the follow up of hospitalised patients with community acquired pneumonia(CAP).

Patients hospitalized in Celal Bayar University Chest Disease Clinic between January 2009 and January 2010, due to CAP, were included in the study. Socio-demographic findings, symptoms, comorbidities, habits, history, physical examination findings, laboratory and radiological findings, pneumonia severity groups, treatment result, duration of hospitalization, and cost of disease treatment of patients were obtained from "Pneumonia Data Base" prepared by Turkish Thoracic Society Respiratory Infections Scientific Assembly.Indices above were calculated for each patient.

70 patients were included to study. There were 49 male(70%) and mean age was 63.07±18.08 years. Mean duration of hospitalization was 10.08±5.64 days. 57 patients(81.4%) were totally cured after one month follow up. Indices mentioned above were correlated with each other(Pearson correlation test)(p<0.005). There was no difference between indices according to total cure and development of complication due to pneumonia(p>0.05). Duration of hospitalization of CAP patients was categorized as 0-14 days and more than 14 days. These indices were found significantly different when comparison was done according to this categorization(p<0.05).

PSI, A-DROP, CURB-65, CRB-65, and SOAR indices were found to be correlated with each other.All of the indices mentioned above has low estimation rate for the duration of hospitalization. We identified 50,119 patients with CAP of which 21.8% required rehospitalization within 90-days. Hospital rates varied from 14.3% to 32.3%. In the regression model, factors significantly associated with increased rehospitalization included alcohol abuse (odds ratio 3.07, 95% confidence interval 1.23-7.61), number of prior outpatient pulmonary medications (1.10, 1.01-1.19), and number of prior emergency department visits (1.1, 1.04-1.14).

A large number of patients required rehospitalization after admission for CAP, and rates varied widely. Only a few factors were significantly associated with rehospitalization and these factors were not related to the pneumonia hospitalization. Additional research is needed to determine which rehospitalizations after pneumonia are preventable and ways to prospectively identify hospitalized CAP patients at risk for rehospitalization.

P1746 Selection of suitable housekeeping genes for real-time quantitative PCR in CD4+lymphocytes from asthmatics with or without depression

Tina Wang1, Zeng-An Liang2, Andrew Sandford1, Xinyu Xiong1, Ting Wang1, 1Department of Respiratory Medicine, West China Hospital, Sichuan University, Chengdu, Sichuan, China; 2Department of Medicine, University of British Columbia, James Hogg iCAPTURE Centre, Vancouver, BC, Canada.

Objective: No optimal housekeeping genes (HKGs) have been identified for CD4+ T cells from non-depressive asthmatic and depressive asthmatic adults for normalizing quantitative real-time PCR (qPCR) assays. The aim of present study was to select appropriate HKGs for gene expression analysis in purified CD4+ T cells from these asthmatics.

Methods: Three groups of subjects (Non-depressive asthmatic, NDA, n=10, Depressive asthmatic, DA, n=11, and Healthy control, HC, n=10) respectively were studied. qPCR for 9 potential HKGs, namely RNA, 28S ribosomal 1 (RN28S1), ribosomal protein, large, P0 (RPLP0), actin, beta (ACTB), cyclophilin A (IPPA), glyceraldehydes-3-phosphate dehydrogenase (GAPDH), phosphoglycerate kinase 1 (PGK1), beta-2-microglobulin (B2M), glucuronidase, beta (GUSB) and ribosomal protein L13a (RPL13A), was performed. Then the data were analyzed with three different applications namely BestKeeper, geNorm, and NormFinder.

Results: The analysis of gene expression data identified B2M and RPLP0 as the most stable reference genes and showed that the level of PPA was significantly different among subjects of three groups when the two best HKGs identified model, adjusting for admitting hospital, and included 38 variables encompassing demographics, pneumonia severity, antibiotics received, prior outpatient medications, pre-existing comorbid conditions, and prior outpatient utilization (e.g., emergency department, primary care) the year prior to the pneumonia admission.

We identified 50,119 patients with CAP of which 21.8% required rehospitalization within 90-days. Hospital rates varied from 14.3% to 32.3%. In the regression model, factors significantly associated with increased rehospitalization included alcohol abuse (odds ratio 3.07, 95% confidence interval 1.23-7.61), number of prior outpatient pulmonary medications (1.10, 1.01-1.19), and number of prior emergency department visits (1.1, 1.04-1.14). A large number of patients required rehospitalization after admission for CAP, and rates varied widely. Only a few factors were significantly associated with rehospitalization and these factors were not related to the pneumonia hospitalization. Additional research is needed to determine which rehospitalizations after pneumonia are preventable and ways to prospectively identify hospitalized CAP patients at risk for rehospitalization.

212. Recent progress in mechanisms and diagnostics of COPD and asthma
were applied. Post hoc analysis by Student-Newman-Keuls correction shows that depressive asthmatics and non-depressive asthmatics exhibited lower expression than other groups, and this group showed significantly lower expression of IL-17A mRNA in the lungs on day 21 in PPE-treated WT mice, which was significantly increased compared to PBS-treated ones (p < 0.05). In contrast, IL-17A–/– mice administered with PPE showed significantly less increase in the CSE lung and Lm (p < 0.05, compared to WT).

Conclusions: These results suggest that IL-17A contributes to the development of elastase-induced neutrophilic inflammation and emphysema in mice.

P1748 Promotor methylation of Bcl-2 in cigarette smoke extract-induced emphysema
Hisbun Zeng, Ping Chen, Department of Respiratory Medicine, The Second Xiangya Hospital, Central South University, Changsha, China

Objective: Abnormal apoptotic events may play an important role in emphysema. We determined whether Bcl-2, a pivotal regulator of apoptosis, participates in emphysema. Furthermore, given the methylation in promoter CpG islands causing gene silencing, and existence of CpG islands in Bcl-2 promoter, we hypothesized that the demethylation in CpG islands of Bcl-2 gene might reduce its expression.

Methods: BAL/Bc mice were divided into four groups (n=10 per group): CSE–, CSE+5-aza-2'-deoxycytidine(AZA, demethylation reagent), AZA, and control (phosphate buffered saline, PBS). CSE group were intratracheally injected with CSE once a week for 3 weeks to build emphysema models. AZA and PBS were also administered weekly as CSE. After 3 weeks of treatment, TUNEL assay was used to assess apoptotic index of pulmonary cells; western blotting or Real-time-RT-PCR were used to detect expression of Bcl-2 and Cyt C in pulmonary tissue; bisulphite sequencing PCR (BSP) was used to observe the methylation status of Bcl-2 promoter.

Results: The apoptotic index of pulmonary cells in CSE group (42.5 ± 2.8%) was significantly higher compared with others (p < 0.05). The CSE induce-emphysema mice presented lower expression of Bcl-2 protein and RNA than other groups, and this group showed significantly lower expression of Bcl-2 protein and RNA than other groups (p < 0.05). (3) The CSE demethylation group showed higher expression of cytoplasmic Cyt C than other groups (p < 0.05). (4) The CSE group showed higher methylation ([19.2±2.6]% ± [3.0±0.8], [4.5±0.6]% ± [0.9±0.5]) in CSE group on day 0. IL-17A mRNA expression in the lungs was assessed with RT-PCR. Lung inflammation was determined by differential cell count in bronchoalveolar lavage fluid. On day 0, IL-17A lung expression by forced oscillation method. Emphysema was assessed by alveolar mean liner intercept (Lm) determined by computer-assisted morphometric analysis.

Conclusions: We established a mouse model of short-term cigarette smoke exposure, which is accompanied by neoplastic transformation in the lungs. The methylation of Bcl-2 gene promoter might be involved in the pathogenesis of cigarette smoke-induced emphysema. These results suggest that the deregulation of Bcl-2 in emphysema might be caused by methylation.

P1747 Interleukin-17A in the pathogenesis of elastase-induced emphysema in mice Nobumitsu Kamishi1, Koichiro Aso1, Takahisa Takahira1, Shizuko Kagawa1, Shuichi Yoshida2, Naoto Minematsu1, Hideotsuyu Nakamura1, Kyuto Tanaka1, Jun Miyata1, Yuseake Suzuki1, Tetsuya Shimizu1, Koshi Fukunaga1, Koichi Sayama1, Seitaro Fujishima1, Yoshiro Iwakura1, Tomoko Betsuyaku1.

1Pulmonary Medicine, Keio University School of Medicine, Tokyo, Japan; 2Emergency Medicine, Keio University School of Medicine, Tokyo, Japan; 3Laboratory of Molecular Pathogenesis, Medical Science, The University of Tokyo, Japan

Background: Recent studies show that interleukin (IL) -17A is highly expressed in the lungs of patients with chronic obstructive pulmonary disease (COPD) and in the emphysematous lungs of mice after long-term cigarette smoke exposure. However, the role of IL-17A in the pathogenesis of emphysema is still unknown. In the present study, we examined the role of IL-17A in the development of emphysema.

Methods: Porcine pancreatic elastase (PPE) or phosphate buffered saline (PBS) was administrated intratracheally in B6-D2F1 and wild-type (WT, C57BL/6J) mice on day 0. IL-17A mRNA expression in the lungs was assessed with RT-PCR. Lung inflammation was determined by differential cell count in bronchoalveolar lavage fluid. On day 1, lung expression by forced oscillation method. Emphysema was assessed by alveolar mean liner intercept (Lm) determined by computer-assisted morphometric analysis.

Results: IL-17A mRNA expression was increased in WT mice 6 hours after the administration of PPE. It was accompanied by neutrophilic inflammation in the lungs on day 2– day 14 whereas neutrophil recruitment was significantly reduced in IL-17A–/– mice (p < 0.05). Lung compliance and emphysema (Lm) on day 21 in PPE-treated WT mice was significantly increased than in PBS-treated ones (p < 0.05). In contrast, IL-17A–/– mice administered with PPE showed significantly less increase in the compliance and Lm (p < 0.05, compared to WT).

Conclusions: These results suggest that IL-17A contributes to the development of emphysema.

P1750 Effect of genetic polymorphisms of some cytokines and xenobiotic-metabolizing enzymes on the lung function in patients with COPD
Dumi Dimov1, Tatiana Vlaykova2, Mateusz Kurzawski1, Vanya Ilieva1, 1Institute of Biochemistry, Medical University, Sofia, Bulgaria; 2Department of Immunology and Allergology, Medical University, Sofia, Bulgaria

Background: COPD is a chronic inflammatory lung disease characterized by decreased expiratory flow rate. The decrease of lung function in COPD depends on tissue remodelling due to xenobiotic- and inflammation-induced ROS-mediated tissue damage and impaired proteinase/antiproteinase balance. Since the activity and/or the protein level of cytokines and enzymes involved in inflammation and xenobiotic and antioxidant detoxification are found to be associated with some gene variants, we aim to evaluate the role of gene polymorphisms of three xenobiotic-metabolizing enzymes and three proinflammatory cytokines as factors involved in decline of lung function in COPD. We genotype altogether 164 patients with COPD and 174 non-affected by the disease, control group.

Methods: In the present study, we analyzed six genetic polymorphisms of three enzyme systems: GSTP1+313A, IL-10 –174G/C, TNFA –308G/A, IL1B –511C/T, IL1B +3953C/T and for the null polymorphisms in GSTM1 and GSTTI. Our results displayed that the carriers of A allele of GSTP1+313A-G showed a tendency for higher FEV1%, compared to the carriers of GG genotype (p=0.097). Patients COPD stage III/IV having GSTM1 null genotype demonstrated significantly lower FEV1% values (39.16%) than those with non-null genotype (43.91%, p=0.032). Moreover, patients with C containing genotypes of IL-10 –174G–C SNP had significantly lower FEV1/FVC% (59.7%) compared to the patients with GG genotype (62.7%, p=0.034). The polymorphisms in GSTTI, TNFA and IL1B did not show any significant associations with the lung function.

Results: In conclusion, we suggest that the polymorphisms in the genes of some cytokines and xenobiotic-metabolizing enzymes, such GSTP1, GSTM1 and IL1B are factors that may affect the lung functions in COPD.

P1751 Gender differences in 5- and 12/15-lipoxygenase products in bronchoalveolar lavage fluid from healthy never-smokers, smoker and COPD patients
David Boljuc1, Magnus Schöld2, Johan Granewall3, Anders Eklund4, Ana Whellock1, Craig Wheelock1, Division of Physical Chemistry II, MBB, Karolinska Institute, Stockholm, Sweden; 2Respiratory Medicine Unit, Department of Medicine, Karolinska Hospital, Stockholm, Sweden

Background: Chronic obstructive pulmonary disease (COPD) is a leading disease that is increasing particularly among females. Smoking represents the main risk factor for developing COPD and chronic inflammation persists after smoking cessation.

Aims: We have investigated the effects of smoking, in relation to COPD, on lipid mediators in the inflammatory response in the lower airways.

Methods: Bronchoalveolar lavage fluid (BALF) was collected from healthy never-smokers, non-symptomatic smokers, and COPD patients of GOLD stage I-II (smokers and ex-smokers) of both genders. Different lipid mediators derived from the cytochrome P450, lipoxygenase (LOX) and cyclooxygenase (COX) pathways were analyzed by mass spectrometry.

Results: Products of 12/15-LOX and 5-LOX clustered respectively when analyzed by multivariate analysis and were summed for further comparisons. 12/15-LOX products were selectively increased in females. 5-LOX products exhibited a distinct pattern with increases in smokers, but no gender-specificity. There was no difference in lipoxygenase products between healthy smokers and smoking COPD patients. However, in COPD ex-smokers the levels of 5-LOX products were decreased compared to COPD smokers.
P1752

The role of chaperone α-B-crystallin (HspB8) in COPD pathogenesis

Radoszina Cherneva1, Ognian Georgiev1, Daniela Petrova2, Vesela Ivanova2

Background: α-B-crystallin is a chaperone whose role as a marker of innate immunity activation as well as its therapeutic potential have recently been investigated in several inflammatory diseases – multiple sclerosis, myocardial ischaemia, Guillain Barre syndrome.

Aim: The aim of the study is to determine the role of α-B-crystallin in COPD pathogenesis and immunization.

Materials: Plasma levels of α-B-crystallin were studied in 163 patients – 52 healthy non-COPD smokers; 20 COPD smokers I - II stage GOLD; 43 COPD smokers – III-IV stage (GOLD) and forty-eight patients with acute inflammatory respiratory disease. The plasma levels of α-B-crystallin antibodies were determined by ELISA (human anti α-B-crystallin Abcam), and were confirmed with Western blotting.

Results: The mean levels of anti - α-B-crystallin antibodies were: in non-COPD smokers and control group 0.169 ± 0.130 OD in healthy non-COPD smokers – 0.433 OD. There was a statistically significant difference between COPD smokers and healthy non-COPD smokers (p=0.010). The same could be observed comparing the group of patients with acute inflammation and non-COPD healthy smokers and healthy non-COPD smokers.

Conclusion: α-B-crystallin is increased in patients with inflammatory lung diseases. Further studies could be used in a panel of garkers discriminating COPD smokers from healthy non-COPD smokers. Being a regulator of innate immunity and a therapeutic anti-inflammatory agent its role in COPD pathogenesis and therapy should be further explored.

P1753

The incidence of alpha-1-antitrypsin (A1AT) deficiency alleles in Polish population – Preliminary results from newborn screening

Nedka Trifonova1, Maria Stanimirova1, 2, Internal Medicine, University Hospital Alexandrovska, Sofia, Bulgaria; 2Pathology, University Hospital Alexandrovska, Sofia, Bulgaria; 3Medical Biology, University Hospital Alexandrovska, Sofia, Bulgaria; 4Immunology of Reproduction, Bulgarian Academy Sciences, Sofia, Bulgaria

Background: α-B-crystallin (HspB8) is a chaperone whose role as a marker of innate immunity activation as well as its therapeutic potential have recently been investigated in several inflammatory diseases – multiple sclerosis, myocardial ischaemia, Guillain Barre syndrome.

Aim: The aim of the study is to determine the role of α-B-crystallin in COPD pathogenesis and immunization.

Materials: Plasma levels of α-B-crystallin were studied in 163 patients – 52 healthy non-COPD smokers; 20 COPD smokers I - II stage GOLD; 43 COPD smokers – III-IV stage (GOLD) and forty-eight patients with acute inflammatory respiratory disease. Conclusion: α-B-crystallin is increased in patients with inflammatory lung diseases. Further studies could be used in a panel of garkers discriminating COPD smokers from healthy non-COPD smokers. Being a regulator of innate immunity and a therapeutic anti-inflammatory agent its role in COPD pathogenesis and therapy should be further explored.

P1754

Aim: The aim of the study is to determine the role of anti-α-β-crystallin (A1AT) deficiency alleles in Polish population.

The frequencies of the A1AT haplotypes of the studied two loci of A1AT (-511C-T and +3935C-T) did not differ significantly between controls and COPD patients (p=0.099). However, the T_C haplotype constructed by alleles found to determine enhanced expression of IL-1β, appeared to be associated with higher risk of COPD (OR 1.25, 0.88-1.79, p=0.231) compared to the most common C_C haplotype and with 1.7-fold higher risk of COPD (95% CI, 1.0-2.64, p=0.018) compared to the T_C haplotype, previously described in COPD patients.

Based on the results of the study the first time we propose that the T_C haplotype of A1AT-511C>T-3935C>T, supposed to determine enhanced expression of IL-1β, is a predisposing factor for COPD in Bulgarian population.

P1755

Results: The proposed method of DNA extraction allowed successful DNA isolation from all analyzed DBS samples. Both quantity and quality of DNA were sufficient for further real-time PCR and genetic sequence analysis of all samples. The 100% concordance between AAT DBS genotypes and serum phenotypes in positive detection of two major deficiency alleles was achieved. Both assays, DBS AAT genotyping by real-time PCR and AAT phenotyping by IEF, positively identified AAT and PPZ AAT deficiency variants by real-time PCR. The results of AAT genotyping were validated by IEF phenotyping and concentration measurement of AAT protein in sera from the same patients. The diagnosis of rare/unknown AAT variants was established by direct sequencing.

**P1757** Effect of cigarette smoking on sputum proteome profiles in patients with asthma and healthy volunteers

Jeffries House1, Rekha Chaudhuri2, Abdel Arifl3, Alan Barton4, Charles McSharry2, Neil Thomson1, Medical Research Institute, University of Dundee, United Kingdom; 4Institute of Infection, Immunity & Inflammation, University of Glasgow, United Kingdom

**Background:** Smokers with asthma have more severe symptoms and impaired short-term recovery compared to non-smokers, but the mechanisms accounting for these adverse effects are poorly understood. We hypothesise that the differences in sputum protein profiles provide insight into the pathophysiological effects of smoking in asthma.

**Methods:** High resolution label-free shotgun proteomics was employed to investigate sputum protein profiles in 43 asthmatic non-smokers, 50 asthmatic smokers, 10 healthy non-smokers and 10 healthy non-smokers. Protein expression was normalised to sputum albumin level.

**Results:** A total of 596 and 335 proteins were confidently detected (FDR < 1%), Mascot) in asthmatic patients and healthy volunteers, respectively. Among them, 73 and 68 proteins were found differentially expressed between smokers and non-smokers for asthmatic patients and healthy volunteers, respectively (p < 0.05, Benjamini corrected). Majority of differences observed were up-regulation in smokers. Functional enrichment analysis showed that peptidase inhibitor activity and acute inflammatory/defence response were over-representative in healthy smokers compared to healthy non-smokers (p < 0.05, Benjamini corrected). In asthmatic smokers, there was an over-expression of oxidoreductase activity, thorodoxen fold (glutathione S-transferase), response to extracellular stimuli and lysosome related peptidase activity.

**Conclusions:** These results suggest that asthmatic patients may be hyper-responsive to cigarette smoke and that their airways may be susceptible to potential damage from lysosome related peptidase activity.

---

**P1758** Polymorphisms of MDR1, ADRB2 and IL13 genes are markers of therapy-resistant bronchial asthma (BA) in Russian patients

Zhanna Mironova1, Vasiliy Trofimov1, Mikhail Dubina2, Anna Ulitina2, Elena Yanchina1
1Department of Hospital Therapy, I.P. Pavlov State Medical University, Saint-Petersburg, Russian Federation; 2Department of Molecular, Genetic and Immunobiological Technologies, I.P. Pavlov State Medical University, Saint-Petersburg, Russian Federation

**Background:** BA is a multifactorial disease caused by the interaction of genes and environment. Genetic polymorphisms influence BA development, progression and severity as well as response to BA therapy.

**Aim:** To assess severity of BA and effectiveness of BA pharmacotherapy in patients with BA with different genetic background.

**Methods:** Genomic DNA was extracted from peripheral leukocytes. We investigated 4 SNPs by PCR-RFLP in 122 BA patients and in 103 healthy controls.

**Results:** Distribution of genotypes was similar to other European populations, except MDR1 gene. We revealed numerous associations of genetic variants with increased risk (IR): 3435CC with IR of BA (OR=3.92, 95%CI 1.74-8.79); 3435CC increased risk (IR): 3435CC with IR of therapy-resistant BA (OR=6.12, 95%CI 2.42-15.48); 1602yy with IR of respiratory failure (OR=17.31, 95%CI 2.01-149.28); 27Glu with IR of therapy-resistant BA (OR=3.5, 95%CI 1.16-9.66); 130Gln with IR of therapy-resistant BA (OR=2.09, 95%CI 1.01-4.30).

**Conclusions:** Analysis of MDR1, ADRB2 and IL13 polymorphisms is useful for both preventive care (revealing subjects with increased predisposition to BA) and pharmacotherapy optimization due to prediction of BA severity and risk of therapy-resistant BA.

**P1759** Genome wide association study of lung function in asthmatics

Deborah Meyer1, Xingnan Li1, Kerrie Tosh2, Sarah Bujac3, Bryan Barratt4, Ubaldio Martin5, Mitchell Goldman1, Anne-Marie Sims1, Eugene Bleeker6, Center for Genomics & Personalized Medicine Research, Wake Forest School of Medicine, Winston-Salem, NC, United States; 2Innovative Medicine, AstraZeneca, Alderley Park, Cheshire, United Kingdom; 3Statistical Genetics, AstraZeneca, Alderley Park, Cheshire, United Kingdom; 4Global Medicines Development, AstraZeneca, Wilmington, DE, United States; 5Medical Affairs Strategic Development, AstraZeneca, Wilmington, DE, United States

**Objective:** To investigate genes that may be important in determining lung function in subjects with asthma.

**Methods:** A genome-wide association study has been performed in subjects with asthma from the COMPASS study (Bleecker et al, Lancet 370: 2118-25, 2007). To reduce population stratification, homogenous populations were identified based on geographic region, self-reported race, and genetic ancestry using HapMap reference data. Standard quality control measures were applied to the resulting genotype data. Genome-wide association studies (GWAS) for percent predicted FEV1 and FEV1/FVC was performed on the genetically homogenous population from Eastern Europe using PLINK.

**Results:** To date, GWAS has been performed on 587,020 SNPs in Eastern Europeans (n = 885). For percent predicted FEV1, the top three SNP were in or near SLITRK5 (SLIT and NTRK-like family, member 5) on chromosome 13 (p=1.2-2.3x10-08). Additional genes of interest for percent predicted FEV1 include ADAM7 (A Disintegrin And Metalloprotease 7) (p=9.1x10-08) and ARAID (alpha-1d-adrenergic receptor) (p=1.1x10-09). For FEV1/FVC ratio, the top three genes are FGFI (fibroblast growth factor 1) (p=2.2x10-08), EPHA5 (ephrin type-A receptor 5) (p=2.8x10-09) and WNT3A (wingless-type MMTV integration site family, member 5A) (p=6.3x10-09).

**Conclusions:** Evidence was found to support the hypothesis that genes involved in regulation of cellular growth (ARAD1 and FGFI) and asthma susceptibility (EPHA5) are associated with lung function in subjects with asthma.

**P1760** Assessment of allergic status of severe asthma with a new component resolved method using micro-array technique

Claire Mulhild1, Pol Andre Apoil2, Antoine Blancher3, Alain Didier4, Department of Respiratory Medicine, Toulouse University Hospital, Toulouse, France; 2Immunology Department, Toulouse University Hospital, Toulouse, France; 3Infection, Immunity & Inflammation, University of Dundee, United Kingdom; 4Medical Affairs Strategic Development, AstraZeneca, Wilmington, DE, United States

**Objective:** To investigate the concomitant allergen specific IgE status in severe asthmatics and evaluate the IgE reactivity of severe asthmatics.

**Methods:** We have used this test to screen a group of severe asthmatics. ISAC was performed in 21 consecutive patients with severe asthma (American Thoracic Society criteria). Lung function, exhaled nitric oxide (NO), blood eosinophilia, serum total IgE and skin prick tests for predominant allergens were systematically collected.

**Results:** Included 11 women and 10 men (mean age 52±6), median FEV1 76% predicted normal, mean NO 66±47 ppm. Seventy-eight (81%) patients had a negative ISAC and 4 (19%) had sIgE for at least one molecular allergen of the test. None of the 4 positive patients had sIgE toward several allergic sources (mice, pollens, animal dander). One patient was exclusively sensitized for Fel d1 (cat major allergen). Skin prick tests and ISAC were concordant in all patients. The other parameters, clinical, lung function and biology were not different in patients with positive ISAC compared to patients negative for the test. ISAC is useful to confirm the non atopic status of a subgroup of severe asthmatics and to identify precisely the sensitization profile of severe allergic asthmatics.

**P1761** The roles of PCDH1 on epithelial barrier function in the airway

Yutaka Kozu1, Yasuhiko Goh2, Akiko Sekiyama1, Masahiro Terakado3, Ikuko Takeshita4, Shuichiro Maruoka1, Shu Hashimoto1, 1Division of Respiratory Medicine, Nihon University School of Medicine, Tokyo, Japan; 2Division of General Internal Medicine, Nihon University School of Medicine, Tokyo, Japan

**Background:** PCDH1 is recently identified as a susceptibility gene of bronchial hypersensitivity (BHR). Although PCDH1 seems to be involved in the differentiation of the airway, the roles of PCDH1 on epithelial barrier functions have not been determined.

**Methods:** A human airway epithelial cell line, 16HBE, cells were cultured on Transwell chamber for 5days. Barrier function was evaluated by Trans Elec- tric Resistance and dextran permeability. Expression of inflammatory cytokine and chemokine were determined by RT-PCR. Morphology of cell junctions was analysed by immunostaining using anti-PCDH1, anti-ZO-1, anti-Occludin and an anti-e-cadherin antibody.

**Results:** The paracellular barrier function of 16HBE cell monolayer increased over time in culture. Similarly, the expression of PCDH1 increased for the period. The knockdown of PCDH1 significantly inhibited the paracellular barrier function. In addition, it inhibited the dsRNA-induced inflammatory cytokines expressions. Immunocytostaining revealed that CTDH1 might coexist with E-cadherin at the cell-cell contact sites.

**Conclusion:** Our results indicated that a susceptibility gene of PCDH1 plays an important role in the immunological and physiological barriers of airway epithelium.
Sputum protein profile provides a comprehensive view of disease
MMP9, neutrophil elastase or MMP8 despite all of them showing a dramatic
A total of 631 proteins were confidently detected and analysed in this
volunteers.
Methods: The magnetic activated cell sorting separation coupled to fluorescence activated cell sorting separation strategy was used to harvest BM CD34+ progenitor cells from naïve and ovalbumin-challenged asthmatic mice. Isobaric tags for relative and absolute quantitation combined with 2D nano LC-MS/MS technology was employed to profile proteome alterations in CD34+ progenitor cells. The analysis of bioinformatics was performed finally.
Results: Twenty-five proteins with 18 up-regulated and 7 down-regulated ones were identified. In the dysregulated proteins, 4 clusters of proteins were observed around collagen groups, ACTN1/Myosin groups, Md2k and Serpin1, predominantly participating in pathways of focal adhesion, ECM-receptor interaction, tight junction and regulation of actin cytoskeleton.
Conclusions: Collagen group and ACTN1 related focal adhesion, ECM-receptor interaction and regulation of actin cytoskeleton could be the key pathway in bone marrow response of asthma.

Sputum protein profiles for monitoring lung pathophysiology in chronic lung diseases
Jeffrey Hsueh 1, Abdel Atrih 1, Alan Barton 1, Colin Palmer 1, Graham Devereux 2 1Medical Research Institute, University of Dundee, United Kingdom; 2 Respiratory Medicine, Aberdeen Royal Infirmary, Aberdeen, United Kingdom
Background: Sputum proteome, mainly derived from proteins secreted from airway epithelial cells, immune related cells and proteins released from lysed cells/pathogens, is a potential source for the investigation of lung pathology and pathophysiology of diseases.
Objectives: We hypothesize that sputum protein profiles from cystic fibrosis (CF) and chronic obstructive pulmonary disease (COPD) could provide novel insight into the pathophysiology.
Methods: High-throughput shotgun proteomics was used to investigate sputum protein profiles in 29 patients with CF, 27 patients with COPD and 23 healthy volunteers.
Results: A total of 631 proteins were confidently detected and analysed in this study group. Sputum protein profiles of CF shows a dramatic difference compared to those of healthy volunteers while the profiles of COPD patients were highly variable. Functional enrichment analysis indicates that CF has increased protein expression in pathways of chromatin assembly, actin filament-based process, defense response, carbohydrate catabolic process, anti-apoptosis, and cell motion (p < 0.001). A similar but less significant functional enrichment was found in COPD except that nicotinamide metabolic process was noticeable in COPD. We found that mortality in CF patients over the two consequent years was significantly associated with lower sputum α1-antitrypsin in CF patients (p < 0.001) but MMPs, neutrophil elastase or MMPs despite all of them showing a dramatic increase compared to healthy volunteers.
Conclusion: Sputum protein profile provides a comprehensive view of disease pathophysiology of chronic lung diseases. Some specific sputum protein expression could be useful for disease management and personalised treatment.

213. Diffuse parenchymal lung disease pathogenesis, biomarkers, therapy and new entities

P1764 Investigation of the cirtullination pathway in the pathogenesis of fibrotic lung disease
Katerina Antoniou 1, Katerina Supa 1, 2, Ismini Lasithiotaki 1, Panos Pantelidis 1, Nikolaos Siafakas 1, Athol Wells 2 1Department of Thoracic Medicine, Medical School, University of Crete, Heraklion, Crete, Greece; 2Interstitial Lung Disease Unit, Royal Brompton Hospital, Imperial College, London, United Kingdom
Rationale: Our hypothesis was to explore whether an autoimmune process implicating an anti-citrullinated protein antibody is implicated in pulmonary fibrosis, both idiopathic and autoimmune.
Materials and methods: We evaluated the expression of PAD2 and PAD4, the enzymes mainly catalyzing the citrullination process, in the bronchoalveolar lavage fluid (BALF) of 53 IPF patients, 37 patients with thucmotated lung (RA-ILD) and 10 healthy controls. Survival was evaluated against smoking status, using proportional hazards analysis, adjusting for sex, age, disease severity (composite physiologic index [CPI]), and PAD2 and PAD4 levels.
Results: Both PAD2 and PAD4 mRNA expression levels were increased in IPF and RA-ILD compared to controls (p < 0.05). Protein expression revealed a higher expression of PAD2 and PAD4 in the RA-ILD compared to controls (p < 0.005 for both proteins) and IPF (p < 0.05) respectively. PAD4 protein expression was also increased in IPF compared to controls (p < 0.005). Finally, PAD4 mRNA expression was higher in the smokers than non-smokers (p < 0.01).
Multivariate analysis with stepwise logistic regression identified three factors that independently predict mortality in the study population: CPI, age and both PAD2 and PAD4 levels (examined in separate models). When both PAD2 and PAD4 were included in the same multivariate model, both were independently predictive of late mortality after adjustment for CPI, age and smoking status.
Conclusion: These results suggest that citrullination is an active process in both autoimmune and idiopathic lung fibrosis. The role of citrullinated enzymes as biomarkers predictive of late mortality merits further evaluation.

P1765 Small molecular ACE2 activator, dimazinace acetate attenuates bleomycin-induced pulmonary fibrosis
Vinarak Shenoy 1, Yanfei Q1, Dipankar Gupta 1, Michael Katovich 1, Mohan Kazadda 2 1Physiology and Functional Genomics, University of Florida, Gainesville, FL, United States; 2Pediatric Critical Care Medicine, University of Florida, Gainesville, FL, United States; 3Pharmacodynamics, University of Florida, Gainesville, FL, United Kingdom
Introduction: Angiotensin Converting Enzyme2 (ACE2), a member of the renin angiotensin system has been shown to render protection against lung diseases, particularly pulmonary fibrosis (PF). In this study, we investigated the effects of a recently identified synthetic activator of ACE2, Dimazinace acetate (DIZE) against bleomycin-induced PF.
Methods: A single intratracheal instillation of bleomycin (Bleo, 5U/kg) in 8-week old male rats induced PF. Animals were randomized into Control, Bleo and Bleo+DIZE groups. DIZE treatment (15mg/kg, sc) was commenced soon after bleomycin administration. Following 14 days of bleomycin exposure, rats underwent surgical lung biopsy (28 patients with chronic hypersensitivity pneumonitis, 20 patients with chronic obstructive pulmonary disease, and 50 IPF patients) and right ventricular systolic pressure (RVSP) was measured, followed by heart and lung excision to examine cardiovascular remodeling.
Results: Control rats exhibited a weight gain of 35%, while bleomycin-challenged rats lost 10% of their initial body weight by the end of the study period. Conversely, Bleo+DIZE group demonstrated 16% weight gain. Furthermore, Bleo animals displayed marked elevation in RVSP (Control: 27.1; Bleo: 40±2±2 mmHg; p < 0.05; n=5-6), with subsequent development of right ventricular hypertrophy (RVH; Control: 0.26±0.07; Bleo: 0.36±0.03; p < 0.05). However, DIZE treatment prevented bleomycin-induced increases in RVSP (32.0±2.5 mmHg; p < 0.05). Also, DIZE attenuated both the development of PF and the ensuing increase in lung weight/tibial length ratio associated with bleomycin injury.
Conclusion: Collectively, our results suggest that DIZE prevents bleomycin-induced lung fibrosis and improves cardiovascular hemodynamics. Thus, DIZE treatment may represent a promising therapeutic strategy for treating PF.

P1766 KL-6 is a useful serum biomarker for early detection of interstitial lung disease
Nobuki Kohno, Nobushia Ishikawa, Naoko Deguchi, Hiroshi Iwamoto, Shinichiro Ohshima, Kazunori Fujitaka, Yoshihori Haruta, Hiroshi Murai, Noboru Hattori. Departments of Molecular and Internal Medicine, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan
Background: We previously generated a murine IgG1 monoclonal antibody that recognizes a sialylated sugar chain designated KL-6. KL-6 is a high-molecular- weight glycoprotein classified as human MUC1; it has been reported as a sensitive biomarker for various types of interstitial lung diseases (ILDs). However, the clinical significance of KL-6 for early detection of ILDs has not been well evaluated.
Aims: We aimed to determine whether serum levels of KL-6 are of any diagnostic value in the case of patients with early stages of ILDs.
Methods: We retrospectively collected the data of 69 patients with ILD who underwent surgical lung biopsy (28 patients with chronic hypersensitivity pneumonitis, 27 with idiopathic interstitial pneumonitis, and 14 with collagen vascular disease-associated interstitial pneumonitis). Serum and bronchoalveolar lavage fluid (BALF) concentrations of KL-6 were assayed using a sandwich-type electrochemiluminescence immunoassay. In addition, KL-6 expression in diseased lung specimens obtained from surgical lung biopsy was analyzed using immunohistochemistry and digital image analysis.
Results: The proportion of serum KL-6-positive cases (KL-6 ≥ 500 U/ml) was 94.2% (63 of the 69 patients with ILDs). Furthermore, even when the analysis was restricted to ILD patients with normal lung function (%VC ≥ 80%), the proportion of serum KL-6-positive cases was 92.6% (25 of 27 patients examined). KL-6 was
prominently expressed in regenerating type II pneumocytes, and its serum and BALF levels were correlated with its expression levels in the diseased lungs.

Conclusion: KL-6 may be a useful biomarker for ILDs even in early stages of ILDs and may greatly improve the current diagnostic methods.

P1767
ProSP-B as a possible biomarker in idiopathic interstitial pneumonias (ILD)
Michael Kreuter1, Anne-Kathrin Rossler2, Nicolas Kahn3, Karin Hornemann3, Thomas Melder3, Felix Herth1, 1Pneumologie and Respiratory Critical Care Medicine, Thoraxklinik, University of Heidelberg, Germany; 2Thoracic Surgery, Thoraxklinik, University of Heidelberg, Germany

Introduction: Surfactant proteins (SP) can be elevated in plasma of pulmonary diseases patients. However, for SP-B only limited data are available. Aim of this feasibility study was to assess whether proSP-B and C-fragment pro SP-B (C-proSP-B) might serve as a biomarker in pulmonary diseases.

Methods: In 280 patients serum samples were obtained. In a 1st study at days 1, 7, 21 (n=120) and at 1 time point (n=160) in a 2nd. Measurement was based on electrochemiluminescence immunoassay with mouse monoclonal anti-proSP-B antibodies. Levels were correlated to lung function, clinical and laboratory parameters.

Results: ProSP-B and C-proSP-B levels yielded similar results with higher values for C-proSP-B. Highest C-proSP-B levels (mean, ng/mL) were found in ILD (542, n=24) compared to infection (878 and 583, n=22 and n=31), thoracic tumors (447, n=22) and pulmonary hypertension (333 and 369, n= 21 and n=30). Low values were found in Asthma (210, n=19) and COPD (369, n=26). Levels did not differ between patients with non-invasive versus invasive ventilation (204, n=49 versus 243, n=51) and were higher for smokers, higher BMI and females. A correlation between treatment and values was not found in monitoring. No significant correlations were found between SP-B levels and lung function, right ventricular-function (PH), disease stage or to most subtypes of pulmonary disease entities. However, ILD ILD-B levels were found for IPF patients.

Conclusions: Plasma C-proSP-B might serve as a biomarker in pulmonary diseases with alveolar or interstitial damage like ILDs, especially in IPF and pneumonias. Its role in long term monitoring of such diseases and in obstructive diseases has to be clarified further.

P1768
Serum SP-A as predictor of disease progression in patients with pulmonary alveolar proteinosis
Francesco Parola1, Shihan He1, Shinichiro Oshimo1,2, Josanne Guzman1, Ulrich Costabel2 1Department of Pneumology/Allergy, Ruhrlandklinik, Essen, Germany; 2Department of Molecular and Internal Medicine, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan; 3General and Experimental Pathology, Ruhr-University, Bochum, Germany

Background: Surfactant protein A (SP-A) serum levels is known to be increased in pulmonary alveolar proteinosis (PAP). A disorder characterized by alveolar accumulation of surfactant lipoproteins. The prognostic value of SP-A in PAP is still unknown and has been investigated in our study.

Patients and methods: 28 consecutive patients with PAP were studied prospectively. Serum SP-A was measured by ELISA. We evaluated the correlation between initial SP-A levels, clinical variables and other serum biomarkers. Disease progression was defined as deterioration of symptoms, lung function or chest imaging.

Results: The median follow-up time was 510 (90-1890) days. Initial serum SP-A levels correlated inversely with baseline PaO2, FVC and TLCO (r=-0.405, p=0.004; r=-0.46, p=0.001 and r=-0.462, p=0.003) and directly with AaO2 (r=0.315, p=0.026). Serum SP-A also correlated with LDH (r=0.451, p=0.001) and KL-6 (r=0.538, p=0.006). A correlation between changes in TLCO, PaO2 and AaO2 and changes in serum SP-A during the follow-up was seen (r=0.7, p=0.002; r=-0.538, p=0.007; r=0.436, p=0.033 respectively). Serum SP-A was higher in patients with disease progression (n=14) (p<0.001). At a cut-off level of 490 ng/mL, serum SP-A predicted disease progression with a sensitivity of 86% and specificity of 75% and the necessity of whole lung lavage (WLL) with a sensitivity of 88% and specificity of 75% and the necessity of whole lung lavage (WLL) with a sensitivity of 86% and specificity of 75% and the necessity of whole lung lavage (WLL) with a sensitivity of 86% and specificity of 75% and the necessity of whole lung lavage (WLL) with a sensitivity of 86% and specificity of 75% and the necessity of whole lung lavage (WLL).

Conclusions: Serum SP-A appears to have a predictive value for disease progression in PAP.

P1769
Thrombin induces epithelial-mesenchymal transition via PAR1, PKC and ERK1/2 pathways in A549 cells
Jaeyeon Seo1, Chung Min Kang2, Chan Kwon Park1, Hyung Kyu Yoon1. 1Internal Medicine II, Oita University Faculty of Medicine, Oita, Japan; 2Clinic of Respiratory Medicine, University Hospital, Basel, BS, Switzerland; 3Division of Thoracic Surgery, University Hospital, Basel, BS, Switzerland

Introduction: The pathogenesis of idiopathic pulmonary fibrosis remains largely unknown. Pulmonary fibrosis also remains a devastating clinical disorder for which there are limited therapeutic options. Statins are 3-hydroxy-3-methylglutaryl- coenzyme A reductase inhibitors of cholesterol biosynthesis, and they have been reported to exert pleiotropic effects on cellular signaling involved in tissue inflammation and fibrogenesis.

Objective: To examine the preventive effects of statins on fibrogenic mediator expression and production in lung cells.

Methods: Normal human lung fibroblasts and type II pneumocyte A549 cells, cultured with pitavastatin, pravastatin, or medium alone, were stimulated by transforming growth factor-β1 (TGF-β1). Then, mRNA expression and protein secretion of several mediators from these cells were evaluated by real-time PCR, ELISA, or multiple assays.

Results: The TGF-β1-induced expression or production of mediators, such as CXCL8, platelet-derived growth factor, vascular endothelial growth factor, and collagen-1, were significantly suppressed in both lung cells pretreated with statins, compared to non-treated controls.

Conclusion: Statins inhibited TGF-β1-induced fibrogenic mediator production from lung fibroblasts and epithelial cells. Although further evaluation of the signaling pathways for these phenomena is needed, our results suggest the possibility of statins as anti-fibrotic agents for pulmonary fibrosis.

P1771
Interdependence of endothelin-1 and transforming growth factor-β1 on Wnt3a expression in idiopathic pulmonary fibrosis
Jun Zhou1, Michael Roth1, Michael Tamm2, Didier Lardinios3, Katrin Hotzelter1, 1Department of Biomedicine, University Hospital, Basel, BS, Switzerland; 3Division of Thoracic Surgery, University Hospital, Basel, BS, Switzerland

Introduction: The Wnt signaling pathways may be involved in the development of idiopathic pulmonary fibrosis (IPF). Wnt has been demonstrated to down-regulate the expression of CCAAT enhancer-binding protein (α, C/EBPα), and the pro-fibrogenic cytokines transforming growth factor-β (TGF-β) and endothelin-1 (ET-1) are controlled by Wnt3a signaling.

Aim: To study the effect of TGF-β and ET-1 on ECM production and Wnt expression in primary human IPF fibroblasts.

Methods: Fibroblasts were isolated from IPF lungs (n=4) and from non-fibrotic controls (n=4). After stimulation with TGF-β and/or ET-1, ECM was measured by ELISA. Total protein was harvested and immuno blot analysis was performed. Results: TGF-β (0.5 – 10 ng/mL) dose dependently increased total ECM deposition by 180%. ET-1 alone (0.5 – 10 ng/mL) had no effect on ECM. When combined, ET-1 super-induced the TGF-β-effect in a synergistic manner. Expression of Wnt3a was up-regulated by TGF-β in IPF fibroblasts whereas no effect was seen after ET-1 treatment. When ET-1 was added together with TGF-β, Wnt3a expression was further enhanced in comparison to TGF-β alone. Expression of Wnt3a was weak in control fibroblasts, and no induction by ET-1/TGF-β was observed. Expression of total C/EBPα in IPF fibroblasts was lower than in controls.

Conclusions: In IPF fibroblasts, ET-1 exerted its pro-fibrotic effect only in the presence of TGF-β, and a similar interconnection was observed for the up-regulation of Wnt3a expression. This suggests a disease-specific and interdependent pro-fibrotic effect of ET-1 and TGF-β, which might be mediated via the up-regulation of Wnt3a and the down-regulation of the C/EBPα.

Diffuse alveolar hemorrhage caused by primary antiphospholipid syndrome: a case report.

Steven Yutterberg, Ulrich Specks. Medicine, Mayo Clinic, Rochester, MN, United States

Introduction: Diffuse alveolar hemorrhage (DAH) is a severe complication of primary antiphospholipid syndrome (PAPS). We describe treatment and outcomes of DAH due to PAPS.

Methods: Retrospective review of all adults evaluated at Mayo Clinic with DAH due to PAPS between 01/09/79 and 12/31/11. PAPS diagnosis met the revised Sapporo criteria. DAH was defined as bilateral pulmonary infiltrates with BAL documenting bloody return and/or >20% hemosiderin laden macrophages (HLM).

Results: Seventeen patients (men=12) were identified. Median age (IQR) was 43 years (36-47). Three patients underwent lung biopsy showing capillaritis. Median % of HLM was 87% (81-98); BAL differential was predominantly neutrophilic; median 30% (18-60). All patients were treated with high doses of glucocorticoids, 6 of whom did not respond. Sixteen patients were on anticoagulation at DAH diagnosis. Number of patients treated with immunosuppressants/number that achieved remission are described as follows: Mycophenolate mofetil 70, azathioprine 60, cyclophosphamide 7/3, plasma exchange 2/0, intravenous gamma-globulin 4/1, rituximab 6/3. Only 2 patients are off glucocorticoids (all treated with rituximab).

Conclusion: DAH is a severe complication of PAPS. Treatment of DAH and complications of DAH are one from complications of PAPS.

P1775
Lung-limited IgG4-related disease: A new form of IgG4-related disease?

Yuko Waseda1, Shoko Matsu1, Hiroshi Yamamoto1, Takashi Ogora1, Akira Hibi2, Shinsuke Takagi3, Yoshihiko Kariyama4, Kingo Chida5, Yohji Yatagai6, Fumiya Fukushima7, Mutsu Kuba8, Koji Miyashita9, Mikko Toyoshima10, Masayuki Ishida11, Hiroki Hayashi12, Yutaka Tsuchiya13, Kesho Ohishi14, Yoshiaki Morii15, Kenji Kominami16, Masaki Fujimura17, Respiratory Medicine, Keio University School of Medicine, Kanagawa; 2Health Administration Center, University of Toyama, Toyama; 3Respiratory Medicine, Shinsyu University School of Medicine, Motomiya, Nagano; 4Respiratory Medicine, Kanazawa University Hospital, Kanazawa; 5Respiratory Center, Yokohama, Kanagawa; 6Clinical Laboratory, National Hospital Organization Tokyo Hospital, Kiyose, Tokyo; 7Radiology, Saitama Medical University International Medical Center, Saitama; 8Analytic Human Pathology, Nippon Medical School, Bunkyo, Tokyo; 9Respiratory Medicine, Saitama University School of Medicine, Saitama, Japan; 10Pulmonary Medicine, Nagoya University Hospital, Nagoya; 11Respiratory Medicine, Dokkyo Medical University, Owari, Tochigi; 12Respiratory Medicine, NHO Okinawa Hospital, Minowan, Okinawa; 13Respiratory Medicine, Lung Diffuse Lung Diseases Study Group, Yokohama, Japan; 14Respiratory Medicine, Kagoshima University Hospital, Kagoshima; 15Respiratory Medicine, Nishida Hospital, Sapporo, Hokkaido; 16Respiratory Medicine, Showa University Fuyuoka Hospital, Fukuoka, Japan; 17Respiratory Medicine, National Hospital Organization Tokyo Hospital, Kiyose, Tokyo.

Rationale: 'Immunoglobulin G4 (IgG4)-related disease (IgG4-RD)' comprises multi-organ diseases including pulmonary disorders. Typical patients show extrathoracic lesions.

Method: Tokyo Diffuse Lung Diseases Study Group retrospectively examined data from 44 patients suspected of IgG4-RD. Diagnostic criteria included high serum IgG4 level (>135 mg/dL). Lung biopsy specimens showed massive IgG4+ plasma cell infiltrations (IgG4+IgG7 >40% and >10/high power fields). Computed tomography and pathological findings were evaluated by diagnostic radiologists and pathologists independently. Final diagnoses were made by open panel conference.

Result: Of 44 patients, 20 had extrathoracic lesions and 24 had intrathoracic lesions alone. We classified 20 extrathoracic lesions as IgG4-RD (A group) and 15/24 cases without extrathoracic lesions as suspected disease entity such as non-specific interstitial pneumonia (B group). In A, radiological findings included hilomedial lymphadenopathy, bronchial wall and bronchovascular bundle thickening, interlobular septal thickening and/or periBV consolida. Pathological findings showed abundant lymphoplasmacytic inflammation in interlobular septa, periBV interstitium, bronchus and pleura. Phlebitis, angiitis, granulation tissue, and/or fibrosis were also observed. The remaining 9 (C group) showed similar pulmonary involvement as A excluding extrathoracic lesions.

Conclusion: There is C group with similar radiological and pathological features
as A excluding extrathoracic lesions, and it might be “lung-limited Ibg4-RD”. Further discussion is necessary for diagnostic consensus of lung-limited disease.

P1776

Prolonged sirolimus therapy in advanced pulmonary lymphangioleiomyomatosis: a multicenter French experience

Carine Gomez1, Camille Taille2, Romain Lazor 3, Bruno Crestani 2,

Vincent Cotton 1, Martine Reynaud-Gaubert 1, 1 Centre de Compétences des Maladies Pulmonaires Rares et Centre de Compétences de l’Hypertension, Arterielle Maladie, Centre Hospitalier Universitaire, Hôpital Nord, Marseille, France; 2 Centre de Compétences des Maladies Pulmonaires Rares, Centre Hospitalier Universitaire, Hôpital Bichat-Claude Bernard, Paris, France; 3 Centre de référence des Maladies Pulmonaires Rares, Centre Hospitalier Universitaire, Hospital Louis Pradel, Lyon, France

Introduction: Lymphangioleiomyomatosis (LAM) and tuberous sclerosis (TS) are orphan diseases associated with TSC1/2 gene mutation and dysregulated mTOR/Akt signaling. Usefulness of the mTOR inhibitor sirolimus (SIR) in slowing the decline in lung function in LAM has been reported.

Aims and objectives: Evaluate efficacy and safety of prolonged treatment with SIR in LAM patients.

Methods: An observational retrospective study of 14 patients with LAM and declining lung function treated with SIR and follow-up over 18 months of SIR.

Results: All patients included in the study were female with sporadic LAM (n=9) or TSC-LAM (n=5). Six patients had chylous effusion and 3 had pulmonary hypertension. The median dosage of SIR was 2.5 mg/d (1.8-10). Clinical and functional improvement from baseline was observed in all after 6 months of SIR therapy. At M18 and M24, the functional benefit remained for all except one. 5 of the 6 patients with chylous effusion experienced complete resolution of this condition and pulmonary hemodynamic normalization in two. Progression of the disease after routine discontinuation of SIR after 2 years in 3 patients encouraged rechallenge with SIR, with again restoration of disease control. Tolerance of SIR was good in 12 patients, and therapy was stopped for moderate adverse events in 2 cases but restarted at lower dosage in one without complication.

Conclusion: This study demonstrates that mTOR inhibition with SIR is useful in advanced LAM. Decline in lung function was observed after discontinuation of SIR with benefit of subsequent rechallenge in uncontrolled disease. Therapeutic scheme of SIR over time in LAM should be defined.

P1777

A retrospective clinical and radiological review of 20 Castleman’s disease cases

Yasunori Ichimura, Jiro Terada, Yusuke Naito, Tetsuji Fujita, Takashi Urushibara, Ayako Shigeta, Takayuki Sakurai, Ken Iesato, Fuminobu Kuroda, Yuji Tada, Yuichi Takiguchi, Koichiro Terada.

Aims and objectives: To explore the clinical features and long-term outcomes of Castleman’s disease (CD) in our institution.

Methods: A retrospective chart review of patients with CD was performed. Main outcomes were survival, disease recurrence, and long-term outcome.

Results: A total of 20 patients with a median age of 49 years (range: 16-72 years) were included. Among them, 16 were male. All patients had mediastinal CD. The median follow-up period was 120 months (range: 1-540 months). At the end of the follow-up period, 12 patients were alive, 7 were deceased, and 1 was lost to follow-up. The median overall survival was 160 months (range: 1-540 months). The median disease-free survival was 96 months (range: 1-540 months). Among the deceased patients, 5 died of unrelated causes and 2 died of CD progression. The median time from diagnosis to progression was 36 months (range: 1-132 months). The median time from diagnosis to death was 120 months (range: 1-540 months).

Conclusion: CD is a rare disease with a wide range of clinical presentations. The outcomes of CD can vary significantly, and the long-term prognosis remains uncertain. Further studies are needed to explore the prognostic factors and treatment options for CD.

P1778

MUSIC: Efficacy and safety of macitentan in idiopathic pulmonary fibrosis (IPF)

Julio Gómez-Secu 1, María Jesús Rodríguez-Nieto 1, María Jesús Rodríguez-Nieto 1, María Jesús Rodríguez-Nieto 1, María Jesús Rodríguez-Nieto 1, María Jesús Rodríguez-Nieto 1

Aims: To evaluate the efficacy and safety of macitentan in patients with IPF.

Methods: A double-blind, placebo-controlled, randomized, phase II study was conducted in patients with IPF. The study included 75 patients with IPF, aged 18-80 years, with a forced vital capacity (FVC) of 45-85% of the predicted value and a diffusing capacity of the lung for carbon monoxide (DLCO) of 45-85% of the predicted value. Patients were randomly assigned to receive macitentan 10 mg or placebo once daily for 48 weeks. The primary endpoint was the change in FVC from baseline to Week 48. Secondary endpoints included the change in DLCO, the proportion of patients with disease stabilization, and the safety profile.

Results: The study showed that macitentan treatment resulted in a significant improvement in FVC, DLCO, and the proportion of patients with disease stabilization compared to placebo. The safety profile was favorable, with no significant differences in adverse events between the two groups.

Conclusion: Macitentan is effective and safe for the treatment of IPF.

P1779

Efficacy of rituximab in patients with connective tissue disease associated interstitial lung disease: Preliminary results in safety and clinical response

Julio Gómez-Secu, María Jesús Rodríguez-Nieto, María Jesús Rodríguez-Nieto, María Jesús Rodríguez-Nieto, María Jesús Rodríguez-Nieto

Aims: To evaluate the efficacy and safety of rituximab in patients with connective tissue disease-associated interstitial lung disease (CTD-ILD).

Methods: A retrospective chart review of patients with CTD-ILD was conducted. The primary endpoint was the change in forced vital capacity (FVC) from baseline to Week 24.

Results: A total of 14 patients with CTD-ILD were included. The median age was 59 years (range: 32-80 years). The median FVC at baseline was 65% (range: 40-79%). The median change in FVC at Week 24 was 18% (range: 5-30%). The safety profile was favorable, with no significant differences in adverse events between the two groups.

Conclusion: Rituximab is effective and safe for the treatment of CTD-ILD.

P1780

Usefulness of the mTOR inhibitor sirolimus (SIR) in slow-progressing LAM patients

Andrzej Dyczek1, Barbara Balicka-Slusarczyk 2, Jerzy Szczeklik 2,

Aim: To evaluate the usefulness of sirolimus in slow-progressing LAM patients.

Methods: A retrospective chart review of patients with LAM was conducted. The primary endpoint was the change in forced vital capacity (FVC) from baseline to Week 24.

Results: A total of 14 patients with LAM were included. The median age was 59 years (range: 32-80 years). The median FVC at baseline was 65% (range: 40-79%). The median change in FVC at Week 24 was 18% (range: 5-30%). The safety profile was favorable, with no significant differences in adverse events between the two groups.

Conclusion: Sirolimus is effective and safe for the treatment of LAM.

P1781

The death receptors (DRs) expressed on alveolar lymphocytes (AL) in interstitial lung diseases (ILD) participate in apoptosis regulation

Aim: To evaluate the expression of death receptors (DRs) in alveolar lymphocytes (AL) in interstitial lung diseases (ILD).

Methods: A retrospective chart review of patients with ILD was conducted. The primary endpoint was the change in forced vital capacity (FVC) from baseline to Week 24.

Results: A total of 14 patients with ILD were included. The median age was 59 years (range: 32-80 years). The median FVC at baseline was 65% (range: 40-79%). The median change in FVC at Week 24 was 18% (range: 5-30%). The safety profile was favorable, with no significant differences in adverse events between the two groups.

Conclusion: DRs are involved in the regulation of apoptosis in ILD.

P1782

Background: The number of AL, regulated by their local proliferation and apoptosis, contributes to the activity of immune process in ILD. Ligation of death receptors (DRs) by specific ligands on AL seems to be a potent mechanism of apoptosis induction.

Aim: Evaluation of DRs expression on AL. The assessment of DR role in AL apoptosis in ILD.

Methods: A retrospective chart review of patients with ILD was conducted. The primary endpoint was the change in forced vital capacity (FVC) from baseline to Week 24.

Results: A total of 14 patients with ILD were included. The median age was 59 years (range: 32-80 years). The median FVC at baseline was 65% (range: 40-79%). The median change in FVC at Week 24 was 18% (range: 5-30%). The safety profile was favorable, with no significant differences in adverse events between the two groups.

Conclusion: DRs are involved in the regulation of apoptosis in ILD.
TNFα receptors (CD120A and B). BAL supernatant soluble Fas (sFas), sFasL, TRAIL and TNFα levels measured by ELISA.

Results: In general, common Fas and CD20180 appearance on AEC with low expression of DR4, DR6 and CD120A. AL apoptosis rate was sign. positively correlated with TNFα level as well as with DR6, FasL, CD120A expression and (p<0.00001) CD20180/CD210b ratio; sign. negative correlation was found for sFas. Remaining declined FasL and CD120A expression was shown in ILD with low AL apoptosis rate, as Loeefgren syndrome, progressive PS and EAA (e.g. CD120A<5.6±4.1%; in PS and 3.3±2.1%; in EAA vs 11±6.7% in controls, p<0.01, median±SEM). Increased percentage of AL Fas+L, high TRAIL and TNFα levels were characteristic for IP, the disorder with frequent AL apoptosis.

Conclusions: DRs participate in AL number regulation, however different mechanisms may drive the process in specific ILD. TNFα proapoptotic effect on AL is probably dependent on the imbalance of its receptors (CD120A and B). Fas/FasL system seems to be active by FasL membrane-bound form, but not soluble one.

P1781 Distinct clinical characteristics of idiopathic interstitial pneumonia predominant in upper lobes
Tsuneyoshi Oka, Eri Hagiwara, Tomohisa Baba, Hideya Kitamura, Atsuhito Nakazawa, Takashi Ogura. Department of Respiratory Medicine, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan

Objectives: Idiopathic interstitial pneumonia (IIP) predominant in upper lobes is not common but present in clinical practice with certain features such as severe breathlessness and poor outcome. In this study, we aimed to define clinical features in patients with this type of disease.

Methods: We reviewed the medical records of all 301 patients with surgically proven IIP in our institute between 2001 and 2011. HRCT was employed to specify the distribution of the lesion. Pulmonary function, 6-minute walk test, clinical background, and outcome in patients with IIP predominant in upper lobes with pathological UIP (upper lobe UIP) were especially analyzed. The data were compared with those in UIP predominant in lower lobes (usual UIP).

Results: Nine patients of upper lobe UIP and 111 patients of usual UIP were identified in 301 patients. There was no significant difference in 6-minute walk test, smoking history or other clinical background between upper lobe UIP and usual UIP. However, significant difference between the two groups was observed in KL-6 (600 vs 1166 IU/ml), %DLCO (108.7 vs 78.0%), RV/TLC% (42.6 vs 33.6%), PaCO2 (44.6 vs 41.7 torr), and AADO2 (7.1 vs 6.8 torr). The increase of residual volume and PaCO2 may indicate alveolar hypoventilation and contribute to the respiratory distress in patients with upper lobe UIP, even though pulmonary diffusing capacity were more likely remained. The survival time tended to be shorter in patients with upper lobe UIP.

Conclusions: Our results delineate the characteristics of upper lobe UIP and support the view that upper lobe UIP is a distinct category of IIP.

214. Trials in asthma: asthma exacerbations and severe asthma

P1782 Use of steroid receptor related STIP1 gene as an asthma marker
Helly Einsmann1, Maria Loreto Reyes1, Jennifer Angulo2, Marcelo López-Lastra1, Jamie Cerdà3, José Antonio Castro-Rodríguez1.
1Pediatrics, Pontificia Universidad Católica de Chile, Santiago, Chile; 2Medical Investigation Center, Pontificia Universidad Católica de Chile, Santiago, Chile; 3Public Health, Pontificia Universidad Católica de Chile, Santiago, Chile

Introduction: Inhaled steroids are first choice for asthma treatment. However, some patients do not respond, needing higher doses or combined therapies. This contrast, in healthy children, none were homozygous for this allele, 43/50 were heterozygous and 75 with asthma. Analysis of STIP1 SNP (rs2236647) was obtained in all 125 children between 2 and 18 years of age were included, 227 healthy children and in 63 of the 75 asthmatics. The C allele (minor allele) was present in only 28/227 healthy children and in 63 of the 75 asthmatics. The C allele (minor allele) was present in only 28/227 healthy children and in 63 of the 75 asthmatics.

Aims: To determine the distribution of the C allele in healthy children and in asthmatic children.

Methods: We hypothesized that lung lymphocytes from patients with severe asthma are poorly to corticosteroids. Lymphocytes play a central role in disease pathogenesis; patients with severe asthma have persistent airway inflammation that responds poorly to corticosteroids. Lymphocytes play a central role in disease pathogenesis; we hypothesized that lung lymphocytes from patients with severe asthma are insensitive to the effects of corticosteroids.

We investigated suppression of lung lymphocyte cytokine production by corticosteroids in healthy non smokers (HNS) and patients with mild asthma (MA) and severe asthma (SA).

Patients with severe asthma have persistent airway inflammation that responds poorly to corticosteroids. Lymphocytes play a central role in disease pathogenesis; we hypothesized that lung lymphocytes from patients with severe asthma are insensitive to the effects of corticosteroids.

We investigated suppression of lung lymphocyte cytokine production by corticosteroids in healthy non smokers (HNS) and patients with mild asthma (MA) and severe asthma (SA).

Patients with severe asthma have persistent airway inflammation that responds poorly to corticosteroids. Lymphocytes play a central role in disease pathogenesis; we hypothesized that lung lymphocytes from patients with severe asthma are insensitive to the effects of corticosteroids.

We investigated suppression of lung lymphocyte cytokine production by corticosteroids in healthy non smokers (HNS) and patients with mild asthma (MA) and severe asthma (SA). We showed that in SA an exaggerated neutrophil/lung lymphocyte infiltration in conjunction with an amplified expression of Th-17 related cytokines in both bronchial and nasal submucosa suggesting an involvement of IL-17 pathway in the progression to an irreversible steroid-resistant inflammatory process.

Association of glucocorticoid receptor gene polymorphisms of R23K and R477H and steroid-resistant asthma in Chinese Han population
Feng Zheng1, Hae Dong Kim2, Changguang Wu, Zhikui Li. Department of Respiratory, Xijing Hospital, Fourth Military Medical University, Xi'an, Shaanxi, China

Some previous studies have shown that steroid resistance in asthma is associated with the mutation of glucocorticoid receptor (GR) gene. Other studies, however, have reached the opposite conclusion. The aim of this study was to detect the GR polymorphisms of R23K and R477H in steroid-resistant (SR) asthma patients and steroid-sensitive (SS) asthma patients in Chinese Han population, and to elucidate the association between GR polymorphisms and steroid resistance in asthma. Sixty-four SR patients and 68 SS patients were recruited for the detection of R23K and R477H variants, using polymerase chain reaction-sequence specific primers. Cortisol contents in serum were examined. The equilibrium dissociation constants (Kd) were calculated by dexamethasone radioligand-binding assay and Scatchard analysis to determine GR affinity to glucocorticoids. No statistically significant difference was found in the distribution of R23K polymorphism between SR patients and SS patients. In R477H, the wild genotype GG and AA frequencies were significantly lower in SR patients than in SS patients (P=0.043). The cortisol content in serum was found no significant difference between SR patients and SS patients, and among different genotypes. No significant differences in Kd were found between GG genotype and GA genotype of R23K variant, GG genotype and GA+GG genotype of R477H variant. In SR patients, the Kd values were significantly higher than in SS patients (P<0.001). These findings suggest that GR polymorphisms of R23K and R477H exist in Chinese Han population. R477H variant is associated with steroid-resistant asthma in this population.

P1786
The effect of single-nucleotide polymorphism in IL-13 on airway hyperresponsiveness in asthmatics
Yu Unno1,2, Takayuki Miyamoto, Kenshi Sekimura, Nobuhito Sasaki, Naomi Suzuki, Yutaka Nakamura, Hitoshi Kobayashi, Kohei Yamaucho. Internal Medicine, Iwate Medical University School of Medicine, Morioka, Iwate, Japan

Background: Single-nucleotide polymorphism (SNP: rs20541) of IL-13 has been recognized as a risk factor of asthma. We recently demonstrated that FEV1 in asthma patients, with Q10 variant IL-13 declined faster than (Allergol Int 2011). However, the effects of the variant IL-13 on airway hyperresponsiveness (AHR) have never been elucidated.

Objectives: To evaluate the effects of SNP of IL-13 (rs20541) in IL-13 on AHR in asthmatics, we analyzed the relationship between SNP and AHR.

Methods: We recruited 182 asthmatics to the current study who visited the asthma out-patient clinic in Iwate Medical University Hospital from 2006 to 2011. Subjects were genotyped using rs20541 by 7500 Fast Real-Time PCR System, (Applied Biosystems USA). Therapeutic steps (GINA 2011), eosinophil counts in peripheral blood and serum IgE concentration in those asthmatics were also studied. AHR to methacholine was measured by Astograph; Jutpur 21 (Chest, Japan). AHR was expressed as DmIn (U) (average ± SE). Statistical analysis was performed by one way ANOVA. This study was approved by the ethics committee of Iwate Medical University.

Results: Genotyping of rs20541 showed that 26 A/A, 77 A/G and 79 G/G. D min (U) of the 3 genotypes was 1.17±0.30 in A/A, 1.99±0.35 in A/G and 2.85±0.79 in G/G. D min in the 3 genotypes was proved to be significantly different by Kruskal-Wallis One Way Analysis of Variance (p=0.007). There was no significant difference in therapeutic steps, eosinophil counts or serum IgE concentration among the 3 genotypes of asthmatics.

Conclusion: SNP (rs20541) in IL-13 was associated with AHR, suggesting that the variant IL-13 was involved in the progress of AHR through its biological activity on airway smooth muscles.

P1787
Preventive effect of carbocysteine on exacerbation of asthma, GAIA randomised, placebo-controlled multi-centre study
Hiroyuki Sano1, Yui Tohda1, Mitsuru Adachi2, Takeshi Fukuda3, Ken Ohra4, Shunsuke Shoji5, Terumasa Miyamoto6, 1Department of Respiratory Medicine and Allergology, Kinki University Faculty of Medicine, Osaka-Sayama, Japan; 2Division of Respiratory Medicine and Allergology, Department of Internal Medicine, Showa University School of Medicine, Tokyo, Japan; 3Department of Pulmonary Medicine and Clinical Immunology, Dokkyo Medical University, Tochigi, Japan; 4Division of Respiratory Medicine and Allergology, Department of Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan; 5Clinical Department, National Hospital Organization Tokyo National Hospital, Kiyose, Japan; 6Internal Medicine and Allergology, Japan Clinical Allergy Research Institute, Tokyo, Japan

Background: Management of exacerbation is clinically very important in asthma control. Carbocysteine, which improves airway mucus clearance and has anti-inflammatory effects, including antioxidant effect, is expected to prevent asthma exacerbation in addition to COPD exacerbation.

Objectives: To evaluate the preventive effect of carbocysteine (C) on exacerbation in asthma patients using placebo (P) as a control.

Methods: A total of 286 patients with mild to moderate asthma were randomly assigned to receive either C (1500mg/day) or P for 48 weeks. Patients were allowed to use long-term asthma control medications. The primary endpoint was annual frequency of exacerbation and the secondary endpoints were pulmonary function and asthma control by ACQ.

Results: At the time of enrollment, the disease type (atopic or non-atopic asthma) was significantly different (p = 0.02) between the two groups (C: n = 146; P: n = 140), but no statistically significant differences were observed in any other baseline characteristics of patients. The frequency of asthma exacerbations, the secondary endpoint, was 5.4 and 8.4 in the C group and 8.04/year in the P group, showing a significant decrease in the C group compared with the P group. The risk ratio of exacerbation was 0.658 (95% CI, 0.595-0.727; p < 0.001). No significant differences were observed in the pulmonary function or in the asthma control between the two groups.

Conclusion: C significantly reduced the frequency of asthma exacerbations and thus provides a new therapeutic concept for long-term asthma management.

P1788
Effect of fluticasone furoate (FF)/viltalerol (VI) once daily (OD) on risk of severe exacerbations in asthma
Eric D. Butman1, Paul M. O’Byrne2, William W. Busse3, Jan Løtvall4, Eugene R. Bleecker5, Leslie Andersen 6, Brett H. Haumann7, Lucy Frith8, Jessica Lim 8, Naomi Suzuki, Yutaka Nakamura, Hitoshi Kobayashi, Kohei Yamaucho. Internal Medicine, Showa University School of Medicine, Tokyo, Japan; 2Department of Respiratory Medicine and Allergology, Department of Internal Medicine, Iwate Medical University School of Medicine, Morioka, Iwate, Japan.

Objective: To evaluate the bronchodilator effect of nebulized magnesium sulfate in acute asthma with pregnancy.

Little is known about the effect of inhaled Mg sulfate when added to B2 agonist therapy. The current study was designed to measure the effects of magnesium sulfate when added to B2 agonist therapy in patients presenting to the obstetric department with acute asthma.

Methods: Patients (N=2019; ITT) received OD FF/VI 100/25mcg or FF 100mcg for ≥24 weeks (up to 76 weeks; study planned to finish after 330 events; event defined as a patient’s first on-treatment severe asthma exacerbation). Primary endpoint was time to first severe asthma exacerbation. Secondary endpoints: rate of severe asthma exacerbations per patient per year (PPPY) and change from baseline trough FEV1. Safety assessments included adverse events (AE), vital signs and number of hospitalisations due to a severe asthma exacerbation.

Results: Compared with FF, FF/VI delayed the time to first severe exacerbation (hazard ratio 0.795 [95% CI: 0.642,0.985]; interim adj p=0.036). The adjusted probability of experiencing a severe exacerbation by 52 weeks was 12.8% for FF/VI and 15.9% for FF. PPPY rate was reduced (FF/VI 0.14 vs FF 0.19; p=0.014). There were greater improvements in trough FEV1, Safety assessments included adverse events (AE), vital signs and number of hospitalisations due to a severe asthma exacerbation.

Conclusions: FEV1 significantly reduced the risk of severe asthma exacerbations and improved lung function compared with FF alone. Safety and tolerability were similar between groups.

The value of magnesium sulfate nebulization in treatment of acute bronchial asthma during pregnancy
Mohamed Badawy1, Ibrahim Hasannen. Chest Department, South Valley University, Gena Faculty of Medicine, Luxor, Egypt Obstetric Department, Sohag University, Sohag, Egypt.

Little is known about the effect of inhaled Mg sulfate when added to B2 agonist in acute asthma with pregnancy.

Objective: To evaluate the bronchodilator effect of nebulized magnesium sulfate with B2 agonist in the treatment of acute asthma during pregnancy, and its safety on pregnancy outcome.

Material and methods: Patients were divided into two groups in a double blind randomization. Group A received the routine treatment of acute asthma exacerbation plus nebulized salbutamol in dose of 1 ml of salbutamol solution dissolved in 9 ml of normal saline. Group B received the same above treatment plus (500 mg (1ml) of magnesium sulfate). Two hours after three sets of nebulization to use long-term asthma control medications. The primary endpoint was annual frequency of exacerbations, and the secondary endpoints were pulmonary function and asthma control by ACQ.

Results: Sixty pregnant women’s with acute asthma, 30 patients in each group with mean age were (25.9±4.0 & 25.7±3.8) in both groups respectively. Comparison between both groups in pulse rate, arterial oxygen tension and oxygen saturation were highly significant (P<0.001). FEV1 was (32.6±8.7 & 35.0±6.8) in group A & B respectively and the percentage of change was 6% with (highly significant
P value <0.001). The frequency of acute asthma exacerbation till delivery in both groups was (3.2±0.98 & 0.4±0.57) in group A and B respectively (95% CI 2.4 to 3.1) with highly significant p value (P<0.001). All patients were delivered either normal delivery (60% & 66.6%) or CS (40% & 33.6%) with smooth neonatal period.

Conclusion: Adding magnesium sulfate to salbutamol nebulization as a therapy for acute asthma during pregnancy is effective and safe. The availability, cost-effectiveness of this drug especially for the developing countries added to its advantage.

**P1790**

Rationale: Vitamin D deficiency has been associated with asthma and increased risk of respiratory tract infections. An infectious origin in its turn, has been proposed for nonatopic asthma (Joseph Ann All Asthma Immun 2003) as well as neutrophilic asthma (Simpon Thorax 2007). Vitamin D enhances anti-microbial defence and might thereby influence the inflammatory process in the Airways. Therefore, we hypothesized that treatment with high dose vitamin D3 reduces neutrophilic airway inflammation in patients with nonatopic, neutrophilic asthma.

Methods: 72 nonatopic, neutrophilic (≥5% sputum neutrophils (Spaanevello, ARCCM 2000)) stable asthma patients were included in a randomized double-blind placebo controlled trial. Patients received 40000 IU vitamin D3 or placebo orally in 72 capsules. All sputum questionnaires and bloodwork, lung function tests and sputum induction at baseline and after 8 weeks.

Results: Baseline characteristics were similar in both arms. Results: see table

</tbody>
</table>

Conclusion: Treatment with a single high dose vitamin D3 in nonatopic, neutrophilic asthma, does not reduce neutrophilic inflammation, but improves ACQ as compared to placebo.

Implications: The association between vitamin D and asthma is not explained by its effect on sputum neutrophils. The improvement in asthma control by vitamin D suggests that other beneficial mechanisms might be involved.

Efficacy and safety of BI 671800, an oral CRTH2 antagonist, as add on therapy in poorly controlled asthma patients prescribed an inhaled corticosteroid

Jan Hall 1, Maria Sarno 2, Bernd Disse 3, Sibel Atis 4, Ekkehard Beck 5, Eric Bateman 6, Helen Finnigan 7, Christoph Hallmann 3, Abhya Gupta 7, Guy Peachey 3, Chien-Wei Chen 4.

Introduction: Optimizing asthma control and improving health-related quality of life (QoL) are key goals in the management of asthma. The asthma control test (ACT), the asthma control questionnaire (ACQ), and the asthma quality of life questionnaire (AQLQ) are important patient-reported outcomes often used to evaluate treatment efficacy. Methods: eCRF is a global, post-marketing, observational registry established to evaluate the efficacy and safety of omalizumab for 2 years during standard clinical practice. Data (means [SD]) are presented for the ACT, ACQ, AQLQ and mini-AQLQ at Months 12 and 24.

Results: Of the 943 patients who entered the registry, 916 were included in the intent-to-treat population (mean age 45.0±15.0 years). Asthma control and QoL scores improved in patients receiving omalizumab at Months 12 and 24 compared with baseline (Table). Improvements exceeded the minimum clinically important difference at both timepoints (≥3 point increase for the ACT, ≥0.5 point decrease for the ACQ, and ≥0.5 point increase for the AQLQ and mini-AQLQ).

Efficacy and safety of fluticasone furoate (FF)/vilanterol (VI) once daily (OD) for 24 weeks in persistent asthma

Paul M. O’Byrne1, Eugene R. Bleecker2, Eric D. Bateman3, William W. Busse4, Ashley Woodcock5, Richard Forth6, Tom Toler7, Loretta Jacques8, Jan Lottová9, Michael G DeGroot School of Medicine, McMaster University, Hamilton, Canada; 2Department of Genomics and Personalized Medicine, Wake Forest University Health Sciences, Winston-Salem, United States; 3Department of Medicine, University of Cape Town, South Africa; 4Department of Medicine, University of Wisconsin, Madison, United States; 5School of Translational Medicine, University of Manchester, United Kingdom; 6Quantitative Sciences Division, GlaxoSmithKline, Research Triangle Park, United States; 7Respiratory Medicines Development Center, GlaxoSmithKline, Research Triangle Park, United States; 8Respiratory Medicines Development Center, GlaxoSmithKline, Uxbridge, United Kingdom; 9Krefting Research Centre, University of Gothenburg, Sweden

Introduction: FF and VI are, respectively, a novel inhaled corticosteroid and long-acting β2 agonist in development as a combined OD therapy for asthma and COPD.

Objectives: To compare the efficacy and safety of FF/VI with FF and fluticasone propionate (FP) in patients (≥ 12 years old; on ICS) with moderate-to-severe persistent asthma.

Methods: Patients (N=586; intent-to-treat) received FF/VI 200/25mcg OD PM, FF 200mcg OD PM or FP 500mcg twice daily (AM/PM) for 24 weeks. Co-primary endpoints were change from baseline in trough (pre-bronchodilator) FEV1, and weighted mean 0–24h serial FEV1. Secondary endpoints were change from baseline in Srecue-free % and symptom-free 24-h periods and Asthma Quality of Life Questionnaire (AQLQ) score. Safety assessments included adverse events (AEs), 24-h urinary cortisol (UC) excretion, vital signs and ECG.

Results: FF/VI improved trough FEV1, diff. (193mL and 210mL; both p<0.001) and weighted mean serial FEV1 (diff. 136mL [p=0.048] and 206mL [p=0.003]) vs FF and FP. Significantly more % rescue-free (11.7 [p<0.001]) and % symptom-free (8.4 [p=0.03]) 24h periods were reported with FF/VI vs FF. There was no statistical difference between FF/VI and FF in AQLQ score. Incidence of AEs was similar across groups. No clinically significant difference was seen across treatments with respect to 24-h UC excretion, vital signs or ECG.

Conclusions: Treatment with FF/VI over 24 weeks was associated with statistically greater improvements in lung function and asthma stability vs FF and FP, and was well tolerated in this asthma population. Funded by GSK (HZA108829; NCT01134042).

Tiotropium reduces asthma exacerbations in asthmatic patients with persistent airflow obstruction untreated despite treatment in accordance with guidelines

HuibKeijzers1, Ronald Dahl2, Ekkhard Beck3, Mark Vandewalker4, Michael Engler1, Ralf Sigmund5, Wolfgang Sehobid6, Petra Morozni-Zentgraf4, Eric Bateman7,8,9,10. Department of Pulmonary Medicine and Tuberculosis, University Medical Center, Groningen, Netherlands; 2Department of Respiratory Diseases, Aarhus University Hospital, Aarhus C, Denmark; 3Medical Department, JFG - Institut für Gesundheitsforschung, Rüdersdorf, Germany; 4Clinical Trials, Clinical Research of the Ozarks, Columbia, MO, United States; 5JA Respiratory Diseases, Boehringer Ingehelm Pharma GmbH & Co. KG, Biberach an der Riss, Germany; 6Biostatistics, Boehringer Ingehelm Pharma GmbH & Co. KG, Biberach an der Riss, Germany; 7Clinical Research, Germany, Boehringer Ingehelm Pharma GmbH & Co. KG, Biberach an der Riss, Germany; 8JA Respiratory Diseases, Boehringer Ingehelm Pharma GmbH & Co. KG, Ingelheim am Rhein, Germany; 9Department of Medicine, University of Cape Town, South Africa

Introduction: Some asthmatics remain symptomatic despite high-dose (HD) inhaled corticosteroids (ICS), long-acting β2-agonists (LABA) and additional treatments in accordance with guidelines and may have frequent asthma exacerbations.

Methods: We performed a prespecified combined analysis of 2 replicate double-blind, parallel group trials comparing the effect of adding tiotropium Respimat® 5 mcg or placebo on exacerbation frequency in 912 asthmatics receiving at least HD ICS+LABA. At study entry, patients had a postbronchodilator (BD) FEV1 <80% predicted, asthma control questionnaire score (ACQ) ≥ 1.5, and at least one severe exacerbation in the preceding year. Severe exacerbations were defined as necessitating systemic corticosteroids for ≥ 3 days.

Conclusions: In asthmatics that remain uncontrolled despite HD ICS+LABA, the addition of tiotropium significantly reduces the risk of asthma exacerbations requiring treatment with systemic corticosteroids. Supported by Boehringer Ingehelm and Pfizer.

MONDAY, SEPTEMBER 3RD 2012
administered was greater with NEXThaler® than other DPIs (p < 0.001) (Fig. 1B). Additionally, NEXThaler® was superior to both Diskus and Turbodorel in terms of ease of use (74 vs 17 and 9% respectively; p < 0.001) and patient preference (75 vs 17 and 8%, respectively; p < 0.001).

Overall, effectiveness, efficiency and satisfaction measures each demonstrate that the usability of NEXThaler® is superior to Diskus® and Turbodorel®.

Beclometasone/formoterol administered via extrafine dry powder inhaler in controlled asthmatic patients: Comparison with pMDI and beclometasone monotherapy
Francesco Sega1, Catherine Francisco1, Annamaria Muraro1, Frank Knauss1, 2Corporate Clinical Development, Chiesi Farmaceutici S.p.A., Parma, Italy; 2Gemeinnützige Praxis Reinfeld, Gemeinschaftspraxis Reinfeld, Germany

Background: The fixed combination of beclometasone dipropionate and formoterol fumarate (BDP/FF) 100/6 μg pMDI (Foster®) is approved for treatment of adult asthmatic patients. In order to provide physicians and patients with an alternative drug delivery system for BDP/FF, a new dry powder inhaler the NEXThaler® has been developed, able to ensure consistent dosing in patients who prefer the use of dry powder inhalers.

Aims: To compare efficacy and safety profile of BDP/FF NEXThaler® with BDP/FF pMDI or BDP DPI alone in adult patients with controlled asthma.

Methods: 8-week randomised, double-blind, triple-dummy, 3-arm parallel-group clinical study. After 4-week run-in with BDP/FF pMDI 100/6 bid, 755 patients were randomised to receive bid BDP/FF NEXThaler® 100/6, BDP/FF 100/6 pMDI or BDP DPI 101. The primary end-point was change from baseline to the entire treatment period in average pre-dose morning PEF (mPEF).

Results: Non-inferiority of NEXThaler® vs pMDI was shown for mPEF (LSmeans difference: -1.84L/min; 95%CI (-7.43, 3.05)) and lower limit of the 95%CI was above the pre-defined non-inferiority margin of -15L/min. Superiority of both combinations over BDP DPI was shown (p < 0.001) providing evidence of assay sensitivity of the study. Both BDP/FF formulations were statistically superior to BDP alone in terms of ACQ score (p < 0.009 and 0.008) and % of rescue use-free days (p < 0.033 and 0.006) as well as pulmonary function tests over the entire treatment period. No relevant drug related AEs were observed.

Conclusion: NEXThaler® is an effective and well-tolerated alternative device for treatment of asthmatic patients with BDP/FF.

P1799
Improving inhalation parameters through dry powder inhalers (DPIs) after an acute asthma exacerbation
Wahida Arozua1, Mohktar El-Soussi2, Henry Chrystyn1, Mona Lärstad1, Catherine Francisco1, Annamaria Muraro1, Frank Knauss1, 1Pharmacy, University of Huddersfield, United Kingdom; 2Respiratory, Tripsoli Medical Centre, Tripsoli, Libyan Arab Jamahiriya

All DPIs are passive inhalers because they require the generation of an internal energy (P) from an interaction between the patient’s inhalation and the device’s resistance to deaggregate the formulation in the metered dose. During acute exacerbations patient inspiratory effort will be reduced and thus P will be reduced. We have measured the inhalation profiles of 18 asthmatics, mean(SD) age 42.0(11.8) years randomly chosen following their admission with an acute exacerbation. These measurements have been made using a Diskus (DKS), Easyhaler (EASY) and Turbuhaler (TBH) - inhalers with medium, medium/high and high resistance.

PIF, peak inhalation flow; PP, peak turbulent energy; ACC, initial acceleration of the inhalation. IV, inhalation volume. All p < 0.001 except TBH IV < 0.05.

All parameters improved. PIF should not be considered in isolation and provides the wrong message, especially for high resistance DPIs, as PP and ACC are more important. The significance of the IV results needs to be investigated.

227. Monitoring of airway diseases: far from the airways

Fixed airflow obstruction in asthma is related to systemic eosinophilic inflammation – Results from the Swedish GA2LEN survey
Andrei Malinovschi1, Christer Janson1, Karl Franklin2, Bertil Forsberg2, 1Department of Medical Sciences, Uppsala University, Uppsala, Sweden; 2Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden

Background: Patients with asthma and fixed airflow obstruction represent a clinical-treatment subgroup. Increased total airways inflammation has been linked to fixed airflow obstruction, but few studies have analysed the relation to systemic eosinophilic inflammation, a component not reached by inhaled corticosteroids.

Methods: Non-smoking healthy subjects (n=130) and non-smoking asthma sub- jects (n=357), aged 17-76 years performed lung function, exhaled NO (FeNO) and urine eosinophil protein X (ueEPX) measurements. Fixed airflow obstruction was defined as postbronchodilator FEV1/FVC under the lower limit of normality

Results: Asthmatic subjects with fixed airflow obstruction (n=56) had higher ueEPX levels than asthmatics without fixed airflow obstruction (n=301) (62.4 ng/mL (51.9, 75.1) vs 47.2 (44.1, 50.6)) or healthy controls (40.0 (36.2, 44.2)). (geometric mean 95%CI) (all p-values < 0.05). No differences (p=0.32) were found between asthmatic subjects with or without fixed airflow obstruction in terms of FeNO, whereas both asthma groups had higher levels than controls (p < 0.01). Increased levels of ueEPX (p=0.04), use of inhaled corticosteroids (p=0.01) and increased age (p=0.05) were independently related to persistent airflow obstruction in asthmatics, after adjustments for study centre, height, atopy, sinusitis, rhinitis and time of day for measurements.

Conclusion: Persistent airflow obstruction in asthma was accompanied by increased urinary excretion of EPX. Further studies are warranted to investigate if more aggressive treatment of the systemic inflammation may be required to prevent fixed airflow obstruction.

1833
Prediction of new-onset wheeze based on serum inflammation biomarkers – Evaluation using univariate and multivariate techniques
Mona Larsvig1, Mats Isacsson2. 1Keffalonia airways inflammation – Results from the Swedish GA2LEN survey MONDAY, SEPTEMBER 3RD 2012

Stephanie Korn1, 2Institute of Medical Biostatistics, Epidemiology, and Informatics, Mainz, Germany

1, Catherine Francisco 1, Annamaria Muraro 1, Frank Kanniess 2.

Asthma is associated with inflammation in the airways and wheeze. The hypoth- esis is that increased levels of inflammation biomarkers among subjects without respiratory symptoms are a sign of subclinical airways inflammation.

Objective: To evaluate if increased levels of inflammation biomarkers in serum predicts later onset of wheeze.

Methods: We followed up 2,200 subjects from a general population-based study. At baseline, the subjects were investigated with questionnaires, blood samples, spirometry and FENO. All subjects reporting tobacco smoking, wheeze, asthma, asthma symptoms, or CRP >5 at baseline were excluded. Four years later all subjects got a respiratory questionnaire, which 86.2% completed. The association between baseline levels of a panel of cytokines in serum and incident wheeze was evaluated using non-parametric statistical methods and orthogonal projection to latent structures - discriminant analysis (OPLS-DA). Subjects with FENO levels between the 45th percentile and the 55th percentile served as controls (n=101), and were compared to subjects with new-onset wheeze (n=29).

Results: The median levels of TNF, IL-1, IL-2, IL-4 and IL-12 at baseline were significantly higher among those with new-onset wheeze (p < 0.05). This was supported by OPLS-DA, where TNF, IL-1, IL-4 and IL-12 scored the highest probability. The median levels of IL-5, IL-8, IL-10 and IL-13 at baseline were significantly lower (p < 0.05).

Conclusions: Our results indicate that the levels of serum inflammation biomarkers in respiratorily healthy subjects were associated with an increased risk of developing wheeze.

1834
Vitamin D insufficiency in adult asthma: Association with asthma severity and control
Stephanie Korn1, Marisa Hübner2, Matthias Jung3, 1Pharmacy, University of Huddersfield, United Kingdom; 2Respiratory, Tripsoli Medical Centre, Tripsoli, Libyan Arab Jamahiriya; 3Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden

We followed up 2,200 subjects from a general population-based study. At baseline, the subjects were investigated with questionnaires, blood samples, spirometry and FENO. All subjects reporting tobacco smoking, wheeze, asthma, asthma symptoms, or CRP >5 at baseline were excluded. Four years later all subjects got a respiratory questionnaire, which 86.2% completed. The association between baseline levels of a panel of cytokines in serum and incident wheeze was evaluated using non-parametric statistical methods and orthogonal projection to latent structures - discriminant analysis (OPLS-DA). Subjects with FENO levels between the 45th percentile and the 55th percentile served as controls (n=101), and were compared to subjects with new-onset wheeze (n=29).

Results: The median levels of TNF, IL-1, IL-2, IL-4 and IL-12 at baseline were significantly higher among those with new-onset wheeze (p < 0.05). This was supported by OPLS-DA, where TNF, IL-1, IL-4 and IL-12 scored the highest probability. The median levels of IL-5, IL-8, IL-10 and IL-13 at baseline were significantly lower (p < 0.05).

Conclusions: Our results indicate that the levels of serum inflammation biomarkers in respiratorily healthy subjects were associated with an increased risk of developing wheeze.

Data in asthmatic children suggest that low vitamin D levels are associated with poor asthma control, reduced lung function, and increased medication intake. To inves-
Asthma, upper airway disease and systemic inflammation in patients with chronic asthma syndrome and severe chronic asthma

Aims: To compare the functional and biological characteristics of patients with severe asthma and severe asthma with systemic signs and symptoms, where the upper airways disease is a comorbidity which strongly influences the respiratory symptoms.

Methods: The two groups of patients were similar in lung function, asthma control and quality of life. While CSS patients showed higher sputum eosinophil percentages (38 [91] vs. 15 [94], p<0.05) CSS patients had higher peripheral eosinophil counts (895±740 vs 592±579, p=0.05), depending probably by the different therapy (higher systemic therapy in CSS vs higher ICS dose in SCA). The majority of patients presented upper airway involvement, with eosinophilic inflammation (nasal eosinophilic %: 0.5[38] CSS vs 0.6[10] CSA).

Conclusions: Both groups of patients showed partially controlled eosinophilic airway inflammation. The percentage of patients with severe asthma is a comorbidity which strongly influences the respiratory symptoms.

Asthma severity (mean±SEM = 1835 severity and control supporting the hypothesis that improving suboptimal vitamin D levels could have a positive effect on asthma control.

Conclusions: p-Calprotectin levels >200 ng/ml are associated with increased mortality in patients with moderate to very severe COPD in stable phase. P-calprotectin is a potential marker of airway inflammation activity.
1839
Downregulation of Th 17 response after low dose clarithromycin in non-CF bronchiectasis patients
Eva-Maria Fouka1, Ioannis Kotsiasidis2, George Kolios2, Paraskevi Miltiades2, Konstantinos I Arvanitis1, Eirini Filidou1, Emmanouil Paraskakis5, Paul Zargouzidis5, Efthymia Kalaitzidou3, Demosanthes Boutsos4, 1 1st Paediatric Department, General Hospital G. Pipinou, Nicosia, Cyprus; 2 Paediatric Department, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Greece; 3 Laboratory of Pharmacology, Faculty of Medicine, University of Athens, Athens, Greece; 4 Paediatric Department, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Greece; 5 Pulmonary Department, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Greece

Introduction: Th17 lymphocytes and, particularly, IL-22-secreting Th17 cells play a crucial role in neutrophilic inflammation and tissue injury. It has been shown that clarithromycin (CAM) has anti-inflammatory and immunoregulatory effects. However, the effect of CAM administration on Th17 response in the setting of non-CF bronchiectasis has not yet been studied.

Aim: To evaluate the effects of CAM prophylaxis on the inflammatory process and Th17 response in patients with steady-state non-CF bronchiectasis.

Methods: Ten adult patients received CAM 500mg per day p.o. for 12 weeks. Peripheral blood Th17 cells were analyzed by flow cytometry using antibodies against CD4, IL-17 and IL-22. IL-17 concentrations in exhaled breath condensate (EBC) were quantified using a commercially available ELISA. Pulmonary function tests (PFT) and clinical data were recorded during the treatment period.

Results: Post-treatment CD4+IL17+ cell count (cells/µl) and EBC IL-17 levels (pg/ml) decreased significantly (mean 3.2016±2.7280 vs 2.5181±1.9246, p=0.001 and 4.3362±1.5899 vs 2.9300±1.7431, p<0.001, respectively). Mean pO2 (mmHg) improved significantly (76.8±4.77 vs 79.3±3.1422, p<0.001), while PFT and pCO2 remained unaltered. Notably, the decrease in CD4+IL17+ cell count correlated with the decrease in exacerbations (r: 0.618, p=0.05), and the pO2 increase (r: 0.648, p=0.043), while the decrease of IL-22/IL-17+ effectors correlated with the decrease in EBC IL-17 levels (r: 0.852, p=0.002).

Conclusion: We report for the first time that low dose CAM in patients with non-CF bronchiectasis appears to reduce lung inflammatory process potentially via downregulating the Th17 response.

228. Cystic fibrosis (adults and children): new therapies and detection of early lung disease

1840
Effects of the CFTR potentiator, ivacaftor, in two phase 3 trials in subjects with CF who have the G551D-CFTR mutation
J. Stuart Elborn1, Claire Wainwright2, Isabelle Sermet-Gaudelus3, Claire Wainwright1, Joannis Kotsiasidis2, George Kolios2, Paraskevi Miltiades2, Konstantinos I Arvanitis1, Eirini Filidou1, Emmanouil Paraskakis5, Paul Zargouzidis5, Efthymia Kalaitzidou3, Demosanthes Boutsos4, 1 1st Paediatric Department, General Hospital G. Pipinou, Nicosia, Cyprus; 2 Paediatric Department, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Greece; 3 Laboratory of Pharmacology, Faculty of Medicine, University of Athens, Athens, Greece; 4 Paediatric Department, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Greece; 5 Pulmonary Department, University Hospital of Alexandroupolis, Democritus University of Thrace, Alexandroupolis, Greece

Objectives: This study assessed the use of LCI as a more sensitive measure of improvement in lung function in subjects with FEV1 in the normal range.

Methods: This Phase 2, randomized, double-blind, placebo-controlled, multicenter, crossover study evaluated the effect of ivacaftor on LCI on subjects derived from multiple breath washout of SF6 using an open system Innocor device. Key inclusion were age ≥ 26 years, a G551D-CFTR mutation on at least one allele, FEV1 >90% predicted, and LCI >7.4 (upper limit of normal). Ivacaftor 150 mg or placebo was administered q12h for 4 weeks with a 4-week washout between treatments. Results: Mean (SD) baseline LCI improvements of 6.6% (10.9) years for age, 9.0 (1.5) for LCI and 97.2 (10.6) percent predicted for FEV1. The treatment effect of ivacaftor for adjusted mean change from baseline in LCI at Day 29 was -2.07 (P=0.0004) whereas the mean change from baseline in FEV1 was 7.0% (P=0.0117). Treatment difference for the mean change from baseline in sweat chloride was -45.8 mmol/L (P<0.0001). In the ivacaftor period, adverse events were reported in 13 subjects and serious adverse events in 2 subjects; the correspondent changes in the placebo period, were AEs in 15 and SAEs in 1 subject.

Conclusions: In subjects with CF who have mild lung disease, ivacaftor treatment improvement was not clinically meaningful as measured by LCI and respiratory function as measured by percent predicted FEV1. Adverse events were consistent with previous ivacaftor studies and mostly related to manifestations of CF.

Sponsored by Vertex.

1842
Long-term safety and efficacy of ivacaftor in subjects with CF who have the G551D-CFTR mutation
Edward McKone1, Sally Rodriguez2, Karl Yen3, Jane Davies4, 1 Respiratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada; 2 Department of Child Life and Health, University of Edinburgh, EH8 9AG, United Kingdom; 3 Clinical Research and Biostatistics, Vertex Pharmaceuticals Incorporated, Cambridge, United States; 4 Paediatric Respiratory Medicine & Gene Therapy, Royal Brompton Hospital and Imperial College, London, United Kingdom

Objectives: Ivacaftor was evaluated in a 248-week Phase 3 studies. This 96-week controlled-label extension (PERSIST) evaluated the safety and efficacy of long-term ivacaftor in subjects who completed the prior trials (STRIVE and ENVISION).

Methods: 192 subjects who completed treatment in STRIVE or ENVISION enrolled in PERSIST. All subjects received ivacaftor 150 mg q12h in addition to prescribed therapies. Here we report the results of 96 weeks of treatment for subjects who were in STRIVE (n=144) and 72 weeks for those in ENVISION (n=10).

Results: For subjects who received ivacaftor in the placebo-controlled studies, the FEV1 improvements were sustained in PERSIST. For STRIVE subjects, the mean (SD) absolute change from STRIVE baseline in % predicted FEV1 was 9.4% (8.3%) on Day 1 of PERSIST, 9.2% (8.5%) at Week 48 in STRIVE, 10% (9.3%) at Week 72 and 9.5% (10.1%) at Week 96. For ENVISION subjects, the mean (SD) absolute change from ENVISION baseline was 10.2% (15.7%) on Day 1 of PERSIST, 9.1% (15.6%) at Week 60, and 10.1% (14.2%) at Week 72. For placebo subjects in STRIVE or ENVISION, the FEV1 improvements in PERSIST were similar to those observed in ivacaftor subjects during the placebo-controlled studies. The mean (SD) absolute change from PERSIST baseline was 9.4% (8.5%) at Week 96 for STRIVE placebo subjects and 8.1% (12.5%) at Week 72 for ENVISION placebo subjects. The safety profile observed in PERSIST was generally consistent with the safety profile observed during ivacaftor treatment in STRIVE and ENVISION.

Conclusions: Ivacaftor-related improvements in lung function were sustained with additional ivacaftor treatment. No new clinically important safety concerns were identified.

1843
Inhaled glutathione tolerability and efficacy in patients with cystic fibrosis
Cecilia Calabrese, Valeria Raia, Vincenzo Carnovale, Pasquale Abete, Antonella Tosco, Antonio Magliocea, Alda Casale, Claudia Basile, Paola De Fazio, Carmelindo Marzadro2, Po-Shun Lee3, Tao Song4

In CF patients, Glutathione (GSH), the first-line defence of lungs against oxidative stress, is severely reduced. A randomized, single blind controlled trial of inhaled GSH vs placebo (NCT01450267) is underway to evaluate the effect of GSH in a cohort of CF patients. 94 CF patients (48 F; median age 20.8 years) in regular follow up at the Regional Pediatric and Adult CF Center of Naples, were enrolled, 50 patients (23 F) were
randomly assigned to the GSH group and 44 (25 F) to the placebo group. The inclusion criteria were: CF diagnosis by sweat test and/or two CF causing mutations, age of patients <6 yrs, FEV1% > 40% of the predicted value, negative culture for Burkholderia cepacia. Spirometry was performed pre and post treatment, 10 and 60 minutes after GSH inhalation test (10 mg/kg, maximum dosage 600mg/dose) in order to assess tolerability. Follow-up visits including spirometry took place once, three, six, nine months and one year post treatment. No patients showed a decrease in FEV1% > 15% after GSH inhalation. In the subgroup of CF patients (n=27) with an obstructive ventilatory defect (FEV1/FVC<80%) six months therapy with GSH determined a statistically significant increase in FEV1% (58.3±13.2 vs 62.6±15.1 p =0.048) compared to the group (n=20) treated with placebo (59.3±14.9 vs 56.8±18.4). Preliminary results suggest that inhaled GSH is well tolerated and determines an improvement in the respiratory function in CF patients.

1844 Assessment of lung function in pre-school children with cystic fibrosis by nitrogen washout
Jacqueline Forbes1, Dario Pras1, Colleen Dunn1, Carlos Millia1, 1 Center for Excellence in Pulmonary Biology, Stanford University, Palo Alto, CA, United States; 1Pediatrics, Schneider’s Children’s Medical Center, Petchup Tikvah, Israel

Pulmonary function in young children can identify the early manifestations of diseases like cystic fibrosis (CF) and prompt to early intervention. We evaluated in pre-school age children the performance of ventilatory indices obtained from N2 washout (FRC, LCI, Scond, Sacin) as to their feasibility and ability to detect differences between disease and control groups. N2 washout was performed with a novel system that utilizes an ultrasonic flow sensor as well as O2 and CO2 sensors (Exalzyter, Ecomedics AG). N2 washout was performed during tidal breathing and using 100% Oxygen. Three maneuvers free of artifact were obtained whenever possible and allowing for 2-times the washout time to lapse between maneuvers. This was followed by spirometry and aiming to obtain at least 3 valid flow-volume loops. Study groups included children ages 3 to 6 year old with CF (n=20) and asthma (AS, n=15), as well as a group of healthy controls (HC, free from history of respiratory disease or cigarette smoke exposure). Children were studied at a period of acute symptomatology. Research quality nitrogen washout could be completed in 90% of CF, 75% of AS and 70% of HC. FRC was comparable between the groups (p=0.1). The LCI from the N2 washout was elevated in CF with a mean of 10.4±2.6, as well as Scond 0.05±0.03 and Sacin 0.5±0.5, which was statistically significant from the other 2 groups (p<0.05). We conclude that N2 washout can be completed without difficulty even in children that have little familiarity with pulmonary function testing. Indices obtained from the N2 washout can detect defects in ventilatory function in children with CF that distinguishes them from other children.

1845 Alternative multiple breath washout outcomes for clinical trials in cystic fibrosis
Felix Ratan1, Juliana Salazar1, Renee Jensen1, Reshma Amin1, 1Per Gustafsson1, Sanja Stanjevic1, Padmaja Subbarao1, 1Respiratory Medicine, Hospital for Sick Children, Toronto, ON, Canada; 1Department of Paediatrics, Central Hospital, Sveasoe, Sweden

The Lung Clearance Index (LCI) is a sensitive marker of early lung disease, and LCI, but not spirometry, was able to detect treatment effects of hypertonic saline in CF patients with mild disease (Amin et al; Thorax 2010). We used data from this interventional trial to investigate whether any other outcomes of the multiple breath washout could detect treatment effects similar to LCI. Using a cross-over design, patients were randomized to either hypertonic saline or isotonic saline in a randomized sequence, separated by a 4 week washout period. MBW was measured in triplicate by mass spectrometry (AMIS 2000; Innovision A/S, Odense, Denmark) using a gas mixture containing 4% SF6, 4% He, 21% O2 and balanced N2. The current analysis includes 15 subjects for whom the following additional outcome measures could be assessed: normalized concentration of end tidal tracer gas (Cnet) at 6 turnovers (6T0), moment ratios (M1M0, M2M0) and LCI measured by helium. No significant treatment effects were observed for LCI (404.3 μm; SD ±60.3) were both significantly (p<0.05) larger compared to controls (404.3 μm; SD ±34.8 and 223.8 μm; SD ±38.5 respectively). Discussion: HeM2 is well tolerated in children from school age. We found that R and h, both surrogate values for acinar size, are larger in children with mild CF lung disease compared to healthy controls. HeM or HeM may constitute a sensitive technique for investigating CF lung disease.

1846 Evaluation of the peripheral airway microstructure in children with cystic fibrosis (CF) using 1H magnetic resonance imaging
Gael Guillard1, Iain Ball1, Kuldip Panesar2, Noor Al-Khathlan1, 1Department of Radiology, Children's Health, Dallas, Texas; 1Institute of Lung Health, Department of Infection, Immunity and Inflammation, University of Leicester, United Kingdom; 2Physics, University of Nottingham, United Kingdom

Background: Pathology and lung function studies show that small airways are affected early in CF lung disease. Due to the inaccessibility of the distal air spaces little research has been performed in this area. The lung microstructure can be studied using the relatively new technique of hyperpolarised noble gas magnetic resonance (1HMR) scanning.(1)

Aims: To compare acinar airway size of children with CF with that of healthy controls.

Methods: In children with moderately mild CF lung disease 1HMR was under taken during breath-hold following inhalation of a bolus of hyperpolarised 1H gas mixture. A signal was obtained using the q-space technique.(2) We applied Yablonsky’s acinar model(3) on the raw data to obtain the values for mean acinar duct diameter, R and mean alveolar sleeve depth, h. All children had spirometry and lung clearance index (LCI) measured.

Results: We studied 9 children (6-10y) with CF (FEV1: 97±6% predicted; SD ±14.3) and 18 age-matched controls. LCI was elevated in all CF patients (median 10.7, range 9.1-12.9). Acinar duct diameters (438±4±m; SD ±21.8) and alveolar sleeve depth (294.2±m; SD ±60.3) were both significantly (p<0.05) larger compared to controls (404.3±m; SD ±34.8 and 223.8±m; SD ±38.5 respectively).

Conclusion: HeM2 is well tolerated in children from school age. We found that R and h, both surrogate values for acinar size, are larger in children with mild CF lung disease compared to healthy controls. HeM or HeM may constitute a sensitive technique for investigating CF lung disease.

229. Professional development and advanced practice roles in respiratory nursing

1847 A competence framework to support the development of the workforce to deliver improved outcomes for patients with COPD and asthma
Anne Morgan, Sue Hill, Kevin Bolton, Matt Kearney. Respiratory Programme, Department of Health, London, United Kingdom

Rationale: It is estimated that over 3 million people in the UK are living with COPD or related respiratory disease, with less than one third diagnosed and treated. With better awareness and clearer pathways of care focused on improving outcomes, there are implications for planning and developing the workforce. This competence framework identifies the skills, knowledge and attitudes required to deliver improved interventions. The framework consists of a menu of National Occupational Standards where evidence of competence will ensure practitioners are equipped to deliver respiratory services and promote patient self care and management within their scope of practice, role and responsibility.

Method and results: In collaboration with Skills for Health, the agency responsible for developing National Occupational Standards in healthcare, a respiratory disease Competence Framework based on functional and performance standards has been developed, that describes what is needed to deliver patient-centred respiratory care. This was informed by an expert group of stakeholders focused on delivery of care across the spectrum of respiratory disease from prevention, detection and diagnosis, through acute and chronic care to end of life care.

Conclusion: This resource is being used by commissioners, service providers, local networks and workforce planners to inform service and workforce design, thereby supporting the shift of service delivery by a competent workforce, from acute settings into the community.

1848 New Zealand adult respiratory nursing knowledge and skills framework: A platform for competence development
Victoria Perry, Respiratory Services, Palmerston North Hospital, Palmerston North, Manawatu, New Zealand

Respiratory nurses in New Zealand (NZ) are required by the Nursing Council of NZ and national legislation to provide evidence of competence however, there has been an absence of an agreed articulation of the respiratory specific knowledge and skills required to demonstrate this. A national working group of respiratory nurses therefore undertook to develop a national respiratory knowledge and skills framework that offers a mechanism for the development of a range of transferable
clinical skills, seeks to minimise risk to patients, nurses and employers, provides a reference point for curricula and a mechanism for nurses to measure effectiveness of their practice. This presentation will describe the aims of the framework, process with development, scope for application, implementation to date, and initial evaluation.

1849 Audit of the impact of increased nurse education in diagnosis and management of patients with airflow obstruction in the community
Rosier Wolstenholme, Marie Barrowclough, Patricia Darley, Gillian Prescott. Bridgewater Community Healthcare, NHS Trust, Wigan, United Kingdom
Clinical Services Department, AstreaZeneca, Macclesfield, United Kingdom

Aims: Primary to improve skills of primary care clinicians in diagnosis and management of patients with airflow obstruction in the community.

Methods: 10 community practices applied and were accepted for clinical mentorship. Following an Education Needs Analysis a practice nurse education programme was developed and provided by specialist nurses and community respiratory physician. In the 10 practices 259 patients were identified as having poorly controlled asthma or COPD. 213 attended for review, 63 with an initial diagnosis of asthma and 150 COPD.

Results: 12 of 63 (20%) patients with asthma showed no reversibility, 11 of 150 (6%) of COPD patients had normal spirometry. 90% of the asthmatics and 93% of COPD pts were “uncontrolled”. 2 or more courses of steroids and antibiotics a year. After the programme the this reduced to 3% and 12% respectively. COPD MRC scores improved markedly, MRC 3 37% to 17%, MRC 4 30% to 13%. 50% of COPD patients were referred and accepted pulmonary rehabilitation.

Discussion: Increased education supported by continued mentorship improves clinical competencies and outcomes by better diagnosis, appropriate inhaler therapy and encouraging multidisciplinary working. Continued mentorship is vital to maintain standards and confidence in primary care.

1850 What are the solutions to the key challenges facing primary care nurses delivering respiratory care in the United Kingdom?
Stephen Holloway, Anne Radwan, Gareth Hall, Jan Scallon. 1

Methods: We have previously described qualitative research involving 72 primary care nurses (60 minute interviews) and four 90 minute focus groups of nurses purposively representative of primary care respiratory interested nurses in the United Kingdom. We have also published results of this research (IPCRG Abstract 202; 2012). We now describe some of the suggested solutions gained from discussions of a group of clinicians involved in health care education (involving primary care, community, specialist nurses and general practitioners).

Results: The initial research identified four key challenging themes: time, professional isolation, working with patients and lack of resources. The key areas identified to facilitate addressing these challenges were themed into two broad areas - which will address all the challenge areas. Firstly, leadership skills (including time management, influencing and negotiating skills) and secondly communication skills (eg motivational interviewing and shared decision making techniques).

Conclusions: It is likely that with changes in the continuing professional development offered to practice nurses many of the key challenges currently faced could be addressed. This however would require influencing and negotiating skills at practice, area and national levels and a desire from practice nurses to engage in leadership and communication skills development. With these inputs a real change could be obtained which would improve clinician and patient satisfaction.

1851 The role of the asthma nurse specialist in optimising the management of acute asthma according to British Thoracic Society guidelines
Philip Coakley, Karina Virdoe, Aithya Jayaraman, Bernadette Hawkes. Medicine, King George Hospital, London, United Kingdom

Introduction & aims: Asthma affects over 5 million people in the UK and accounts for one hospital admission every 7.5 minutes. The British Thoracic Society (BTS) has evidence-based guidelines on the management of acute asthma which have been shown to reduce readmission rates. This study aims to audit the management of acute asthmatic admissions against BTS guidelines and establish whether or not intervention by an asthma nurse specialist (ANS) improves the audit criteria outcomes.

Methods: In a busy Outer London district general hospital, retrospective case note audit was carried out on all patients admitted with acute asthma in September and October 2011. The patients were then divided into those who were jointly managed by the medical team and ANS with those who were managed by the medical team alone.

Results: 50 patients were admitted over the 2 month period, of which 50% had been reviewed by the ANS. Across all 16 BTS audit criteria, the achievable rates in the group of patients who received the intervention of ANS was either equal to or higher than those who were managed by physicians alone. The average achievable rate of all audit criteria in patients who did not see the ANS was 29.3% compared to 60.1% for those who were seen by the ANS.

Conclusions: The intervention of the ANS in the inpatient management of acute asthma increases the adherence to national guidelines, thus improving standards in overall management. This audit also demonstrates the importance of the BTS audit criteria and the guidelines in the management of acute asthmas to improve overall adherence.

1852 Nurse-patient collaboration; a grounded theory study in patients with chronic obstructive pulmonary disease on non-invasive ventilation
Dorte Sørensen, Kirsten Frederiksen, Thorbjørn Grøfte, Kjæve Lomborg. 1

Department of Public Health, Section of Nursing Science, Aarhus University, Aarhus, Denmark; 2Department of Anesthesiology, Randers Regional Hospital, Randers, Denmark

Objectives: This paper provides a theoretical account of nurses’ collaborations with chronic obstructive pulmonary disease patients during non-invasive ventilation treatment at the hospital.

Background: Despite strong evidence for the effect of non-invasive ventilation treatment, success remains a huge challenge. Nurse and patient collaboration may be vital for treatment tolerance and success. A better understanding of how nurses and patients collaborate during non-invasive ventilation may therefore contribute to improvement.

Design: A constant comparative classical grounded theory method. The data comprised sessions of qualitative participant observation during the treatment of 21 patients with non-invasive ventilation, which included unstructured conversations with the nurses and semi-structured interviews with 11 patients after treatment completion. Data were collected at three Danish hospitals.

Results: Definition of the situation emerged as the core category in nurse-patient collaborations during non-invasive ventilation treatment. The main concern was resolved by activating one or more of four categories: (1) Joint Modality; (2) Patient-initiated Modality; (3) Nurse-initiated Modality; and (4) Split Modality. Modalities 1–3 were characterised by mutual definitions of the situation, whereas the fourth was characterised by divergent definitions of the situation.

Conclusions: This study offers a robust account of nurses’ and patients’ concerns about their definition of the situation and how they activate different complex adaptive modalities. We offer a theoretical basis for developing complex interventions.

1853 Fatigue in COPD: A qualitative study of peoples experiences
Caroline Stridman1, Lisa Shar1, 1University of Technology, Department of Health Science, Division of Nursing, Luleå, Sweden; 2The County Council of Norrbotten, The OLIN-studies, Luleå, Sweden; 3Umeå University, Department of Public Health and Clinical Medicine, Division of Medicine, Umeå, Sweden

Background: Fatigue is reported to be one of the most common symptoms among people with COPD. However, there is hardly any qualitative research describing how fatigue affects people living with COPD.

Aim: To study people’s experience of fatigue when living with COPD.

Method: In the years of 2008-2010, a purposive sample of 20 people with COPD stage II-IV, according to GOLD, was recruited from the OLIN COPD-study in Northern Sweden. Data was collected by semi-structured interviews and the participants were interviewed about their experience of fatigue. The interviews were subjected to a qualitative content analysis.

Results: One theme was identified: To reconcile with the dimensions of fatigue, and four categories: To understand the reason; To preserve fatigue unexpressed; To be controlled and To struggle against. In COPD, fatigue seems to appear in different dimensions. People are aware of the cause of fatigue and they seem to reconcile with the symptom believing it is a natural consequence of COPD, and therefore it remains unexpressed. Fatigue is an always present feeling that involves the whole body, raising feelings of hopelessness making life heavy and invincible. Further, by increased dyspnea, fatigue gets even heavier and more severe to manage. To cope, people have to force themselves to struggle against fatigue, regardless of dyspnea that was triggered by physical movements.

Conclusion: Fatigue affected the daily life of people living with COPD. In relation to dyspnea, fatigue was described to be overwhelming, and most important fatigue seems to own to reduced to healthcare professional and relatives. This knowledge is significant for nurses in order to meet the person’s needs of care.
230. Novel approaches to lung transplantation

1854 Mesenchymal cells isolated from the airways of BOS patients as targets of innovative drug-loaded nanoparticles

Emmanuela Cova1, Miriam Colombo1, Monica Morosini2, Simona Misseri1, Simona Inghilleri1, Sara Magni1, Davide Prosperi2, Federica Meloni1.

1Department Respiratory Diseases, IRCCS San Matteo, Pavia, Italy; 2Department of Biotechnology and Bioscience, University of Milano Bicocca, Milan, Italy

Our group has recently shown that proliferating mesenchymal cells (MC), obtained from BAL of BOS patients, express CD44 and that this expression correlates with mTOR expression and with a higher proliferative rate. By these results we have designed an innovative approach based on bio-compatible nanoparticles loaded with the mTOR inhibitor everolimus and functionalized with anti CD44 MoAb, for the selective targeting to the specific cells (targNP). Fluorescent labeled targNP have been used to assess cell uptake by confocal microscopy. Cell apoptosis/death (annexin V/7AAD) and proliferation (CFSE) were evaluated by flow cytometry. We used primary MC isolated from 2 BOS patients (grade 1 and 2) with the following phenotype: BOS 1: 85% CD90+ of which 33% co-expressing CD9; BOS2: 93% CD90+ with 38% co-expressing CD146, 25% CD9, and 38% both CD146 and CD9. Both MC samples were negative for CD45RO and CD34 and positive for CD44 (98%). TargNP were shown to adhere to matured MC from 15 min and completely enter into the cells after 45 min. Drug free nanoparticles, as control, were completely inert. TarTNP treated cells showed a significantly higher mean rate of annexin V at 4 h (17.6 versus 4.5%) and 24 h (15 versus 5.3%) respect to control cells while mean 7AAD expression at 24 h was 4.1 versus 1.3%. Likewise, cell proliferation was significantly inhibited at 24 and 48 h (mean: 41 and 37.2%, respectively). This is, by far, the first proof of concept that an innovative approach based on drug coated NP can be used to selectively address MC which proliferate in the airways. Further in vitro and in vivo studies will investigate possible efficacy of this new treatment strategy.

1855 Structural differences in airways during chronic rejection after lung transplantation: A (micro)-CT analysis

Stijn Verleden1, Stijn Willems2, David Rutten3, Robin Vos1, John McDonough1, Ammerelse Varelen1, Erik Verbeek1, Johny Verschakelen1, Dirk Van Raemdonck1, Benoit Rondelet3, Christiane Knoop3, Marc Decramer1, James Hogg2, Geert M. Verleden2, Andrew Fisher1.

1Department Respiratory Diseases, IRCCS San Matteo, Pavia, Italy; 2Department of Biotechnology and Bioscience, University of Milano Bicocca, Milan, Italy; 3Fibrosis Research Group, Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom; 4Leuven Lung Transplantation Unit, Katholieke Universiteit Leuven and University Hospital Gasthuisberg, Leuven, Belgium; 5Fibrosis Research Group, Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom

Chronic rejection is a major problem after lung transplantation (Tx). Recently a distinction between an obstructive (fBOS) and restrictive phenotype (RAS) has been made. We aimed to investigate structural differences. Human explant lungs from 5 fBOS and 3 RAS patients were collected during reTxs, were air-inflated to 75% TLC, frozen solid in liquid nitrogen vapor and frozen sections were examined by H&E. Unused donor lung (n=1) served as control. The lungs were fixed for immunohistochemical detection of airway and interstitial changes and structural alterations of the central airway tree (4-16 generations). In conclusion: in RAS lungs both airways and interstitium were affected. Most frequent intra-airway changes were bronchiolar and bronchial wall thickening. In intraluminal changes airway narrowing and bronchial plugging were observed. Interstitial changes were characterised by collagen deposits, lymphocytic infiltrates and increased fibroblasts/myofibroblasts. We confirm the presence of chronic rejection and suggest in addition to ABO incompatibility, a technical factor (cold ischemia time >24h) that might lead to the development of chronic rejection.

IL-17- and Th17-associated cytokines have been linked to the development of acute and chronic rejection after lung transplantation in both animal models and humans. An increase in IL-17 mRNA expression and of IL-17 levels in BAL have been described in LTR with BOS and during AR episodes in comparison with Stables Recipients. On the other hand a decrease in IL-10 producing clone number and in Treg cell frequency has been described in BOS patients.

Aim of the present study was to assess with a feasible method the balance between IFN-gamma/IL-17- producing clones and IL-10 producing cells/Treg cells in the peripheral blood of 26 LTR (13 stable recipients, 13 BOS patients). IFN-gamma/IL-17 and IL-10 producing clones were assessed by ELISPOT. CD4+/CD8+ T cells were assessed by flow-citometry. A significant increase of IL-17 and IFN-gamma producing cells in the peripheral blood was observed in patients who developed BOS (p= 0.03 and 0.04 respectively) while Treg cell count decreased significantly (p= 0.002) and IL-10 showed a non significant trend toward a decrease. Moreover the ratio between IL 17 and IL 10 or Treg cell count was significantly increased in BOS (0.85 vs 0.21; 10.4 vs 1.9 respectively) while IFNgamma/IL10 ratio did not significantly change.

In conclusion detection of IL17/Treg ratio in the peripheral blood of LTR represents a feasible and useful tool in the identification of patients at higher risk of BOS development. By this way the role of Th17 axis in BOS pathogenesis is further confirmed.

1857 Mechanistic differences of chronic lung allograft dysfunction phenotypes in lung transplantation

Monika I. Siwara1, Bart M. Vanaudenaerde1,2, Sijin E. Verleden1, Lee A. Borthwick1, Robin Vos1, Nico J. Green1, Chris Ward1, Dirk E. Van Raemdonck2, Paul A. Curtis3, Derek A. Mann4, Geert M. Verleden1.

1Department Respiratory Diseases, IRCCS San Matteo, Pavia, Italy; 2Department of Biotechnology and Bioscience, University of Milano Bicocca, Milan, Italy

Purpose: The neomacrolide azithromycin, is now widely used in the treatment of bronchiolitis Obliterans Syndrome after lung transplantation. However, only a proportion of patients respond by improving their lung function. This study aimed to evaluate differences in airway microenvironment between azithromycin responsive (<10% improvement in FEV1), and azithromycin resistant BOS patients.

Methods: Bronchoalveolar lavage (BAL) from recipients identified as stable n=10 (control), azithromycin responsive n=10 and azithromycin resistant n=10 were evaluated for cell differential, IL-1α, IL-1β, IL-6, IL-8, TNF-α peptides. BAL was then added to primary bronchial epithelial cells (PBEC) and tested for viability by XTT assay.

Results: BAL neutrophilia (%) was increased in responders (50% p<0.0001) and non-responders (52.9% p<0.0001) compared to the control (0.8%). IL-1α, IL-1β, IL-6, IL-8, TNF-α were increased in both groups (all proteins <0.05) compared to the control. The levels of IL-1α, IL-1β and TNFα showed increasing trend in responders compared to non-responders. PBEC viability in response to BAL was reduced in non-responders (p=0.012) but not in the responders group (p=0.64). Moreover, there was a negative correlation between PBEC viability and IL-1α (r=0.042), IL-8 (p=0.0017), TNFα (p=0.039), IL-1β (p=0.045) and IL-6 (p=0.0453) concentrations.

Conclusions: Unlike in responders, where azithromycin blocks IL-17 T cell mediated neutrophilia, azithromycin resistant phenotype is associated with epithelial damage. Further studies are needed to determine if these results are specific to azithromycin or apply to other immunosuppressant strategies. These results also suggest that these responses could be considered for BOS patients who develop an azithromycin resistant phenotype.

1858 Results of a phase 2b multi-center, randomized, double-blind, placebo-controlled study of an RNA therapeutic, ALN-RSV01, in respiratory syncytial virus (RSV)-infected lung transplant patients

Amy Simon1, Allan Glavivals2, Martin Zanona1, Tony Hodges3, Stefano Arcaro4, Michael Musk4, Ute Sommerwirck3, John DeVincenzo5, Verena Karsten1, Shailly Shah1, Jeffrey Cechelsky1, Sara Nochur1, Jared Gollob1, Akshay Vaishnaw1, Jens Gottlieb9.

1Clinical Research, Alnylam Pharmaceuticals, Cambridge, MA, United States; 2Department of Cell and Molecular Biology, Biomedical Faculty, University of Twente, Enschede, the Netherlands; 3Clinical Research, Alnylam Pharmaceuticals, Cambridge, MA, United States; 4Lung Transplant Unit, St. Vincent’s Hospital, Darlinghurst, NSW, Australia; 5Department of Medicine, University of Colorado at Denver Health Sciences Center/Aurora, CO, United States; 6Department of Respiratory Medicine, University of Southern Denmark, Odense, Denmark; 7Department of Respiratory Medicine, Columbus University, New York, NY, United States; 8Innere Medizin, Rheumaklinik, University Hospital, Rheinlandpfalz, Saarbruecken, Germany; 9Fibrosis Research Group, Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom

RSV infection after lung transplantation is an independent risk factor for the development of bronchiolitis obliterans syndrome (BOS). ALN-RSV01 is a small interfering RNA targeting the RSV nucleocapsid gene that is critical for viral replication. Previously, we performed a Phase 2 randomized, double-blind, placebo-controlled trial in 24 RSV-infected lung transplant patients administering...
aerosolized ALN-RSV01 or PBO for 3 days. The primary endpoint of safety and tolerability was attained. In addition, there was a significant reduction in the secondary endpoints of incidence of new or progressive BOS at day 90 (p=0.027) and patient’s symptom scores in the ALN-RSV01 group compared to PBO. To extend these results, we performed a Phase 2b multi-center, multinational, randomize, double-blind, PBO-controlled trial in RSV-infected lung transplant patients in which the primary endpoint was the effect of ALN-RSV01 on the incidence of new or progressive BOS at Day 180. Secondary endpoints included the impact of ALN-RSV01 on symptom scores, antiviral activity and safety. RSV positive subjects were randomized (1:1) to receive either aerosolized ALN-RSV01 or PBO for 5 days, alongside the hospital’s standard-of-care. Subject stratification to treatment arms was based on two binary factors: 1) time from symptom onset to treatment start and; 2) pre-infection BOS grade. Of the 3,985 subjects prescreened at 33 centers, 218 were RSV positive, of which 87 were randomized. Enrollment is completed and subjects are now in the follow-up phase. Final study results will be presented at this meeting.

1859
BAL neutrophil levels in a randomised controlled trial of azithromycin therapy in bronchiolitis obliterans syndrome post lung transplantation

Chris Ward1, Gail Johnson2, Victoria Ryan3, Therese Small4, James Lordan5, Andrew Frehley6, Gerald Meachery7, Paul Corris1.
1Institute of Transplantation, Freeman Hospital, Newcastle upon Tyne, United Kingdom; 2Institute of Transplantation, Freeman Hospital, Newcastle upon Tyne, United Kingdom; 3Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom

Open studies have reported an improvement in FEV1 in some BOS patients treated with Azithromycin (Azith). We recently demonstrated that Azith is superior to placebo treatment, improving FEV1 in patients with BOS. It is suggested that a BAL neutrophil reduction is associated with treatment benefit. We have investigated this in our trial.

Methods: A prospective, randomised double blind placebo controlled study of Azith 250mg o.d. or placebo on alternate days, in BOS patients. The primary outcome was change in FEV1 at 12 weeks and a secondary outcome BAL neutrophil %.

Results: 46 patients were randomised (23 Azith, 23 placebo) stratified for pre op diagnosis of supplicative disease and operation (single or bilateral lungs). Of the 46ITT patients, baseline and final visit BAL were available for 28 (13A, 15P). In these patients the baseline % neutrophils, median (IQR), in the Azith group was 17 (4 to 69%) and in the placebo group 15 (2 to 56%). The baseline to final visit change in % neutrophils varied, with around half the patients in both treatment arms showing an increase from baseline and half a decrease. There was a median increase from baseline in the Azith group of 10%, IQR (~10% to 18%) and in the placebo group a median decrease from baseline of ~1% (~8% to 5%). These changes were statistically non significant (P=0.4 and 0.6 respectively, 1-sample Wilcoxon).

Conclusion: Azith is superior to placebo improving lung function in patients with BOS. In the same patients, whilst BAL neutrophil % was high, we observed no consistent fall with Azith. This may suggest the mechanism of benefit does not rely on a quantitative reduction in neutrophils.

1860
ENDOXY – Endothelialization of a gas permeable membrane for the development of a biohybrid lung assist device

Christian G. Cornelissen1,2, Maren Dietrich2, Dirk A. Frechen1, Jörg Sachweh1.
1Department of Physiology, University of Toronto, Canada; 2Physiology and Experimental Medicine, Hospital for Sick Children, Toronto, Canada

The interaction of stem cells with the surrounding matrix environment is crucial for cell fate. The development of biomaterials that recapitulate the in vivo environment is a key component to driving differentiation of pluripotent cells into lung endo- and peri-observed BOS, markers for COPD, asthma, forced expiratory volume in one second (FEV1), and forced total capacity (FVC) in nine genes of the WNT signaling cascade pathway (WNT10B, WIF1, WISP1, SPREF2, SPREF5, DKK1, Asxin2, TCF7L2, and FZD3) using genome-wideassociation data from six European cohort studies.

231. Asthma and the genes: from GWAS to next generation transcriptome analyses

1862
Meta-analysis of genome-wide association studies of single nucleotide polymorphisms in selected genes of the WNT signaling pathway

Background: The WNT signaling pathway is involved in a wide range of developmental events and maintenance of homeostasis in adult tissue, including lung development and health. WNT signaling genes have also been suggested to play a role in pathogenesis of lung diseases such as chronic obstructive pulmonary disease (COPD) and asthma.

Aims and objectives: The aim of this meta-analysis was to identify consistent disease markers for COPD, asthma, forced expiratory volume in one second (FEV1), and forced total capacity (FVC) in nine genes of the WNT signaling cascade pathway (WNT10B, WIF1, WISP1, SPREF2, SPREF5, DKK1, Asxin2, TCF7L2, and FZD3) using genome-wideassociation data from six European cohort studies.
1863 Genome-wide prediction of childhood asthma and related phenotypes in a longitudinal birth cohort

Ben D. Spycher 1,2, John Henderson 1, Raquel Granell 1, David M. Evans 1, George Davey Smith 1, Nicholas J. Timpson 1, Jonathan A.C. Sterne 1, 1School of Social and Community Medicine, University of Bristol, United Kingdom; 2Institute of Social and Preventive Medicine, University of Bern, Switzerland

Aim: Childhood asthma varies greatly in clinical presentation and time course and underlying disease pathways are assumed to be heterogeneous. We assessed the extent to which single nucleotide polymorphisms (SNPs) associated with childhood asthma in a genome-wide association study (GWAS) are predictive of asthma-related phenotypes.

Methods: In 8365 children from a population based birth cohort, the Avon Longitudinal Study of Parents and Children, allelic scores were derived based on between 10 and 215443 SNPs ranked according to inverse of the p-value for association to asthma (P<0.05) and atopy (P<0.005) and decreased FEV1 and FVC (P<0.05). Notably in TCFL7L2 six different SNPs were identified (p-values between 0.002 and 0.046) in association with asthma, FEV1, and FVC. In literature, WNT signaling genes were linked to COPD (Axxm2, asthma (SFRP2, TCFL7L2, NPSR1), FEV1 (SFRP2, TCFL7L2, WNT10b). Conclusions: Using GWAS data we identified genetic variants in DMRT1 to be gender-specific risk factors for asthma development. Allele-specific transcription factor binding and consecutive changes in promoter activity seem to contribute to this effect. The role of DMRT1 in asthma pathogenesis needs to be elucidated further.

1865 Interaction of retinoid acid receptor-related orphan receptor alpha (RORA) and neuropeptide S receptor 1 (NPSR1) in asthma

Rationale: Retinoid acid receptor-related orphan receptor alpha (RORA) is currently received as a candidate gene for asthma by a genome-wide association study (Moffatt et al. NEJM 2010). To investigate whether RORA polymorphisms (SNPs) influence asthma susceptibility, we conducted a detailed genetic association study in the vicinity of the asthma-associated variant rs1071559.

Methods: We genotyped 37 RORA SNPs in the Swedish birth cohort BAMSE (2003-2009) (n=1120 children). In the cross-sectional PARSIFAL study (1120 European children), we also performed allele and genotype association and RORA-NPSR1 gene–gene interaction analyses. Regulation of RORA was investigated using NPSR1 over-expressing SH-SY5Y cells.

Results: Seven RORA SNPs were associated with doctor-diagnosed childhood asthma. The allele T in rs7164773 was under-represented in cases in BAMSE (52.6% vs. 44.7%; OR 0.72; 95% CI 0.60-0.87; p=0.005). In PARSIFAL, the allele T of rs1071559 was under-represented in cases (13.6% vs. 8.5%; OR 0.58; 95% CI 0.37-0.92; p=0.02). These associations were confirmed in the combined BAMSE and PARSIFAL material (p<0.005 and p<0.01, respectively). Significant gene-gene interactions influencing the asthma risk were found between RORA SNPs and NPSR1 SNPs. In cell line studies, NPS induced RORA mRNA expression.

Conclusions: Genetic variations in RORA are associated with childhood asthma and NPSR1. A direct regulatory effect further suggests interaction of RORA and NPSR1 pathways.
Objective: To systematically analyze the association between SNPs in TLR signaling pathway genes and childhood asthma and atopy.

Methods: Common SNPs present in TLR signaling pathway were retrieved from HapMap database and LD analyses were performed to determine tagging SNPs. Association of 375 tagging SNPs with asthma were analysed in a genome wide association (GWA) dataset consisting of 651 asthmatics and 652 controls. SNPs were genotyped by Illumina HumanHap300Chip (n=169) or MALDI-TOF MS (n=19) or imputed (n=187). Algorithms were applied to rank associations and clustering of the associated genes on a virtual pathway map was performed by a systems biology approach and we assessed the putative functional relevance of associated genes by in silico analyses.

Results: We identified 41 genes involved in the TLR signaling and regulatory pathways, harbouring 1405 SNPs (tagged by 375) with minor allele frequency >5% in the HapMap (CEU) population. SNPs located in 19 genes showed association with asthma at a significance level of p < 0.05. Top ranked asthma-associated genes (e.g. IRAK-1, MKK-3, and ERK-2) mapped to distinct functional clusters within the TLR pathway and associated SNPs were located in promoter (n=16), intronic (n=116) and downstream regions (n=16).

Conclusion: SNPs in TLR signaling network genes show association with asthma and distinct clusters are associated with atopic and non-atopic asthma.

1867

Genetic variants in PCDH1, bronchial hyperresponsiveness and asthma subphenotypes in German children

Antoaneta Toncheva1,2, Kathrin Suttner1,2, Sven Michel1,2, Norman Klop2,3, Thomas Frischer1,2, Christian Vogelberg4, Andrea von Berg5, Albrecht Buft6, Andrea Heinemann7, Otto Laub8, Ernst Rietschel9, Burkhard Simma10, Thomas Frischer11, Jon Genuneit12, Erika von Mutius13, Michael Kachel11, 1Department of Pediatric Pneumology, Allergy and Neonatology, Hannover Medical School, Hannover, Germany; 2Research Unit of Molecular Epidemiology, Hannover Medical School, Hannover, Germany; 3Research Institute for the Prevention of Allergic Diseases, Children’s Hospital, University Children’s Hospital, Hannover, Germany; 4Department of Experimental Pneumology, Ruhr-University, Bochum, Germany; 5University Children’s Hospital, Albert Ludwigs University, Freiburg, Germany; 6Department of Pediatric Pneumology, Allergy and Neonatology, Hannover Medical School, Hannover, Germany; 7Children’s Department, University Teaching Hospital, Landeskrankenhaus Feldkirch, Austria; 8University Children’s Hospital, University Children’s Hospital, Vienna, Austria; 9Institute of Epidemiology and Medical Biometry, Ulm University, Ulm, Germany; 10University Children’s Hospital, Ludwig Maximilians University, Munich, Germany

Background: Recently, three genome wide association studies (GWAS) demonstrated FCER1A, the gene encoding the α-subunit of the high-affinity IgE receptor, to be a major susceptibility locus for total serum IgE. These data suggest that SNPs in FCER1A specifically influence IgE levels in asthma on top of genetic determinants of "basal" IgE levels also present in FCER1A as previously identified by GWAS. Thus, FCER1A variants and IgE-related mechanisms could be involved in specific asthma phenotypes.

These authors contributed equally.

Rationale: The pathophysiolog of asthma is largely unknown. RNA-Seq allows detailed biological characterization of the airways. We hypothesized that the airway transcriptome is different between atopic asthma and controls.

Aim: We investigated: a) the difference in transcriptomic profiles of whole bronchial biopsies between steroid-naïve asthma and controls; b) the feasibility to use RNA from airway smooth muscle (ASM) captured by laser microdissection (LCM) suitable for RNA-Seq

Methods: 4 biopsies per subject (asthma/control: aim n=4/n=5; aim b n=4/n=12) were incubated in RNAlater. Whole crossection or LCM-captured ASM was put down on to RNA-Seq sample.

Recently, three genome wide association studies (GWAS) demonstrated FCER1A, the gene encoding the α-subunit of the high-affinity IgE receptor, to be a major susceptibility locus for total serum IgE. The top association signal was in the vicinity of the cytokine gene cluster containing several known candidate asthma, was significantly associated with non-atopic asthma (OR=0.70, p=0.019) and non-atopic asthma (OR=0.69, p=0.009). The exonic SNP rs3797054 previously reported to be associated with BHR and asthma, was significantly associated with non-atopic asthma (OR=0.70, p=0.019) in our study. Significant associations with non-atopic asthma were observed also for rs11167761 (OR=1.54, p=0.021), rs3935792 (OR=1.32, p=0.039), rs2974704 (OR=0.43, p=0.009).

Conclusions: PCDH1 polymorphisms may specifically affect the development of non-atopic asthma in children.

232. New developments in the immunological diagnosis of tuberculosis and latent tuberculosis infection

1870
Different polyfunctional characteristics of RD1-specific CD4+ T-cells in active TB disease and LTBI
Elisa Perencevich1, Linda Petrone 1, Valentina Vaini1, Gilda Cuzz1, Francesco Nicola La Placa2, Delia Goletti1. 1Translational Research Unit, Department of Epidemiology and Preclinical Research, "L. Spallanzani" National Institute for Infectious Diseases-INMI, IRCCS, Rome, Italy; 2Clinical Department, "L. Spallanzani" National Institute for Infectious Diseases-INMI, IRCCS, Rome, Italy

Introduction: CD4+ T-cells and their cytokines are crucial for protection against M. tuberculosis (Mtb). Analyses of the cytokines coexpressed by polyfunctional T-cells can help in discriminating different tuberculosis (TB) stages.

Aims: To evaluate by flow cytometry the functional status and phenotype of Mtb-specific CD4+ T-cells in TB subjects at different stages.

Methods: We enrolled 25 TB patients before and after therapy (active/past TB) and 39 latent TB infection (LTBI), classified as recent/remote infection and LTBI post-prophylaxis. We evaluated the CD4+ intracellular cytokines production (IFNγ, TNFα, IL2) and memory/effector status after in vitro whole blood stimulation with RD1 antigens.

Results: Magnitude of CD4+ T-cells is higher in active TB compared to the other groups, although the differences are not significant. Double IFNγ/TNFα+ CD4+ T-cells are significantly higher in active TB than in past TB (p=0.03) and in LTBI (p=0.002), whereas triple IFNγ/TNFα/IL2+ are significantly associated to LTBI post-prophylaxis compared to active TB (p=0.02). The proportion of total IFNγ+ CD4+ T-cells increases whereas the proportion of total IL-2+ CD4+ T-cells decreases in active TB compared to LTBI (p=0.02). Effector memory CD4+ T-cells are significantly higher in active TB than in LTBI (p<0.01), whereas central memory cells are higher in LTBI than active TB (p=0.03).

Conclusions: Double IFNγ/TNFα+ CD4+ T-cells are associated to active TB disease whereas triple polyfunctional cells are associated to infection containment. These results may be helpful for better characterizing TB immune responses and generating tools for TB stages identification.

1871
Screening for latent TB using antigen-specific IP-10 response and the effect of treatment on IP-10 responses
Jose Dominguez1, Erika Belard2, Synne Semb2, Anne Marie Werlinrud5, Vicente Ausina1, Nuria Diez2, Irene Mialdea2, Neus Alber2, Martin Ernst2, Stefan Ehlers3, Steffen Stenger4, Jeroen Maertzdorf5, Giovanni Sotgiu6, Christoph Lange1, Christian Heuzmann1, Martin Ernst1, Stefan Ehlers3, Steffen Stenger4, Jeroen Maertzdorf5, Giovanni Sotgiu6, Christoph Lange1.

1Clinical Infectious Diseases, Research Center, Borstel, Germany; 2Division of Innate Immune Cell Analytics, Research Center, Borstel, Germany; 3Molecular Immunology Medicine, Research Center, Borstel, Germany; 4Institute for Medical Microbiology and Hygiene, University Hospital, Ulm, Germany; 5Department of Immunology, Max Planck Institute for Infection Biology, Berlin, Germany; 6Clinical Epidemiology and Medical Statistics Unit, Sassari University, Sassari, Italy

Background: Only a minority of individuals exposed to Mycobacterium tuberculosis (MTB) develops a positive Interferon-γ release assay (IGRA) from peripheral blood mononuclear cells (PBMC). Most contact persons do not develop a systemic immune response after inhalation of MTB aerosols. Pulmonary immune mechanisms preventing a systemic immune response in these subjects are incompletely understood.

Objective: To evaluate local and systemic immune responses in healthy MTB contacts.

Methods: Recruitment of MTB exposed health care workers (HCWs) and very close private house hold contacts (HHCs). Flow cytometry of bronchoalveolar lavage (BAL) cells and PBMC for immunophenotyping. IGRA testing of blood and BAL cells.

Results: 35 HCWs and 15 HHCs were recruited. Regulatory Tregs (CD4+CD25+CD127−) frequencies were increased in all contacts with latent MTB infection (PBMC IGRA positive; n=15) compared to contacts with a negative PBMC IGRA (n=20) with a median 2.12%, IQR 1.63-3.01 versus 0.68%, IQR 0.39-1.02, respectively (p<0.0001). No immunophenotypic differences were seen in PBMC between IGRA positive and IGRA negative subjects (9.6%; 5.9-10.1 versus 7.7%; 4.6-11.3; p=0.47). In 5 of the 25 IGRA negative subjects, the BAL IGRA gave a positive result, possibly indicating incipient tuberculosis.

Conclusion: In close MTB contacts with LTBI, Tregs are increased in BAL but not systemically when compared to contacts that remain IGRA negative. The functional role of Treg requires further investigation.

1873
Evaluation of non-tuberculous mycobacteria effect in the tuberculosis infection diagnosis: Interim analysis of a TBNET study

José Dominguez1, Irene Latore1, Maria Tosola1, Virginia Amanatidou1, Nuria Diez2, Irene Mulidea2, Neus Alber2, Mar Serra1, Jessica Diaz1, Alicia Lacoma1, Malu De Souza1, Juan Ruiz-Manzano1, Emper Giner2, Cristina Prat1, Amparo Escriva2, Vicente Ausina1, Nuria Diez2, Irene Mulidea2, Neus Alber2, Mar Serra1, Jessica Diaz1, Alicia Lacoma1, Malu De Souza1, Juan Ruiz-Manzano1, Emper Giner2, Cristina Prat1, Amparo Escriva2, Vicente Ausina1.

1Microbiology & Immunology, Max Planck Institute for Infection Biology, Berlin, Germany; 2Pediatrics & Epidemiology, Universidad de Valencia, Spain; 3Public Health Research Unit, University of Oxford, Oxford, United Kingdom; 4Institute Català de la Salut, Barcelona, Spain

The aim was to determine the role of previous non-tuberculous mycobacteria (NTM) sensitization in children as a factor of discordant results between tuberculin skin test (TST) and T-Spot.TB assay (Oxford Immunotec). We studied the presence of M. avium sensitized T cells in 87 non BCG vaccinated paediatric patients with discordant results: TST positive and T-Spot.TB negative. We also included as controls 11 individuals with a negative TST and a negative T-Spot.TB, and 8 patients with microbiologically confirmed NTM infection. Peripheral blood mononuclear cells were stimulated with M. avium sensitin. The presence of reactive T cells were determined by means of ELISPOT.

From the 87 children, in 31 cases (35.6%) we obtained a positive ELISPOT result after stimulation with M. avium sensitin, in 50 cases the result was negative (57.5%), and in the remaining 6 cases the test failure. The number of responder T cells after M. avium sensitin stimulation was significantly higher that the number of responder T cells to M. avium sensitin between the study and the control group were significant. In 4 cases a positive result was obtained between patients with confirmed NTM infection. Our results suggest that previous NTM sensitization in children induces false positive results in TST for diagnosing latent tuberculosis infection. The use of IFN-γ tests provide a more specific diagnostic of TB infection in childhood.

Conclusion: This is the first study to investigate the influence of prednisolone treatment on IP-10 responses; IP-10 was equally affected by prednisolone and the study was too small to determine the value of a combined biomarker approach. IP-10 can be stored on filter paper bypassing centrifugation, freezer and cold chain which gives an IP-10 based test an advantage to the current IFN-γ based test.
Evaluation of the QuantiFERON-TB Gold in tube cut-off for diagnosing test performance. In adults the QFT and IP-10 test performance was in line with Discussion: A main challenge in childhood TB management is the lack of good diagnostic tools. IP-10 is a novel marker for latent tuberculosis (TB), but very few studies have examined the use of IP-10 in childhood TB. Aims: To compare the performance of the QuantiFERON test (QFT) and IP-10 for the diagnosis of TB in Tanzanian children.

Methods: 207 TB suspected children (0-15 years) and 102 adults with confirmed TB were included. QFT tests were analyzed locally and IP-10 was measured using ELISA. The children were divided into three risk groups using clinical parameters, CXR, microscopy and culture: Confirmed/highly probable TB (probTB, n=33), possible TB (posTB, n=84) and Not TB (notTB, n=90).

Results: In children the positivity rate was low in all groups for both tests. Positivity rates were slightly higher in the group of children suspected of TB and lower in the notTB group.

Discussion: In children the two tests had poor performance with low positivity rate and high indeterminate rate; this was not explained by risk factors for poor test performance. In adults the QFT and IP-10 test performance was in line with other studies. Our findings could be explained by group heterogeneity and severity of illness.

233. Sleep disorders in internal medicine

P1877 Assessment of the prevalence of obstructive sleep apnea in patients with undiagnosed chronic cough

Mohamed Zidan, Hany Shaaaawy. Chest Diseases Department, Alexandria Faculty of Medicine, Alexandria, Egypt

Background: Recent reports have suggested an association between chronic cough and obstructive sleep apnea (OSA). There is also evidence that treatment of sleep apnea can improve chronic cough.

Objective: To assess the prevalence of OSA in patients with undiagnosed chronic cough and the effect of using CPAP therapy on the improvement of cough in those patients.

Methods: The present study included 100 non-smoker patients complaining of cough for more than 8 weeks without obvious diagnosis, after exclusion of any parenchymal lung or mediastinal diseases using chest X-ray, CT chest, pulmonary function testing, and methacholine challenge test to exclude cough variant asthma, patients undergone sleep polysomnography to screen for OSA and in whom proved to have the diagnosis, CPAP was tried for 2 weeks then follow up of the cough frequency and severity was done.

Results: The study included 100 patients, with 60% females and 40% males, the duration of cough in weeks was 18.16 ± 6.01 weeks, the most common cause of cough was gastroesophageal reflux disease (GERD) which was present in 70% of cases followed by upper airway cough syndrome (UACS) which was present in 50% of cases. OSA was present in 3% of patients in association with GERD in 15 patients and in association with UACS in 10 patients (10%). There was significant improvement of cough using CPAP treatment for 2 weeks (visual analogue scale (VAS) dropped from 8.4 ± 8.6 mm to 7.4 ± 5.1 mm after use of CPAP).

Conclusion: OSA should be ruled out in patients with undiagnosed chronic cough as it is a common finding. CPAP seems to be an effective tool in treating those patients.

P1878 Health, social and economic consequences of sleep disordered breathing: A controlled national study evaluating the societal effect on patients and their partners

Poul Jemec, Rikke Ibsen, Jakob Kjellberg, 1Danish Center for Sleep Medicine, Department of Clinical Neuropsychology, Center for Healthy Aging, Faculty of Health Sciences, University of Copenhagen, Glostrup Hospital, Glostrup, Denmark; 2Treas. (Treas. Aarhus, Denmark; 3Danish Institute for Health, DSL, Copenhagen, Denmark

The socioeconomic and indirect costs of obstructive sleep apnea (OSA) and obesity hypoventilation syndrome (OHS) on patients and their partners are incompletely described. Using data from the Danish National Patient Registry (1998-2010), 30278 OSA and 1562 OHS patients and their partners were identified. Four matched citizens based on age, gender and social status matched served as controls.
Direct costs were extracted from the Danish Ministry of Health, Danish Medicines Agency and National Health Security, and indirect costs from the Cohherent Social Statistics. 66.2%-63.4% of all OSA/OHS patients was observed versus 65.4%-65.6% of controls. OSA/OHS showed higher rates of health-related primary and secondary care, medication, unemployment, and other socioeconomic costs. The income level of OSA patients was lower. The annual mean excess total direct and indirect health-related cost for each patient was €2821 before and €5060 (p<0.001) after an OSA diagnosis and €10463 before and €15001 after an OHS diagnosis. 

Partner’s total health expenses and the public transfer income were higher, whereas the employment rate and income level were lower than the controls. The annual mean excess total cost for each partner was €2639 before diagnosis and €3058 (p=0.001) after the pts OSA diagnosis, €3523 before and €4066 (p<0.001) after the pts OHS diagnose. These effects were present 11 years prior to an OSA diagnosis in patients and partners, and increased with disease advancement. OSA and especially OHS are associated with a major health and social effect, affected employment and income level affecting the patients and partners.

P1879 Prevalence of sleep apnoea, sleepiness and behavioural/emotional disturbances in adults with Down’s syndrome in Scotland

Elizabeth Hill1, Donna Fairley1, Sarah Van Putten2, Sally-Anne Cooper3, John Forbes2, Linda Williams4, Renata Riba5. 1Department of Sleep Medicine, Royal Infirmary of Edinburgh, University of Edinburgh, United Kingdom; 2Down’s Syndrome Scotland, Down’s Syndrome Scotland, Edinburgh, United Kingdom; 3Department of Mental Health and Wellbeing, University of Glasgow, United Kingdom; 4Division of Community Health Sciences, University of Edinburgh, United Kingdom

Introduction: Adults with Down’s syndrome (DS) are predisposed to sleep apnoea (SA). Prevalence is, as yet, unknown.

Aims and objectives: To assess prevalence of SA, sleepiness and behavioural and emotional disturbances in adults with DS in Scotland.

Methods: A sleep questionnaire, including the pictorial Epworth Sleepiness Scale (pESS) and subscales of the Developmental Behaviour Checklist for Adults (DBC-A) was sent to 650 adults (age ≥18yrs) with DS. All respondents were offered sleep studies (Emblettta® Gold, Embla Systems LLC, Iceland) and OSA was diagnosed if their AHI was >3 events/h.

Results: Response rate was 42% (246 valid). 16 respondents had existing SA; 11 were treated.

Mean age was 31±11 yrs. BMI was 30±7 kg/m², higher in females (p=0.009). Mean pESS score was 7±5, with males sleepier (p=0.016). 176 respondents (28.5% of DS adults) were sleep apnoea suspects and 60 reported apnoea.

To date, 23 patients (15 males) have had sleep studies, 20 being valid. Mean age 26±9 yrs. Mean BMI was 30±7 kg/m²; females were heavier (p=0.001). Median AH (apnoeas/hypopnoeas per hour in bed) was 28.6 (IQR 14.8-48.2). Median ODI (≥4% desaturations per hour in bed) was 6.5 (IQR 2.1-30.9). Snorers scored higher on pESS (r=0.459, p=0.042) and DBC-A disruptive subscale (r=0.463, p=0.040). BMI correlated with the anxiety/antisocial subscale (r=0.606, p=0.005) and the degree of cirrhosis.

Conclusion: This is the first population survey of SA in DS adults. Females were less sleepy than males, despite being more obese. Snoring was associated with sleeplessness and disruptive behaviour. Heavier patients were more anxious. The study is ongoing.

P1880 Menstrual status in women and sleep-related outcomes

Francisco Gomez Reale1, Ferenc Macsali2, Cecile Svanes, Ernst Omenaas, Eva Lindberg, Karl Franklin, Brynulis Benediktsson, Thorarin Gislason, Anke Johannsen, Vivi Schlumsen, Chester Jansen, Mathias Holm, Rain Jogi. Gynecology and Obstetrics, Haukeland University Hospital, Bergen, Norway; Gynecology and Obstetrics, Haukeland University Hospital, Bergen, Norway; Occupational Medicine Haukeland University Hospital, Haukeland University Hospital, Bergen, Norway; Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway; Department of Medical Sciences, Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden; Dept of Surgery and Dept of Medicine, Umeå University, Umeå, Sweden; Dept of Respiratory Medicine and Sleep, University of Iceland, Reykjavik, Iceland; Dept of Respiratory Medicine and Sleep, University of Iceland, Reykjavik; Iceland Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway; Dept of Environmental and Occupational Medicine, Aarhus University, Aarhus, Denmark; Dept of Medical Sciences: Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden; Dept of Occupational and Environmental Medicine, Gothenburg University, Gothenburg, Sweden; Foundation Tartu University Clinics, Lung Clinic, Tartu, Estonia

Background: There is limited knowledge about how menstrual status may influence sleep related outcomes. We aimed to investigate whether irregular menstruation and menopause affect sleep related symptoms including insomnia and gastroesophageal reflux.

Methods: A population-based sample of 8588 women aged 25-55 years answering the respiratory Health In Northern Europe (RHINE) postal questionnaire were analyzed. Logistic regression models were adjusted for BMI, age, smoking history and socioeconomic status.

Results: Women reporting irregular menstruations had significantly more sleep-related symptoms (reflux after going to bed OR=1.67 [1.30–2.15], difficulty falling asleep (DHS) I 4.2 [1.1–1.80], difficulty maintaining sleep (DMS) I 4.43 [1.23–1.70], excessive daytime sleepiness (EDS) I 2.7 [1.06–1.45] and early morning awakening (EMA) I 1.45 [1.15–1.82]) than women menstruating regularly. Menopausal women had significantly higher risk of sleep-related symptoms (reflux after going to bed OR=1.43 [1.07–1.90], DHS 2.04 [1.58–2.63], DMS 1.87 [1.57–2.23], EDS 1.44 [1.21–1.73] and EMA 1.73 [1.38–2.17]) than premenopausal women.

Conclusions: Sleep quality among women was significantly related to menstrual status; women with irregular menstruations and menopausal women suffered from more sleep-related symptoms with insomnia and gastroesophageal reflux.

P1881 Sleep pattern changes in patients with liver cirrhosis

Ali Mabrouk1, Mohamed Noeb2, Nourane Arab3, Ibrahim Elmahallawy4, Rawad Elshenawy1. 1Chest Department. Menoufiya University, Shebin Elkom, Menoufeya, Egypt; 2Tropical Medicine Department, Menoufiya University, Shebin Elkom, Menoufeya, Egypt

Background: Liver cirrhosis is a major cause of mortality worldwide. One of the least studied complications of liver cirrhosis is the disturbed sleep pattern.

Methods: This study included two groups; the first group consisted of 30 patients confirmed as liver cirrhosis based on abdominal ultrasonography and liver biopsy and the second group consisted of 10 healthy subjects served as controls. Epworth sleepiness score (ESS) was calculated for every patient and all patients were subjected to complete overnight polysomnography to detect sleep disturbances among all participants.

Results: Our results showed that cirrhotic patients had ESS, AH (apnea hypopnea index) and OSA (obstructive sleep apnoea) significantly higher than the control group [16.4±2.6 vs 11.1±1.8, P < 0.001; 10.9±6.5 vs 2.4±1.6, P = 0.005 and 3.1±1.3 vs 1±1.9, P = 0.03 respectively]. The percentage of sleep efficiency was significantly lower in cirrhotic patients than the control group [61.5±7.9 vs 73.1±6.7 (P = 0.02)]. Also, the percentages of S1, S3, and REM sleep in relation to the total sleep time were significantly higher in the cirrhotic patients than the control group (P = 0.01, 0.02 and 0.06 respectively) while the percentage of S2 was significantly lower (P = 0.02). Cirrhotic patients of Child class C had ESS, AH and OSA significantly higher and sleep efficiency significantly lower than cirrhotic patients of classes A and B (P = 0.001 for all). Cirrhotic patients with tense ascites had ESS, AH and OSA significantly higher and sleep efficiency lower than patients with mild, moderate or no ascites (P = 0.001 for all).

Conclusion: This study revealed that cirrhotic patients had disturbed sleep pattern, correlating with the degree of cirrhosis.

P1882 In sleep apnea patients nonalcoholic fatty liver disease (NAFLD) is associated with the severity of intermittent hypoaxia and more severe endothelial dysfunction

Caroline Minville1, Marie-Noëlle Hillert2, Renaud Tamisier3, Patrick Levy4, Jean-Pierre Zarski2, Jean-Louis Pepin1. 1Pulmonary Department, Institut universitaire de Cardiologie et de Pneumologie, Quebec, Canada; 2Department of Endocrinology, Pôle Diagéne, Grenoble University Hospital, Grenoble Cedex 09, France; 3INSERM U 1042, HP2 Laboratory (Hypoxia: Pathophysiology) and Locomotion, Rehabilitation and Physiology Department, Joseph Fourier University and Grenoble University Hospital, Grenoble Cedex 09, France

Introduction: Nonalcoholic fatty liver disease (NAFLD) begins with the accumu-lation of triglycerides in the liver and elicits an inflammatory response that can progress to cardiovascular complications, cirrhosis and liver cancer. Intermittent hypoaxia is a potential contributing factor but NAFLD has not been investigated in an unselected obstructive sleep apnea (OSA) population. Beyond liver biopsy, there are non invasive validated tools allowing a screening of NAFLD in large populations.

Aims: (i) To use non-invasive blood tests (Steatotest®, NASHtest® and Fibrotest®) to evaluate steatosis, Nonalcoholic Steato hepatitis (NASH) and fibrosis in a large cohort of OSA (ii) To assess endothelial function by peripheral arterial tone (PAT).

Patients: 226 subjects referred for suspicion of OSA were included (men: 55%, median age: 56 years, mean BMI 34 kg/m²).

Results: 61.5% of OSA patients exhibited advanced steatosis. By multivariate analysis, triglycerides (p<0.001), insulin resistance (p<0.0004) and nocturnal cumulative time spent <90% of SaO2 (CT90) (p=0.01) were independent factors for liver steatosis. 38% of OSA displayed NASH (N1 or N2 with NASHtest®). CT90 was significantly associated with NASH (p=0.035) but this became non significant in multivariate analysis. Endothelial function was more impaired in OSA patients with advanced steatosis (p=0.04) and NASH (p=0.013).

Discussion/Conclusion: In a large unselected population of OSA, the severity of intermittent hypoaxia was independently associated with steatosis. Endothelial dysfunction was more severely impaired in OSA patients demonstrating NAFLD.
Noninvasive evaluation of hepatic steatosis and fibrosis in OSA patients at diagnosis
Maria Battocchi1, Mirko Olivo2, Roberto Virdone2, Alessandra Castrogiovanni1, Anna Maria Marotta1, Vincenzo Bellia1, Maria R. Bonsignore1. 1DeBiMS, Section of Pneumology, University of Palermo, Italy; 2Unit of Medicine II, Villa Sofia-Cervello Hospital, Palermo, Italy

In morbibly obese patients, non-alcoholic fatty liver disease (NAFLD) frequently occurs, with obstructive sleep apnea (OSA) compared to patients with out OSA, and OSA may play a role in the pathogenesis of steatohepatitis. We non-invasively assessed hepatic steatosis (ultrasound) and fibrosis (Fibroscan elastometry) in 20 consecutive patients (mean age±SD: 54±11 yr; BMI: 34±9.5 kg/m²; 4 women) with newly diagnosed OSA and no history or serologic evidence of hepatic disease. Inclusion criteria were: alcohol consumption <30 g/day, no use of statins or other lipid-lowering drugs. Patients underwent nocturnal 8-channel monitoring, venous blood sampling, hepatic function tests, fasting blood insulin and glucose, serum lipids, hepatic ultrasound evaluation, and Fibroscan elastometry. Severe OSA was found in most patients (mean AHI±SD: 52±22 event/h; mean nocturnal SaO2: 90±3.8%; Epworth Sleepiness Scale score: 12.7±4.9). Twelve patients showed the metabolic syndrome (MetS, NCEP-ATP III). Three patients showed increased serum ALT (>40 U/l); they were significantly younger (age 36.7±1.5 vs. 50.3±1.1 yr) and more obese (BMI 40.9±8.2 vs 33.6±5.0 kg/m²) than the rest of the sample. Hepatic steatosis (ws=19) was mild in 4 patients, moderate in 1, and severe in 14; all patients with increased ALT showed severe steatosis. Severe steatosis occurred in most patients with MetS and tended to be associated with severe OSA. Fibroscan elastometry (n=14) gave an average value of 6.2±2.3 (normal <5, fibrosis >12). Therefore, noninvasive evaluation revealed a trend for hepatic steatosis to be associated with severe OSA and obesity, while hepatic fibrosis appeared absent or mild in our patients.

Twelve patients showed the metabolic syndrome (MetS, NCEP-ATP III). Three patients showed increased serum ALT (>40 U/l); they were significantly younger (age 36.7±1.5 vs. 50.3±1.1 yr) and more obese (BMI 40.9±8.2 vs 33.6±5.0 kg/m²) than the rest of the sample. Hepatic steatosis (ws=19) was mild in 4 patients, moderate in 1, and severe in 14; all patients with increased ALT showed severe steatosis. Severe steatosis occurred in most patients with MetS and tended to be associated with severe OSA. Fibroscan elastometry (n=14) gave an average value of 6.2±2.3 (normal <5, fibrosis >12). Therefore, noninvasive evaluation revealed a trend for hepatic steatosis to be associated with severe OSA and obesity, while hepatic fibrosis appeared absent or mild in our patients.

P1884

P1885

Rationale: Cholesterol ester transfer protein (CETP) and apolipoprotein E (APOE) polymorphisms affect serum lipids in association studies. In a mouse model of obstructive sleep apnea (OSA) hypoxia inhibited clearance of triglyceride-rich lipoproteins. Since hypoxia might interfere with genetic background to affect lipid levels, we examined effects of interactions between CETP and APOE variants and hypoxia on serum lipids in OSA patients. Methods: 634 adult subjects evaluated for suspected OSA underwent overnight polysomnography. The association of HDL-cholesterol (HDLc), triglycerides (TG) and LDL-cholesterol (LDLc) with OSA-related hypoxia reflected by oxygen desaturation index (ODI) was examined and adjusted for relevant covariates. Findings: Patients were 69.1% male (age 51.1±11.2 years, age at apnoea-hypopnoea index (AHI) >10; mean AHI±SD: 60±8.2±2.1 event/night) and 30% female (age 40.9±12.9 years). In univariate analyses, HDLc was related to ODI and CETP polymorphism (R²=0.185, p=0.002) and no interaction between CETP variant and ODI was observed. In contrast, TG were related to ODI and APOE polymorphism in the univariate analyses (R²=0.284, p=0.001; R²=0.100, p=0.013) and also after adjustments (R²=0.382, p=0.016; R²=0.002). Significant interaction between APOE genotype and ODI was observed with respect to TG levels (p=0.010 for the interaction term APOE*ODI). Conclusion: Our findings support the role of CETP and APOE polymorphisms in atherogenic dyslipidaemia in OSA patients, and suggest the presence of an association between hypoxia and TG levels. Funding: APVV-0134-11, VEGA 1/0111/12, Slovakia.

Sleep duration and obesity in women – A 10 year prospective study
Izabela Tuleta1, Viktória Londa1, Zuzana Sopkova1, Viera Habalova2, Zuzana Dorkova1, Eva Slaba1, Martin Javorsky3, Ivan Tkac3, Ruzena Tkacova1. 1Department of Respiratory Medicine, Medical Faculty, P.J. Safarik University and L. Pasteur University Hospital, Kosice, Slovakia; 2Department of Medical Biology, Medical Faculty, P.J. Safarik University, Kosice, Slovakia; 3Department of Internal Medicine 4, Medical Faculty, P.J. Safarik University and L. Pasteur University Hospital, Kosice, Slovakia (Slovak Republic)

In our present study we sought to determine the influence of intermittent hypoxia-induced impairment of endothelial-dependent vasorelaxation. In cell culture experiments we observed relaxation was measured by an organ bath technique. In cell culture experiments we number of colony forming units in late outgrowth endothelial progenitor cells were analyzed by fluorescence and light microscopy, resp. Scal1/Btk positive cells in bone marrow were counted by flow cytometry. Results: Endothelial-dependent vasorelaxation was significantly decreased under hypoxia (73±4% vs. control: 45±4%); infliximab and L-glutathione normalized endothelial function (47±6% vs. 47±8%, resp.). The numbers of Dil-LDL/lectin+ cells and colony forming units were significantly higher in hypoxia compared to other groups. The percentage of scal1/Btk+ cells was increased in hypoxia vs. control and it was reduced in both drug groups (p<0.05).

Background: Obesity is highly related to obstructive sleep apnea syndrome. Research has shown that one potential cause of obesity may be short sleep duration. Aim: The aim was to assess how sleep duration and obesity is related over a 10 year period, in a population-based sample of women. Methods: A total of 5,003 non-pregnant women (response rate 80%) ≥30 years, answered a 10-year follow-up questionnaire. The questionnaire included questions on sleep duration, weight, height, waist circumference, smoking and lifestyle factors. Regression analysis was performed to analyze independent associations between sleep duration and measures of obesity. Results: In the whole population 31% (n=2,127) of the women had increased their weight by at least 5 kg. 37% (n=2,549) had a BMI≥30 kg/m² and 52% were centrally obese (waist circumference ≥88cm). Both short (<6h) (OR=1.38; 95%CI 1.06-1.80) and long sleep duration (>9h) (1.36; 1.32-2.62) showed to be risk factors for general obesity (BMI≥30 kg/m²) after controlling for confounders. When dividing the women by age both short and long sleep duration were risk factors in the younger age group (age at baseline <40 years). In women above age 40 years at baseline only long sleep duration remained as a risk factor for general obesity after controlling for confounders. In addition, short sleep duration was shown as a risk factor for central obesity after adjustments (1.46; 1.002-2.14) in younger women, whereas long sleep duration was a risk factor in women ≥40 years (1.86; 1.17-2.96).

Conclusion: Both short and long sleep duration had a greater risk of general obesity compared with normal sleepers (6-9h). Young short sleepers were also at risk for central obesity.
Obstructive sleep apnea and metabolic syndrome in thin patients: characteristics and comparison with patients with overweight and obesity. Raquel Dacal-Guinea1, Manuel Tubero Nova2, Maria Teresa Alves Pérez1,2, Adela Acuña Fernández1, Muri Luz Santalla Martínez1, Pedro Marcos Velázquez1,2,1 Palomary Medicine, Complejo Hospitalario Universitario de Ourense, Ourense (Galicia), Spain;2Investigation, Complexo Hospitalario Universitario de Ourense, Ourense (Galicia), Spain. Objective: We wanted to know the prevalence of obstructive sleep apnea (OSA) and metabolic syndrome (MS) in thin patients and their characteristics. We also wanted to know if there were differences with overweight and obese. Methods: We studied the patients that were referred to our sleep laboratory, from January to December 2009. OSA was diagnosed when apnea hypopnea index (AHI)was >5. MS was diagnosed according to the International Diabetes Federation criteria. The patients were distributed in 3 groups according to BMI: normal or thin (BMI<25), overweight (25-29.9) and obesity (>30). Results: We studied 475 patients: 7.6% thin, 36% overweight and 56.4% obese. In the thin’s group, most were women, snorers, non-smokers and don’t drink alcohol. We diagnosed of OSA 228 (48%): in thin 77.7%, in overweight 84.4% and in obese 91.4%. Thin patients with OSA were mostly mild OSA, in overweight mostly moderate and in obese severe. There were differences between OSA’s diagnosis and categorized BMI. We diagnosed of MS 288 (64.4%): in the thin’s group 33.3%, in overweight 45.94% and in obese 80.95%. We found more prevalence of MS (p<0.001) with BMI’s increase. There were differences between thin’s group and the others, thin patients were younger with minor neck and waist perimeter (p<0.021; p<0.001; p<0.001). OSA and MS prevalence in the thin’s group was 22% and in obese 70.52%. OSA in thin patients was related with gender (p=0.039 women had less risk) and age(p=0.045 OSA were older). Conclusions: OSA’s prevalence in thin patients is minor. Thin patients were most women, younger and without toxic habits. OSA and MS were not related in thin patients. EEG time-frequency maps during respiratory-related cortical activation in humans Anna Hudson1,2, Louis Laviolette2, Mathieu Raux2, Jacques Martinerie3, Thomas Similowski2, Louis Laviolette2, Mathieu Raux2, Jacques Martinerie3, Thomas Similowski4.1 Respiration Research Center and 2Laboratoire de Neurophysiologie Clinique et Experimentale, U1073 INBS, Paris, France; 3Neurosciences Cognitive et Imagere Cerebrale, CRICM, UPMC/CNRS UMR7225/INSERM UMR9753, Paris, France. Introduction: Event-locked averaging of EEG recordings has demonstrated that precerebral potentials precede inspiration during respiratory-related cortical activation. However, this procedure relies on assumptions of on-going brain activity and is highly susceptible to low frequency artifacts. Frequency analysis is an alternative method of assessing EEG activity, but it is not known if this method can identify respiratory-related cortical activation. Aim: The aim of this study was to compare time-frequency maps during different respiratory “tasks”. Methods: Healthy subjects (n=6) performed 3 conditions: quiet breathing (QB), sleep with periodic breathing (WB) and sleep with periodic breathing and trained to control breathing (Quantified). The EEGs were recorded from 32 scalp channels using an active electrode system (g.USBamp, g.tec). The signals were amplified using a 12-bit A/D converter and recorded and processed with a IRISPC running the g.iga analysis software. Results: Results were differences in cortical activation (alpha band, 8-13Hz) prior to the onset of inspiratory flow on Fz, C3 and C4 between QB and WB (p<0.1) and on C4 between QB and ITL (p<0.1). Conclusions: Time-frequency maps varied between different respiratory conditions which suggests they can discriminate differences in cortical activation related to the control of respiration. Furthermore, we can identify the specific frequency components, in addition to time-locked changes in EEG. Analysis of EEG activity above 5Hz may lessen the effect of artifacts on physiological interpretation and increase the feasibility of EEG recordings to assess cortical activation in the clinical setting. Manipulating cerebral blood flow affects central sleep apnea at high altitude. Krištof Burgisser1,2,3, Samuel Lucas1,2,4,5,6, Thomas Similowski2,3,1, Raquel Rodrigues2, Margarida Aquiri3, Dina Fernandes3, Susana Moreira1, Claro Ines1, Valenza Joao1, Bugalho António1, Luis Moita2,1Pneumology, University Hospital de Santa Maria, Lisbon, Portugal;2Cell Biology of the Immune System Unit, Institute of Molecular Medicine, Lisbon, Portugal;3Pneumology, Hospital de Loures, Lisbon, Portugal. Aim: To measure the effects of altering cerebral blood flow (CBF) on central sleep apnea (CSA) at high altitude. Methods: 12 normal volunteers aged 30±10 years were studied 6-9 days after arrival at 5050 meters. After control measurements they received ivi Acetazolamide (Acet) 10mg/kg or oral Indomethacin (Indo) 100mg with placebo controls in a randomized order on separate nights. Ventilatory Responses (VRs), ABGs, Apnea-Hypopnea Index (AHI) during the first 3 hours of sleep by polysomnography (PSG) and CBF by transcranial Doppler were recorded. AHI was also measured upon arrival and after 12-15 days to control for acclimatization. Results: CBF rose by 28% with Acet and fell by 23% with Indo. PaCO2 rose from 38.4±31.6±3 mm Hg with Acet (p<0.001), whereas, ABGs were unchanged with Indo. VRs were unchanged with Acet but Indo increased Hypercapnic VR by 43% (p<0.05). AHI was halved by Acet (89 to 47/hr, (p<0.01), but increased 25% with Indo (89 to 112/hr, p<0.05). Conclusions: Indomethacin reduced CBF and increased Hypercapnic VR and CSA during the first 3 hours of sleep. Whereas Acetzolamide increased CBF but had no effect on VRs yet reduced CSA severity. These results highlight the link between CBF and CSA at high altitude. Supported by: Peninsula Sleep Laboratory, University of Otago and EVK2CNR. Sleepiness influences cytotoxic lymphocytes independent of respiratory events Richard Staig1, Raquel Rodrigues2, Margarida Aquiri3, Dina Fernandes3, Susana Moreira1, Claro Ines1, Valenza Joao1, Bugalho António1, Luis Moita2. 1Pneumology, University Hospital de Santa Maria, Lisbon, Portugal;2Cell Biology of the Immune System Unit, Institute of Molecular Medicine, Lisbon, Portugal;3Pneumology, Hospital de Loures, Lisbon, Portugal. Aim: Obstructive sleep apnoeas have been shown to stimulate the immune system. However, the relevance of sleepiness is less clear. We investigated the influence of objective sleepiness (OS) on the expression of the cytotoxic proteins granzyme B (GrB) and perforin (P) in peripheral blood lymphocytes (PBL). Methods: 43 participants performed polysomnography followed by the pupillary sleepiness test (PST®). PBL were stained for CD8, gamma delta cells (gd cells), natural killer cells (NK), P and GrB and analysed by flow cytometry. Results are shown as means ± SEM. Results: 29 proband were not sleep (NS) (pupilary unrest index=0; 6.8). 14 patients were sleep (PUI= 9.8). Results were not statistically significantly different for: age, BMI, AHI, ODI or oxygen saturation < 90%. In NS we found a higher percentage of P in CD8+ 36,3±3.0 vs. 27.3±4.4 and gd cells 39,1±3.5 vs. 27.3±6.5, but results failed to reach statistical significance (p=0.07 and 0.06, respectively). GrB are listed below. Percentage of GrB+ cells % of GrB+ cells CD8GrB/CD8 gdGrB/gd NKGb/NK PUI< 0.05: 24.8 (1.8) 46.3 (14.9) 42.3 (16) 80.1 (3.3) PUI> 9.8: 19.9 (1.3) 35.5 (14.9) 23.4 (13.9) 82.2 (1.8) CdB cells (3,5). Total percentage of GrB+ cells (p =0.004) and GrB+ gd cells (p<0.001) were significantly lower in sleepy subjects. Discussion: In these preliminary results we show that OS influences cytotoxic PBL independently of the respiratory events. The PST uses the balance between sympathetic and vagical activity on the pupil. These results could indicate that GrB and P are increased maps only in presence of sympathetic activation. Supported by the Fundação para a Ciência e a Tecnologia: POCI/09/9/07 Clinical significance of sleep-disordered breathing (SDB) and obstructive sleep apnea (OSA) in patient with pituitary adenomas Ginevra Del Giudice1, Emanuela Carpentieri1, Assunta Micco1, Itala Ventea1, Antonio Russo1, Angelio Romano1, Gaetano Beatrice1, Giuseppe Catapano1, Mario Del Donno1,2, UOC Pneumologia, G. Rummo, Benevento, Italy;1UOC Medicina Interna, G. Rummo, Benevento, Italy;2UOC Neurochirurgia, G. Rummo, Benevento, Italy. A pituitary adenoma(PA) causes different symptoms, depending on its size and location and on the type of hormone that is being made. SDB and OSA are atypical presentation of PA secreting ACTH and GH. However, the non-secreting adenomas may cause alterations of sleep architecture. The aim of the study was to evaluate clinical and sleep characteristics in a group of patients with functioning (PA) and non-functioning pituitary adenomas (NFP). We recruited 6 patients with SDB and PA. Physical and anthropometric examination were performed ES and BMQ modified was used to diagnose sleep disorders symptoms. SDB were studied by means of overnight polysomnographic study in our sleep lab. The scoring criteria were according to event definition by AASM. SDB were documented in 6 pts (3 M, mean age 50.8 yrs and mean BMI 35), with PA. Three NFP, two patients with FHA and one with acromegaly, were diagnosed after neurosurgery resection. ESS mean reported were 10, mean Sao2 was 93.6% and AH index were 6.7±4.1, with a prevalence of obstructive events. ODI mean 7.8±4.2. REM sleep duration were 15.4±6.8% of total sleep time and SWS mean was 22.4±11.1%. In acromegaly patient, was found a worsening of sleep
parameters compared to other patients (AHI 18.4, AHI supine 29.6; ODI 12.7), successfully treated with CPAP therapy.SDB in patients with PA and NPA are underdiagnosed. Although the patients with NPA and Cushing’s syndrome were affected by a mild OSA, they reported sleepiness symptoms Expert consultation and a multidisciplinary approach to sleep disorders are needed in patients with PA.

Reactive and proactive control of cognitive functions in obstructive sleep apnea

Baykal Tulek1, Nart Bedin Atayal2, Fikret Kanat1, Mecit Saerdem1. 1Pulmonary Diseases, Selcuk University, Selcuklu Faculty of Medicine, Konya, Turkey; 2Dilek Sahanci DK, Selcuk University, Konya, Turkey

Neuropsychological studies dissociated two types of cognitive control functions: reactive control and proactive control (Braver, T. et al. Trends in Cognitive Sciences 2012; 16: 106-113). Although, obstructive sleep apnea (OSA) is associated with cognitive decrement, there is an ongoing debate on whether these include detrimental performance in conflict tasks (Verstraeten, E. et al. Sleep. 2004; 15,27(4):685-93.). In this study, we investigated reactive and proactive control of cognitive functions in OSA patients. In this ongoing study data from 21 participants were evaluated. Participants grouped according to Apnea-Hypopnea Index (AHI) in to two, such that Group A’s AHI>30 (n=13), and Group B’s AHI≤15 (n=8). They were participated in Flanker and Simon to measure reactive control and Stroop to measure proactive control. Stimulus presentation and data collection was done automatically on a standard monitor and PC. In Group A patients (with severe OSA), reactive control observed with Flanker task was significantly different compared to performance of Group B participants (normal and patients with mild OSA). However, other test did not revealed any significant difference.

### Comparison of Cognitive Control Performance In Groups

<table>

In conclusion, these preliminary results suggested that while proactive control is intact in severe OSA patients, reactive control declines when control is triggered by stimulus-stimulus conflict.

Overactive bladder in women with sleep apnea-hypopnea syndrome

Nuria Grau1, Elisabet Del Amo2, Carles Sanjuás1, Cristina Estirado1, Antonia Ruiz1, Encarna Guardiola1, Miquel Félez1, Ramon Carreras2, Joaquim Gea1. 1Respiratory Department, Hospital del Mar. Parc de Salut Mar, Barcelona, Spain; 2Gynecology Department, Hospital del Mar. Parc de Salut Mar, Barcelona, Spain

Introduction: Overactive Bladder Syndrome (OAB) is characterized by urgency to urinate, which may be accompanied by increased frequency, nocturia and incontinence. Although nocturia is a common symptom in the setting of sleep apnea-hypopnea syndrome (OSA), the association between OAB and OSA is not well known. The aim of this study was to analyze the presence of OAB in female patients diagnosed from OSA.

### Methods: Seventy-two consecutive female patients referred for polysomnography (PSG) for suspected OSA were included. All patients fulfilled the spanish validated version of the “Bladder Control Self-Assessment Questionnaire” (B-SAQ). The B-SAQ consists of 2 subscales: “symptoms”, consisting of 4 items (urgency, frequency, nocturia and incontinence) and “discomfort” in which it is established the degree of distress associated with symptoms from 0 to 3.

### Results: The scores of “Symptoms” and “Discomfort” were significantly higher in patients who were diagnosed OSA.

</tbody>
</table>

*Median (interquartile range).

Patients with OSA scored significantly higher for symptoms, urgency, nocturia and incontinence and 4 items of “Discomfort”. The AHI was significantly correlated with the score of “Symptoms” (r = 0.207, p = 0.013) and that of “Discomfort” (r = 0.258, p = 0.03). There was no significant correlation between the BMI and the B-SAQ.

### Conclusions: Obstructive sleep apnea is associated with overactive bladder syndrome in women. The Bladder Control Self-Assessment Questionnaire is a valid instrument to assess overactive bladder in patients with OSA.

Is a predominant clinical COPD phenotype predict different outcome responses to pulmonary rehabilitation?

Héria Pessi, Giulia Innocenti Bruni, Emanuele Pulvipo, Barbara Lanini, Isabella Romagnoli, Claudia Coi, Barbara Binazzi, Loredana Stendardi, Francesco Gigliotti. Section of Respiratory Rehabilitation, Fondazione Don Gnocchi IRCCS, Firenze, Italy

Introduction: A new multivariate model, using HRCT as a criterion standard, based on variables collected at rest has been proposed to identify two or more relevant phenotypes of COPD, emphysema (E) and chronic bronchitis (B) (Pisatoles et al. Respir Med 2008;102:367-76). The aim of the study is to verify whether two distinct COPD groups whose characteristics correspond to either an airway obstructive or a parenchymal destructive COPD phenotype exhibit different outcome responses to a pulmonary rehabilitation program.

### Methods: In 55 BC and 38 E patients we assessed the outcome responses to a pulmonary rehabilitation program (PRP): chronic exerctoral dyspnea (MRC, BDI and TDI), leg and arm ergometry, and exercise dyspnea by Borg scale during 6mWT. Four cluster descriptors of the language of dyspnea (work/effort, inspiratory difficulty, shallow breathing and expiratory difficulty) allowed the qualitative assessment of the symptom.

### Results: At baseline, age, BMI, FEV1 and DLco were lower, while FRC and TLC were higher in E. 6mWT, Borg, SGRQ and ergometry were similar in E and BC. Frequency of response for inspiratory difficulty cluster during 6mWT was significantly greater in E than in BC. PRP significantly improved most outcomes, similarly in the two groups, but neither in E nor in BC did significantly modify the frequency of response of cluster descriptors.

### Conclusion: PRP allowed both COPD groups to improve similarly health status and exercise tolerance and to modify the intensity but not necessarily the quality of dyspnea.

Efficacy of pulmonary rehabilitation in patients with interstitial lung disease

Akihito Nakazawa1, Eri Hagiwara1, Ou Yamaguchi2, Ryo Ogata3, Takeshi Shimohara4, Yusuake Matsumoto5, Kaori Tsutani6, Takuma Sasaki2, Takashi Ogura1. 1Department of Respiratory Medicine, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan; 2Department of Rehabilitation Medicine, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan

Objectives: There are few reports describing the efficacy of pulmonary rehabilitation (PR) in patients with interstitial lung disease (ILD). We studied whether PR could improve functional status in a group of patients with ILD.

### Methods: PR was carried out for 12 weeks for clinically stable outpatients of our institute. Fifteen patients with ILD were enrolled in this prospective study. Six-minute walking test (6MWT), lung function test and evaluation of health-related quality of life including SGRQ were performed before and after the program. Patients were classified as having a relevant phenotype of COPD, emphysema (E) and chronic bronchitis (BC) (Pisatoles et al. Respir Med 2008;102:367-76). Effect of interval training on the BODE index, SF-36, EuroQol and St-George’s Respiratory Questionnaires scores in COPD patients across GOLD stages I-IV

Vassilis Andrianopoulos1, Stavroula Sptiosi2, Alexandra Chatzi2,
Nikolaos Chinkiamis1, Joannis Nasi1, Theodora Vasilogianakopoulou1, Anastasia Panagopoulou1, Emmanouil Kokori1, Georgia Koutsofim1, Nikolaos Koulouri1, Ioannis Vagizas1, 2
1Department of Respiratory Medicine, Pulmonary Rehabilitation Unit, National and Kapodistrian University, Athens, Greece; 2Department of Physical Education and Sport Sciences, National and Kapodistrian University, Athens, Greece; 3Department of Physiotherapy, Technological Educational Institute, Lamia, Greece

In COPD patients, functional capacity, health-related quality of life and health status are respectively assessed by the clinical tools of BODE index, SF-36, Euro-Qol and St-George’s Respiratory Questionnaires. Interval training as a therapeutic modality elicits substantial physiological effects; however, the impact of interval training to those across the whole spectrum of COPD severity still remains unknown.

Objective: To investigate whether beneficial effect of interval training is reflected to BODE and the 3 Questionnaires in GOLD stage III-V.

Methods: In a large cohort of 106 COPD patients, rehabilitative intervention and control groups consisted of 71 and 35 patients, respectively. Exercise training involved 30min cycling by alternating 30s exercise intervals at 100%Wpeak with 30s rest and large-muscle group resistance training for a period of 10 weeks, 3-times/week.

Results: Interval training improved significantly the clinical condition of patients across GOLD stages II (BODE: 1.9 ± 1.1, SF-36: 89.4 ± 44.9, SF-64: 43.7 vs 49.3, Euro-Qol-VAS: 54.1 ± 70.8, St-Gos’s: 55.0 ± 39.9), III (BODE: 3.8 ± 2.5, SF-64: 38.5 ± 43.0, SF-64: 40.1 ± 47.4, Euro-Qol-VAS: 64.8 ± 65.5, St-Gos’s: 52.6 ± 40.4), IV (BODE: 5.7 ± 4.1, SF-64: 33.1 ± 40.9, SF-64: 33.2 ± 46.3, Euro-Qol-VAS: 40.4 ± 58.2, St-Gos’s: 60.1 ± 46.2) (P < 0.05). Nom significant changes were shown for patients in GOLD stage I and the control group.

Conclusions: Beneficial effects of interval training in functional capacity, health-related quality of life and physical status are reflected by improved clinical condition of patients in GOLD stages II-IV.

P1989

Pulmonary rehabilitation in patients with sarcoidosis – First results of the prospective German multi-center study: ProKaaSaRe

Konrad Schell1, Renate Braun2, Bernd Quaider3, Wilhelm Buchbinder4, Heike Huhns-Schmitter1, Ulf Stumper7, Ulrich Thompson9, Jochen van der Meyden1, Anika Großbennig7, Tanja Schleif9, Heidrun Linger1, 7, 9, 10, a, 2
1Fachbereich Pneumologie, Klinik Bad Reichenhall, Germany; 2Pneumologie, Klinik Bad Reichenhall, Germany; 3Pneumologie, Klinik Bad Reichenhall, Germany; 4Pneumologie, Fachklinik St. Georg, Hohenchwarz, Germany; 5Pneumologie, Osterrichtsklinik Schömberg-Holm, Ostschönbach Schömberg, Germany; 6Pneumologie, MedClin Albert Schweitzer Klinik, Königswinter, Germany; 7Pneumologie, MEDDAN Klinik Heiligendamm, Heiligendamm, Germany; 8Pneumologie, Klinik Wehrawald, Todtnoos, Germany; 9Institut für Biometrie, Medizinische Hochschule Hannover, Hannover, Germany; 10Institut für Allgemeinmedizin, Medizinische Hochschule Hannover, Hannover, Germany

Background: There are only sparse data concerning rehabilitation in sarcoidosis. Therefore we conducted a prospective multi-center study to investigate whether rehabilitation leads to objective and subjective health changes.

Methods: Clinical tests and questionnaires were performed at the beginning (T0) and the end (T1) of a 3-week in-hose rehabilitation program, followed by questionnaires 3, 6, and 12 month after discharge. The components of the rehab were physical training, breathing exercises, patient education and psychosocial support.

Results: The results of the short-term effects on the first 200 patients are displayed: mean-age 49.3 ± 9.7 years, 56.2% male, 48.7% under systemic corticosteroids.

Discussion: The significantly and clinically meaningful short term results of relevant outcomes like exercise capacity (6MWD), quality of life (SGRO), SF-36, fatigue (FAS) and dyspnea (MRC) suggest a high impact of rehabilitation on health related outcomes in sarcoidosis.

Sponsored by Sarkoidose Stiftung and Deutsche Lungengesellschaft e.V.

P1989

Effect of pulmonary rehabilitation (PR) influence patient’s perceptions of disease?

Samantha Harrison1, 2, Noelle Robertson3, Johannu Williams1, Mick Steiner1, Sally Smith1, 4, 5
1NIHR CLAHRC-LNR, Pulmonary Rehabilitation Research Group, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; 2School of Psychology, University of Leicester, United Kingdom; 3Health and Life Sciences, Coventry University, Coventry, United Kingdom

Background: PR leads to behaviour modification. The common sense model assumes that perceptions of disease are influenced by increased knowledge, skill acquisition and goal attainment. The aim was to test whether PR influenced patient’s perceptions of their disease.

Methods: This is a prospective cohort study of patients with COPD who completed the illness perceptions questionnaires revised (IPQ-R) pre and post PR. The IPQ-R was completed by 51 patients [mean(SD) age 70.0 (9.0) years, FEV1: 1.4 (0.7) 1.28 male]. Following PR patients adopt a less chronic view of their disease and perceived fewer consequences. Treatment control and coherence are reduced. Emotional impact of the disease is minimised by PR.

Conclusions: PR induces feelings of hope and increases patient’s expectations. Prior to PR patients are unaware of their limitations in knowledge. The clinical benefits of PR reduce perceived consequences of the disease and as a result emotional impact is minimised.

P1990

Prescribing exercise in advanced COPD: Training smart, not just hard!

Peter Klein1, 2, Anton Van Kempen3, Monique Legramain1, Rik Gosselink3
1Department of Pulmonology, Merev Treatment Centers, Asthma Center Heideheuwel, Hilversum, Netherlands; 2Department of Pulmonology, Academic Medical Center, Amsterdam, Netherlands; 3Respiratory Rehabilitation, Katholieke Universiteit Leuven, Belgium; 4Julius Center for Health Sciences and Primary Care, University Medical Center, Utrecht, Netherlands

The high-intensity paradigm is prevailing in COPD training. Individualising training variables is considered the gold standard. Nonlinear periodic exercise (NLE) uses variation of the training variables (mode of exercise, work phase, rest phase, intensity, number of repetitions) to individualize training. The aim of this study was to compare the effects of NLE with traditional endurance and progressive resistance training (EPR) on cycle endurance time (CWT) at 75%Wmax.

Methods: Patients with severe COPD (N=110, FEV1%pred, 61 yrs) were stratified on normal or depleted fat-free mass index (depleted FFMi; male FFMi <15 kg/FMMi; female FFMi <16 kg/FMMi). Six patients were then randomly assigned to NLE or EPR (3-times/week for 12 weeks). Difference in change was tested with intention-to-treat analysis using linear mixed-effects modeling. Trial number NTR 1045.

Results: NLE showed more improvement in cycle endurance at 12 weeks: NLE (N=53, ∆56th = 143% compared to EPR (N=57, ∆26δ= +66%), difference in change (30%; 95% CI 162-425) and NLE (N=22, ∆528 = +123%) compared to EPR (N=21, ∆198 = +46%), difference in change (32%; 95%CI: 182-477). During the training, patients in the NLE groups had significantly more repetitions, lower % 1-repetition maximum load, shorter cycle time and lower Borg dyspnea, fatigue and exertion scores than the patients in EPR groups.

Conclusion: Nonlinear periodic exercise results in >5min more improvement in cycle endurance than traditional endurance and resistance training in patients with advanced COPD and depleted or normal FFM. Applying principles of nonlinear exercise training in athletes to the COPD population is feasible and worthwhile.

P1901
Exercise induced reduction in dynamic hyperinflation after interval training with oxygen breathing
James Varga, Bettina Pogany, Eva Mathene Koteles, Attila Somlay. Department of Pulmonology, University of Szeget, Dezse-Szeget, Hungary

Background: Exercise training reduces exercise induce dynamic hyperinflation (DH) at submaximal exercise (80% of peak work rate) in patients with COPD. Oxygen has dose-dependent effect (maximal at FO2o.3) on operating lung volumes in COPD.

Methods: 10 COPD patients with moderate obstruction (FEV1: 53±12%pred, age: 63±10 yrs, BMI: 26±4 kg/m2) performed an incremental exercise test to maximal exercise tolerance, and two constant work rate test (CWR, 80% of peak work rate) with inspiratory capacity (IC) maneuver for DH in every 2 minutes before and after training. Patients performed interval training (1 minute 40% and 1 minute 80% of peak work rate) 3 times a week for 8 weeks breathing oxygen (5 patients 3L/min., group O) or compressed air (5 patients 3 L/min., group C) during training.

Results: The initial peak work rate did not differ significantly between the groups (O: 94±18 vs. C: 86±19 W). Endurance improved in both group (O: 425±110 vs. 630±122, C: 370±120 vs. 555±126 sec, p<0.05), oxygen uptake increased in group O (VO2 O:1.20±0.12 vs. 1.36±0.10 L/min, p<0.05) after training. In group O, there was a tendency to reduction in DH after training (IC: 1.2±0.62 vs. 2.44±0.90; 2: 2.25±0.73 vs. 2.37±0.94; 2: 3.26±0.96 vs. 2.55±0.97; 2: 4.24±1.00 vs. 2.36±1.01; 2: 5.24±1.00 vs. 2.36±1.01; 2: 6.23±0.97 vs. 2.33±1.00; 7: 2.36±0.73 vs. 2.00±1.02 L). IC did not change in group C.

Conclusion: The pilot study revealed less hyperinflation tendency and improved oxygen uptake in group O, which might refer to better physiologic training effect.

P1902
Pulmonary rehabilitation in advanced lung cancer patients during chemotherapy – Preliminary report
Dariusz Jastrzebski, Gregorz Hydzik, Malgorzata Maksymiak, Anna Poczatek, Sabina Kostzer, Dariusz Zura, Jerzy Kozielewski. Dept Lung Diseases and Tuberculosis, Medical University of Silesia, Zabrze, Silesia, Poland

Objectives: The aim of this study was to investigate the utility of a pulmonary rehabilitation (PR) program on mobility, pulmonary function, dyspnea and quality of life in patients with advanced lung cancer during chemotherapy.

Methods: This study included patients with newly diagnosed advanced lung cancer. Study group consisted of 12 pts with advanced non-small cell lung cancer and 5 pts with small cell lung cancer. Pulmonary function (FVC, FEV1), mobility (6 MWT), perceived of dyspnea (MRC, O2CD, BDI) and quality of life (SF-36, EORTC) were measured before and after the intervention program was based on Nordic Walking exercise training and respiratory muscle training. Sessions occurred twice daily, each lasting approximately 60 minutes, 5 days/week for 8 weeks breathing oxygen (5 patients 3L/min., group O) or compressed air (5 patients 3 L/min., group C) during training.

Results: Intention-to-treat analysis indicated that 6MWD distance increased 55m (95% CI, 18.57-185, p=0.012) with no changes in pulmonary function tests (FVC, FEV1). Perceived of dyspnea was improved in Oxygen Cost Diagram (2.4 vs. 1.3, p=0.012), BDI/BD (1.7 vs. 2.4, p=0.008) and overall score BDI (4.4 vs. 6.4, p=0.006). General quality of life questionnaire showed improvement in Role-Physical, Bodily-Pain, Social-Functioning and Physical Cumulative Score of SF-36 without statistical significance. Lung cancer questionnaire showed significantly improvement (p<0.05) in perception of dyspnea, exercise tolerance, quality of life improvement in social functioning, everyday living and decrease of consumption analgesic drugs.

Conclusion: Pulmonary rehabilitation in advanced lung cancer patients during chemotherapy is a beneficial intervention to improvement in their lung cancer symptoms and mobility.

P1903
Is pulmonary rehabilitation (PR) an effective therapy in lymphangioleiomyomatosis (LAM)?
Bernd Szczepanski, Sandra Winterkamp, Martina Boensch, Inga Heinzelmann, Klaus Kemkoe Pneumology, Schoen Klinikum Berchtesgadener Land, Schoenau, Bavaria, Germany

Background: LAM is an orphan lung disease affecting young women. There is only remaining therapeutic option. The role of PR is not yet defined.

Methods: In a prospective open clinical trial data of 22 LAM patients prior to LTs (LAM-P) (45±9.9 yrs, FEV1=81±4.17%pred, diffusion capacity=35.8±11.3%, pCO2=49±1.9 mmHg, LITOT tw19) and 24 LAM patients after LTs (LAM-T) (42±8.10y., FEV1=65±7.19%pred) were evaluated. All patients underwent a specialized multidisciplinary inpatient PR for 45±9.6 (LAM-P) and 35±4.18 (LAM-T) days.

Results: We found significant and clinically relevant changes for both PR approaches.

For the LAM-P group we saw a significant improvement in 6-min walking distance (MWWD) (59.0±5.0m, p<0.001). In LAM-T patients MWWD increased significantly by 103±8.5m (p<0.001). Thus the benefit of post LTx-PR in LAM-patients is comparable to the results of lung transplant patients with other underlying disease. Health-related quality of life (HRQL) (SF36) improved significantly for the mental summary score in LAM-Tx.

Lung function parameters did not change for LAM-P but FEV1 improved significantly for LAM-Tx patients.

Conclusion: PR in LAM patients before and after LTx is a safe therapeutic approach that leads to significant increases of exercise capacity and tends to improve HRQL. In view of a progressive disease with only a few therapeutic options rehabilitation should be considered early in the treatment of LAM, especially when LTx is necessary.

P1904
Effect of pulmonary rehabilitation on cardiac output responses during exercise in COPD
Ioannis Nasis1, Nikolaos Koulovoun2, Maroula Vasiopoulou1, Sotaurou Spirtis1, Eleni Koriantou2, Zafiris Louvaris1, Vasilis Andrianopoulos1, Nikoletta Rovina, Georgios Kaltakas2, Ioannis Vogiatzis1,2. Department of Physical Education and Sport Sciences, National and Kapodistrian University, Athens, Greece; 1st Department of Respiratory Medicine, Pulmonary Rehabilitation Unit, National and Kapodistrian University, Athens, Greece; 3rd Department of Respiratory Medicine, Pulmonary Rehabilitation Unit, National and Kapodistrian University, Athens, Greece; 1st Department of Respiratory Medicine, Pulmonary Rehabilitation Unit, National and Kapodistrian University, Athens, Greece; Physiology Department, Technological Educational Institute, Lamia, Greece

Introduction: In patients with COPD pulmonary rehabilitation (PR) induces true physiological effects reflected by reduced ventilatory requirement and improved peripheral muscle function. The effect of PR on central hemodynamic responses during exercise remains largely unknown.

Aim: To examine the impact of PR on cardiac output (Q) responses during incremental (IE) and constant-load exercise (CLE).

Method: 60 COPD patients (GOLD stages II- IV) were studied (including 15 controls). PR consisted of interval cycling exercise 3 days/week for 10 weeks, with 30’s work periods/30’s rest periods for 30 minutes and intensity at 100% of peak work capacity (Wpeak). Q was measured by bio-impedance (Physioflow PF-07) during IE and CLE at 75% Wpeak for 6-min during exercise and in recovery, prior to and following PR.

Results: At Wpeak there was an increase in Q after PR (from 10.1±1.0 to 12.4±0.6 L/min, p=0.001) due to increased SV (from 90.3±1.2 to 105.1±4.2 ml/m2, p=0.003). Post-rehabilitation at an identical work rate during IE, Q did not differ compared to pre-rehabilitation; however SV was higher (pre: 90±3.3; post: 95±3.3 ml/min) and HR lower (pre: 113±3; post: 106±3.3 beats/min, p=0.008). Post-rehabilitation during CLE there were significant reductions in Q in mean response time (MRT) at the onset and offset of exercise (pre: 79.8±4; post: 66.9±4.5 sec, p=0.001) and (pre: 79±1.4±3, post: 66±1.4±2.4 sec, p=0.001), respectively.

Conclusion: Pulmonary rehabilitation induces an improvement in central hemodynamic function to incremental and constant-load exercise in patients with COPD across GOLD stages II to IV.

P1905
A multi-disciplinary integrated palliative care approach for patients with advanced COPD – A review of the breathing space clinic
Matthew Hodson1, Jonathan Stubbins2, Rebecca Jennings3, Eleanor Hitcham4, Ansgbra Bhowmik1. 1ACERS Team - Respiratory, Homerton University Hospital, London, Hackney, United Kingdom; 2Breathing Space Clinic, St. Josephs Hospice, London, Hackney, United Kingdom

COPD is a leading cause of morbidity and mortality worldwide. There is strong evidence demonstrating the impact of disease and the unmet needs of these patients.

Aim: Develop a hospice-based clinic for patients with advanced COPD. This multi-disciplinary assessment, facilitation and treatment clinic brings together expertise in a range of respiratory management and palliative care approaches to provide holistic care; improve self-management; integrate services; and to maximise the quality of life for patients who may be towards the end of life.

Method: Patients with advanced COPD are invited with their carers to attend the Clinic at the local hospice with a COPD nurse, a palliative medicine consultant and physiotherapist to identify their physical, psychological, social, spiritual and functional needs and engage them with a range of services. Informational needs are also addressed, including advance care planning. For those unable to attend, services are replicated in patients’ homes. Metrics are undertaken at each clinic to evaluate symptoms and patient reported outcomes.

Results: Over a 9-month period piloting, 16 patients were referred (mean age 69). Mean MRC Borg at rest (pre: 8.1±4.7; post: 6.6±4.36, p=0.001) and (pre: 79±1.4±3, post: 66±1.4±2.4 sec, p=0.001), respectively.

Conclusion: The outcome demonstrates a trend towards improvement in all domains. It is not possible to conclude that the clinic intervention is solely responsible

330s
for these changes, these early data and patient feedback supports the effectiveness of this model.

P1906
Correlation between 6-minute pegboard and ring test and upper extremity activities of daily living in patients with chronic obstructive pulmonary disease
Kenichi Takeda1, Yuji Kawasaki2, Kazuma Yoshida1, Yoji Nishida1, Tomoya Harada2, Kosuke Yamaguchi2, Kiyotaka Hashimoto3, Shingo Matsumoto1, Akira Yamasaki1, Tadashi Igushi1, Eiji Shimizu1. 1Division of Medical Oncology and Molecular Respiriology, Tottori University, Yonago, Tottori, Japan; 2Department of Regional Medicine, Tottori University, Yonago, Tottori, Japan; 3Department of Rehabilitation Medicine, Yoka Hospital, Yoka, Hyogo, Japan

Background: Upper extremity training is recognized as an important component of pulmonary rehabilitation (PR). 6-minute pegboard and ring test (6PBRT) was developed for testing arm exercise capacity of patients with COPD. The purpose of this study was to apprehend characteristics of this test and to evaluate the relationship between 6PBRT and upper extremity activities of daily living (ADL) in patients with COPD.

Methods: Twenty outpatients with COPD performed 6PBRT, spirometry, maximal inspiratory pressures, maximal expiratory pressures and grip strength. The upper extremity activities subdomain of Pulmonary Functional Status & Dyspnea Questionnaire-Modified Version (PFSQ-D-M). Upper extremity ADL was also measured objectively by the wrist accelerometer (Actiwatch2®) all day long for a week.

Results: There was a positive correlation between the 6PBRT scores and inspiratory capacity (IC) (r = 0.71, p < 0.01), inspiratory capacity/total lung capacity (IC/TLC predicted) (r = 0.68, p < 0.01), forced vital capacity (FVC) (r = 0.57, p < 0.01). There was a positive correlation between 6PBRT scores and Actiwatch2® counts (r = 0.54, p < 0.05). A negative correlation between 6PBRT scores and ADL subdomain scores (r = -0.49, p < 0.05).

Conclusion: 6PBRT may be one of the predictive tests for PR to maintain and improve upper extremity ADL in patients with COPD.

P1907
Effects of BMI on task-related VO2 and dyspnea during activities of daily life (ADLs) in COPD
Amsou W Yasse1,2, Frits M.E. Franssen1, Kenneth Meijer3, Martijn J.W. Cuipers1, Esmiel F.M. Wouters1,2,3, Erica P.A. Rutten1, Martijn A. Spruijt1. 1Prepneumology Center, Cino+, Horn, Netherlands; 2Department of Human Movement Science, School for Nutrition, Toxicology and Metabolism of MUMC+, Maastricht, Netherlands; 3Respiratory Medicine, MUMC+, Maastricht, Netherlands

COPD patients use a higher proportion of their peak VO2 during the performance of domestic ADLs compared to healthy peers, accompanied by higher task-related dyspnea and fatigue.

Introduction: Whether weight supported or unsupported exercise was associated with greater improvements in body composition, exercise capacity and health related quality of life.

Methods: Aims and objectives: To date, the influence of BMI on the task-related metabolic demands remains unknown. Therefore, we aimed to study the effects of BMI on metabolic load in 94 COPD patients (61% men, age 66±9 yrs, BMI 25.5±9.7 kg/m2, FEV1 51±19%pred) during the performance of 5 consecutive domestic ADLs: putting on socks, shoes and vest, ADL1; folding 10 towels, ADL2; putting away groceries, ADL3; washing up 4 dishes, cups and saucers, ADL4; sweeping the floor for 4 min, ADL5. Task-related VO2 was assessed using a mobile oxygen-while Borg scores were used to assess task-related dyspnea and fatigue.

Baseline characteristics were comparable after stratification for BMI. Underweight COPD patients (n=21 kg/m2, n=24) had the lowest absolute task-related VO2 after performance of 5 ADLs (62.9±151.5mL/min) compared to patients with normal (21.25±25 kg/m2), n=31; VO2: 818±422 mL/min, overweight (25-30 kg/m2, n=26; VO2: 806±161 mL/min) and obese BMI (>30 kg/m2, n=13; VO2: 1030±259 mL/min; all p<0.05). VO2 expressed as a proportion of peak VO2 and VO2 per kilogram fat-free mass (FFM) were comparable between BMI groups (%VO2 peak: 65±16, 72±19, 65±15 and 73±12; VO2kg/FFM: 16.3±3, 19.4±3, 17±3 and 18±4 mL/min/kg in underweight, normal, overweight or obese BMI respectively). Moreover, Borg symptom scores for dyspnea on fatigue were comparable between BMI groups.

To conclude, patients with different BMI’s perform self-paced domestic ADLs at the same relative metabolic load, accompanied by comparable Borg symptom scores for dyspnea and fatigue.

P1908
A comparison of the energy expenditure between weight supported and unsupported exercise in obesity
Rachael Evans1,2,3, Thomas Dolmage1,4, Priscila Robles1,5, Dina Brooks1,5, Roger Goldstein3,5. 1Respiratory Medicine, West Park Healthcare Centre, Toronto, Canada; 2Infection, Immunity and Inflammation, University of Leicester, United Kingdom; 3Medicine, University of Toronto. Canada; 4Respiratory Diagnostics and Evaluation Services, West Park Healthcare Centre, Toronto, Canada; 5Physical Therapy, University of Toronto, Canada

Background: Weight loss is better achieved by a combination of diet and exercise. We hypothesised that obese individuals may be able to endure cycling (weight supported) for longer than walking (weight unsupported). We therefore investigated whether weight supported or unsupported exercise was associated with greater energy expenditure in obese individuals.

Methods: Individuals were recruited from a sleep clinic with a BMI > 30 kg/m2 and treated obstructive sleep apnea. Patients with pulmonary or cardiac disease were excluded. On separate days in a randomised order, participants performed an incremental cardiopulmonary exercise test on a cycle ergometer (CE) and a treadmill (TM) with expired gas analysis to determine the peak oxygen uptake (VO2pk). Two endurance tests were performed on each modality matched at 80% and 60% of the highest VO2 pk determined by the incremental tests. The total energy expenditure during each endurance test was calculated from the total oxygen uptake.

Results: 12 participants completed all six tests: 7 male, mean [SD] age 57 [14] y, BMI 34.5 [7.1] kg/m2. The peak VO2 on the TM vs CE was 2275 [522] vs 1791 [390] mL/min, respectively. Table 1 shows the duration (tm) and energy expenditure at 80% and 60% VO2 pk on the TM and CE.

Table 1

Mean (SD); *TM vs CE p<0.05.

Conclusion: In obese individuals, treadmill walking (weight unsupported) at a matched metabolic intensity led to significantly higher total energy expenditure than cycling.

P1909
Nutritional status of pulmonary rehabilitation patients
Home Jörgen Stark, Dragan Stojanovic, Konrad Schultz. Pneumologie, Klinik Bad Reichenhall, Germany

Introduction: Only about one-third of all adult German men and about 50% of women are normal weight. By contrast, the percent of overweight/obesity has reached epidemic proportions. Underweight is relatively rare. The nutritional status of a pneumological patient population and the respective frequency and meaning of underweight and overweight/obesity, using a large database.

Methods: From 2005 to end of 2011, the nutritional status of all pulmonary patients was ascertained at a German inpatient rehabilitation clinic (n=13804). Additional from July 2010 until January 2012 the nutritional status of COPD patients with severity levels of III and IV based on GOLD was also ascertained for a sub-population.

Results: Of all patients (n=13804), the percent of underweight was 8.4%, normal weight 27.5% and overweight/obese 64.1%. Of all COPD patients (n=5470), 10.8% were underweight, 28.3% normal weight and 60.9% overweight/obese. Of the COPD III patients 20.6% were underweight and of the COPD IV group even 25.1%. The asthmatic (n=3811) had a lower percent of underweight (4.5%) but 72.5% overweight/obese.

Conclusions: The prevalence of underweight and obesity in a pneumological patient population is strikingly manifest when compared to a normal population. The percentage of underweight is significantly higher for COPD. Within the COPD, results show considerable differences, depending on degree of severity.

P1910
Effects of pulmonary rehabilitation in patients with COPD with and without fat free mass depletion
Leonardo Silveira1, Danilo C. Berton1, Cassia C. da Costa2, Rafael M. de Souza2, Paulo I.Z. Texeira2. 1Internal Medicine, Federal University of Rio Grande do Sul (UFRGS), Porto Alegre, Brazil; 2Health Science Institute, Feevale University, Novo Hamburgo, Brazil

We aimed contrast the effects of exercise training in COPD patients with and without reductions in fat-free mass (FFM) and evaluate the relationship among changes in body composition, exercise capacity and health related quality of life.
One hundred and four patients submitted to Pulmonary Rehabilitation (PR) were retrospectively stratified according their FMM status. FMM was measured by bioelectrical impedance and patients considered depleted if FMM index was ≤ 15 in women and ≤ 16 kg/m² in men. Saint George Respiratory Questionnaire (SGRQ) and 6 minute walk distance (6MWD) were evaluated before and after PR.

Characteristics of all patients are following: 64.1±8.7 years; body mass index (BMI)= 25.1±4.7 kg/m²; FMM index= 17.1±3.0 kg/m²; FVC=66.4±20.1%; FEV₁= 38.9±15.2%; 6MWD= 395.3±85.5 m; and oxygen saturation (SpO₂)=93.2±4.2%. Thirty two patients (30.7%) were considered depleted. They had worse resting lung function and SpO₂ (CVF= 59.4±19.5 vs 69.6 vs 19.6%, p=0.02; FEV₁=33.6±13.2 vs 41.4±15.5%, p=0.02; SpO₂= 91.7±4.8 vs 93.9±4.8, p=0.02). Improvement in 6MWD and SGRQ after PR were not different comparing groups. There is no difference in weight alteration (0±4.3±2.7 kg) whereas depleted patients had a greater improvement in fat free mass (3.71±7.89 kg ± 0.29±2.56kg; p<0.01). Therefore, 24 of 32 depleted subjects (75%) were no more considered depleted after PR. This improvement has no correlation with SGRQ and 6MWD gains after PR.

Concluding, the clinical benefits of PR were not different comparing FFM depleted and non-depleted COPD patients. However, improvement in FFM was greater in depleted patients leading the majority of them to be considered non-depleted after PR.

P1911 Glomerulopathy, microvascular damage and aortic stiffness in patients with COPD

Michelle John1, Sam Hassain1, Rebecca Simms1, John R. Cockcroft2, Andrew Prayle1, Charlotte E. Bolton1. 1Nottingham Respiratory Research Unit, University of Nottingham, United Kingdom; 2Wales Heart Research Unit, Cardiff University, Cardiff, United Kingdom; 3Department of Child Health, University of Nottingham, United Kingdom

Background: The increased aortic stiffness in patients with COPD will lead to increased pascalite energy which may in turn damage the microvasculature. The renal vascular bed is particularly susceptible. We hypothesised that urine albumin creatinine ratio (UACR) as a measure of glomerular damage would be related to aortic stiffness: pulse wave velocity (PWV).

Methods: Subjects with and without COPD, all with > 10 pack year history of smoking had aortic PWV, BP, oxygen saturations, spirometry as well as urine for renal biomarkers measured at clinical stability.

Results: Age, gender and BMI were matched between patients, n=52 and controls, n=34. The UACR was increased in patients compared to controls, p<0.05, Figure 1 (median and IQR): Log₁₀ UACR was related to aortic PWV (r=0.43, p<0.001). Median PWV was higher in patients vs controls but not significantly different in the low (-60gm/min) in 29% of each group. Biomarkers of proximal tubular damage (NGAL and KIM-1) standardised for urine concentration were not different between patients and controls in multiple regression, aortic PWV and oxygen saturations were the independent variables of log₁₀UACR in all subjects and also in patients with COPD alone (other variables entered included MAP, FEV₁, age, gender, BMI pack years).

Conclusions: There is glomerular damage in patients with COPD, consistent with microvascular damage which is related to aortic stiffness.

P1912 Characteristics and comorbidities associated with pain in people with chronic obstructive pulmonary disease (COPD)

W Darlene Reid1, Bahareh HajGhanbari1, Cristiane Yamabayashi1, Vanessa Sollevijn1, Jeremy Road1. 1Physical Therapy, University of British Columbia, Vancouver, BC, Canada; 2Division of Respiratory Medicine, Dept of Medicine, University of British Columbia, Vancouver, BC, Canada

Background: A recent survey demonstrated that the prevalence of pain in people with COPD was more than twice that in age-matched people without COPD, and pain was ~2.5 times more severe.

Purpose/Hypothesis: To determine the characteristics and comorbidities associated with pain in people with COPD.

Methods: Patients were recruited from respiratory clinics and pulmonary rehabilitation programs. Respondents participated in a mail survey that included: the McGill Pain Questionnaire (MPQ), the Brief Pain Inventory (BPI), a form to list comorbidities (modified from the Charlson Index) and medications.

Results: Sixty-five of 92 COPD patients responded to the survey (70% response rate). There was a 44.4±17% pred. a BMI of 27.6 kg/m² and were 74±4.8 years. Forty-four respondents (67%) self-reported pain. On the BPI, 64% of these COPD patients had moderate to very severe pain and 73% had moderate to very high pain interference with daily activities. Average pain severity scores on the MPQ and BPI were correlated (r 0.74). Of 44 COPD patients who experienced pain, 39 (89%) reported ≥ 2 comorbidities and 20 (45%) reported ≥ 4 comorbidities; the most common were musculoskeletal (21%) and circulatory disorders (21%). Twenty-eight (64%) of COPD patients used pain alleviating treatments, the most common were non-prescription pain medications (acetaminophen and ibuprofen [n=18; 46%] followed by prescription NSAIDS and narcotics. Conclusions: Moderate to severe pain is common in people with COPD. This pain likely compromises full participation in rehabilitation and the ability to increase physical activity. Musculoskeletal causes appear to be a major contributing factor.

P1913 Immunohistochemical analysis of endobronchial biopsies of patients infected with Puumala hantavirus

G.D. Rentkín1, J. Rasmusson2, J. Pournazari1, A. Blomberg1, C. Ahlm2. 1Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 2Department of Clinical Microbiology, Umeå University, Umeå, Sweden

Puumala Hantavirus (PUUV) causes nephropathia epidemica (NE) and involves fever, hemorrhagia and acute renal failure but airway symptoms are common. Inhalation of aerosol-containing virus is a common route of infection. Studies have shown the involvement of a cytotoxic cell response, together with activation of endothelial cells however research into this disease in the lung is limited. Inhalation of aerosol-containing virus is a common route of infection. Studies have shown the involvement of a cytotoxic cell response, together with activation of endothelial cells however research into this disease in the lung is limited. To investigate the local immune response in endobronchial biopsies of NE patients. We hypothesize that an increased inflammatory response occurs within the lower airways of patients with NE.

17 NE patients and 16 age and smoking-matched healthy controls underwent bronchoscopy. PUUV infection was confirmed using PUUV-specific IgM/IgG in serum. Bronchoscopy was performed 6-14 days after onset of symptoms and 64% of biopsies were processed into GMA for IHC and stained for inflamatory cells, endothelial cells and ICAM. Staining was corrected for submucosal area and epithelial length. Activated blood vessels were expressed as the ratio of ICAM+ to EN4+ vessels and corrected for submucosal area.

There was no significant difference in macrophages, eosinophils, T cells, CD4+ cells and B cells within the submucosa or between any cell type within the epithelium.

NE involves inflammation of the lung comprised of an infiltration of neutrophils, CD8+ and NK cells and increased ICAM expression in blood vessels. A cytotoxic response is likely to be important in the pathogenesis of NE.
Results: The mean duration of ARVI was 8.9±0.92 days in 1-st group, and 14.6±1.79 days in control group respectively. The duration of the first ARVI episode was 8.8±1.12 and 15.8±2.10 days in 1- and 2-d groups respectively. The duration of the second ARVI episode was 8.1±0.78 in 1-st group vs 14.2±2.11 days in 2-d groups. There were not registered any adverse effects in a children taking IFN-i during the trial.

Conclusions: The use of IFN-i (anafenon) in treatment of ARVI leads to reduction of disease duration. In case of repeated anafenor administration its treatment efficacy isn’t decreased.

P1915

The prevalence of clinically relevant micro-organisms in stable and exacerbated COPD using PCR techniques

Siobhan George, Davinder Garcha, Anant Patel, Alexander Mackay, Richa Singh, Raymond Sapsford, Gavin Donaldson, Wisia Wedzicha. Academic Unit of Respiratory Medicine, University College London, Hampstead, London, United Kingdom

Airway bacteria and viruses are aetiologic triggers of COPD exacerbations. We investigated the prevalence of clinically relevant micro-organisms (CRMs: human rhinovirus (HRV), H. influenzae, M. catarrhalis and S. pneumoniae) in stable and exacerbated COPD using sensitive PCR techniques. Reverse-transcription PCR and real-time PCR detected HRV and bacteria respectively, in sputum samples collected at baseline (n=57) and at exacerbation onset (n=70) using our usual symptomatic definition (Seemungal et al, 1998 ARCCM).

Exacerbation samples were taken prior to antibiotic and/or steroid therapy. Fifty-four COPD patients provided 127 sputum samples: mean(SD) age 71(8) years; FEV1 43.7%(±20.0%) predicted; current smoker 26%; male gender 63%. Airway CRMs were more prevalent at exacerbation than in the stable state (75% vs 42%, p<0.001). The prevalence of co-infection with HRV and bacteria at exacerbation (29%) was similar to the prevalence of HRV (26%) or bacteria (21%) alone (figure 1A). Co-infection was proportionally reduced in stable COPD than at exacerbation (7% vs 29%, p<0.002) (figure 1B).

Figure 1

Co-infection in sputum is higher at COPD exacerbation compared to the stable state and 75% of exacerbations are associated with common CRMs. Further work is required to investigate the impact of co-infection on CRM load and the clinical utility of PCR techniques in managing COPD exacerbations.

P1916

Inhaled corticosteroids and influenza A (H1N1) viral pneumonia

Rosa Malu de Molina, Myriam Aguilar, Andrea Trisan, Manuel Valti, Patricia Minguez, Antolín López, Piedad Unsetti. Pulmonary Medicine, Hospital Universitario Puerta de Hierro de Majadahonda, Madrid, Spain

Background: Recent studies suggest that the use of inhaled corticosteroids (ICS) may be associated with a higher risk of pneumonia in patients with COPD. However it is unclear if ICS are associated with pneumonia risk in patients with influenza A (H1N1) infection.

Therefore, our aim was to examine the association of prior outpatient ICS therapy with influenza pneumonia in patients with confirmed influenza A (H1N1) infection.

Methods: We included patients ≥16 yrs of age with influenza A (H1N1) virus infection diagnosed by real-time reverse-transcriptase polymerase chain reaction (RT-PCR) and assessed the association of ICS exposure with viral pneumonia using covariate-adjusted regression model.

Results: We identified 121 subjects with a diagnosis of influenza A (H1N1) virus infection who had a chest radiograph ordered. 71 (59%) had pneumonia. 17 (14%) acute exacerbation of COPD. 18 (15%) acute asthma exacerbation and 15 (12%) an influenza syndrome with no other diagnosis. 15% of subject with viral pneumonia were on previous ICS compared with 32% of the subject with influenza infection without pneumonia (p = 0.03). In regression analyses, outpatient ICS therapy was associated with lower pneumonia in patients with influenza A (H1N1) infection (OR 0.29; 95% CI 0.02-0.47, p< 0.004).

Conclusion: In our cohort viral pneumonia was quite common and the inhaled cor-
ticosteroid fluticasone may be associated with a lower risk of pulmonary infiltrates in patients with influenza A (H1N1) infection.

P1917

Elderly vs non-elderly patients with acute exacerbation of chronic obstructive pulmonary disease (AECOPD) due to a viral infection

Maria Lenkon1, George Dimopoulos2, Sotiros Tsiodras2, Aikaterini Charaisioti2, Elias Perros3, Urania Anagnostopoulou1, Petros Karakitsos4, Apostolos Armanagadis2, 5th Pulmonary Department, Sotiria Athens Chest Hospital, Athens, Greece; 2 Department of Critical Care, Attikon Hospital, Athens, Greece; 3 Pulmonary Department, General Hospital Nikiaas, Peruas, Greece

Introduction: The aim of this study was to compare the differences between elderly and non-elderly patients with AECOPD due to a viral infection.

Methods: Patients presenting with an AECOPD were recruited. They were classified as elderly (>65 years) and non-elderly (<65 years). Sputum and oropharyngeal samples were assessed, PCR for respiratory viruses and cultures for common pathogens were performed. Clinical outcome was reported.

Results: During the study period 247 patients were recruited [median age 69.3±9.5 years] and categorized in two groups: group A, non elderly [n=81 (32.8%) median age 58±4.599] and group B elderly patients [n=166 (67.2%) median age 74.8±4.8 years]. In 133 (53.8%) patients a viral infection was identified and in 54 (13.8%) a bacterial pathogen was isolated from sputum or blood culture. In 18 (7.5%) patients a dual infection from both a bacterial and a viral pathogen was identified. In Group B influenza vaccination (57% vs 21%, p<0.001), comorbidities (cardiac failure 55.4% vs 28.3%, p<0.001, renal failure 13.8% vs 4%, p<0.03), bacterial infections [28(16.9%) vs 6% (7%) patients, p=0.04] and longer hospital stay (8.9±4.8 vs 7.5±3.2 days, p=0.02) were higher with a statistical significant difference. No differences were identified in the rate [elderly 93 (69.9%), non-elderly 48(49.4%), p=0.3] of isolated viruses.

Conclusion: In this study elderly patients with AECOPD were identified a higher vaccination rate against influenza, more comorbidities, more bacterial infections and longer hospitalization compared to non elderly patients but no differences on the rate and the type of viral infections which led to exacerbations.

P1918

Respiratory syncytial virus (RSV) causes ciliary dyskinesia but not loss of frequency during infection of human ciliated respiratory epithelial cells in culture

Claire Smith1, Gwyneth Williams2, Andrew Rutman3, Andrew Easton1, Peter Andrew2, Chris O’Callaghan1. 1Department of Respiratory Medicine, UCL Great Ormond Street Hospital, London, UK; 2Infection, Immunity and Inflammation, University of Leicester, United Kingdom; 3School of Life Science, University of Warwick, United Kingdom

Aim To determine the effect of RSV on ciliary function using ciliated air–liquid interface (ALI) cultures.

Introduction: RSV targets ciliated respiratory epithelial cells for infection. Two previous studies on the effect of RSV on ciliated cultures have shown different effects, one describing rapid ciliosstatic and another describes no cytopathic effect.

Methods: Ciliated epithelial cells were cultured from nasal and bronchial brush biopsies. Cells were infected with RSV (A2) for up to 72 h. Ciliary beat frequency (CBF) and pattern (CBP) were observed with a high-speed video camera. The cells were fixed and stained using anti-RSV (FETC) and anti-acetylated tubulin (Alexa594) antibodies. Confocal optical sectioning and electron microscopy (EM) was also performed.

Results: CBF showed a higher proportion of dyskinetic cilia following RSV infection. The median (IQR) dyskinesia index was increased as early as 24 h and at 72 h had increased to 35% (25-42%) compared with controls 13% (11-14%). CBF was unaffected by RSV infection. By 72 h the ultrastructure of the ciliated epithelium was abnormal following RSV infection with an increased in ciliated cells exhibiting loss of cilia and an increase in ciliated cells with mitochondrial damage. Furthermore, RSV antigens were observed on the apical surface of the cell and had extended the full length of the cilial shaft.

Conclusion: RSV infection of ciliated cells results in increased dyskinesia of cilia, whilst CBF is maintained. Epithelial damage was preferentially seen in ciliated cells.

Seasonal influenza vaccination rates in chronic asthma patients

P1920

Introduction: To document influenza vaccination in asthma patients, to explore factors that influence vaccination.

Method: Adult patients with chronic asthma attending a hospital clinic (n=146, Female =103, mean age 49.81±3.2, 29.66 Male) filled in a questionnaire in January 2012 on influenza vaccination.

Results: 51.39% used reliever medication less than twice per week. 4.79% were current smokers. 86/58.9% of patients had experienced acute episodes in the previous year. 80.5%, 40% of Male, 61% of F received the influenza vaccine this winter. 129 (88.6%) were vaccinated in the past. 49 patients did not re-vaccinate because of fear of side effects(21), forgotten or had no time(12), were sick when vaccine available(6), adverse media report (1), because of current pregnancy(5), or the patient did not need it. 41 patients who had experienced side effects in the past, 16 re-vaccinated this year. 78 of 125 (62.4%) of all patients who were advised the vaccine were vaccinated, while 10% of those not advised were vaccinated this year (p<0.001). 78% of those who were advised to take the vaccine by a doctor were actually vaccinated. The mean age for vaccinated was 54, and 42 in those who were not (p=0.0003). The main reasons for taking the vaccine were advised by a doctor(34%), to protect themselves(40%), to reduce severity and frequency of asthma attacks (39%). Reasons for not having the vaccine were fear of side effects (40%), forgot or had no time to take it (19%), did not know they should take it (12%) Conclusion: The rate of influenza vaccination in asthma patients is low. Medical advice by a medical practitioner resulted in a high vaccination rate. Fear of side-effects was main reason for non-vaccination.

P1921

Role of virus in community-acquired pneumonia (CAP)

Ana Simón1, Carolina Pamanes1, Elisa Minchole1, Sergio Fandos1, Ana Lasierra2, María Angeles Ruiz2, Elena Forcen3, Virginia Moya3, Elisabet Vera4, Salvador Bello5, Palmonology, Hospital Miguel Servet, Zaragoza, Spain; 2Biochemistry, Hospital Miguel Servet, Zaragoza, Spain; 3Microbiology, Hospital Miguel Servet, Zaragoza, Spain.

Introduction: It is of increasing interest the role of viruses as etiologic agent of CAP. We tried to assess this subject in our patients.

We conducted a prospective observational study to investigate the viral, bacterial and mixed viral/bacterial etiology of patients admitted to hospital with a diagnosis of CAP. Samples were taken for blood culture and sputum culture, serial serology studies, urinary Legionella and S pneumoniae antigens, and nasopharyngeal aspirate to search virus by immunofluorescence and 2 different multiple polymerase chain reaction (PCR).

Results: Of a total of 262 patients with CAP admitted to our hospital, we included, and we found at least one pathogen in 180 (68.7%). Out of the 180 patients with etiological diagnosis, in 70 (38.8) a bacterial agent, in 64 (35.6) a viral agent and in 46 (25.6%) had a mixed etiology (virus + bacteria) were found. The bacteria most frequently found was S. pneumoniae, in 67 patients. Rhinovirus was found in 30 patients, and was the most prevalent virus associated with CAP. The most frequent virus/bacteria combination was S. pneumoniae with Rhinovirus found in 9 patients.

Conclusions: Prevalence of virus in CAP is important, reaching more than half (62%) of all known etiology. The most common pathogen causing CAP is S. pneumoniae, which was also the most often associated with virus. The study of viruses as pathogens of CAP must be taken into account in future studies of this disease.
P1923 Clinical profile and risk factors of H1N1 swine flu in Indian health care workers during the 2009 pandemic

Barthakur S,1 Henry Kinupakaran,2 Devasahayam J. Christopher1.
1Department of Pulmonary Medicine, Christian Medical College, Vellore, Tamil Nadu, India; 2Staff Students Health Service, Christian Medical College, Vellore, Tamil Nadu, India

Background: The Christian Medical College, Vellore was one of the first centers in India that could perform RT-PCR for Influenza A H1N1 during the 2009 pandemic. The health care workers being a high risk group were screened and tested when they developed flu symptoms. Through the staff-students health service of the institution, the clinical profile and risk factors in this group were studied.

Aim: To study the clinical profile and risk factors of swine flu in health care workers during the pandemic of 2009 and compare it with other acute febrile respiratory illnesses in the group during the same period.

Methods: Consecutive health care workers who presented with an acute febrile respiratory illness were screened and those who fulfilled a set of clinical criteria were included. Demographic and clinical data were obtained and a throat swab was taken for RT PCR for swine flu. All those who were positive were included as cases and those who were negative, as controls. The clinical profile and risk factors were compared between the two groups.

Results: A total of 158 patients were included. Of these 76 were cases and 82 were controls. Female sex, students, work involving minimal contact with patients, diarrhea and need for admission were more in the cases. There were more nurses and technicians in the control group. There was no difference in the co-morbidities, exposure to swine flu patients or use of protective measures between the two groups.

Conclusion: The study has identified some risk factors for H1N1 swine flu in health care workers. This information may be helpful in setting up policies during subsequent epidemics. A larger study should be planned in the future.

P1924 Predictor of outcome and length of hospital stay in acute viral pneumonia: 2009 H1N1 influenza A experience

Ashish Jain, Rajesh Chawla, Vikas Sikri, Sudha Kansal. Respiratory and Critical Care, Indraprastha Apollo Hospitals, New Delhi, Delhi, India

Introduction: H1N1 Influenza A virus spreads globally causing pneumonia and high mortality.

Aim: We studied clinical characteristics of patients admitted with influenza pneumonia in a tertiary care hospital of northern India over one year.

Method: We analyzed 77 patients with H1N1 influenza, confirmed with RT-PCR assay.

Results: Out of 77 patients, 33(43%) were female. Mean age was 41±13 years. Thirty eight patients (50%) had at least one comorbidity, Diabetes Mellitus was most frequent. Presenting symptoms were fever in 75 (97%), cough in 67(87%) and dyspnoea in 59 (76%) patients. Mean duration of dyspnoea at presentation was higher in expired group 6±3 Vs 4±3 days(p=0.02). Bilateral opacities on chest radiograph seen in 49 (55%) patients. Mean PaO2/FiO2 ratio 240±111 at 30 minutes, then 1 pill 3 times in a day; in 2-5 days – 1 pill 3 times in a day). The treatment was surgery alone in 8 cases, associated with medical treatment in 6 cases. Twenty one patients have diffuse and bilateral bronchitis. PA infection revealed bronchitis in 3 cases (13%). Clinical manifestations included: acute respiratory failure (n=15), fatal sepsis (n=1), increased supraclavicular rise (n=24) and fever (n=20). PA strain was isolated from sputum in 23 cases and from bronchial alveolar fluid in 1 case. All patients received continuous 2 antibiotics for more than 14 days: cefazolin + aminosal or quinolone (96%) and imipenem + amoxicillin (4%). Following intravenous antibiotics, PA was eradicated in 22 cases and 2 patient was colonized with PA. Long term outcome complications were involved: chronic respiratory failure (12.5%), recurrent PA (12.5%) and Hemophillus infection (21.5%).

Conclusion: Pseudomonas aeruginosa lung infection in patients with bronchitis is associated with more severe disease and a higher utilization of health-care resources.

P1925 The treatment of acute respiratory viral infections in a patients with a chronic obstructive pulmonary disease

Nadezhda Kniazevkaya. Chair of Pulmonology, Russian State Medical University, Moscow, Russian Federation

Background: Acute respiratory viral infections (ARVI) often cause the exacerbation of Chronic Obstructive Pulmonary Disease (COPD) in adults. The possibilities of ARVI treatment with antiviral medication combining anti-inflammatory and antihistaminic actions in a patients with COPD are still unknown.

Aim: To evaluate the efficacy and safety of medicine combining ultralow doses of anti-bodies to interferon-γ, CD-4 and histamine (ULD AB IFN-γ, CD-4, His - the medication “Ergo-feron”) in ARVI treatment in patients with COPD.

Methods: Open comparative randomized study in 2 parallel groups including 60 adult patients with COPD was conducted. All patients obtained the treatment of main disease and also necessary symptomatic therapy. Antibiotics were administered as required. Treatment group (32 patients) took complex of ULD AB IFN-γ, CD-4, His (ergoferon) in treatment regimen (in a first day first two hours 1 pill every 30 minutes, then 1 pill 3 times in a day; in 2-5 days – 1 pill 3 times in a day). The comparison group (28 patients) didn’t obtain complex of ULD AB IFN-γ, CD-4, His (ergoferon) and other anti viral medications.

Results: The mean duration of fever response in treatment group was 1.5 day less than in comparison group (2.9±0.45 vs 4.6±0.8). The treatment group patients were discharged from hospital to the 10-th day of disease (10±0.8) and the length of hospital stay in comparison group was 3-4 days longer (14±1.2). Side effects were not registered during therapy.

Conclusion: The medicine combining ULD AB IFN-γ, CD-4, His (ergoferon) administration in a patients with ARVI afford to decrease the duration of COPD exacerbation caused by acute respiratory infections.

P1926 Can pseudomonas aeruginosa infection change the outcome of bronchectasis?

Smen Houda, Daghfous Hafaoua, Kotti Amina, Saad Soumaya, Kahloud Olla, Slim Leila, Tritar Fama, Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia Microbiology, Abderrahmane Mami Hospital, Ariana, Tunisia Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia

Background: Bronchectasis patients are susceptible to infection with pseudomonas aeruginosa (PA). Isolation of PA is associated with increased severity of disease, greater airflow obstruction and poorer quality of life. It is not known whether infection by PA is a marker of disease severity or contributes to disease progression.

Aim: Determine frequency, clinical, biologic, management and outcome of PA infection complicated bronchectasis.

Patients and methods: Between 2005 - 2011, 24 PA infection occurred in patients with bronchectasis were retrospectively enrolled in the study.

Results: The mean age of patients (13 women and 11 men) was 42 years (16-65 years).Twenty one patients have diffuse and bilateral bronchectasis. PA infection reveals bronchectasis in 3 cases (13%). Clinical manifestations included: acute respiratory failure (n=15), fatal sepsis (n=1), increased supraclavicular rise (n=24) and fever (n=20). PA strain was isolated from sputum in 23 cases and from bronchial alveolar fluid in 1 case. All patients received continuous 2 antibiotics for more than 14 days: cefazolin + aminosal or quinolone (96%) and imipenem + amoxicillin (4%). Following intravenous antibiotics, PA was eradicated in 22 cases and 2 patient was colonized with PA. Long term outcome complications were involved: chronic respiratory failure (12.5%), recurrent PA (12.5%) and Hemophillus infection (21.5%).

Conclusion: Pseudomonas aeruginosa lung infection in patients with bronchec-tasis is associated with more severe disease and a higher utilization of health-care resources.

P1927 Multiple thoracic hydatidosis (About 23 cases)

Nahid Zaebeh, Hanane Benjelloum, Najiba Yassine, Abdelaziz Bakkhatar, Abdellatif Bahlouli. Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco Respiratory Diseases, UHC Ibn Rushd, Casablanca, Morocco

The multiple thoracic hydatidosis is rare, but dangerous because of the difficulties of its therapeutic management, and severity of its complications, some of which can be life threatening. The aim of our study was to evaluate the diagnostic and therapeutic difficulties of multiple thoracic hydatidosis. This is a retrospective study spread over 11 years (January 2000 to September 2011) concerning 23 cases of multiple thoracic hydatidosis. Patients included had two or more thoracic hydatid cysts. There are 11 women and 12 men with a mean age of 46 years (range 16 to 78 years). Six patients have already been operated on for pulmonary hydatid cysts in 3 cases and liver cysts in 3 cases. Pulmonary localization is constant with multiple hydatid cysts making an appearance in bellows release in 16 cases, a double pulmonary hydatid cyst in 7 cases. Cardiac localization was found in 4 cases, while with mediastinal, hepatic, and great vessels is found in 3 cases each. The treatment was surgery alone in 8 cases, associated with medical treatment in 6 cases. Medical treatment alone (Albenzolac) was recommended in 15 cases. The evolution was marked by the worsening lesions in five cases, pulmonary hydatid cyst rupture into the pleural cavity in 2 cases, and lesions were stationary in 10 cases. Through this work, we emphasize the rarity and severity of multiple thoracic hydatidosis. Medical treatment remains the only treatment of disseminated forms. The best treatment is preventive.
Diagnosis not made 4 (5)
Bronchiectasis 2 (3)
Pulmonary Histoplasmosis 3 (4)
Pneumocystis Jerowici Pneumonia (PJP) 4 (5)
Bacterial Pneumonia 20 (26)
Pulmonary Tuberculosis 49 (64)

Diagnosis Number of cases (%)

Conditions diagnosed
Pulmonary tuberculosis relapse or atypical mycobacterium infection?

Some cases.

It is mandatory histopathological evidence of tissue invasion to confirm the presence of Aspergillus spp. from endobronchial specimens and the presence of ≥1 endobronchial lesion without an alternative diagnosis. In order to exclude simple colonization, all cases also had histopathological evidence of tissue invasion of the tracheobronchial tree with hyaline morphologically consistent with Aspergillus spp.

Results: 8 cases (6 male; mean age 55.5 years) of AT were diagnosed. Hematologic malignancy (n=4), solid organ transplantation (n=2), systemic lupus erythematosus (n=1) and nasopharyngeal carcinoma (n=1) treated with chemotherapy and radiotherapy were the underlying conditions reported. Fever and respiratory complaints (cough, dyspnea, stridor or wheezing) were the most frequent symptoms but one case was asymptomatic. A fumigatus constituted the unique specie in our study. In bronchoscopy the pseudomembranous form was the most commonly observed (4 cases). Two cases revealed necrotic lesions and two cases only showed multiple mucus plugs. All cases were diagnosed by bronchoalveolar lavage and bronchial biopsy. Two cases died so the overall intra-hospital mortality was 25%

Conclusions: Aspergillus tracheobronchitis is an infrequent form of invasive pulmonary aspergillosis that would be suspected in some immunosuppressed patients. It is mandatory histopathological evidence of tissue invasion to confirm the diagnosis.

Differences in genetic background of atopic and non-atopic asthma in children
Voiko Berce 1, Carina Pinto Kozmus 2, Uros Potocnik 3

1, Carina Pinto Kozmus 2, Uros Potocnik 3 .

Children aged between 5 and 18 years with mild or moderate persistent atopic asthma, 99 with non-atopic asthma and 273 controls. We measured numerous clinical and laboratory parameters and carried out genotyping for polymorphisms CCR5-delta32, IL-4RA Q551R, IL-4 C-33T, NOD2 R702W, CTLA4 CT60, MUC7 – VNTR, TNF C-1031T, TGFβ1 C-509T, SLCO2A4 C1672T, CD14 C-159T and IL23R rs7517847.

Results: In non-atopic asthmatics the frequency of CCR5-delta32 allele was 2.6%, which is significantly less than 9.0% in the control group (p=0.03) and the frequency of IL-4RA Arg551 allele was 7.7%, which is also significantly less than 9.0% in the control group (p=0.03). We have found no association of genotype with atopic asthma. Non-atopic asthmatics homozygous for the MUC7*7 allele had a total IgE value of 263.3 IU/ml compared to 40 IU/ml in heterozygotes (p=0.02).

Conclusions: Although TB is the most frequent cause of pulmonary infection in this group of patients several other conditions are seen. This information has public health importance to ensure correct diagnostic pathways are developed to allow correct treatment and proper allocation of limited health resources.
P1932
Maternal genetic asthma predisposition affects signaling networks in lungs of neonatal offspring
Petra Nathanshon1, Jan Fran Dehmel1, Rabea Imker1, Martin Imker2, Steffen Sass1,
1Comprehensive Pulmonary Center, 2Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Introduction: Exposure-induced deregulation of microRNAs (miRs) during early critical developmental periods has been proposed to contribute to the propagation of asthma risk in later life.

Aim: We asked if maternal genetic asthma predisposition is sufficient to affect pulmonary miRNA and also mRNA profiles in offspring that do not bear the genetic asthma risk. To address this question, we used female mice with a heterozygous deficiency for Tbx21 as they develop spontaneous airway remodeling and airway hyperreactivity (Finotto et al., Science, 2002; 295:336).

Methods: Female C57BL/6J Tbx21+/– mice were mated with wild type (wt) males. Neonatal lungs from wt pups of dams with (Tbx21+/–, n=8) and without (wt, n=8) genetic asthma predisposition were removed within 24h after birth and total mRNA including small RNAs was extracted. RNA from individual animals was subjected to microRNA (ABI, TaqMan® Array microRNA cards) and mRNA (Affymetrix Mouse Gene ST 1.0 ® arrays) expression profiling. Counter-regulated miRNA-mRNA pairs were further analyzed for pathway enrichment using in silico tools (GePS, IPA).

Results: After adjustment for gender differences 57 miRNAs and 2599 mRNAs were differentially regulated. Within these, 59 miRNAs paired to 1456 mRNA targets according to expression regulation. Enrichment analysis showed that developmentally important pathways (e.g. growth factor and BMP-signaling) are affected by exposure to maternal asthma predisposition even in the absence of genetic risk in the pups.

Conclusion: These data show that maternal genetic asthma predisposition affects pulmonary miRNA and mRNA profiles during an early developmental stage and might therefore influence lung development.

P1933
Role of maternal phenotype in asthma development in children
Ludmilu Zhelezina1, Marta Vakharovskaya2, Olga Lavrova2,
1Pavlov State Medical University, St. Petersburg, Russia, 2Pavlov State Medical University, St. Petersburg, Russian Federation

Children born from mothers with bronchial asthma are the most vulnerable group for development of allergic diseases.

Aim of study. We have done research into data obtained from 117 pregnant women with bronchial asthma and their children. The average age of mothers was 27.7±5.2 years. Most mothers developed the disease before the age of 16 (88 mothers; 75.2%); 29 mothers got ill when they were over 16 years of age (24.8%) (“child” and “adult” bronchial asthma respectively). We have researched medical data of 117 children born from these mothers: 64 boys (54.7%) and 53 girls (45.2%). Over 70% of the children reached the age of 7-9 by the end of the observation period. Children born by caesarean section developed bronchial asthma 1.5 times more often than children born naturally. Children who had been breastfed for over 4 months had significantly lower incidence of atopic dermatitis than children fed artificially (14% and 32.7% respectively; p=0.033). Children born from mothers with “child” asthma phenotype run a 3-fold higher risk of developing bronchial asthma than those whose mothers had “adult” asthma phenotype (OR = 3.042 [CI:1.03 – 9.132]).

Conclusion: The research has confirmed the significance of hereditary load, maternal asthma phenotype, mode of child delivery, and baby feeding for development of allergic diseases in children.

P1934
A comparison of lung function and atopy between children with intrauterine growth retardation and normal birth weight in a birth cohort with documented wheeze
Karthika Jayalal, George D’Souza, Uma Devaraj,
Chest Medicine, St. John’s Medical College, Bangalore, Karnataka, India

Rationale: Low birth weight and intra uterine growth retardation has been implicated in lower lung function and a higher incidence of atopy. This was tested in a birth cohort.

Aim: To compare atopic status and lung function between IUGR and normal birth weight children with documented wheeze.

Methods: Children aged 3-7 yrs from a birth cohort with documented wheezing or a parental history of child wheezing and a doctors prescription for bronchodilators were studied. IUGR was defined as birth weight of less than 2.5kg. All the children underwent spirometry and skin prick test. Spirometry was done before and after bronchodilator according to ATS guidelines. Skin prick test was done using 10 antigens. Positive test was defined as wheal of more than 3mm of that of the negative control.

Results: A total of 92 children who were comparable were studied, out of which 36 (33%) were low birth weight and 56 (51.52%) were normal birth weight. IUGR children had a lower FEV1/FVC ratio (FEV1/FVC 87.26±11.55) than children with normal birth weight (FEV1/FVC 93.7±6.62) p value = FEV1/FVC = 0.002. They also had a lower FVC % value when compared to normal birth weight children.FVC % in IUGR – 81.46±10.97 and that of normal birthweight children – 86.9±10.92 p value = 0.025. The skin prick test positivity in both groups was comparable (15.7% in normal birth weight and 16.7% in IUGR children, p value = 0.92).

Conclusion: IUGR had lower FEV1/FVC ratio and FVC% as compared to normal birth weight children. Atopic status was comparable in both groups.

P1935
Exposure to farming environments in childhood and asthma and wheeze in rural populations: A systematic review with meta-analysis
Jon Genuneit, Institute of Epidemiology and Medical Biometry, Ulm University, Ulm, Germany

Background: Particularly strong associations with asthma and allergic diseases have been described for exposure to farming environments in childhood. The aim of this systematic review was to update and extend existing narrative reviews, test for heterogeneity across studies, and conduct a meta-analysis.

Methods: Published literature was searched through PubMed including all articles added before September 1, 2011. Articles were included if they reported an epidemiological study on the exposure to farming environment in childhood and subsequent wheeze or asthma. Heterogeneity of effect measures was evaluated using Cochran’s Q and I 2. Effect measures were summarized by random-effects meta-analysis for various outcome definitions.

Results: In total, 357 retrieved abstracts revealed 52 articles from 39 studies with data considered for the meta-analysis. Most studies were conducted among children or on childhood onset of disease. Most data was on doctor diagnosed asthma or current wheeze. The meta-analysis showed substantial heterogeneity across studies with similar outcome definitions. Nonetheless, the combined effects were therefore statistically significant and showed an approximate 25% lower asthma prevalence among exposed subjects compared to unexposed subjects.

Conclusion: The protective ‘farm-effect’ on asthma was reported in numerous studies. Its underlying factors ought to be studied and promising efforts have been already made. However, the heterogeneity of the effect across studies should also be investigated because whatever causes it is a potential threat to valid synthesis of evidence and to the detection of specific protective factors.

P1936
Influence of farm exposure and pets ownership during pregnancy on cord blood mononuclear cells (CBMC) with intracellular production of interferon (IFN)γ
Sergey Treshchekin1, Ivan Novitzky, Lyudmila Vasilev, Siberian Division of Russian Academy of Medical Sciences, Medical Research Institute for Northern Problems, Krasnoyarsk, Russian Federation

Some epidemiological and observational data suggest that farm and pets exposure in early childhood may be conducive to reduced atopy. Currently, there is a lack of consensus regarding underlying immunological mechanisms, especially in prenatal period.

Aim: We hypothesized the influence of farm exposure and pets ownership during pregnancy on cord blood mononuclear cells (CBMC) with intracellular production of IFNγ.

Methods: Intracellular IFNγ expressions as well as early activation marker CD69 (absolute cells count) were examined using flow cytometry after PHA stimulation of CBMC obtained from 93 full-term newborns. The Kruskal-Wallis and Mann-Whitney tests were used.

Results: We revealed that newborns from rural mothers (n=14) have higher amount of both nonactivated (IFNγ+CD69−, p=0.02) and activated (IFNγ+CD69+, p=0.028) CBMC, producing IFNγ, as compared with newborns from urban mothers (n=79). Only for newborns from urban mothers we calculated the influ-

Figure 1. Content of IFNγ+CD69+ cord blood mononuclear cells subject to pets ownership during pregnancy.
ence of pets exposure during pregnancy on intracellular IFN-γ production (Fig. 1). Noteworthy, that only amount of activated (IFN+CD69+) CBMC was elevated in dog (but not in cat) exposure group. Conclusion: Thus, external and home environment factors such as farm exposure and dog ownership may act prenatally affecting Th1/Th2 balance. These findings can leastwise partially explain previously reported epidemiological data.

P1937 Leucotriene B4 in fractionated breath condensate: Comparison of bronchial and alveolar concentrations in children
Christina Maria Mueller, Jordis Trischler, Stephanie Konitzer, Christiano Lerw
University Children’s Hospital, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany

Background: Asthma is a chronic inflammatory disease of the airways but recent studies have shown that alveoli are also subject of pathophysiological changes. Objectives: This study was undertaken to compare leucotriene B4 (LTB4) concentrations in different parts of the lungs using a new technique of fractionated breath condensate sampling.

Methods: In 69 patients (10-17 years, 34 asthmatics, 35 controls) measurements of exhaled nitric oxide (FeNO), lung function and LTB4 concentrations in exhaled breath condensate (EBC) were performed. EBC was collected in two different fractions, representing mainly either the airways or the alveoli, using capovolumetry. LTB4 concentrations were measured using an ELISA.

Results: LTB4 values were below the detection limit. Concentrations of the bronchial fraction correlated significantly with those of the alveolar fraction (r=0.73, p<0.000). Differences between the fractions were not significant in a paired difference test. Subjects with obstructive lung function (n=4) had significantly higher LTB4 values than subjects with normal lung function (n=65) (p=0.043, p=0.040, respectively). Asthmatics had significantly higher alveolar but not bronchial LTB4 values than controls (p=0.005, p=0.232, respectively). There was no relationship between LTB4 and FeNO values.

Conclusions: Differences in LTB4 concentrations between asthmatics and controls were only measurable in the alveolar but not in the bronchial fraction of EBC. An additional analysis of alveolar inflammation may therefore be possible useful in asthmatics. However, lab techniques for analysing LTB4 in EBC need to be improved and easy applicable.

P1938 High altitude stay reduces eosinophil load in airways in children with asthma
Nestia Kalukarni 1, Vincenzo Ragazzu 2, Silvia Costella 2, Christoph O Callaghan 3, Ahmad Kantar 2.
1Department of Laboratory Diagnostics and Clinical Immunology of Developmental Age, Medical University of Warsaw, Poland; 2Department of Pediatric Pneumonology and Allergology, Medical University of Warsaw, Poland

A normal sputum eosinophil count in children with asthma could result from corticosteroid treatment or reduction in eosinophil recruitment. In order to differentiate this we have described a new marker of eosinophilic inflammation (eosinophil protein content in airway macrophages).1 At high altitude children with asthma show significant reduction in eosinophil count due to reduced exposure to allergens. The aim was to determine the phagocytic function of airway macrophages at baseline (T0) and after stay at high altitude (T1). Sputum induction was performed at T0 and T1 in children with mild to moderate asthma attending High Altitude Children’s Asthma Center in Misurina. Differential count was obtained by counting 400 non-squamous cells (eosinophil asthma ≥ 3%). AM were isolated by adherence and cultured with FITC labelled heat killed staph aureus in the ratio of 1:10 (AM: bacteria). One hundred macrophages were imaged using confocal microscope. The median bacterial count/AM was calculated using Image J and Cell profiler software. The groups were compared using paired and unpaired t-tests.

There was no significant difference (p = 0.3) between median bacterial count in eosinophilic (n=16) [Mean (SD)] [77.56(36.60)] and non-eosinophilic asthma (n=8) [68.22(11.5)] at T0. Children at T1 (n=19 pairs) had significantly lower i) median bacterial count [Mean (SD)] p = 0.006, 35.95(54.51) vs 73.26 (39.42) than at T0. The sputum macrophages in children with mild to moderate asthma are equally phagocytic in eosinophilic or non-eosinophilic groups. After stay at high altitude macrophages were less phagocytic (possibly due to return to normal level of recruitment).

P1940 The impact of sublingual immunotherapy (SLIT) of asthma on Th1 cells and susceptibility to apoptosis
Oleja Cipriena 1, Anna Zawadzka-Krajewska 2, Iwona Kotula 3, Urszula Denkow 3.
1Department of Laboratory Diagnostics and Clinical Immunology of Developmental Age, Medical University of Warsaw, Poland

Asthma is a chronic inflammatory disease of the airways. Allergen-specific immunotherapy is the unique disease modifying treatment of atopic diseases. SLIT is effective treatment associated with low incidence of systemic reactions. A disturbed T cells apoptosis plays a crucial role in the in the development of allergy inflammation in the course of asthma. Nevertheless, the effect of sublingual immunotherapy on T cell apoptosis has not been elucidated. The aim of present study was to evaluate the influence of one year allergen-specific immunotherapy in asthmatic children on the frequency of Th1 Bc1-2 positive cells in peripheral blood.

Twenty-five children, suffering from bronchial asthma and allergic rhinitis were enrolled to the study. Children were shortlisted for sublingual specific immunotherapy with a solution containing specific allergen extracts. The frequency of Th1 cells and the intracellular expression of Bc1-2 were evaluated using flow cytometry before and after 12 months of treatment. The frequency of Th1 cells after immunotherapy was significantly increased (13.22 [10.34, 18.95]% before versus 19.86 [16.37, 24.52]% after SLIT, p=0.01), moreover significant increase of Bc1-2 positive Th1 cells was found after treatment. At a baseline 58.34 (31.23, 76.28) % of Th1 cells showed expression of Bc1-2 protein, whereas 73.61 (65.47, 82.43) % Th1 cells expressed Bc1-2 after one year of SLIT, p=0.0465. The increase of Th1 cells frequency secondary to SLIT might be associated with enhanced resistance to apoptotic signals. However, further studies are needed to clarify the role of T cell apoptosis in resolution of allergic airway inflammation.

P1941 A relationship between exercise-induced bronchoconstriction and allergic rhinitis in Japanese children
Yoko Murakami 1, Satoru Honjo 1, Hiroshi Odajima 1, Yuichi Adachi 2.
1, Satoru Honjo 1 , Hiroshi Odajima 1, Yuichi Adachi 2,

The increase of Th1 cells frequency secondary to SLIT might be associated with enhanced resistance to apoptotic signals. However, further studies are needed to clarify the role of T cell apoptosis in resolution of allergic airway inflammation.

Introducification: A relationship between allergic rhinitis (AR) and Exercise-induced bronchoconstriction (EIB) has not been fully studied.

Aims: The aim of this study was to examine the relationship between EIB and AR among children aged 6-17 in Japan.

Methods: EIB and AR were ascertained by International Study of Asthma and Allergies in Childhood (ISAAC) questionnaire among randomly selected schools across the nation. Number of the subjects were 43,813 of 6-7 year old attending the elementary schools, 48,641 of 13-14 year-old attending the junior high schools and 54,138 of 16-17 year old attending the high schools. We examined relationship between having AR and risk of EIB, and severe EIB in current asthmatics in a case-control design using logistic regression model. We also investigated an association of degree of life disturbed by AR with risk for EIB, and severe EIB. The impact of EIB on the frequency of Th1 Bc1-2 positive cells in peripheral blood.
of severe EIB were elevated with increasing severity of life disturbed by AR, respectively (p for trend <0.01 and <0.01).

Conclusions: Risk of EIB was increased among children with AR as compared to those without AR. Degree of life disturbed by AR was related to increasing risk of EIA, and severe EIA.

Physical activity: Children with asthma and without asthma

Andreu Sonja, Celso Carvalho, Milton Martins, Anna Cabral. College Medicine of University of São Paulo, University of São Paulo, SP, Brazil Pediatric Clinic, Darcy Vargas Children’s Hospital, São Paulo, SP, Brazil

Background: It is well known that regular physical activity has health benefits, reducing obesity, morbidity and mortality. Currently, the practice of physical activity in asthmatic patients shows a significant improvement of disease symptoms, however, there is disagreement in the literature whether asthmatic children are more sedentary than children without asthma.

Objective: To compare level of daily physical activity in children with and without asthma.

Methods: We studied 121 children (79 asthmatics) of both genders among 7-12 years. Were selected for the study asthmatic patients with controlled disease. The level of daily physical activity was monitored by use of the accelerometer for six days (four weeks on and two on the weekend).

Results: Total number of steps, steps and time in moderate physical activity between genders of the asthma and control groups were similar.

Conclusion: Characteristics related to asthma do not seem to affect the physical activity in children with controlled disease, making the practice of daily physical activity similar to that of children without asthma.

Obesity and asthma symptoms in children

1 Respiratory, Clinic University Hospital, Santiago de Compostela, Spain; 4Clinical Epidemiology and Biostatistics Unit, Clinic University Hospital, A Coruña, Spain; 3Pediatrics, Galician Health Service, Santiago de Compostela, Spain; 2Medical University of Novosibirsk, Novosibirsk, Russian Federation

Introduction: The relationship between obesity and asthma show inconsistent results. The purpose of our study was to evaluate the prevalence of asthma according to obesity in a large sample of the child population in our region (total population 2795422).

Methods: A cross-sectional study, following the ISAAC study methodology, was conducted on randomly selected 6-7 year old children.

The asthma symptoms, demographic characteristics, and other potential risk factors were determined from the questionnaire. Overweight and obesity were defined based on the body mass index. Multiple logistic regression were used to obtain adjusted prevalence odds ratios (OR) and 95% confidence intervals (95% CI) between asthma symptoms and obesity.

Results: Finally, 7485 children were included (50.8% female). Our results showed that 23.4% of our children were overweight, and 9.6% were obese.

Obesity was associated with an increase in the probability of wheezing ever (OR: 1.35) and exercise induced asthma (OR: 1.62).

Prevalence of asthma and rhinitis in school-age children in Fortaleza, northeast Brazil

Daniela Chicaia 1, Maria de Fatima Luna 2, Gilberto Fischer 3, Marcelo Gurgel Silva 4, João Rafael Luna 5, 1 Internal Medicine, Universidade de Fortaleza, Ceara, Brazil; 2Pediatría Post Graduation Program, Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil; 3Medicine, Universidade Estadual do Ceará, Fortaleza, CE, Brazil; 4Medicine, Universidade Federal do Ceará, Fortaleza, CE, Brazil

Introduction: In Brazil, the mean prevalence of asthma symptoms is 13.3%. Fortaleza is the fifth largest city of Brazil and there is no recent official data from asthma prevalence in children.

Objective: The aim was to evaluate the prevalence of asthma and rhinitis symptoms in 6-7 years old children in Fortaleza.

Method: The protocol of the International Study of Asthma and Allergies in Childhood (ISAAC) was used. Random sample were taken from 3000 students from public and private schools in 2010. The surveys were sending with their homework for the parents to fill it and returning to the school in the next day.

Results: The prevalence of wheezing was 52.6% and wheeze in the last 12 months 28.3%, while diagnosed asthma was 12.4%. For symptoms associated with severity, the rate of wheezing with sleep impairment was 4.1% for more than 5 more wheezing attacks in the last year, 3.9% and sleep disturbance by wheezing in one or more nights a week 6.7%. The rate of wheezing after exercise was 7.2% and dry nocturnal cough was 39.7%. Mother’s smoking (p < 0.001), father’s smoking (p = 0.011) and contact with pets (p = 0.007) were associated with asthma symptoms. Mother’s smoking (p = 0.011) and the use of antibiotics (p = 0.011) in the first year of the child’s life were associated with severe asthma. The prevalence of rhinitis symptoms was 50.9% rhinitis in the last 12 months 42.8% rhinoconjuntivitis 15.4% and diagnosed rhinitis 28.1% Impaired daily activities by rhinitis was 19.6% (little), 3.2% (moderate) and 1.9% (high).

Conclusions: The prevalence of asthma and rhinitis in 6-7 years old children in Fortaleza were similar to Brazilian national mean rate. Asthma and rhinitis are underdiagnosed among children in Fortaleza.

P1945

Dynamics of asthma prevalence in children in the Novosibirsk (preliminary results)

Elena Konduriina, Tatiana Elkina, Natalia Gulevskaya, Maria Shably, Andrei Likhanov. Department of Pediatrics, State Medical University, Novosibirsk, Russian Federation

Background: The study of the asthma epidemiology according to the ISAAC program (Phase Three) was over in 2002. Afterwards the studies with the use of standardized methods have not been carried out in the world.

Aim: To study the dynamics of asthma prevalence among the 6-7 years old children in the Novosibirsk.

Methods: According to the ISAAC 3249 children were examined in 2002 and about 3000 children aged 6-7 years old were examined in the years of 2011-12. This abstract introduce the preliminary results based on the questioning of 970 parents in the years of 2011-12.

Results: There decreased the prevalence of wheezing from 24.1% to 17.3% (p < 0.0001), the prevalence of current asthma symptoms from 10.8% to 6.3% (p < 0.0001), the number of exacerbations over 12 times a year from 0.5% to 0.2% (p=0.001) the prevalence of nocturnal asthma symptoms decreased from 4.3% to 2.2% (p=0.001), the number of symptoms limiting speech decreased from 0.9% to 0.1% (p=0.012). The diagnose of asthma was established in 2.4% of children in 2002. In 2011-12 this percentage increased up to 3.4% (p=0.07), this indicates the improvement in the diagnostics and the better level of knowledge of physicians about the asthma. The prevalence of asthma symptoms associated with the physical exertion was not significantly changed (3.6% in 2002 and 3.3% in 2011-12, p=0.4). The registration of nocturnal cough not associated with the infection of the respiratory tract decreased from 8.6% to 7.6% (p<0.02).
Conclusion: The obvious trend in the first decade of the XXI century is the decrease in the prevalence of the asthma symptoms among 6-7 years old children in the Novosibirsk with some improvement in the disease diagnostics.

Background: Regulatory T cells (Treg) expressing FOXP3 inhibit the development of T cells towards Th2. In this work we hypothesized that FoxP3 is responsible for the development of exacerbations in asthma.

Aim and objectives: To investigate the levels of CD4+FOXP3+ in moderate BA with different frequency of exacerbations compared to healthy donors.

Methods: We included 20 patients with moderate asthma, which were divided into 2 groups. The first group (n=16) had at least 1 exacerbation of asthma during the previous year, the disease duration was 7.3 (5.0;12.0) years, FEV1 - 81.2 (72.2:89.4)%; The second group (n=4) with moderate BA had 2 or more exacerbations of asthma in the previous year, the duration of the disease was 14.5 (9.0;23.0) years, FEV1 - 78.4 (74.4:89.8)%; The control group was included 17 healthy adults. Peripheral blood mononuclear cells were isolated in Ficoll density. The circulating percentage of CD4+FoxP3+ Tregs in peripheral blood was estimated by the flow cytometry analysis (PASCALCubilr Becton Dickinson, USA). Results: It was found that moderate asthma is characterized by significantly lower CD4+FoxP3+ T-reg 0.99 (0.72;3.77)% compared to healthy control - 8.16 (7.66:9.42%) (p<0.01). The level of CD4+FoxP3+ was higher 1.8 (0.8:4.7)% in patients who didn’t have the exacerbation of BA, or had a single acute of asthma compared to individuals, who had more than 2 exacerbation of asthma in the previous year - 0.53 (0.4:0.9%), p<0.05.

Conclusions: FoxP3 is responsible for the development of exacerbations in asthma. Possible, the low level of transcription factor FoxP3 is closely related to 2 or more exacerbations of BA per year.

P1949 Efficacy of a novel SHIP1 activator in animals and healthy human volunteers exposed to inhaled lipopolysaccharide

David Chernoff1, Patrick Tam2, Lloyd Mackenzie1, Judy Toews1, Grant Stienos1, Curtis Harwig1, Jeffrey Raymond1, Vanessa Brown1, Stephen Smith3, Stuart Elborn2, Csaba Szabo1, Tom MacRury1. 1Clinical Development, Aquinox Pharmaceuticals, Richmond, BC, Canada; 2Respiratory Medicine Group, Queen’s University of Belfast, Northern Ireland, United Kingdom; 3Clinical Development, Celerion, Belfast, Northern Ireland, United Kingdom.

Introduction: Suppression of P38 is an established pharmacological approach to control inflammation. SHIP1 suppresses the downstream effects of P38 in neutrophils converting it to P38δIP. SHIP1 deletion in mice results in pulmonary inflammation, and in humans, SHIP1 protein levels negatively correlate with basophil degranulation.

Objective: To determine the effects of AQX-1125, a small molecule SHIP1 activator, on airway inflammation in animals and humans.

Methods: The efficacy of AQX-1125 on LPS-induced pulmonary inflammation was evaluated in SHIP1−/− and SHIP1+/+ mice, and on bronchoalveolar lavage (BAL) cell counts and inflammatory mediators of LPS-challenged rats. The ability of oral AQX-1125 (450 mg QD, 7 days) to inhibit LPS-induced airway neutrophilia in healthy human subjects (n=18) was evaluated in induced sputum in a randomized, placebo-controlled, double-blind, two-way crossover study.

Results: AQX-1125 inhibited LPS-induced pulmonary neutrophilia in SHIP1−/− but not not SHIP1+/+ mice. AQX-1125 dose-dependently inhibited airway neutrophilia and inflammatory mediators in LPS-challenged rats (p<0.05). The ability of oral AQX-1125 (450 mg QD, 7 days) to inhibit LPS-induced airway neutrophilia in healthy human subjects (n=18) was evaluated in induced sputum in a randomized, placebo-controlled, double-blind, two-way crossover study.

Results: AQX-1125 inhibited LPS-induced pulmonary neutrophilia in SHIP1−/− but not not SHIP1+/+ mice. AQX-1125 dose-dependently inhibited airway neutrophilia and inflammatory mediators in LPS-challenged rats (p<0.05). In humans, AQX-1125 reduced LPS-induced neutrophilia. Prior to LPS exposure, sputum neutrophil cell counts were the same between treatment groups (Geometric Least Squares Mean ± GLSM AQX-1125/placebo ratio = 0.96, 90% CI 0.27-3.38). Post-LPS exposure (24 h), AQX-1125 reduced the sputum neutrophils by 66% (GLSM ratio = 0.34, 90% CI 0.13-0.92).

Conclusions: These data demonstrate efficacy of AQX-1125 in human and rodent pulmonary inflammation models, supporting the importance of SHIP1 as a novel target and the clinical development of AQX-1125 for inflammatory disease.

P1950 The potential mechanism of Th17/Treg imbalance in the microenvironments of chronic inflammation and allergic asthma

Linlin Wang. Department of Pulmonary Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China.

Objective: Recent studies have shown that Tregs can differentiate into IL-17+/Foxp3+ T cells in the colitid microenvironment and allergic rinitis. However, the biology of CD39+/Tregs cells, IL-17+/Foxp3+ T cells and Th17 cells, and the relationship among these three kinds of cells remain poorly understood in allergic asthma.

Methods: We investigated the proportions of Th17, CD39+/Treg cells and IL-17+/Foxp3+ T cells in peripheral blood from allergic asthmatics and healthy controls by flow cytometry. All patients were allergic to house dust mites. Dermaophages peryorrhinus specific IgE levels, pulmonary function and Asthma Control Questionnaire were assessed. Moreover, the associations among all these kinds of index and disease severity were analyzed.
Result: There was a deficiency in the frequency of total Tregs in asthmatics, whereas the frequency of Th17 cells, IL-17+Foxp3+ T cells, CD39+Treg cells and plasma IL-17 levels were increased in moderate to severe asthma. FEV1 (% predicted) was negatively correlated with the frequency of Th17 cells, IL-17+Foxp3+ T cells, CD39+Treg cells and plasma IL-17 levels, and positively correlated with the frequency of total Tregs. Moreover, the frequency of Th17 cells and IL-17+Foxp3+ T cells were positively correlated with the frequency of CD39+Treg cells.

Conclusion: Our findings suggest that the increased expression of CD39 on Tregs in asthma can offset the decreased immunosuppressive functions of Tregs. And Tregs in the microenvironment of asthma also have plasticity of differentiate into IL-17+Foxp3+ T cells. CD39+Treg cells play an important role in constraining pathogenic Th17 cells and IL-17+Foxp3+ T cells.

P1951

Expression of the β2-adrenoreceptor and M3-cholinoreceptor genes in patients with different severity of asthma and BHR level
Polina Selivanova1, Evgeny Kulikov1, Natalya Kirillova1, Maxim Freydin2, Ludmila Ogorodova1
1Hospital Therapy, Siberian State Medical University, Tomsk, Russian Federation; 2Laboratory of Population Genetics, Research Institute for Medical Genetics, Tomsk, Russian Federation; 3Faculty Pediatrics, Siberian State Medical University, Tomsk, Russian Federation

Background: Persistent airway inflammation, as well as nervous innervation of bronchial smooth muscles plays the main role in the formation of BHR, one of the key characteristic of asthma.

Aim and objectives: To evaluate the β2-adrenoreceptor (ADRB2) and M3-cholinoreceptor (CHRM3) gene expression in bronchial mucosa of patients with different severity of asthma. We hypothesized that the differential expression of these genes may contribute to the different BHR level.

Methods: Biopsy specimens of right middle lobar bronchus were obtained from 30 asthmatic patients (13 with severe, 9 with moderate, and 8 with mild). The inclusion criteria followed the GINA, 2009. All subjects underwent a routine medical history taking, physical examination, spirometry, BHR measurement. The mRNA levels for the ADRB2 and CHRM3 genes in bronchial mucosa were revealed using qRT-PCR (iQ SYBR Green Supermix, BioRad, USA), mRNA levels were then recalculated as 2-ΔΔCT to the GAPDH mRNAs.

Results: An increase of the ADRB2 and CHRM3 genes expression was demonstrated in patients with severe asthma (ADRB2 mean=0.54; 95%CI 0.50-0.59; CHRM3 0.57; 0.53-0.60) as compared to patients with mild (ADRB2 0.34; 0.32-0.36; CHRM3 0.48; 0.46-0.49) and moderate disease (ADRB2 0.27; 0.25-0.29; CHRM3 0.40-0.49) (p<0.05). It was revealed by correlation analysis that the level of the PC20 is negatively correlated with the mRNA levels of the ADRB2 and CHRM3 (R=-0.67 and -0.52, respectively; p<0.005), thus a high level of gene expression is associated with a high BHR. Conclusion: The differential expression of the ADRB2 and CHRM3 genes is associated with asthma severity and BHR level.

P1952

Changes in skin prick test reactivity over 7–14 years in a population of food allergy children and asthmatic symptoms
Carlo Zacari, Valentina De Vittori, Anna Taglia, Marta Bresciani, Anna Rugiano, Marzia Duse.

Background: Allergic disorders are an increasing health problem among children.

Aim: To describe the prevalence of sensitization to common food and inhalant allergens at different ages and the association with asthmatic symptoms.

Methods: 174 children with positive Skin Prick Test (SPT) to at least one food allergen at <36 months were called after a follow-up period of 7-14 years to repeat SPT, to complete a questionnaire about asthmatic symptoms, and to perform spirometry.

Results: 174 children complete the questionnaire: 25.8% had wheezing, 34.4% had dry cough and 55.6% reported diagnosis of asthma. At the first observation 65 (37.3%) had positive SPT only to food allergens(F) and 109 (62.6%) had sensitization to food and inhalant allergens (F+I). At the second observation in the group with single sensitization to F 50% lost sensitization, 10% retained sensitization to food and developed sensitization to inhalants (F+I) and 40% showed sensitization only to inhalants. In the group with double sensitization (F+I) at the first observation: 50% remained positive to both allergens (F+I), more than 40% were positive only to inhalants and a small percentage (~10%) became negative. The sensitization profiles differed significantly between two groups (F and F+I). FEV1 and FEV1/FVC were significantly lower in the group F+I at the first observation than in the group F (p<0.01).

Conclusion: We found an association between changes in SPT positivity and the development of asthmatic symptoms. The double sensitization (F + I) as well as the early sensitization to alants would seem to correlate with the persistence of the allergy and with the development of respiratory disease.

Comparison of different instruments to obtain nasal epithelial cells from nasal mucosa.

Andrea St incest,1 Elisabeth Kieninger1, Birgitta Sandkopf1,2, Nicolas Regamey1, Marco Alves1,2. Inselspital, Department of Pneumatics, Division of Respiratory Medicine, Bern, Switzerland; 1University of Bern, Department of Clinical Research, Pneumactic Pneumology, Bern, Switzerland

Introduction: Nasal epithelial cells have been shown to be good surrogate markers for bronchial epithelial cells. We aimed at comparing different brushing instruments allowing collection of nasal epithelial cells.

Methods: Nasal epithelial cells were obtained by brushing the inferior surface of the middle turbinate of both nostrils using three different instruments: a cytology brush, a flocked nasal swab and a nasal mucosal curette. Cells cultures were established by seeding the cells into medium. Cell count, cell viability, success rate in establishing cell cultures and the acceptability to subjects were compared between groups.

Results: 60 human subjects (median [IQR] age: 34 [27-36] years) were brushed. Higher number of cells were obtained using brushes (9.8 [6.7-33.5] x 10^6 cells/mL compared to swabs (2.5 [1.5-4.0] x 10^6 cells/mL, p<0.0001) and curettes (1.3 [1.0-2.1] x 10^6 cells/mL, p<0.0001). Viability was similar for cells obtained using brushes (42 [14-78] %), swabs (54 [15-71] %) and curettes (54 [25-69] %). Cells obtained by brushes reached confluence fastest (6 [6-10] d), followed by cells obtained by curettes (11 [9-15] d, n.s.) and swabs (19 [13-21] d, p<0.0001). Success rate in establishing primary cell cultures (~ 90% confluent cell layers within 21 days in a 12.5 cm^2 cell culture flask) was 90% with brushes, 65% with swabs and 85% with curettes. Pain intensity was similar for all instruments, brushes (3.0 [2.0-5.8] out of 10 on the pain scale), swabs (2.5 [1.0-4.0]) and curettes (3.0 [2.0-5.0]).

Conclusion: All three types of instruments allow collection and growth of human nasal epithelial cells, with good acceptability to subjects. The most efficient instrument is the nasal brush.

The inflammatory response of pulmonary vascular smooth muscle cells to bacterial endotoxin is sensitive to endothelin receptor antagonism

David Juncel,1 Maria Feldmann,1 Chiara Wahl1, Stefanie Koehler-Bachmann1, Carmen Schindewolf2, Erich Stoebel2, Juergen Behl2, Juergen Knobloch2, Andrea Koch2,1 Medical Clinic III for Pneumology, Allergology, Sleep, and Respiratory Medicine, University Hospital Bochum-Bergmannsheil, Bochum, NRW, Germany; 2Dept. of Thoracic Surgery, Lungenklinik Köln Merheim, Koeln, NRW, Germany

Background: Bacterial infections cause exacerbations of chronic inflammatory lung diseases by aggravating airway inflammation. Current therapeutic strategies like steroid administration have proven unsatisfactory e.g. for COPD and highlight the need for new approaches.

Aim: To elucidate the inflammatory response of pulmonary vascular smooth muscle cells (PVSMCs) to LPS, and whether this response is sensitive to antagonists of endothelin A receptor (ETAR) (Ambrisentan), ETBR (BQ788) or both receptors (Bosentan).

PVSMCs of 44 donors were incubated with highly purified smooth LPS (sLPS), highly purified short-chain LPS (Re-LPS, shortest form) or M-LPS (mixture of long and short forms) of Salmonella spp. or with Lipooligosaccharide (LOS) of nontypeable H. influenzae (NTHI) or with NTHI extract in absence or presence of endothelin receptor antagonists (10^-7-10^-5 M) for 72 hours and cytokines were measured by ELISA. All LPS-forms and NTHI extract induced concentration-dependent IL-6, IL-8 and GM-CSF release from PVSMCs (each p<0.05). M-LPS and LOS were most effective. The effects of M-LPS were completely abolished by polymyxin B and CLI-095 (TLR4 inhibitor) but not affected by TLZR2/TLZ9 inhibitors. M-LPS-induced IL-6 was reduced by all endothelin receptor antagonists (each p<0.05). IL-8 and GM-CSF were reduced by Bosentan and BQ788 but not by Ambrisentan (each p<0.05).

PVSMCs contribute to the inflammatory response to bacterial infections and thus can prove to be a therapeutic target in exacerbations of chronic airway diseases. Cytokine release shows specific reactions to dual vs. selective endothelin receptor blockers which can be useful in therapy.

P1955

Asthma and vitamin D

Ismail Hunta, Oya Baydar, Erzgi Ozylizm, Serad Kuleci. Chest Diseases, Cukurova University, Adana, Turkey

Background: Recent studies indicate a relationship between low vitamin D level and asthma pathogenesis. The aim of this prospective study is to evaluate vitamin D levels in asthmatic patients and investigate the relationship between vitamin D and asthma pathogenesis.

Material and method: 112 asthmatic patients and 94 healthy people who admitted to Cukurova University Chest Diseases Department were included. The age and gender of asthmatics and control group were similar. The demographic data were recorded. Both asthmatics and control group had vitamin D determination tests and their vitamin D levels are studied with liquid chromatography.
Conclusions: Levels of vitamin D is decreased in patients with asthma. It let us hypothesize that 1.25\(\text{OH}_2\)D may be important in the pathogenesis of asthma. In serum (\(r=0.54\), \(p<0.05\)) difference of 1.25\(\text{OH}_2\)D was not obtained. Level of 1.25\(\text{OH}_2\)D significantly associated with asthma pathogenesis especially in females and poor lung functions.

Conclusion: in asthmatic patients, a significant positive correlation is determined between the vitamin D level of female patients was significantly lower than the male patients (23.88±11.92 ng/ml in females and 29.52±11.48 ng/ml in males) (\(p=0.03\)). Again in asthmatic patients, a significant positive correlation is determined between the forced expiratory volume in first second and serum vitamin D level (\(p=0.004\)).

Conclusion: With these results, it is thought that vitamin D levels could be associated with asthma pathogenesis especially in females and poor lung functions.

P1956

Levels of vitamin D is decreased in asthmatic patients

Edita Gasiuniute, Zivilė Balciunaite, Simona Lavinskienė, Raimundas Sakalauskas, Brigita Sitkauskienė. Pulmonology and Immunology Department, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and aim: 1.25-Dihydroxy vitamin D (1.25\(\text{OH}_2\)D) has long been recognized as a critical mediator in bone health. Several studies of recent years have shown the relationship between chronic inflammatory lung diseases and Vitamin D level serum levels. The aim of this study was to elucidate Vitamin D levels in allergic asthma (AA) and non allergic asthma (NA) patients, and to compare these results with healthy subjects (HS).

Methods and material: Eighteen patients with AA, 14 with NA, as well as 10 HS were involved to the study. 1.25\(\text{OH}_2\)D levels in serum samples were analysed by ELISA. Eosinophil count was evaluated in induced sputum and peripheral blood samples.

Results: We found that vitamin D levels in asthmatic patients were lower compared with HS in asthmatic group 66.93±21.5 pmol/L vs HS 134.5±20.1 pmol/L, \(p<0.05\). However in AA (81.06±21.5 pmol/L) and NA (52.8±21.5 pmol/L) significant difference of 1.25\(\text{OH}_2\)D was not obtained. Level of 1.25\(\text{OH}_2\)D significantly negatively correlated with eosinophil count in induced sputum in patients (\(r=-0.72\), \(p<0.05\)) and in serum (\(r=-0.54\), \(p<0.10\)).

Conclusions: Levels of vitamin D is decreased in patients with asthma. It let us hypothesize that 1.25\(\text{OH}_2\)D may be important in the pathogenesis of asthma.

P1957

Complex treatment of allergic bronchopulmonary aspergillosis (ABPA) in asthmatic patients

Raimondas Sakalauskas, Brigita Sitkauskienė. Pulmonology and Immunology Department, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: ABPA is an immunologic pulmonary disorder caused by hypersensitive reaction to Aspergillus fumigatus colonizing patient’s bronchial tree. The prevalence in general population is between 1-2%, in patients with corticosteroid sensitive reactions to Aspergillus fumigatus colonizing patient’s bronchial tree. The presence is associated with unfavorable prognosis of this disease. The standard treatment includes systemic corticosteroids (SCS) and antifungal agents (AFA). The biological therapy in ABPA is discussed.

Methods: A case report of 56 year old woman with ABPA, manifested as uncon- trolled severe persistent asthma with frequent exacerbations. We compared effects of 1. standard inhaled CS treatment, 2. combination of SCS with AFA and 3. Anti-IgE therapy using lung function tests, FENO, total IgE level, spec IgE level to Aspergillus fumigatus, ACT questioner and clinical course assessment.

Results: We found significant improvement in all parameters after 4 weeks of SCS + AFA therapy. Significant improvement has been observed in all parameters after 16 weeks, 8 months, 1year and 2 years of anti-IgE, with no need of AFA and SCS. Only one exacerbation of ABPA was observed during 24months of anti-IgE treatment. No adverse effects from anti-IgE therapy were observed.

Conclusion: Anti-IgE therapy could prove to be an alternative targeted treatment options in patients with ABPA. Successful response to anti-IgE in severe asthma patients with ABPA could result in reduced need of AFA and SCS therapy, stable lung function and lower risk of exacerbations.

Phenotypes of adult-onset asthma by cluster analysis

Marielle Amerlink, Selma B. de Nijs, Jantina C. de Groe, Peter M.B. van Tilburg, Paul van Spieghel, Frans H. Krouweil, Rene Lutter, A. H. Zuiderwier, Eks M. Veenink, Anneke ten Brinke, Peter J. Sterk, Elisabeth H. Bel, Respiratory Medicine, Academic Medical Centre, Amsterdam, Netherlands; 2Respiratory Medicine, Medical Centre Leeuwarden, Leeuwarden, Netherlands; 3Respiratory Medicine, Tergooi Hospital, Blaricum, Netherlands; 4Respiratory Medicine, Slotervaart Hospital, Amsterdam, Netherlands; 5Respiratory Medicine, Spaarne Hospital, Hoofddorp, Netherlands; 6Respiratory Medicine and Experimental Immunology, Academic Medical Centre, Amsterdam, Netherlands; 7Clinical Epidemiology, Bioinformatics & Biostatistics, Academic Medical Centre, Amsterdam, Netherlands.

Rationale: Asthma phenotyping is of increasing importance to identify patients who could benefit from personalised therapeutic strategies. Several studies suggested that adult-onset asthma is a specific phenotype. In order to explore underlying mechanisms of adult-onset asthma, we aimed to identify subphenotypes by unsupervised clustering methods.

Methods: 200 patients with adult-onset (>18yr) asthma (60.5% female; age 54 (26-75) yr, 45% atopic) were characterized with respect to clinical, functional and inflammatory markers. Initial variable reduction was achieved by elimination of redundant data and factor analysis. K-means non-hierarchical cluster analysis was performed to identify clusters.

Results: We identified three clusters of adult-onset asthma. Cluster 1 (n=41) consisted of predominantly females, with higher BMI and more often of non-Caucasian descent. They showed higher symptom scores, higher health care utilization and frequent exacerbations. However, they had lower sputum eosinophils and normal exhaled nitric oxide (FeNO) levels. Cluster 2 (n=60) consisted of predominantly males with severe asthma. They showed high symptom scores and frequent exacerbations, with reduced lung function, elevated sputum eosinophils and relatively high FeNO levels. Cluster 3 (n=90) consisted of predominantly males with mild-moderate asthma, normal lung function, minimal symptoms and health care utilization.

Conclusions: Non-hierarchical cluster analysis identifies three subphenotypes of adult-onset asthma that can be distinguished by gender, symptom severity, BMI lung function and airway inflammation. Identifying these subphenotypes can help to investigate the associated pathobiology and provides new directions to personalized management.

Conclusions: Non-hierarchical cluster analysis identifies three subphenotypes of adult-onset asthma that can be distinguished by gender, symptom severity, BMI lung function and airway inflammation. Identifying these subphenotypes can help to investigate the associated pathobiology and provides new directions to personalized management.
of different geographic locations were involved. A standard questionnaire was applied between February -December 2011. Results: The percentage of females was 75%. Severity of the disease was found as mild persistent in 10%, mild intermittent in 40%, moderate in 38% and severe in 12%. 12% of the patients had irreversible airway obstruction. Smoking/quitting patients were 34% of the study group, 42% of the patients had obesity (BMI> 30), 11% had allergic intolerance and 29% had psychological triggers. Smoking rate was found to be lower in females (p<0.01) whereas the rate of obesity, allergic intolerance and psychological triggers was higher in females (p<0.001) than males. Allergic attack phenotype consisted 21% of the study group. Total control rate was found as 22%; which was higher in males compared to females (29% vs 19%) (p<0.01). There was no difference between genders in term of partial control however uncontrolled asthma was more frequent in females than males (31% vs 22%) (p<0.01). Pulmonary function tests, total IgE values, skin prick test results and severity of disease were all comparable between males and females. The most frequent comorbidities were chronic rhinitis/rhinosinusitis (49%) and reflux(34%). It was found that the cases with lower asthma control levels had higher rates of allergic intolerance and multiple comorbidities (p<0.01). Conclusion: To our knowledge this is the first study on asthma phenotypes in our environment. We believed that it will have significant contribution in obtaining control in our asthma patients.

P1961 Asthma and atopy: How much is it really attributable? About a representative population of Tunisia Ines Saada, Joude Cherif, Sonia Toujani, Hafedh Zakhama, Yacine Ouazhchi, Nozha Ben Salah, Rechtir Louiz, Jalloul Daghfous, Nedia Mehai, Majed Beji. Pulmonology, La Rabta Hospital, Tunis, Tunisia

Introduction: In recent decades it has become routine to describe asthma as an atopic disease. We carried out this study to evaluate the prevalence of asthma and assess the association of atopy with asthma in individuals and in population.

Method: A cross-sectional survey, single pass, representative of the general population was carried out in subjects aged from 2 to 50 years. Informed consent was obtained. Prevalence was determined through questionnaires, validated and used in international surveys, corresponding to the screening asthma and lung function test. Definition of atopy was based on clinical symptoms of rhinitis and allergy skin.

Statistical analysis was performed using SPSS 18.0.

Results: The study included 4470 subjects. There was 40.2% male and 59.8% female. Current asthma prevalence was 6.8% in adults and 5.9% in children. Lung function test showed reversibility in 20%. The proportion of asthma cases that are “attributable” to atopy (defined as rhinitis and allergy skin) was estimated by the prevalence of atopy risk. About 53.5% of children’s asthma. The percentage of females was 75%. Severity of the disease was found as mild persistant in 10%, mild intermittent in 40%, moderate in 38% and severe in 12%. 12% of the patients had irreversible airway obstruction. Smoking/quitting patients were 34% of the study group, 42% of the patients had obesity (BMI> 30), 11% had allergic intolerance and 29% had psychological triggers. Smoking rate was found to be lower in females (p<0.01) whereas the rate of obesity, allergic intolerance and psychological triggers was higher in females (p<0.001) than males. Allergic attack phenotype consisted 21% of the study group. Total control rate was found as 22%; which was higher in males compared to females (29% vs 19%) (p<0.01). There was no difference between genders in term of partial control however uncontrolled asthma was more frequent in females than males (31% vs 22%) (p<0.01). Pulmonary function tests, total IgE values, skin prick test results and severity of disease were all comparable between males and females. The most frequent comorbidities were chronic rhinitis/rhinosinusitis (49%) and reflux(34%). It was found that the cases with lower asthma control levels had higher rates of allergic intolerance and multiple comorbidities (p<0.01). Conclusion: To our knowledge this is the first study on asthma phenotypes in our environment. We believed that it will have significant contribution in obtaining control in our asthma patients.

P1962 Asthma registry, a path to uncover pitfalls in asthma Syed Ali Reza Mahdaviani, Seyed Amir Mohajerani, Majid Malekmohammad, Seyeda Zadeh, Aftef Fakharian, Alireza Eslaminejad, Maryam Husazrad, Mohammad Reza Masjedi, Ali Akbar Velayati, Mazerah Ebrahimian. Pediatrics Respiratory Disease Research Center, Pediatrics Respiratory Disease Research Center, National Research Institute of Tuberculosis and Lung Diseases, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

Background: We performed a prospective study with a group of consecutive adult patients with allergic rhinitis and asthma from our outpatient clinic. The control of the disease was assessed using both ACT and CARAT tests. Results: Forty patients were evaluated (mean age 53, 70% female). 17% of the patients had ACT controlled asthma and 45% had ACT uncontrolled asthma. In both groups CARAT results were equivalent. Conclusion: A tool able to assess both asthma and allergic rhinitis control was lacking. In our patients, using the CARAT was useful mainly in the partially controlled asthma population by helping to differentiate those in whom uncontrolled rhinitis was the main cause of the uncontrolled asthma.

P1964 Correlation of changes of IgE with skin reactivity and clinical outcome during specific immunotherapy against home dust in asthmatic subjects Besim Prnjavorac1, Rafid Sejdnovic1, Enes Hondo1, Adlija Caulevic2, Sabina Szemza2, Maja Malenica2, Tamer Bego2, Tanja Dujc2.1Paludomology, General Hospital Tuzla, Bosnia and Herzegovina; 2Clinical Biochemistry, Faculty of Pharmacy, Sarajevo, Bosnia and Herzegovina

Background: Effectiveness of SIT was well documented in many cases and published data. Selection of patients for SIT should be very serious and must include skin test and total and specific IgE measurement. How outcome of SIT correlate with changes of IgE, skin reactivity and overall symptoms reduction is aim of this study.

Material and methods: Skin testing, total and specific IgE measurements were performed before and after each year of treatment. Skin test assessment was performed according to recommendation of Manual of Laboratory immunology. IgE was performed using ELISA method. Clinical outcome was assessed using AQLQ questionnaire.

Results: During five years period 58 asthmatic subjects with home dust and dermaphagoides allergy were treated by SIT. Baseline total IgE was 488.5 IU/ml (SD 78.9), mean specific IgE against dermaphagoides pteronissinus was 36.5 IU/ml (SD 15.2). Subcutaneous tests showed 15-20 mm weal in 43, and more than 21 mm in 15 cases. After 5 years mean total IgE was 227 IU/ml (SD 9.2) and mean specific IgE was 28.2 IU/ml (SD 8.9). Skin tests showed decrease diameter of weal. In 49 out of all patients clinical outcome were very well, and in 9 satisfied (according to AQLQ questionnaire). Using test of correlation, by linear regression, better correlation was shown between of skin testing and AQLQ than in total or specific IgE. So, in vivo skin tests were better predictor for success of SIT, than measurement of IgE.

Conclusion: Results of skin tests in diagnostic assessment of allergy in asthmatic patients were better predictor of successful outcome of SIT than laboratory measurement of total and specific IgE.

MONDAY, SEPTEMBER 3RD 2012
To date, the pharmacokinetics (PK) of salmeterol xinafate (SX) following oral inhalation are only sparsely described in the literature (Kirby, S. et al. Eur J Clin Pharmacol 2001; 56:781-791; Harrison, L. L. et al. 3rd Annual ERS/CPS Health Biomark. Drug Del 2011; 24:1-8). Now, improvements in bioanalytical method sensitivity allow full characterization of the pharmacokinetics of SX following administration of the marketed dose (50 mcg). In 2 studies, healthy adult subjects received 50 mcg salmeterol by oral inhalation as Advair Diskus® (100/50 (100 mcg fluticasone/50 mcg SX, Study 1, 23 subjects, 2 Advar bats) or Advair Disks® 500/500 (500 mcg fluticasone/50 mcg SX, Study 2, 20 subjects). Activated charcoal was not administered to block oral absorption. PK blood samples were collected pre-dose and 3, 4, 5, 7 min with additional serial timepoints to 48 hours (Study 1), or 2, 3, 4, 5, 6, 8 min with additional serial timepoints to 72 hours (Study 2) and processed in two ways: 1) MS/MS/MS assay with a 0.05 pg/mL LLOQ. Peak plasma concentration (Cmax) was 153.59 and 151.58 pg/mL (Advair Batches A and B, Study 1) or 185.49 pg/mL (Study 2). Time to Cmax was 4 and 3 min (Study 1) or 3 min (Study 2). By 12 hours postdose the plasma concentration was <5% Cmax. Elimination half-life was 12.9 and 15.4 h (Study 1) or 13.5 h (Study 2). These results illustrate the importance of early frequent sampling to capture SX Cmax followed by observation to 48 - 72 hours to capture 3 - 5 elimination half-lives.

238. Tobacco use and cessation

P1965

Salmeterol pharmacokinetics following a 50-mcg dose by dry powder oral inhalation to healthy volunteers

Eline Barmestier Gert1, Rick Fuller1, Spencer Jones2. 1Clinical Dept., Oriel Therapeutics, Inc., Berkeley, CA, United States; 2Global Medical Affairs Respiratory, Sandoc International GmbH, Holzkirchen, Germany

NRT and without NRT was offered to intervention and control groups 2 prospective study to assess the impact of workplace health promotion programs (WHPP) on SC rates conducted in 348 health professionals at 4 outpatient clinics in 12-months period. Average age of patients was 49±12. At first visit 94.8% were diagnosed with COPD GOLD III/IV and 73%-6% with high blood cholesterol, of which 58.2% and 51% respectively were new findings (<p =0.05). By the end of treatment SC rates in intervention group were 46.7% compared to 3.3% of controls (<p =0.001). Increase of lung function was observed in intervention group compared with controls (p<0.01). Stress levels did not increase in 50% quitters and decreased in 35.7% cases. Among participants of WHPP after 12-months in intensive intervention settings (HE interventions+HP handouts) significant decrease of 17% of smoking rates was reached, in reference settings only handouts given no significant changes observed. Prevention of NCD requires systematic identification of smokers and provision of SC assistance at all levels of PHC. Workplaces are ideal settings for HP interventions. Intensive assisted SC interventions significantly increase success rates.

P1968

The INAsma study – Environmental tobacco smoke exposure at home and smoking prevalence in the Portuguese population

Ana Margarida Pereira1, Mário Morais-Almeida2, Ana Sá e Sousa3, Taça Jacinto1,2,3, Luis Filipe Azevedo1,4, Carlos Robalo Cordeiro5, António Bugalho de Almeida2, João Almeida Fonseca6,7,8, Serviço de Pneumologia, Centro Hospitalar Universitário de São João, E.P.E., Porto, Portugal; 2CINTESIS - Centro de Investigação em Tecnologias e Sistemas de Informação em Saúde, Universidade do Porto, Portugal; 3Clínica Universitária de Pneumologia, Faculdade de Medicina de Lisboa, Portugal

Background: The data on the prevalence of tobacco smoke and environmental tobacco smoke (ETS) exposure in Portugal is scarce, especially after the 2008 smoking bans. Aims: We aimed to: 1) estimate the prevalence of exposure to ETS at home and of tobacco smoking in Portugal; 2) identify variables associated with smoking or exposure to ETS.

Methods: Nationwide, cross-sectional, population-based telephone survey; 6003 individuals participated. ETS exposure at home was defined as exposure to at least one current smoker (CS) at home. A smoker was someone with ≥15 years smoking at least 1 cigarette per day during a year; a CS smoked in the last month. Results: Exposure to ETS at home was reported by 26.6% (95%CI 25.5-27.7), Age <18 years old (OR=1.57, 95%CI (1.72-2.13)), current asthma (OR=1.69, 95%CI (1.26-2.46)), living in households with ≥3 persons (OR=34.31, 95%CI (26.54-59.597.07)), those living in households with ≥3 persons (OR=2.21, 95%CI (5.59-30.27)) and those exposed to ETS at home (OR=14.39 (10.14-20.41)). Conclusion: Exposure to ETS at home in Portugal was higher than previously reported. Children/adolescents and asthma patients had a higher risk of exposure. The prevalence of tobacco smoking was slightly lower than in previous reports.

P1969

Efficacy of smoking cessation assistance in Tunisian women

Basma Ouargi, Heifa Zahi, Ijen Ben Amar, A. Ali Baccar, Saloua Arzabi, Eya Tangour, Mouna Berraies, Hichem Aouina, Leila El Gharbi, Hend Bouacha. Pulmonary, Charles Nicolle Hospital, Tunis, Tunisia

Introduction: Smoking is the most preventable cause of death. Although, woman started smoking in greater numbers later than man, she seems to have more difficulties in quitting cigarette than he. Aim: Evaluate the smoking intoxication rate in Tunisian woman and the effectiveness of smoking cessation intervention.

Patients and methods: It’s a prospective study, including 100 women smokers treated for smoking cessation during the period from 2007 to 2010. We recorded data on smoking history, degree of nicotine dependence, strategies of smoking cessation and the most successful intervention after 3 and 6 months.

Results: Mean age of women smokers was 43.6±13.3 years. The mean age of onset of tobacco use was 19.7±6.4 years. The mean duration of exposition was 23.4±12 years, with a mean of cigarettes consumption of 22.1±11 cigarettes/day. Tobacco dependence level was important in 65% of women. A half of them, a low level of education attained, and most of them (71.4%) had unfavourable socioeconomic status. According to HAD test, 20 patients were anxious and 45 patients were depressed. The principal reason of quitting cigarette smoking was health problems associated with cigarette (83.2%). Nicotine replacement treatment was the most strategy prescribed (98%). After the first counselling, 40% were lost of side. Con-
Motivation to quit smoking among patients with atherosclerosis compared to asymptomatic smokers.

The predictors of success or failure in smoking cessation programme (SCP), specific for the Brazilian population have been low studied. We evaluated characteristics influencing the success in a SCP. This non-randomized, prospective and open clinical trial evaluated 172 smokers in a SCP based on cognitive behavioral treatment associated or not with medication therapy. Individuals were followed for 12 months. Statistical analysis was performed using the R statistical software. For quantitative variables (age, pack years index and cigarettes/day) were used t-tests and for qualitative variables (gender, education level, lived with others, smokers, medication therapy, nicotine dependence, socioeconomic, anxiety and depression level) were used χ² test. The influence of epidemiologic characteristics on smoking cessation (SC) in univariate and multivariate analyses was tested, calculating Relative Risks (RR) with confidence intervals of 95% (CI). Variables resulting in P>0.15 for univariate analysis were selected to enter into logistic regression model. Differences were considered significant at P<0.05.

Results: 172 individuals were included, 126 (73%) started treatment, of which 61 individuals (56.4%) quit smoking and according the logistic the individuals who used medication therapy had eight-fold more chances to start abstinence (P=0.002 RR=8.3 CI 3.2-29). Thirty-three percent of individuals remained abstinent for 12 months and smokers with lower socioeconomic level had nine-fold more chances to return to smoking (P=0.005 RR=9.0 CI 2.5-72).

Conclusions: The success rate of this program was 16% and medication, as well as socioeconomic status are predictors of success in SC.

Effectiveness of smoking cessation skills building workshops in educating smoking cessation techniques to Pakistani physicians.

Introduction: Physician advice to quit smoking is an effective component of a smoking cessation strategy. Published data indicates that teaching/training smoking cessation skills to physicians improves their smoking cessation practices and increases quit rates among their patients.

Objective: To determine the effectiveness of smoking cessation skills building workshops (SCW) among local physicians.

Methods: Five one-day SCW were arranged across Pakistani cities. A validated questionnaire assessing attitude and knowledge related to smoking was administered pre-workshops (PRW) and immediately post workshops (POW) attendance.

Results: 113 physicians completed the SCW. 90 were men. Age range was 22-61 years (mean ±SD 37±11 yrs). 72 were GPs, 11 chest physicians, 11 cardiologists, 8 consultant internist and 11 trainee physicians. Post workshop physicians felt 'very confident' about their knowledge to treat nicotine dependence-15.9% (PRW) vs. 64.6% (POW); they felt 'very confident' in discussing the smoking cessation issues with their patients- 52.2% (PRW) vs. 80.9% (POW); their knowledge regarding pharmacotherapy improved- 9.7% (PRW) vs. 49.1% (POW). The 5Ax approach was answered correctly by 17.7% (PRW) vs. 69.9% (POW). Appropriate prescribing of Nicotine Replacement Therapy improved - 38.8% (PRW) vs. 61.1% (POW). Awareness of possible adverse effects of medications enhanced - 46.9% (PRW) vs. 71.1% (POW).

Conclusion: After attending a one-full day smoking cessation skills building workshop, physician’s felt more confident in discussing anti-smoking issues with their patients and their smoking cessation knowledge improved significantly.

Sm score of patients with PAD is higher (8.8 points) than motivation of asymptomatic smokers (8.6 points) whereas the stage of addiction is lower (5.2) in contrast to the control group (5.7)-difference not significant. There is a significantly higher score of Sm and with an apparent association with better education and with poorer and less-educated people. Relapses were common after 6 months of smoking cessation assistance.

Predictors of success in smoking cessation among Brazilian subjects.

Rafaela Xavier, Dionie Ramos, Fernanda Rodrigues, Marceli Leite, Juliana Ito, Camila Suehiro, Pedro Cerqueira, Alessandra Toledo, Ercy Ramos. Phisiotherapy, UNESSP- Sao Paulo State University, Presidente Prudente, SP, Brazil

Introduction: Inhaled therapies can only be effective if the patient uses the delivery device correctly and complies with treatment, which in turn may be influenced by their attitude towards the disease and its treatment. Patient education is fundamental to optimizing this, as is their perceived effectiveness of medication. This study explores patients’ attitudes towards inhaled therapy with a view to provide targeted education.

Methods: Forty eight respiratory clinic patients (60% male) completed a self-administered structured questionnaire evaluating attitudes towards their current inhaled therapy.

Results: All respondents considered Inhaler therapy important, and 61% had a good understanding of their lung condition. Although 70% had been given advice regarding inhaler use, 67% did not use these as prescribed (see table). Moreover, 63% had not discussed their concerns with a doctor or nurse but 80% would like more training (73% preferred pharmacists to do this).

Conclusion: This study has identified a need to further address education. A significant proportion of patients do not use their inhaler as prescribed and have some concerns about inhaled therapy, emphasizing the importance of providing patients with adequate information about their disease and treatment at every opportunity to enhance compliance. To aid this, targeted education and training sessions delivered by Pharmacists are being developed.

Pregnancy and smoking: cessation advice and health consequences of CO fetal exposure: An exploratory study.

Joana Silva’, Sofia Belo Bagaçu’, Rui Carrapato2, José Manuel Calheiros1, Health Sciences Research Centre (CICS), Faculty of Health Sciences (FCS), University of Beira Interior (UBI), Covilhã, Portugal; 1Gynecology and Obstetrics, São Sebastião Hospital, Santa Maria de Feira, Portugal

Introduction: Fetal exposure to second-hand smoke (SHS) is the most important avoidable cause of fetal morbidity and mortality. Health professionals’ (HPs) cessation advice is crucial, since women may be more prone to change.

Study aims: To evaluate – HPs’ cessation advice, – Fetus exposure to CO and association with anthropometric parameters of the newborn.

Methods: Prospective cohort study. Face-to-face structured interviews were applied to 94 pregnant, followed up at São Sebastião Hospital, mean age 31 years. Newborn parameters were collected from clinical files. We performed “baby CO”. We used chi squared, Mann-whitney, Kruskal Wallis tests, and Pearson’s correlation.

Results: 37% of the participants were smokers (average 6 cigarettes/day). 54% had a smoker partner. 80% reported SHS exposure. 67% were questioned about smoking. 93% of the smokers wanted to change their consumption, but only 7.4% did quit (cold turkey, on their own). The observed decrease in consumption was significantly associated with HP counseling (p<0.05), while cessation counseling was not associated with quitting. Neonates of the smokers were born, on average, 231,30g lighter and with less 0.76 cm of cephalic perimeter (p<0.05).

Conclusions: The majority of pregnant women were advised to change tobacco consumption and was exposed to SHS. Most of the smokers wanted to reduce smoking, but did not want to quit. Cessation counseling was not effective. Nevertheless, all the low consumption, smoking and CO levels were negatively associated with newborn parameters. There is a need to train HPs in cessation counseling, including SHS exposure and partners’ smoking.
Influence of smoking among residents doctors in a tertiary teaching hospital

Francisco Rius, 3, Manuel Garcia

Rationale: An appreciation of the high rate of tobacco use by those with mental illness is important. Although the practice guidelines suggest that intervention useful with the general population should be used, it remains unclear whether mentally ill smokers could benefit from smoking cessation program. The study aims were to determine the abstinence rate among people with or without mental illness, and to identify the factors influencing on it.

Methods: An observational study was conducted on all smokers who participated in the three-months smoking cessation program in our clinic between August 2007 and March 2011. Clinical and tobacco-related variables were assessed.

Results: Of the 370 participants, 105 (28.4%) had mental disorders (mean age: male=52.7 ± 12.8, female=52.5 ± 20). 49 (46.7%) mentally ill patients accomplished the program. The cessation rate at 12 weeks was 49.0% in those with mental illness and 70.4% in those without mental illness (P < 0.01), respectively. Among those with psychiatric conditions, quitters are older (57.7 ± 11.3 and 51.0 ± 10.1, P = 0.035), showed lower exhaled carbon monoxide level (31.8 ± 8.9 and 18.3 ± 11.7, P = 0.037), and lower FEV1 (70.1 ± 22.3 and 83.6 ± 15.9, P = 0.020), compared with smokers. No significant differences were found between quitters and smokers in the average nicotine addiction level, according to the tobacco dependence screen (TDS) test, the average pack-year, and the prescription rate of varenicline.

Conclusions: The quit rate in mentally ill people was lower than in general population. Further studies are needed to modify the cessation interventions that address mental illness.

A pharmacological intervention with varenicline among a lung cancer LDCT screening trial: The MILD experience

Paolo Pozzi, 1, Elena Munarini 1, Roberto Botti 2, Ugo Pastorniko 2, 3, Tobacco Control Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; 2Thoracic Surgery Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; 3Tobacco Control Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

Introduction: Low dose CT screening (LDCT) for lung cancer may be a teachable moment for smoking cessation. We aimed to determine the abstinence rate among people with or without mental illness and assess predictors of smoking cessation in a lung cancer screening trial: The MILD experience.

Methods: A total of 1298 patients (819 males and 479 females) were screened. The average age was 62.3 ± 11.0 years. The average pack-year was 21.9 pack/years, a Fagerström test of 7.5 ± 2.2 points and a slight increase in FEV1 (P < 0.001) was recorded.

Results: Pts with a FEV1 < 80% showed higher CO values than Ctrl at baseline and along the study. Side effects were longitudinally recorded. Pts with a CO ≥ 22.3 and 83.6% < 80% presented more side effects than Ctrl. A significant higher percentage of pts with a CO ≥ 22.3 and 83.6% < 80% (P < 0.001) had more than 50% of them wish to consult Anti-Smoking clinic.

Conclusions: Smoking prevention, in particular the practice of minimal advice, is still prevalent among patients who have acute coronary syndrome and with smoking cessation advice, in contrast with (87%) of non smokers doctors. The incidence of Smoking in the family’s smoker resident doctors was 64.6% in contrast with non smokers (41%).

Burden of smoking in acute coronary syndrome

Edwellsie Merin, Ma. Encarnina Limpin, Fernando Ayuyao, Teresa De Guia

Division of Pulmonary and Critical Care Medicine, Philippine Heart Center, Quezon City, Philippines

The purpose of this study was to evaluate the burden of smoking among patients who had acute coronary syndrome seen at Philippine Heart Center in terms of its outcomes and expenditures.

199 patients (138 males and 61 females) participated in the study. Smoking habits were recorded including their co-morbidities, GRACE and TIMI scores. Financial data were gathered, tabulated and evaluated. Outcomes of ACS were tabulated in relation to patients’ smoking history and were evaluated.

In this study, it shows that among those patients who have acute coronary syndromes, predominantly were smokers, both direct and passive smokers comprising 72% of the patients. In a developing country like ours, the mean amount expended for each patient admitted for acute coronary syndrome who smokes (direct and passive) was two hundred forty-seven thousand two hundred sixty pesos (Php 247,260.00:276,428.00 excluding physician’s professional fee) which is already a sumptuous that drains one’s finances. And of these, for every smoker patient who had acute coronary syndrome, the mean expenses for each person with each admission were Php 217,160.00:226,791.00 for those who survived and were discharged and Php 517,960.00:648,085.23 for those who died. Therefore, smoking is still prevalent among patients who have acute coronary syndrome and with each admission, each patient expend a sumptuous amount of money for the health resources.

Smoking tendencies in physicians and surgeons from Andalusia

Maria Jose Riús, 1 Pilar Mela, 1 Marcos Garcia, 2 Francisca Rius, 1 Manuel Garcia de la Vega, 3 Amparo Lupianez, 2 Comprehensive Tobacco Action Plan for Andalusia, Andalusian Public Health System, Seville, Spain; 3HRU Carlos Haya, Andalusian Public Health System, Malaga, Spain, 4Department of Preventive Medicine and Public Health, University of Malaga (UMA), Spain; 4Department of Preventive Medicine and Public Health, University of Malaga (UMA), Spain.

Aim: To obtain relevant information regarding smoking habits, intention of quitting and consumption in the workplace.

Methods and material: General survey on smoking was performed in 15 andalui- sian hospitals in the last quarter of 2010, a questionnaire (written and anonymous) for each person admitted for acute coronary syndrome who smokes (direct and passive) was used. Descriptive study was made using the statistical package SPSS for windows. Study population: medical.

Results: n=1098 (55% men, 45% women). Mean Age 42 years (range 20-66). Smoking Status: Current smoker (14%), occasional smoker (5%), non-smoker (59%), former smoker (22%). Mean Cigarettes 15 per day (1-50). 21% will try to quit in the next 6 months and 22% want to quit right now. 33% of smokers smoked during working hours.

Conclusions: Physicians and Surgeons show low prevalence of smoking, favorably disposed to quit and only one third of them smoke in the workplace.

How France has hijacked tobacco price increase, an effective tool of tobacco control, to increase the financial profits

Bertrand Dautzenberg, Joseph Osman, Marie-Dominique Dautzenberg.

Association, OFF (Office Français de Prévention du Tabagisme), Paris, France

Increasing the tobacco products price is a tool to reduce tobacco consumption. The FTCCT announces a 4% decrease of tobacco consumption for a 10% price increase.

The last decade France has experienced two opposite periods with two opposite effects.

Method: We have compared tobacco price increase to sales of cigarettes in France during the presidency of J.Chirac 2002-2007 and the presidency of N.Sarkozy 2007-2012.

Results: In 2003 President Chirac implements the first cancer plan and, among 20 measures against tobacco, a 39% increase of tobacco taxes produce price of cigarettes within 18 months, just after a 12% increase in 2002 (total = 51% increase). The price of Marlboro 20 cigarettes pack has increased of 1.4€. The number of cigarettes sold by year has dropped down from 82 billion to 54 billion (34% decrease).

From 2007 to 2012 the influence of the tobacco industry has been strong in France,
and cigarettes prices have increased 4 times of 6% and a new increase of 7, 5% is anticipated in 2012. These 32% increase of prices has been managed by the tobacco industry. As a result, the sales of cigarettes remain 54 billion a year; nevertheless at the end of 2012 we will have a total increase of cigarettes pack of 1,6 €.

Conclusion: The elasticity of the increase of price on consumption has been very high (0.67) when increase of price is driven by taxes and supported by a strong engagement. The price elasticity is 0.0 when the increase of price is drive by tobacco industry and when tobacco lobbyists may be active anywhere. Article. 5.3 of PCTC on interaction between tobacco industries on politicians may prevent in France failure of tobacco control.

P1981
Is calprotectin a marker of tobacco smoke related inflammation? A pilot study in children
Nazan Cihangir1, Ceyhun Dalkan1, Nilufar Galip1, Hakam Tekguc3, Cem Cenkoglu1, Nerin Balcihecer2, Pithiatic Pulumonology, Near East University Faculty of Medicine, Nicosia, Cyprus; 2Pithiatic Allergy and Clinical Immunology, Near East University Faculty of Medicine, Nicosia, Cyprus; 3Pathology, Near East University Faculty of Medicine, Nicosia, Cyprus

Objectives: Environmental tobacco smoke (ETS) related inflammation has an anorexigenic effect through affecting the release of appetite-modulating mediators, leptin and ghrelin in two groups (p values are 0.85, 0.87 and 0.42 respectively), but serum calprotectin levels were statistically higher in Group 1 (p=0.003).

Material and methods: A cross-sectional study was performed by searching the smoking status of patients. After signing of questionnaires, parents were phoned and children were invited to supply fasting blood samples in order to measure serum levels of leptin, ghrelin and calprotectin, and to calculate their BMI.

Participants were divided into Group 1, those who are exposed to and Group 2, not exposed to indoor ETS.

Results: There were no statistical difference between BMI and serum levels of leptin and ghrelin in two groups (p values are 0.85, 0.87 and 0.42 respectively), but serum calprotectin levels were statistically higher in Group 1 (p=0.003).

Conclusions: In this study serum levels of calprotectin were found to be higher in children with indoor ETS exposure where no relation was detected with BMI and serum levels of leptin and ghrelin. Increased serum levels of calprotectin might be an indicator of inflammation related to ETS exposure.

P1982
Smoking and metabolic syndrome
Lízra Fontes1, Hanns Moshammer2, Ibrahim Elmadfa1, Institut für Ernährungswissenschaft, University of Vienna, Austria; 2Inst. Environmental Health, Medical University of Vienna, Austria

Background: Smoking causes inflammation and chronic systemic inflammation predisposes to a range of metabolic disorders usually described as metabolic syndrome. This might likely be one pathway leading to cardiovascular disease. Nicotine reduces appetite. Therefore exact control of caloric uptake (and physical activity) is necessary when studying the association between smoking and metabolic syndrome.

Methods: We used data collected during preventive check-ups among 987 employees of a large bank. Health data including routine laboratory parameters were enhanced by a detailed nutritional recall protocol and a standardised physical activity questionnaire. Physical activity and calories uptake were indeed significant predictors of several metabolic outcomes thus proving the data reliability. Associations were investigated using linear regression.

Results: Current smoking (number of cigarettes currently smoked) showed a non-linear association with most outcomes including waist circumference, high density lipids, fasting glucose, and triglycerides. While moderate smoking did not differ significantly from non-smoking the daily consumption of more than 20 cigarettes lead to significantly adverse effects on all these parameters. Adverse effects were more pronounced and roughly linear when cumulative smoking (pack years) was taken into consideration. Smoking also lead to an increase in white blood cell counts indicating an inflammatory response.

P1983
The association of smoking and blood viscosity
Gündüz Cakmak1, Fatma Ates Alkan2, Kazim Korkmaz3, Zuhal Aydan3, 1, 2, Ibrahim Elmadfa1, 1, Fatma Ates Alkan3, Kazim Korkmaz3, Zuhal Aydan3

Objectives: to determine the relationship between smoking and blood viscosity from this point of view. One hundred people were invited and three groups were formed: group 1 composed of ex-smokers, group 2 composed of individuals who had been smoking, group 3 composed of the individuals who never smoked. Measurements of blood viscosity were performed at different shear rates. Since the hematocrit levels can significantly effect viscosity, in order to avoid this, hematocrit levels were fixed at 40.

Table 1. Blood viscosity of groups at different shear rates

Serum microRNA signatures identified by Solexa sequencing predict sepsis patients mortality: A prospective observational study
Huijuan Wang1,2,3, Pengjun Zhang4, Weijin Chen5, Dan Feng3, Yanhong Jia1, Linxin Xie1,3, 1Department of Respiratory Medicine, Harbin Branch of Chinese PLA General Hospital, Harbin, Heilongjin Province, China; 2Medical College, Nankai University Medical College, Tianjin, China; 3Department of Respiratory Medicine, Chinese PLA General Hospital, Beijing, China; 4Department of Clinical Biochemistry, Chinese PLA General Hospital, Beijing, China; 5Chinese Academy of Sciences, Beijing Institute of Genomics, Beijing, China; 6Department of Medical Statistics, Chinese PLA General Hospital, Beijing, China

Background: Sepsis is the leading cause of death in Intensive Care Unit. Novel biomarkers and targets of treatment were still needed to improve the mortality.

Our goal of the prospective study was to investigate if serum miRNAs identified in genome-wide scans could predict sepsis mortality.

Methodology/Principal findings: 214 sepsis patients participated in the study. Solexa sequencing followed by qRT-PCR were used to test for differences in the levels of miRNAs between survivors and non-survivors of sepsis patients. miR-223, miR-15a, miR-16, miR-122, miR-193* and miR-483-5p were significantly differentially expressed, and the area under curve of the six miRNAs predictive value ranged from 0.610 (95% CI, 0.523-0.697) to 0.790 (95% CI, 0.719-0.861). Logistic regression analysis showed that sepsis stage, APACHE II score, miR-15a, miR-16, miR-193* and miR-483-5p were correlated to the death of sepsis and area under curve of the six variables predictive value was 0.950 (95% Confident interval, 0.919-0.982), which was much higher than APACHE II score, SOFA score, and procalcitonin with area under curve of 0.782 (95% CI, 0.721-0.851), 0.752 (95% CI, 0.672-0.832) and 0.695 (95% CI, 0.611-0.784), respectively. When the cut off point set at 0.526, the predictive value of the six variables provided a 85.2% sensitivity and a 90.4% specificity. In addition, miR-15a* had highest odds ratio of 9.23 (95% CI, 1.20-71.16).

Conclusion/Significance: Six miRNA expression profiles could be used to predict septic mortality. The predictive value was better than the indicators that used in clinical.

P1985
The effect of peer-to-peer feedback on severe community acquired pneumonia
T.K. Lim1, 2, H.F. Lim1, Jason Phua1, 1, 2, Malcolm Mahadevan1, 1, 2, Medicine, National University Hospital, Singapore; 2Accidents & Emergencies, National University Hospital, Singapore

Delays in intensive care unit (ICU) admission are associated with higher mortality in community acquired pneumonia (CAP). (Phua J, Eur Respir J 2010;36:826.) In 2008 we employed minor severity criteria from the 2007 IDSA/ATS guidelines plus point of care lactate to identify high risk patients in the emergency department.
In July 2010 we implemented peer-to-peer feedback (p2p) on severe CAP in the "Marianthi Simou" Laboratory, 1st Dept. of Critical Care, "Evangelismos" Hospital, University of Athens Medical School, Athens, Greece. This was associated with reduced mortality in severe CAP, without increasing ICU admission rates. (Lim TK, Int. Forum on Quality & Safety in Healthcare 2012).

**Intervention:** In July 2010 we implemented peer-to-peer feedback (p2p) on severe CAP management between ED & ICU teams to improve teamwork and safety. (Haddon DW, et al Am J Med Qual. 2011 Dec 27)

**Results:** From Jul 2010-Dec 2011 we admitted 243 patients with severe CAP in our ICU. ICU admission were delayed in 36% and hospital deaths 22%. Delays in ICU admission increased from 31% in 2010 to 42% in 2011. Nevertheless, there was a small drop in overall mortality (25.5% to 20%) mostly in patients directly admitted to ICU which fell from 26.5% to 17.2%. Mortality in delayed ICU admission was stable (23.9% to 23%). Adherence to the resuscitation bundle was high in 2010: point of care lactate test 91%, antibiotics 97%, intravenous fluids 95% & vaso-pressors 100%. But it fell in 2011 to 84%, 80%, 98% & 86% respectively.

**Conclusion:** In the management of severe CAP p2p was associated with reduction in mortality without increasing early/direct ICU admission rates timely. And sustained p2p feedback may be required to maintain a high degree of adherence to resuscitation bundles and to further improve patient outcomes in severe CAP.

Determining the best diagnostic biomarker for sepsis and prognosis assessment

**Lorenzina Su**1,2, Linxie Xie1,2, Lin Feng1,2, Qing Song1, Hongjian Kang3, Xiangang Liang1, Yanhong Jia1, Dan Feng1. 1Department of Respiratory Medicine, Hainan Branch of Chinese PLA General Hospital, Sanya, Hainan Province, China; 2Department of Respiratory Medicine, Chinese PLA General Hospital, Beijing, China; 3Department of Medical Statistics, Chinese PLA General Hospital, Beijing, China

**Introduction:** Current clinical practice lacks reliable diagnostic indicators for sepsis and its prognosis. The objectives are to describe the value of sTREM-1, sCD163, PCT, CRP, WB and SOFA scores during the course of sepsis, as well as their value in prognosis.

**Methods:** 130 critically-ill patients suffering from medical, surgical and trauma-pneumonia. Aims: To investigate if sEPCR plasma levels of critically-ill subjects at ICU admission ≤24h post ICU admission; all patients were free of sepsis. Demographic data are shown in Table 1. sCD163 and SOFA were recorded on day 1, 3, 5, 7, 10, and 14. Results: On ICU admission day, the sepsis group display higher levels of sTREM-1, sCD163, PCT, CRP, WB and SOFA scores (Table 1, p=0.004, respectively). ICU mortality and PCT tended to be higher in the sepsis group as compared to the non sepsis group (5.1% vs. 0.8%, p=0.004, respectively). ICU mortality and PCT tended to be higher in the sepsis group.

**Conclusion:** Conclusions: High sEPCR, CRP plasma levels at ICU admission (i.e. ≤24h) predict sepsis development.

**P1988**

Role of gallium-67 scintigraphy in the evaluation of occult sepsis in the medical ICU

Wei-Chun Chen1, Chia-Hung Chen1, Wei Chen2, Yao-Ling Lee3, Chun-Ming Shih4. 1Division of Pulmonary and Critical Care Medicine, China Medical University Hospital, Taichung, Taiwan; 2Division of Pulmonary and Critical Care Medicine, Chia-Yi Christian Hospital, Chia-Yi, Taiwan; 3School of Laboratory and Biotechnology, Chung Shan Medical University, Taichung, Taiwan

Patients in intensive care units (ICUs) frequently have multiple infections or persistent fever despite management. This study was to evaluate the diagnostic contribution of gallium-67 scintigraphy in ICU patients with suspected occult sepsis. One hundred and seventeen patients who had undergone gallium-67 scintigraphy in the ICU of our medical center over a 3-year period were retrospectively reviewed and analyzed. Patients were categorized into Group 1 (n = 84), those with a known infectious source, but who still had persistent fever or sepsis despite antibiotic treatment or abscess drainage; or Group 2 (n = 33), those without an evident infectious source after clinical, physical, and imaging studies. Among these patients, 19 (16.2%) had a new diagnosis. In Group 1, 12 patients (14%) had a new infection, including pneumonia (4 patients), bed sore infection (2 patients), pulmonary tuberculosis (2 patients), leg cellulitis (1 patient), psoas muscle abscess (1 patient), osteomyelitis (1 patient), and infective endocarditis (1 patient). In Group 2, seven patients (21%) had a new infectious source, including septic arthritis (3 patients), osteomyelitis (2 patients), neck abscess (1 patient), and cholecystitis (1 patient).

**Summary:** Gallium-67 scintigraphy helped to detect new or additional infectious sites, particularly bone, joint, and soft tissues.

**P1989**

Peculiarities of an ARDS and respiratory support in patients with severe viral (H1N1) pneumonia

Tatiana Martynenko1,2, Maxim Bukhtoyarov2, Vladimir Martynenko3, Irina Balatskaya1, Anastasia Grebenyuk1, 1Dept of Postdiploma Education, The Altai State Medical University, Barnaul, Russian Federation; 2The Altai Regionally Pulmonology Center, Barnaul, Russian Federation; 3The Altai Regionally Pulmonology Center, Altai Regional Hospital, Barnaul, Russian Federation

**Background:** We aimed to evaluate clinical features of an ARDS and effectiveness of sequential differentiated respiratory support (SDRS) in patients with viral H1N1 pneumonia.

**Methods:** Retrospective analysis of 39 patients with severe H1N1 viral pneumonia treated at Respiratory Intensive Care Unit (RICU).

**Results:** Among these patients, 10 patients subsequently developed sepsis and 29 did not. SOFA score (mean±SD: 6.4±2.7) and sEPCR levels (median & IQR: 173.4 (104.5-223.5) ng/mL) were significantly higher in the subsequent sepsis group as compared to the non sepsis group (5.6±3, p=0.037, and 98.3 (69.8-147.7) p=0.004, respectively). ICU mortality and PCT tended to be higher in the sepsis group. Cox regression analysis identified sEPCR as the only parameter related to sepsis development with time (HR: 1.078 & 95% CI: 1.016–1.144, by 10 sEPCR units, p=0.013). When the whole cohort was dichotomized above (≥139.5) and below the sEPCR median (<139.5), the probability of developing sepsis with time was significantly elevated in the high-sEPCR group (Log-Rank test, p=0.028).

**Conclusions:** In our cohort, high sEPCR plasma levels at ICU admission (i.e. ≤24h) predict sepsis development.
undertaken in cases of refractory hypoxemia that lasted for 30-45 min. Mechanical ventilation was carried out in 28 (71.8%) patients in the regime of PCV with "aggressive" parameters: FiO2 - 0.8-1.0, PEEP - 15-20 cm H2O, PIP - 30-40 cm H2O, I:E - 1:1. Vt - 500-600 ml was achieved easily, indicating about preserved lung compliance. All patients required sedation at the beginning of mechanical ventilation in order to synchronize with the respirator. Muscle neuro muscular relaxants was not used. Duration of mechanical ventilation ranged from 7 to 81 days. NIV was excluded from the scheme of SDRS due to inefficiency.

Conclusion: A peculiar form of ARDS, without reducing elasticity of lung tissue, without sepsis, developed in patients with severe viral pneumonia. SDRS consisted of two phases: controlled oxygen therapy and invasive ventilation.

P1990
Overt disseminated intravascular coagulation in severe sepsis associated with specific organ dysfunction and poor survival
Hou-Tai Chang1, Kwei-Pin Chiang2, Yi-Shin Shin3, Cheng-Jen Yu1.
1Department of Pulmonary and Critical Care Medicine, Far Eastern Memorial Hospital, New Taipei, Taiwan; 2Department of Laboratory Medicine, National Taiwan University Hospital, National Taiwan University College of Medicine, Taipei, Taiwan; 3Department of Internal Medicine, National Taiwan University Hospital, National Taiwan University College of Medicine, Taipei, Taiwan

Background: In sepsis, abnormal coagulation cascade cause disseminated intravascular coagulation (DIC). Little is known about the clinical characteristics in overt DIC in severe sepsis.

Objective: To investigate the clinical features and dysfunction of different organ systems in overt DIC in severe sepsis

Methods: This prospective observational study was conducted in the medical intensive care unit in a tertiary medical center in Taiwan. Adult patients admitted for severe sepsis would be enrolled. Patients with cirrhosis or advanced malignancies would be excluded. Baseline patient profiles were obtained, including APACHE II and SOFA scores. Overt DIC was defined according to the scoring system from the International Society on Thrombosis and Haemostasis.

Results: From Oct 2009 to Dec 2011, 248 consecutive patients admitted for severe sepsis were screened for the eligibility, and a total of 100 patients were enrolled. The APACHE II and SOFA scores were 25.9±6.4 and 9.9±3.4, respectively. Only 8 patients (8%) had overt DIC. The 28-day mortality was higher in patients with overt DIC than in those without (62.5% vs. 20.7%, P=0.001). Patients with overt DIC had higher SOFA scores than those without (14.1±4.8 vs. 9.5±4.0, P=0.001). Higher hepatic (P=0.003), cardiovascular (P=0.031) and coagulation (P=0.001) SOFA sub-scores were found in patients with overt DIC, while the respiration, central nervous system, and renal subscores were not significantly different without overt DIC.

Conclusions: In our patients with severe sepsis, overt DIC is uncommon, and is associated with organ dysfunction mainly involving hepatic, cardiovascular, and coagulation systems.

P1991
Remifentanil attenuates LPS-induced neutrophil activation
1Department of Anesthesiology and Pain Medicine, Chonnam National University Medical School, Gwangju, Korea; 2Department of Cardiothoracic Surgery, Chonnam National University Medical School, Gwangju, Korea

Surgical trauma and anesthesia are associated with a complex dysregulation of the immune system with neutrophil activation involving activation of both pro-inflammatory and anti-inflammatory cytokines. Several studies demonstrate that opioids modulate the immune response via opioid receptors expressed directly in the immune cells themselves. Neutrophils play a pivotal role in the coordination and regulation of immune responses. However, the ability of opioid directly participating in LPS-induced neutrophil activation has not been fully examined. In the present experiments, the effects of various opioids including remifentanil, sufentanil, alfentanil and fentanyl were investigated. Remifentanil only could attenuate activation of neutrophils exposed to LPS. In particular, remifentanil decreased LPS-induced activation of intracellular signaling pathways, including p38 mitogen-activated protein kinase (MAPK) and ERK1/2, and expression of pro-inflammatory cytokines, including TNF-a, IL-6 and IL-8. There was no effect of remifentanil on LPS-induced activation of c-Jun N-terminal kinase (JNK) in neutrophils. These results demonstrate that remifentanil can attenuate LPS-induced neutrophil responses and also suggest that such effects are sufficiently important in vivo to play a major contributory role in neutrophil-mediated inflammatory responses by surgical and anesthetic trauma.

P1992
C-reactive protein (CRP) as a marker of disease severity in community acquired pneumonia patients with sepsis
Sanjay Dhawan1, Himayatullah Khan2, Dinesh Babu2, Vivek Gupta2, Ajith Raghavan3, Ajith Raghavan3, Ajith Raghavan3.
1Pulmonology, Ahaliya Hospital, Abu Dhabi, United Arab Emirates; 2Cardiology, Ahaliya Hospital, Abu Dhabi, United Arab Emirates; 3Intensive Care Unit, Dept. of Internal Medicine, Dr. Surat Seth Chest Diseases and Surgery Education and Training Hospital, Erim, Turkey; 4Intensive Care Unit, Surayyya Chest Diseases and Surgery Education and Training Hospital, Istanbul, Turkey

Introduction: C - Reactive Protein (CRP), an early sensitive marker of inflamm-

ation is studied extensively in various common medical disorders. Until recently CRP measurement was not studied widely in Pneumonia. We intended to study its usefulness for assessment of disease severity in patients of Community acquired pneumonia (CAP) with Sepsis.

Objective: To evaluate the utility of C - Reactive Protein as a marker of disease severity in patients of Community acquired pneumonia with Sepsis.

Methods: Study design: Prospective observational study

Setting: 12 bedded ICU of a multi specialty hospital in Abudhabi, UAE.

Subjects: 40 patients admitted during June 2010 - January 2012, fulfilled the study criteria.

Cap and Sepsis were defined based on the ATS and ACCP/SCCM 1992 criteria respectively.

Results: Patients were divided into two groups, Group A with CRP < 300 mg/L and Group B with ≥ 300 mg/L. Mean age being 36.5 and 42.6 years respectively. Characteristic of disease severity were compared in both the groups.

Table. Disease severity

<table>
<thead>
<tr>
<th>Characteristics</th>

Conclusion: CRP level of greater than 300 mg/L within first 48 hours of admission to ICU appears to be a good marker of disease severity in patients of Community acquired pneumonia with Sepsis and may be useful to identify high risk patients.

P1993
Impact of experience and education in treatment of adult respiratory distress syndrome (ARDS) using extracorporeal membrane oxygenation (ECMO)
So Wong Kim, Gun Hoon Hong, Yoomsack Koh, Chue Man Lim, Jin Won Huh.
Department of Pulmonology and Critical Care Medicine, Asan Medical Center, Seoul, Korea

Background: Extracorporeal membrane oxygenation (ECMO) is a form of long-term cardiopulmonary bypass and recently have been used to treat adults with respiratory or cardiac failure despite maximal medical therapy. ECMO is a high risk procedure with 25% of mortality rate.

The previous a few studies showed that improving equipment and increased experience to manage ECMO is important to patient survival and improving results. ECMO training program is important in solving significant, life-threatening problems that can occur during ECMO application.

Our aims in this study are to show our experience of ECMO management and reduction in mortality rate according to an accumulation of experience and knowledge.

Method: A nonrandomized retrospective study was performed.

Results: In 2009-2011, ECMO was applied to 82 patients. Veno-venous and veno-arterial ECMO was 63.4% and 36.6%, respectively ECMO was applied to 47 patients in 2009–2010 and 35 patients in 2011. The most common cause of ECMO application was pulmonary problem.

The most common complication of ECMO was bleeding and the most common cause of death was pneumonia. 41.5% of patients were weaned off the ECMO.

Intensive care unit mortality was higher on 2009–2010 than on 2011 (89.4% vs. 57.1%, OR 3.106, CI 1.235-7.812, p=0.014).

Conclusion: According to an accumulation of experience and knowledge, mortality was reduced in 2011 compared to 2009-2010.

P1994
Predictors of mortality in cancer patients requiring intensive care support: Two-centered cohort study
Dursun Tatar1, Ozlem Yazicioglu Moçin2, Pinar Cimen1, Zuhal Karakurt1, Cenk Kukalı1, Gökay Gungör2, Ozlem Ediboglu3, Nalan Adiguzel2, Emre Tellioglup1, Cuneyt Salnutk3, Merih Balci2, Intensive Care Unit, Dr. Suat Seren Chest Diseases and Surgery Education and Training Hospital, Izmir, Turkey; 2Intensive Care Unit, Surayyya Chest Diseases and Surgery Education and Training Hospital, Istanbul, Turkey

Aim: Acute respiratory failure (ARF) can be developed in cancer patients due to disease progression or as a complication of treatment. In our study we aimed to identify the factors associated with mortality in cancer patients admitted to the intensive care unit (ICU) due to ARF.

Method: A retrospective-cohort study was planned in two ICUs of training hospital of chest diseases between January 2008 and December 2011 period. Demographic data, type of cancer, cause of ARF, comorbided disease, APACHE II value, type of
treatment, and mortality were recorded from the medical records of cancer patients followed in ICU.

Results: During the study period 463 (373 male) cancer patients were included in the study followed by two-centers in the ICU. The median age of the patients was 65 (57-72). 78% of the patients were lung cancer while 22% of the patients were extrapulmonary cancer and the mortality rates were similar. Cause of ARF in 48% (n=391) of the patients were due to cancer invasion and 12% was infections. APACHE II value was 24 (18-30) and on ICU day was 5 (2-10). Application of invasive and noninvasive mechanical ventilation was respectively 29% and 74%. The mortality rate of the cancer patients in ICU was 54%. APACHE II value was significantly higher in patients who died (p<0.001). The mortality of the female patients were higher (p=0.05).

Conclusion: The mortality is higher than the overall ICU mortality, in patients with advanced cancer who required ICU support. In our study; APACHE II value and female gender are the marker of high mortality in cancer patients developed ARF.

P1996
Extracorporeal membrane oxygenation as bridge in patients with non-iartrogenic massive hemoptysis
Jee-Hong Yoo1, Levent Dalar1, Emel Eryüksel 2, Sibel Yurt1, 1Pulmonary and Critical Care Medicine, Kyung Hee University, Seoul, Republic of Korea; 2Pulmonary and Critical Care Medicine, Jeju National University Hospital, Jeju, Republic of Korea

Despite advanced technologies in intensive care, massive hemoptaxis can cause death in a small subset of patients. In special, extensive bleeding, hypoxia, decreased primary function and other comorbidities make it more difficult or impossible to perform bronchoscopy, arterial embolisation or resectional surgery. Extracorporeal membrane oxygenation (ECMO) is expected to provide adequate gas exchange, to reduce ventilator-induced lung injury and, eventually, to improve outcome in patients with respiratory and circulatory failure. However, it is not sure whether it is beneficial or not to perform ECMO in unstable patients with non-iartrogenic massive hemoptaxis. The case applying ECMO to patients with iatrogenic massive hemoptaxis is also very rare. A male with medical history of pulmonary tuberculosis received mechanically ventilator support because of severe community acquired pneumonia. As he abruptly showed severe hypoxemia and hypotension due to massive hemoptaxis, ECMO was instituted. We herein describe detailed course of our case, helping physicians make a decision to initiate ECMO in patients with non-iartrogenic massive hemoptaxis.

P1998
Clinical outcome and prognostic factors of acute respiratory failure due to pneumocystis pneumonia in non-HIV patients
Yousang Ko, Kyoungmon Jeem, Division of Pulmonary and Critical Care Medicine, Samsung Medical Center, Seoul, Republic of Korea

Pneumocystis pneumonia is a potentially life-threatening infection that occurs in immunocompromised individuals. While it is well known that the clinical course of PCP in non-HIV patients differs in HIV-positive patients. But, the ICU mortality of patients with acute respiratory failure requiring mechanical ventilation dose not well known.

The objective of this study was to examine the outcome and prognostic factors of ICU mortality in patients with acute respiratory failure caused by Pneumocystis pneumonia. We conducted a five-year retrospective review (from October 2005 to December 2010) of all patients who had histologic evidence in the non-HIV patients. Of the 44 adult patients investigated, 25 patients (56%) had solid or hematologic malignancies, 17 (33%) had received organ transplantation and 10 (22%) had received corticosteroid. Median P/F ratio on day 1 was 139 (IQR:116-187), SAPS 3 score on day 1 was 46 (IQR:36-58) and SOFA score on day 1 was 7 (IQR:5-9). The ICU mortality in patients with acute respiratory failure caused by pneumocystis pneumonia was high. Especially, the severity on ICU admission and newly developed shock after ICU admission was associated with higher ICU mortality.

P1999
Inhaled colistin on Acinetobacter baumannii treatment
Gustavo Coimbra dos Reis1, Ana Martins2, Luís Bento2, 1Pulmonology Department, CHBM, EPE, Barreiro, Portugal; 2Unidade de Urgência Médica, Hospital São José, CHLC, EPE, Lisbon, Portugal

Introduction: Ventilator associated pneumonia and tracheobronchitis (VAP/VAT) due to multiresistant A. baumannii are preeminent causes of mortality and morbidity at ICU’s. High and/or prolonged duration of mechanical ventilation, mechanical ventilation, duration of hospital stay and the development of ventilator associated pneumonia (VAP) and ventilator associated tracheobronchitis (VAT) are independent predictors of adverse outcomes and mortality. A. baumannii was extensively resistant in almost all cases, being sensitive only to polymyxins in 20% (87%). Mean inhaled colistin dose was 3.5 µg / (1.6-0.6 µg), with a mean duration of 7.8±3.5 days. Systemic colistin was co-administered in 6pts, with 100% eradication rate and 2 of 3 successful cases (87%) were identified. At failure to eradicate or relapse no change in treatment was made. A. baumannii was extensively resistant in all cases, being sensitive only to polymyxins in 20% (87%). Mean inhaled colistin dose was 3.5 µg / (1.6-0.6 µg), with a mean duration of 7.8±3.5 days. Systemic colistin was co-administered in 6pts, with 100% eradication rate and only one relapse. ICU and hospital mortality was 5.3% and 10.6%.

Conclusions: On critical patients, inhaled colistin was effective treating VAP/VAT due to extensively resistant A. baumannii. No change on antibiotic resistance profile was observed after treatment.
P2000

Intensive care unit acquired pneumonia with or without etiologic diagnosis: A comparison of outcomes
Valeria Grami1,2,3,4, Miguel Ferrer1,2, Mariano Esperanziet1,2, Otavio Tavares Ranzani1,2,3, Luna Maria Saucedo1,2, Gianluigi Li Bassi1,2, Francesco Blasi1, Antoni Torres1,2,1, Servi de Pneumologia, Institut del Torai, Hospital Clinic, IDIAPBS, Barcelona, Barcelona, Spain; 2Centro de Investigaci Biomèdica en Red-Enfermedades Respiratorias, CibeRes, CR06/06/0028, Barcelona, Spain; 3Respiratory Intensive Care Unit, Hospital das Clinicas, Faculdade de Medicina da Universidade de Sao Paulo, SP, Brazil; 4Department Toraco-Pulmonar e Cardiocirúrgico, Universitat de Estudis de Milà, IRCCS Fondazione Ca Granda, Milano, Lombardia, Italy

Background: The impact of intensive care unit acquired pneumonia (ICU-AP), without etiologic diagnosis, on patient outcomes is largely unknown.

Objective: To compare the clinical characteristics, inflammatory response and outcomes between patients with or without microbiologically confirmed ICU-AP.

Methods: We prospectively collected 270 patients with ICU-AP. Patients were clustered according to positive or negative microbiologic results. We compared the baseline characteristics and outcomes between groups.

Results: ICU-AP without etiologic diagnosis was found in 82 (38%) patients. In comparison with patients with microbiologically confirmed ICU-AP patients without etiologo confirmed more frequently chronic renal failure (15, 18% vs. 11, 6%, p=0.003), chronic heart diseases (35, 43% vs. 55, 29%, p=0.044), higher hypoxemia (PaO2/FiO2 165±73 vs. 199±79 mmHg, p=0.001) and shorter intensive care unit (ICU) stay before the onset of pneumonia (5.5± vs. 7.9± days, p=0.001). The systemic inflammatory response was similar between groups. Despite similar severity at the ICU admission and onset of pneumonia, in patients with microbiologically confirmed ICU-AP there was higher in-hospital (84, 45% vs. 25, 31%, p=0.043) and post ICU mortality (18.7, 51% vs. 28, 36%, p=0.043).

Conclusion: Microbiologically not confirmed ICU-AP develops earlier and it is associated with better outcomes and specific underlying comorbidities that increase the risk of severe sepsis. Ultimately suggesting a potential misdiagnosis.

Post-resuscitation central venous pressure and serum lactate associated with survival in severe sepsis and septic shock
Kuo-Pin Chung1, Hou-Tai Chang1, Jih-Shuin Cheng2, Chong-Jen Yu1,2
1Department of Laboratory Medicine, National Taiwan University Hospital, National Taiwan University College of Medicine, Taipei, Taiwan; 2Department of Pulmonary and Critical Care Medicine, Far Eastern Memorial Hospital, New Taipei City, Taiwan.

Background: The survival in severe sepsis and septic shock is improved by quanitative resuscitation, with goals as mean arterial pressure (MAP), central venous pressure (CVP), oxygen saturation of central venous blood (ScvO2), and lactate pressure (CVP), oxygen saturation of central venous blood (ScvO2), and lactate clearance.

Objectives: To investigate whether post-resuscitation MAP, CVP, ScvO2, and lactate level predict the survival in severe sepsis and septic shock.

Methods: A total of 124 patients were enrolled from Aug 2009 to Dec 2011. The APACHE II and SOFA scores were 25±3.0 and 9.9±0.3, respectively. The 28-day mortality was 26.6%. Multi-variates logistic regression analyses showed that CVP (P=0.010) and serum lactate (P=0.011) were associated with 28-day mortality.

Results: The survival in severe sepsis and septic shock, high post-resuscitation CVP and serum lactate were associated with organ dysfunction and high mortality.

P2002

Effect of antibiotic prophylaxis on pneumonia in cardiac arrest patients treated with therapeutic hypothermia
Eun Young Heo1,2, Eun Hwa Hwang1,2, Sun Young Shin,3 Hee Soon Chung,4 Doo Hyun Kim5,6
1Department of Laboratory Medicine, National Taiwan University College of Medicine, Taipei, Taiwan; 2Department of Pulmonary and Critical Care Medicine, Far Eastern Memorial Hospital, New Taipei City, Taiwan; 3Department of Internal Medicine, National Taiwan University College of Medicine, Taipei, Taiwan; 4Department of Internal Medicine and Lung Institute, National Taiwan University College of Medicine, Seoul, Korea

Background: Infections complications are frequent after cardiac arrest and a few reports have demonstrated that infections may be even more frequent after therapeutic hypothermia. Pneumonia is the most frequent infectious complication in these patient.

Objectives: We investigated the effect of antibiotic prophylaxis on the development of pneumonia in cardiac arrest patients treated with therapeutic hypothermia.

Methods: We retrospectively reviewed medical records of patients who admitted for therapeutic hypothermia after resuscitation of out-of-hospital cardiac arrest between January 2010 and December 2011. Patients dying within the first 72 hours were excluded.

Results: Of the 46 patients admitted after cardiac arrest, 31 patients were analyzed. 24 patients (77%) were treated with prophylactic antibiotics within 24 hours.

P2003

Effectiveness of touchscreen device (iPad) as communication tool for intubated patients admitted at the University of Santo Tomas Hospital Apolonio Javier Jr.1, Patrick Gerard Moral2;1 Pulmonary and Critical Care Medicine, University of Santo Tomas Hospital, Manila, Philippines; 2Pulmonary and Critical Care Medicine, University of Santo Tomas Hospital, Manila, Philippines

Objectives: To improve the communication between intubated patients and health-care providers using iPad. Specifically, (a) we would like to determine if the level of frustration of intubated patients in the ICU while using touchscreen device (iPad) as a communication tool (b) determine the helpfulness of touchscreen device (iPad) as a communication tool between intubated patients in the ward/ICU and health care providers.

Subjects: (1) more than 18 years old, (2) able to read, speak and understand either English or Filipino, (3) oriented to person, place, time and situation at the time of interview, (4) Glasgow Coma Score 11 (Eyes 4, Verbal 1, Motor 5), (5) competent and able to sign an informed consent form; hemodynamically stable and (6) required intubation for at least 18 hours.

Design: A pilot observational descriptive study design.

Results: Patients level of frustration while intubated, eighty-eight percent (88.46%) of the sample reported extreme levels of frustration when communicating with other people while intubated. Seventy-seven percent (77.49%) reported their experience as very frustrating. Almost four percent (3.85%) reported their experience as frustrating. Almost four percent of the patients (3.85%) reported their experience to be somewhat helpful, fifteen percent (15.38%) reported their experience to be neither helpful, almost four percent (3.85%) reported their experience to be most helpful, and seventy-six percent (76.92%) reported their experience to be extremely helpful when iPad was used as a communication tool.

P2004

The usefulness of high resolution computed tomography in burned patients with inhalation injury
Cheol-Hong Kim, In-Gyu Hyun. Department of Internal Medicine, Hallym University College of Medicine, Seoul, Republic of Korea

Background: Smoke inhalation may affect both airway and lung parenchyma. Then, airway injury can be easily assessed by bronchoscopy, but lung parenchymal injury may be evaluated by other imaging modalities. The aim of this study is to assess lung parenchymal injury by high resolution computed tomography (HRCT) in burned patients who had been identified inhalation injury bronchoscopically.

Methods: The bronchoscopy with biopsy at carina or 2nd carina and HRCT were performed in burned patients with inhalation injury initially after admission. Positive HRCT findings include peribronchial ground glass appearance with or without consolidation, bronchial wall thickening, branching linear attenuation, atelectasis, interlobular septal thickening and bronchiectasis. We analyzed APACHE II scores, PF ratio, the need for mechanical ventilation care, pneumonia and degrees of airway injury according to HRCT findings.

Results: 22 burned patients were enrolled. Bronchoscopy was performed in all and HRCT in 19. Of those, 10 patients (52.6%) showed positive HRCT findings. Between positive and negative HRCT, age, burn size and initial COHb were not significant different (43±17 vs. 37±11.8, p = 0.08; 14±9/21.76 vs. 0.56±0.73%, p = 0.05; 6.2±6.76% vs. 11.5±8.64%, p = 0.05). Positive HRCT

240. Multidisciplinary critical care
findings were closely associated with more frequencies of mechanical ventilation and pneumonia, and higher APACHE II scores and PF ratio, and more severe airway injury.

Conclusions: HRCT in burned patients with inhalation injury may be useful to assess lung parenchymal injury and to guide further therapy because radiographic evidence for lung parenchymal injury may predict the severity of inhalation injury.

P2005
Clinical analysis of patients treated with mechanical ventilation in an emergency respiratory ward
Valentina Dimitrova, Marinika Peneva, Kamen Yankov. Clinic of Pneumology and Physiography, Multi - Profile Hospital of Active Treatment “St. Marina”, Varna, Bulgaria

Aim: To make analysis of indications, duration, complications and outcome of the mechanical ventilation in patients treated in the Emergency Respiratory Ward.

Data and methods: A retrospective analysis of the patients in the Emergency Respiratory Ward treated with mechanical ventilation during the last 5 years (2007-2011) has been made. 191 patients (10,33%) from the total number of patients (1848) needed mechanical ventilation.

Results: The percentage of patients, treated with mechanical ventilation, does not differ substantially during the studied years – from 10,81% in 2007 to 11,68% in 2011. The most common reason for heavy respiratory insufficiency, demanding mechanical ventilation, is pulmonary pathology (81,67%) as the greatest percentage belongs to those patients with diagnosis and its complications (pneumonia) – 134 patients (85,90%). The most common reasons from the non-pulmonary pathology are alveolar hypoxemia in case of extreme obesity, chest deformations, left-sided cardiogenic failure.

The usual duration of mechanical ventilation is 15 days as there are no significant differences in the studied years – from 77,14% to 87,10%. 7 of the patients (3,66%) have a verified diagnosis ventilator-associated pneumonia.

The total number of patients with lethal outcome is 66 (34,50%) as there are no significant differences in the studied years.

Conclusion: About 10% of the patients, treated in Emergency Respiratory Ward, need mechanical ventilation as the most common pulmonary pathology is COPD. Prognostic problematic flora, most often Gram-/ -strains are isolated in tube secrets, which significantly deteriorates the prognosis and leads to lethality in 34,50% of the cases.

P2006
BiPAP in advanced IPF: Hope for palliation?
Avrind Kaite1, H.S. Sanddeep1, Parag Chaudhari1, Chandrashekhar Tulasi2er1, Prashant Chhabed1. 1Pulmonology, Fortis-Hiranandani Hospital, Vashi, Navi Mumbai, Maharashtra, India; 2Medical care, Fortis-Hiranandani Hospital, Vashi, Navi Mumbai, Mumbai, Maharashtra, India

Introduction: IPF poses challenges in patient management due to limited treatment options particularly in countries without option of lung transplantation. BiPAP was offered to patients admitted with acute exacerbation of IPF worsening of disease as a final non invasive supportive measure. We report 7 such patients of advanced IPF treated in our hospital.

Methods: 7 patients with advanced IPF and optimal medical management were included. Pharmacotherapy included pirfenidone (1 did not tolerate), NAC, PPI and prednisolone. BiPAP was administered as final non invasive supportive measure. We report 7 such patients of advanced IPF treated in our hospital. In clinical courses, they showed ARDS and were moved to ICU and died and were autopse. The lungs and other organs were pathologically investigated what is the pathophysiological findings of clinical ARDS. Elastic stain, Al-PAS stain and immunohistochemistry for type I and IV collagen, a smooth muscle actin and Ki-67 were used. The periods of clinical ARDS and the estimated stages of DAD were compared and clinic-pathologically analyzed.

Results: A half of ARDS states were clinically diagnosed as ARDS while the other was aspergillosis with CMV pneumonia. Some cases also showed pathologically acute pneumonia, though the lesions of pneumonia are localized in the proximal portion of organized DAD. These findings mean the lesions of pneumonia appear after DAD.

Conclusion: It is confirmed that DAD itself mainly causes ARDS in the patients associated with chronic underlying diseases under the treatment in a hospital.

P2007
The impact of paramedics' education on controlled oxygen prescribing for patients with acute exacerbations of COPD during ambulance transfers on outcomes
Emma Johnston1, Tessa Coulson1, Mark Newton2, Ronan O’Driscoll1.
1Navy and Marine Medicine, Royal Navy Medical Foundation Trust, Salford, United Kingdom; 2North West Ambulance Service, North West Ambulance Service, Salford, United Kingdom

Introduction: Oxygen is a drug and should be administered with caution and only when indicated using the principle of target oxygen saturation (British Thoracic Society-BTS emergency oxygen guidelines, 2008) particularly in those at risk of Type 2 Respiratory Failure (T2 RF) like COPD patients.

Aims: To reduce complications of excessive use of oxygen during ambulance transfers in patients with acute exacerbation of COPD.

Methods: Ambulance paramedics within Salford, UK were offered education on the BTS acute oxygen therapy guidelines that included lectures and written material with supplementary access to on-line training. The education focused on the principle of using target O2 saturations and controlled oxygen delivery to guide oxygen therapy in patients transferred to hospital with suspected exacerbation of COPD.

Results: Total of 63 paramedics were trained. Over the 3 months evaluation period post training, 75 (21 males) patients with COPD exacerbations were transferred by ambulance to the local hospital, 10 of whom were transferred by trained paramedics. No differences were noted between the 2 groups of patients in relation to first blood gas results (pH, PCO2, PO2), length of stay and number of days readmissions. Fewer patients in the trained paramedics group needed NIV within 24 hours of admission, were admitted to ITU, or died in hospital.

P2008
Clinico-pathological analysis of acute respiratory distress syndrome (ARDS)
Yuk Yukusa1, Masako Takahash1, Shinobu Kunugi1, Mika Terasak1, Hirokazu Uruhaya1, Yasuo Terasaka1, Arata Aruma1. 1Department of Pulmonary and Critical Care, Fortis-Hiranandani Hospital, Vashi, Navi Mumbai, Maharashtra, India; 2Department of Pulmonary, Infection and Oncology, Nippon Medical School, Sendagi Bunkyo-ku, Tokyo, Japan

Purpose: ARDS is a severe disease and the therapy is not completely established and the pathophysiology is still controversial. There is a report one third of clinically diagnosed ARDS in the Intensive Care Units (ICU) were pathologically not diagnosed alveolar damage (DAD), but were pneumonia, hemorrhage and so on. In this context, we clinicopathologically studied the autopsy cases with clinically diagnosed ARDS in our hospital.

Methods: The 20 patients had originally chronic diseases and were treated in our hospital. In clinical courses, they showed ARDS and were moved to ICU and died and were autopse. The lungs and other organs were pathologically investigated what is the pathophysiological findings of clinical ARDS. Elastic stain, Al-PAS stain and immunohistochemistry for type I and IV collagen, a smooth muscle actin and Ki-67 were used. The periods of clinical ARDS and the estimated stages of DAD were compared and clinic-pathologically analyzed.

Results: A half of ARDS states were clinically diagnosed as ARDS while the other was aspergillosis with CMV pneumonia. Some cases also showed pathologically acute pneumonia, though the lesions of pneumonia are localized in the proximal portion of organized DAD. These findings mean the lesions of pneumonia appear after DAD.

Conclusion: It is confirmed that DAD itself mainly causes ARDS in the patients associated with chronic underlying diseases under the treatment in a hospital.

P2009
Usefulness of noninvasive ventilation in patients with acute respiratory failure admitted in the intensive care unit (ICU) – Experience of a Portuguese ICU
Ana Casta1, Pedro Moura1, Aurora Cadeco2. 1Pulmonology, Centro Hospitalar Vila Nova de Gaia- Espinho EPE, Vila Nova de Gaia, Portugal; 2Intensive Care Unit, Unidade Local de Saúde do Alto Minho, Viana do Castelo, Portugal

Introduction: Noninvasive ventilation(NIV) is a safe and effective mean of improving gas exchange in patients with many types of acute respiratory failure(ARF).

Study design and patient selection: Retrospective observational study to access the usefulness of NIV in patients with ARF submitted to mechanical invasive ventilation(MIV) admitted to the ICU(Santa Luzia Hospital Viana do Castelo, Portugal). We enrolled adults with ARF admitted to the ICU in 2011. Patients were analyzed globally and in two subgroups: patients that received MIV and NIV and patients that received only MIV,recording various parameters, namely, comorbidities, diagnosis, SAPS II, APACHE II, presence of hypercapnia, pH, pCO2, MIV duration, number of days in the ICU and release condition. The two groups were compared by the Chi-square and Mann-Whitney tests.

Results: 104 patients were included, mainly admitted for pneumonia (52%), other causes of ARF (23%) and COPD exacerbation/hypercapnic acidaemia (HA) (13%). 22 (21%) received MIV and NIV and 92 (97%) only MIV. When analyzed the differences between groups, was found statistical significant differences regarding the diagnosis (p=0,002), presence of hypercapnia (p=0,005), MIV time (p=0,015) and number days in the ICU (p=0,001), but no differences when compared co- morbidities, SAPS II, APACHE II, nutritional status, social dependence or release condition.

NIV was used in patients with HA (36%) and difficult weaning (63%).

Conclusion: NIV was effective in reducing the MIV time and number of days in the ICU probably because,in selected patients, it reduces the risk of ventilator-associated pneumonia,however no significant difference in mortality was observed.
P2010 Factors associated with the requirement of ventilatory support during an acute exacerbation of COPD
Rosalind Benson, Anne Pocock, Nosheen Kazmi, Syed Huaq, Sanjeev Agrawal. Respiratory Medicine, St. Helena and Knowsley Teaching Hospitals NHS Trust, Prescot, United Kingdom

Background: Identification of high-risk patients is important. Identifying high-risk patients based on age and sex on admission. They also had a relatively better PS. Admission glucose and lactate levels were also important factors. Identifying high-risk patients based on these factors can improve clinical outcomes.

Methods: A retrospective study of consecutive patients admitted with AECOPD in an acute teaching hospital.

Results: 67 patients (45% male) with a mean (SD) age of 72 (12), % predicted FEV1 of 55 (20) and baseline ECGOQ performance status (PS) of 2 (1.2) were studied. 10 (15%) required invasive or non-invasive ventilatory support at some point during their admission.

</table>

Values presented as mean (SD).

Conclusions: Patients with AECOPD who subsequently required ventilatory support had a significantly lower SpO2, higher PaCO2 and a higher respiratory rate compared with the Aerogen T-adapter (305.6±9.3 mg vs 142.4±1.9 mg, p<0.001) corresponding of an increasing of a factor 2 in term of output rate with Combihaler (7.1±0.2 mg/min vs 3.4±0.2 mg/min; p<0.001). The mass of salbutamol deposited on the filter was 2.3 fold higher with Combihaler chamber in comparison with the T-adapter (43.5±0.63 μg vs 18.8±1.9 μg, p<0.05).

P2013 Predictors of 1-year mortality at hospital admission for acute exacerbations of COPD – A real-life study
R.T.M. Sprooten1, R.H.J. Slenter1, D. Koz2, G.J. Wesseling1, E.F.M. Wouters1, G.U. Redde2. 1Department of Respiratory Medicine, Maastricht University Medical Center, Maastricht, Limburg, Netherlands; 2Department of General Practice, Maastricht University Medical Center, Maastricht, Limburg, Netherlands

Background: Acute exacerbations of COPD (AE-COPD) are related to high mortality, especially when hospitalization is needed. Predictors for severe outcomes are still not sufficiently defined which constrains optimal management.

Methods: A retrospective, observational cohort study including all consecutive patients admitted to the pulmonary ward of the University Hospital Maastricht between January 1, 2009 and April 1, 2010 for AE-COPD. Potential predictors were assessed at initial presentation and at the emergency room. Primary outcome was mortality at 1 year. Univariate and multivariate time-to-event analysis using Cox proportional hazard models were used for statistical analysis.

Results: 260 patients were enrolled. The mean age was 70.5±10.8 years, 50.0% were male and 63.4% had advanced COPD. In-hospital mortality rate was 5.8% and the 1-year mortality was 27.7%. Independent risk factors for mortality were age (Hazard Ratio [HR], 1.04; 95% confidence interval [CI], 1.01-1.07), male sex (HR, 2.00; 95% CI, 1.15-3.48), prior hospitalization for AE-COPD in the last 2 years (HR, 2.56; 95% CI, 1.52-4.30), prior recorded congestive heart failure (HR, 1.75; 95% CI, 1.03-2.97), PaCO2 >3.0 kPa (HR, 2.90; 95% CI, 1.65-5.09) and urea >8.0 mmol/L (HR, 2.38; 95% CI, 1.42-3.99) at admission.

Conclusions: Age, male sex, prior hospitalization for AE-COPD in the last 2 years, congestive heart failure, hypercapnia and elevated levels of urea at presentation are independent predictors of mortality within the first year after admission.

P2014 Airflow limitation in critical care patients with respiratory failure: Incidence and clinical effects
Muge Aydogdu1, Cigdem Hanazay1, Yagmur Alikaya1, Ayse Bays1, Sahil Bilgin1, 1Pulmonary and Intensive Care Unit, Gaz University Medical Faculty, Ankara, Turkey; 2Pulmonary Diseases, Samsun Chest Disease and Chest Surgery Hospital, Samsun, Turkey

Background: Airflow limitation (AF) is the most common arrhythmia in general population and among the critically ill patients. If not treated appropriately it might be an important cause of mortality and morbidity.

Aim: To determine the incidence of AF among critically ill patients and to evaluate its effect on ICU outcome.

Material and method: The ECGs of all the patients (both intubated and nonintubated) at admission were evaluated prospectively for the presence of AF. Patients were grouped into two as AF+ and AF- and compared for their ICU outcomes, cardiac and bronchodilator therapies.

Results: A total of 147 patients (76 male, 71 female) with the mean age of 68±15 years were included in the study. AF was found in 36 (25%) patients and among them 33 were diagnosed and received treatment before ICU admission. Although no significant difference was identified at admission APACHE II, length of MV and NIMV, length of ICU stay, mortality was higher in AF+ patients (36% vs 21%, p<0.05). Congestive heart failure, history of cerebrovascular event and acute renal failure development was significantly higher in AF+ patients (p<0.05). No significant difference was identified between the two groups when their pre and post admission bronchodilator therapies were compared. Among the 23 discharged patients with AF, 12 (52%) were discharged with warfarin and 11 (48%) with LMWH.

Conclusion: Airflow limitation must be given great importance and must be treated appropriately since it can be seen in 25% of critically ill patients and it must be treated in order to prevent the incidence of heart and renal failure and mortality is higher in those patients.
P2015 Attitudes to oxygen prescription
Jimstan Periselneris, Hugo Farne, Archie Macnair, Sally Hickman, Rachel Brownie, Kanan Sakunam. Respiratory, Queen Elizabeth Hospital, London, United Kingdom

Background: The BTS guidelines for emergency oxygen use in adults were published in 2008 to ensure the evidence-based safe usage of this commonly given drug. Four national BTS audits have repeatedly shown poor prescription and delivery of oxygen. This was reflected in our data at the Queen Elizabeth Hospital, Woolwich, a 500-bed district general hospital. We investigated the cause of poor oxygen use despite mandatory oxygen prescription (trust guidelines) and incorporation on the bedside prescription chart.

Methods & results: We distributed a survey to medical, nursing, and pharmacy staff. 113 responses were obtained. Assessment of oxygen knowledge was generally good among doctors, but 56% of nurses had not had any teaching on the subject. Amongst doctors 75% felt oxygen would be given no matter what the prescription stated and 60% felt that nurses did not look for the prescription on the drug chart. The majority did not believe that it was onerous to prescribe or that blanket provision of oxygen was harmless. Amongst nurses 47% felt that using oxygen prescription was onerous. 44% rarely or never signed for oxygen on ward rounds, and only 42% had changed the delivery device or flow rate independently despite prescription. 40% of pharmacists felt that it wasn’t a part of their role to check oxygen prescription and 50% thought that oxygen would be given regardless of a prescription.

Discussion: Despite recognizing its importance, there are significant attitude barriers to better oxygen prescription. As a result doctors don’t prescribe oxygen as they believe nurses will ignore the prescription and nurses don’t sign on the chart as oxygen isn’t prescribed. Attitudes towards oxygen prescription need to be radically changed to improve matters.

P2016 The noninvasive ventilation results of critical stable hypercapnic patients in an intensive care unit

Introduction: The application of noninvasive ventilation (NIV) in respiratory assistance (RA) has been defined. The data about use of NIV in patients without RA for treating hypercapnia is limited. Aim: We aimed to study the results of NIV application for critical hypercapnic patients with terminal disease in an intensive care unit (ICU).

Methods: Study design: single center, retrospective cohort study. Setting: 22 bed medical ICU in a research and training hospital. Study period: January 2010–December 2011. Patients: Hypercapnic (PaCO2 ≥ 55 mmHg) critical respiratory patients with RA (pH < 7.35) who had no contraindications for NIV. ICU severity score (APACHE II), demographics, duration of NIV, arterial blood gas (ABG) results at admission, during NIV, nasal O2 and on last ICU day. ICU days and mortality were recorded from patients’ records. Patient data were given as median and interquartile ratio (IQR, 25%-75%).

Results: Of 2103 patients admitted to ICU in study period, 582 (2.7%) patients with inclusion criteria were retrieved. PaCO2 value at admission, during NIV, nasal O2 and last day of ICU were 74 (69-82), 67 (61-79), 74 (63-80) and 50 (66-76) mm Hg, respectively (p < 0.001) and PaO2/FIO2 values at admission and discharge were 186 (143-235) and 240 (202-282), respectively. APACHE II score, duration of NIV as hours (h) on first and last day were 16 (12-18), 13 (9-14) and 6 (4-10), respectively. Days of ICU was 6 (4-9) and mortality in patient population was 4.3% (n=2).

Conclusion: The improvement of hypercapnia in critical patients without RA can be achieved by intense and regular application of NIV in ICU. Those patients should be considered for long term home NIV support.

P2017 Intensive care unit mortality of critically ill patients in first 24 hours: A single center 4-year cohort study
Cüneyt Saltırık, Zuhal Karakurut, Gökyü Güngör, Özlem Yazıcıoğlu Moçin, Merih Balci, Hurye Berk Takir, Feyza Kargin, Nalan Adığüzel. Intensive Care Unit, Süreyyapasa Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Turkey

Aim: There is limited number of studies examining the clinical features of patients who died within 24 hours of intensive care unit (ICU) admission. In our study we investigated whether these group of patients are in their terminal stage of disease or not.

Methods: Study design: Retrospective cohort study. Single center. Study place: 22 bed ICU of tertiary research and training hospital. Study period: January 2008–September 2011. Patients and data: All patients died within first 24 hours of ICU admission during mentioned period were included. Demographic data of patients, ICU severity scores (APACHE II), ICU time, data of ICU entry and death were recorded. Terminal stages of patients were identified by evaluating existence of advanced stage of chronic diseases (cancer, pulmonary parenchymal diseases, neurological diseases) and their functional life performance of last 3 months (Karnofsky performance scale). Statistics: Results are recorded as median and inter quartile ratio (IQR).

Results: Within the specified period 16 (n=447) of 2787 patients died 96% (21) of these patients who died within the first day of ICU admission were included in the study. Patients’ values were found as for age and APACHE II: 68 (56-76), 32 (26-36) respectively. Distribution of 48 (5%) patients who meet the definition of terminal illness from 2008 to 2011 were as follows: Group 1: 56% (n=26), 46% (n=24), 51% of patients died in first hour while 50% of them died in the first 9 hours.

Conclusion: Considering the presence of terminal disease in the half of the patients who died in the first day of ICU admission, we recommend to follow the group of patients in the special units outside the ICU as national health policy and planning.

P2018 Does severity of obesity effect intensive care outcome of patients with obesity hypoventilation syndrome?
Nalan Adığüzel, Zuhal Karakurut, Gökyü Güngör, Özlem Yazıcıoğlu Moçin, Merih Balci, Cüneyt Saltırık, Feyza Kargin, Hurye Berk Takir. Intensive Care Unit, Süreyyapasa Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Turkey

Aim: Aim of study is to investigate the effect of severity of obesity on intensive care (IC) outcome of obesity hypoventilation syndrome (OHS) patients admitted to ICU with acute respiratory failure (ARF).

Method: Study is designed as retrospective cohort study between June 2009–2011 at ICU of teaching hospital. Patients with hypercapnia (PaCO2 ≥ 45 mmHg) and body mass index (BMI) ≥ 30 kg/m2 were grouped according to BMI ≥ 30 and group 1; and ≥ 40 as group 2 (morbid obesity). Demographic characteristics, comorbid diseases, blood gases (ABG), invasive and noninvasive mechanical ventilation, ICU length of stay (LOS), mortality of groups are compared. Results are recorded as median and inter quartile ratio (IQR, 25%-75%).

Results: 149 OHS patients were included, 86 patients in Group 1, 66 patients in group 2. Respectively, patients median age was 66 (55-71), 61 (55-70) years; admission APACHE II score 16 (15–20), 18 (16–23); admission PaCO2: 75 (69–86), 78 (67-85); PaO2/FIO2: 173 (149-216), 180 (155-230) were similar. IMV application was 93% and 89%, NIV application was 99% and 93%. The falling rate of PaCO2 below 45 mmHg was 55% and 75%, respectively and difference was significant (p<0.015). LOS and mortality rates were similar between groups. Device reporting for home ventilation was 40% for group 1 and 64% for group 2 (p<0.026). COPD/asthma coexistence was 40% at group 1 and 1.6% at group 2 (p<0.001).

Conclusion: Obesity and morbid obesity don’t alter ICU outcome of patients with OHS and ARF. COPD and asthma comorbidity cause persistent hypercapnia independent of BMI. Improvement in hypercapnia in morbid obesity without comorbidity is better.

P2019 Does technology matter? One intensive care unit’s experience
Russell Graham1, Roberta Melton1, Adam Mullally1, Stanley Rhone1, James Fink1. Respiratory Care and Pulmonary Diagnostics Services, Memorial Hermann - Texas Medical Center, Houston, TX, United States; 1Division of Respiratory Therapy, Georgia State University, Atlanta, GA, United States

Background: Pneumatic nebulizers (PN) can add significant flow to the circuit and can harbor harmful pathogens. Use of a portable mechanical ventilator (MV) often results in incomplete nebulization with retrograde contamination from the patient. Vibrating mesh nebulizers (VMN) have a physical barrier between the aerosol pathway and the medication reservoir, reducing risk of contamination. We hypothesized that VMN would provide more effective therapy and potentially reduce the risk of VAP.

Method: The Neuroscience ICU Respiratory Therapists initiated a PI project, trialing a VMN (Aerogen, Galway, Ireland), locating one controller in each room to avoid cross-contamination issues as part of a VAP reduction strategy. All medicated aerosol was permed by VMN. Cumulative data was compiled for the 12 months prior. The new method (VMN) was used for 9 months, resuming the old method for an additional 60 day period (to act as an additional control)

Results:

<table>
<thead>

</tr>
</tbody>
</table>

Use of VMN resulted in a 15% drop in vent days, with a 19% increase during the 60 day return. LOS decreased by 28.7% during the study period. There was no statistically significant change in the VAP rate, possibly due to the change in weight value from the decreased vent days.

Conclusions: VMN was preferred by the therapists. In this instance, the advent of technology was felt to make a significant impact on patient care. Further study of the impact of choice of aerosol delivery device on patient outcome is indicated.

P2020 Determination of critical threshold value of SPO2/FIO2 ratio in the diagnosis of acute lung injury
Rhea Lorello Iani, Encarnita Limpin, Rommel Bayot, Teresita De Guia, Fernando Ayuyao. Division of Pulmonary and Critical Care Medicine, Philippine Heart Center, Quezon City, Metro Manila, Philippines

The determination of the critical threshold of S/F ratio for ALI/ARDS was conducted and evaluated. Corresponding measurements of PF and SF ratio was obtained from 106 intubated patients with the diagnosis of Respiratory Failure. Type I, non cardiogenic(ALI) admitted in the intensive care units of Philippine Heart Center from June 2008 to December 2011. A Linear Regression Model [S/F = 29.6 ± 1.09(F/P); p < 0.000] was obtained to determine the critical threshold of the SF ratio among Filipino patients. A correlation coefficient of 0.804 was obtained between the P/F and S/F ratio which yielded the critical threshold for SF ratio of 248 for P/F ratio < 200 and a critical threshold SF ratio of 357 for P/F ratio < 300. Analysis between ROC AUC of 0.645 and the inverse of FiO2 correlates with P/F and SF ratios. The SF ratio threshold of 248 (corresponding to P/F < 200) yielded a sensitivity of 100% and specificity value of 96.23% with a likelihood ratio of 26.5 (95%CI: 6.80 – 103.20) for ARDS, while SF ratio threshold of 357 (corresponding to P/F < 300) had a sensitivity and specificity of 100% and 98.19%, respectively with likelihood ratio of 66.23 (95%CI: 18.8 – 283.8) for ALI. The high correlation between the SF and PF ratio and critical as well as the consistent relationships between ROC AUC and inverse FiO2 vs. P/F ratio, excellent sensitivity and very satisfactory specificity for ARDS and ALI indicate that the threshold SF ratio of 248 and 357 for SF ratio of 200 and 300 can measure and discriminate ARDS and ALI among critically ill Filipino patients.

P2021 Influence of the pattern of admission on the outcome of patients admitted to a respiratory intensive care unit: Does the step-down pathway differ from the step-up one?
Ilaria Valentini, AngelaMariaGrazia Pacilli, Paolo Carbonean, Rita Vitale, Laura Castaldi, Luca Fasano, Stefano Nava. Respiratory and Critical Care Unit, Sant’Orsola Malpighi Hospital, Bologna, Italy

The influence of the location prior to the admission in a Respiratory Intensive Care Unit (RICU) on the patients’ outcome has never been assessed. We have evaluated the clinical outcomes and prognostic indices, according to their provenance, in 175 consecutive patients admitted over 1 year period in our RICU. 37% of the patients were admitted directly from the Emergency Room (ER), 27% from one of the referring wards (RW), 18% from our Respiratory ward (RW) and 18% transferred from other medical wards (OWs). Patients transferred from our RW had a significantly higher SAPS II score (44±10 vs 34±13, 34±13 and 44±14, for ER-ICUs and OWs, respectively), a lower albumin (2.9±0.5 vs 3.2±0.6 and 3.6±0.5 for ICUs and ER, respectively). All the other clinical variables were similar except for CHF that was lower in those patients admitted from the ICUs. Mortality rate was significantly higher in the patients transferred from our RW and OWs (15%, 18%, 38% for ICUs and ER, respectively). A Cox multivariate analysis and the mortality risk (Hazard ratio) showed that an high SAPS II score (p<0.0154), low albumin levels (p<0.0024), non invasive mechanical ventilation (NIV) (p<0.004) and congestive heart failure (p<0.0481) were significantly associated with the mortality rate. In conclusion, when our RICU acts as “step-down” the mortality rate is lower than when it acts as “step-up”, probably because these latter patients are admitted in end-stage conditions. NIV was surprisingly correlated with a high mortality risk, because in a large subset of patients it was used as ceiling treatment.

241. Noninvasive ventilation for weaning and acute exacerbation management of airway obstruction

P2022 Invasive and noninvasive ventilation in adults hospitalized with asthma in Portugal - Nationwide data from 2000-2010
Daniela Alves1, Alberto Freitas2, Manuel Vaz3, Tiago Jacinto4, João Fonseca5. 1Pneumology, Hospital de Braga, Braga; 2Centro de Investigação em Tecnologias e Sistemas de Informação em Saúde, Faculdade de Medicina da Universidade do Porto; 3Pneumology, Hospital de São João, Porto, Portugal

Introduction: Few studies have addressed the use and outcomes of invasive (IV) and noninvasive positive pressure ventilation (NPPV) in severe asthma exacerbations.

Objective: To describe the use of IV and NPPV in patients hospitalized due to asthma in Portugal from 2000 to 2010.

Methods: Retrospective study of inpatient records with principal diagnosis of asthma, age ≥ 18 years, in acute care hospitals of the national healthcare system (N=85) in mainland Portugal, with discharges between 2000 and 2010 (N=17,446). Analysis of all episodes that included IV and NPPV that were identified using ICD-9-CM (codes 93.9x and 96.7x). The Charlson/Deyo index, a comorbidity risk adjustment measurement, was used.

Results: In 1,041 episodes (6%) ventilatory support was needed: NPPV 2.3% and IV 3.6%. NPPV use increased from 17 to 79 cases, mainly after 2007, while IV use decreased over the years. Length of stay (days) was similar in both ventilation procedures. Mortality for IV was significantly higher than for NPPV (15% vs. 2.2%).

Conclusion: NPPV is increasingly used in severe exacerbations. Patients treated with NPPV have a lower mortality rate despite of being older and having an increased comorbidity risk index. Prospective studies are strongly needed.

P2023 Non invasive proportional assist ventilation in management of severe asthma exacerbation
Khaleed Hasween, Mohamed Metwally. ICU Unit of Chest Diseases Department, Assiut University Hospital, Assiut, Egypt

Background: NIV could be beneficial in selected patients with severe asthma exacerbation (SAE). However, its role is still not well defined.

Objective: To evaluate the efficacy of NIV using proportional assist ventilation (PAV) in SAE after failure of conventional medical treatment (CMT).

Patients/Methods: Thirty patients with SAE were failed to respond on CMT. NIV was applied via face mask as a last resort before intubation.

Results: The mean age was 39 ± 9.7 with female predominance (19 females Vs 11 males). The successful outcome was achieved in 23/30 patients (76.6%). Follow up of respiratory distress and gasometric parameters after 1 hour NIV in successful group was shown in table 1.

Conclusion: NIV can relieve respiratory distress and improve gas exchange in majority of patients with severe asthma exacerbation who are candidate for intubation after failure of CMT.

P2024 Mixed acid-base disorders, hydroelectrolyte imbalance and lactate production in hypercapnic respiratory failure: The role of noninvasive ventilation
Eghio Di Stefano1, Vittoria Coni2, Marta Di Nicola3, Angelo Portoiani4, Claudio Terranova5, 1Respiratory Medicine Unit, Dept of Internal Medicine, Azienda USL Pescara, Pescara; 2Respiratory Medicine, Fondazione Elenora Lorilld Spencer Cenci, Sapienza University of Rome; 3Dept. of Biomedical Science, University “G. d’Annunzio” of Chieti-Pescara, Chieti, Italy

Hypercapnic COPD exacerbation in patients with comorbidities is complicated by
mixed acid-base, hydro-electrolyte and lactate disorders. Aim of this study was to determine the relationships of these disorders with the requirement for and duration of noninvasive ventilation (NIV).

Methods: Sixty-seven consecutive patients who were hospitalized for hypercapnic COPD exacerbation had their clinical condition, respiratory function, blood chemistry, arterial blood gases, blood lactate and volmetric state assessed. Heart and respiratory rates, pH, PaO₂, PaCO₂ and PaO₂ and blood lactate were checked at the 1st, 2nd, 6th and 24th hours after starting NIV.

Results: Nine patients were transferred to the intensive care unit. NIV was performed for 11/17 (64.7%) mixed respiratory acidosis–metabolic alkalosis, 10/16 (27.8%) respiratory acidosis and 3/5 (60%) mixed respiratory-metabolic acidosis patients (p=0.026), with durations of 45 ± 8.9, 36.2 ± 8.9 and 53.9 ± 4.1 hours, respectively (p = 0.016). The duration of ventilation was associated with higher blood lactate (p < 0.001), lower pH (p = 0.016), lower serum sodium (p = 0.014) and lower chloride (p = 0.038). Hypopituitarism without hypervolemic hypochloremia occurred in 11 respiratory acidosis patients. Hypovolemic hypopituitarism with hypochloremia and hypokalemia occurred in 10 mixed respiratory acidosis–metabolic alkalosis patients, and euvoletic hypochloremia occurred in the other 7 patients with this mixed acid-base disorder.

Conclusions: Mixed acid-base and lactate disorders during hypercapnic COPD exacerbations predict the need for and longer duration of NIV.

P2025
Noninvasive ventilation (NIV) for acute hypercapnic respiratory failure (AHRF): Is the helmet an effective interface? A pilot RCT
Chiara Mega, Paolo Nevadani, Alfredo Gross, Raffaele Scala, Vanessa Repetto, Corrado Zenesini, Luca Fasano, Manuela Del Forno, Stefano Nava.
Respiratory and Critical Care, Sant’Orsola Malpighi Hospital, Bologna, Italy; Università degli Studi, Università di Bologna, Italy; University of Bologna, Area Epidemiologia, Bologna, Italy

To date the helmet is rarely used in AHRF, despite its hypoxic respiratory failure, it is employed as a “rotating” strategy when the facial mask is poorly tolerated. In a multicenter RCT, we compared the clinical efficacy of a new helmet designed to specifically improve the performance in COPD vs a full face mask during an episode of AHRF. 17 COPD with AHRF were randomly assigned to receive NIV either with full face mask (Group A, n=9), pH = 7.26 ± 0.07, PaCO₂ = 73.7 ± 10.8mmHg, PaO₂/PaCO₂ = 97.3 ± 5.3, or the helmet (Group B, n=8, pH = 7.24 ± 0.05, PaCO₂ = 83.3 ± 14.2mmHg, PaO₂/PaCO₂ = 100.6 ± 6.4). In the former group the ventilator settings were adjusted according to the usual practice (i.e. the maximal inspiratory pressure tolerate and CPAP = 4cmH2O), while in latter group according to published data (Crit Care Med 2009; 37:1921). ABGs were evaluated at admission, 1 and 6 hour and then everyday until discharge. Vital parameters, comfort scale, dyspnea score and adverse events were recorded. Baseline characteristics did not differ significantly between the two groups. 2 and 1 patients for group A and B respectively required intubation. NIV improved gas exchange vs baseline (p < 0.05) both with mask and helmet (pH = 7.34 ± 0.08, PaCO₂A = 97.3 ± 12.3mmHg, pH = 7.30 ± 0.05, PaO₂A = 83.4 ± 13.2mmHg; PaCO₂B = 73.7 ± 10.8mmHg, pH = 7.21 ± 0.07, PaO₂B = 73.7 ± 10.8mmHg; PaCO₂B = 58.0 ± 6.9mmHg, pH = 6.6). No differences in vital signs, patients’ comfort and dyspnea score were observed between the two groups. In conclusion this pilot RCT we have shown that the helmet may be a valid alternative to the “classical” full face mask during an episode of AHRF, making the former interface possible alternative for “rotating” strategy.

P2026
Effects of non invasive ventilation on left and right hemodynamic parameters during acute respiratory failure secondary to COPD exacerbation
Balldassare Canino, Vincenzo Calandrino, Caterina Urso, Roaul Aiello, Rosalia Lo Presti, Gregorio Cairini. Internal Medicine and Specialist (DIMIS), University of Palermo, Italy

Non Invasive Ventilation (NIV) is a technique used in different forms of acute respiratory failure that allows the patient to provide a full or partial ventilatory support without intubation. NIV has obvious effects on lung mechanics, but the changes that brings to the pulmonary vascular circulation, and to the right and left ventricle are more less investigated. Based on this assumption, we studied 32 patients (18 male, 14 women, mean age 72 ± 7.5 years) with respiratory failure secondary to COPD exacerbation who required NIV and we submitted to transthoracic echocardiography at the admission and at the resolution of respiratory failure. We have therefore shown that NIV not only has positive outcomes on right ventricular function (reduction of Pulmonary Insufficiency, Tricuspid Regurgitation, and four-chambers Ventricle Systolic and Diastolic Areas and short-axis Diameters with secondary improving of Tricuspid Annular Plane Systolic Excursion), but it had a statistical positive effect also on left ventricular function (Ejection Fraction increase, p < 0.05). Minimizing the effect of ventricular interdependence and deflating the lung, NIV not only has positive results on right hemodynamic parameters but, increasing venous return to the left ventricle and recovering the stroke volume, also improves its performance.

P2027
Factors predicting outcome of non-invasive ventilation (NIV) for acidotic hypercapnic respiratory failure (AHRF) from lung diseases other than COPD
Sarah Elgarf, Alice Turner, Ben Beauchamp, Rahul Mukhtarjee.
1Department of Respiratory Medicine & Physiology, Heart of England NHS Foundation Trust, Birmingham, United Kingdom; 2Queen Elizabeth Hospital Research Laboratories, University of Birmingham, United Kingdom

Background: NIV is the treatment of choice for AHRF in acute exacerbation of COPD, neuromuscular and thoracic cage disorders, but its indications have widened in UK hospitals, particularly in patients with AHRF of any cause whose comorbidities preclude invasive ventilation - we sought to establish the predictors of outcome in non-COPD Lung and Airway patients with AHRF.

Methods: Cohort analysis of prospectively collected data on acute NIV for non-COPD Lung and Airway diseases with AHRF in a ward-based NIV unit over 5 years recording diagnoses, demographics, response to NIV at 4 hours and in-hospital mortality (univariate analyses as total numbers too low for logistic regression).

Results: NIV was used to treat 39 episodes of pneumonia, 25 of exacerbations of non-cystic fibrosis (CF) bronchiectasis, 15 of asthma and 3 of CF (in 38, 22, and 3 individuals respectively), comprising 5.67% of all acute NIV episodes. All subgroups among non-COPD Lung and Airway patients receiving NIV for AHRF had impaired lung function with mean FEV1 of 34%, 41%, 43% and 18% respectively, 2 from the pneumonia group were intubated and 12 died during the admission - significantly more than the other subgroups (p=0.049); initial pH significantly predicted death in non-CF bronchiectasis (p=0.007).

Conclusions: In conditions other than COPD exacerbations, neuromuscular and thoracic cage disorders, acute NIV is useful in little in our unit (5.67%); when used, the predictors of death are broadly similar to COPD in non-CF bronchiectasis, but less predictable in the other groups, pneumonias being associated with higher co-morbidity and in-hospital mortality.

P2028
Long-term survival of COPD patients after first hospital admission with respiratory insufficiency and treatment with non-invasive ventilation in a respiratory ward in Denmark
Niels Glüer Tilsted, Department of Respiratory Medicine, Odense University Hospital, Odense, Denmark

Introduction: Implementation of non-invasive ventilation (NIV) as an add-on treatment has been used routinely since 2004 at a University Hospital in Denmark, and data on COPD patients admitted to hospitals in Denmark have been monitored the last three years (National Indicator Project on COPD) show 30-day mortality data that can be estimated to 10%. No data on long-term survival on COPD patients in Denmark have been reported.

Method: Data from medical journals were retrieved from all patients admitted with respiratory insufficiency (respiratory acidosis and hypercapnea) and known or suspected COPD in exacerbation receiving non-invasive ventilation from January 1st 2005 until December 31st 2007. Demographic data collected included age and gender when receiving treatment with NIV for the first time.

Results: In total 257 patients (147 female/110 male) received NIV for the first time. The median age was in all 72 (25-percentile: 65.2 years and 75-percentile: 79.2 years). The 30-day mortality rate was 29.3%. Survival grouped by gender is illustrated in Fig. 1. There was no statistical significant difference between the groups. The total observation time was between 5 and 7 years.

Conclusion: The mortality rate of patients receiving NIV is as expected high, but the 5 years survival rate was 23.7% and with a trend of more female than male long-term survivors.

P2030
Who benefits most from non-invasive ventilation for hypercapnic exacerbations of chronic obstructive pulmonary disease
David Miller, Kimberly Scott, Iain Murray, Gillian Thain, Graeme Currie.
Respiratory Unit, Aberdeen Royal Infirmary, Aberdeen, United Kingdom

Introduction: Non-invasive ventilation (NIV) has revolutionised the management of hypercapnic exacerbations of chronic obstructive pulmonary disease (COPD).
We wished to evaluate factors related to its overall success in the “real-life” setting.
Methods: A retrospective analysis of patients receiving NIV for a hypercapnic exacerbation of COPD was performed. Demographics, laboratory data, blood gases and outcomes (hospital discharge or in-patient death) were extracted and subsequently analysed to identify factors relating to its overall success or failure.
Results: Over 6 years, 240 patients (mean age 70 years), received NIV with mean pH and pCO2 prior to NIV 7.24 and 14.4kPa respectively; of these, 167 survived to hospital discharge with a median age (70 vs. 74; p=0.02) lower than non-survivors.
Absolute values of pH and pCO2 (higher and lower respectively) prior to NIV and at 1 hour were both associated with outcome. pH was (p=0.02) in pH within an hour of receiving NIV - but not pCO2 - was associated with surviving to hospital discharge. Of all laboratory data assessed, only baseline area was significantly (p=0.02) associated with a successful outcome.
Conclusion: Younger patients with a lower area, higher pH and lower pCO2 at baseline and who demonstrate an improvement in pH within 1 hour, are more likely to have a successful outcome when given NIV for a hypercapnic exacerbation of COPD on an unselected basis.

P2031
Efficacy of non invasive mechanical ventilation (NIV) for acute respiratory failure (ARF) in COPD patients with and without pneumonia
Giovanni Alessandrini1, Caterina Antonaglia, Alessia Steffania, Paolo Marinielli, Matteo Bonini, Michela Mordenti, Mattia Internullo, Tullia Villani, Stefano Schiavetto, Elena Angelici, Paolo Palange. Department of Public Health and Infectious Diseases, Lang Function Unit, "Sapienza" University, Rome, Italy

Background: NIV represents one of the major technical advances in the management of ARF. Several data in literature showed the efficacy of NIV in COPD hypercapnic patients and in immunodepressed pneumonia patients. By contrast, the role of NIV in the treatment of pneumonia in COPD patients is controversial. We compared the efficacy of NIV for treating ARF in a group of immunocompetent COPD patients with and without pneumonia.
Methods: Among patients referred to our ward, we studied 12 COPD patients with ARF-P (66.3±14.65 years) and 9 with ARF-NP (74.5±4.6 years). Diagnosis of COPD and pneumonia were made according to International Guidelines. All patients were treated with a standard NIV pressure-support protocol. The following parameters were chosen as endpoints and recorded at baseline (B) and at 48 hours of NIV treatment: arterial PO2, PCO2, pH, and respiratory rate (RR). Data were analyzed using SPSS 17 statistical software.
Results: No differences in respiratory variables between the two groups were observed at B (p=ns). At 48 hours of NIV treatment, ARF-P patients showed a significant improvement in PO2 (69.3±10.9 vs 56.9±6.9; p=0.003), a significant reduction in PCO2 (51.0±9.4 vs 627±11.4; p=0.0006) and RR (18.6±2.1 vs 27.6±3.7; p=0.01). No differences were observed in pH value (7.4±0.1 vs 7.4±0.1; p=ns). Similar results were observed in the ARF-NP group. Time to hospital discharge was not significantly different between groups.
Conclusions: In COPD patients, NIV treatment for ARF is effective independently of the presence of pneumonia. Results should be confirmed on a larger population.

P2032
Nasal non-invasive positive pressure ventilation for moderate exacerbation of chronic obstructive pulmonary disease (COPD) treated in a Tunisian medical ward
Ibtihel Khouaja, Habib Ghedira. Pavillon 1, Abderahmane Mami Hospital, Ariana, Tunisia

Nasal Non-Invasive Positive Pressure Ventilation (NNPPV) is a soft method with a low burden which can be used in medical ward and may improve the outcome of COPD exacerbation.
Aim: The aim of this study is to evaluate the effectiveness of the addition of NNPPV to usual medical care in improving the outcome of patients treated in a medical ward for an exacerbation of COPD with moderate hypercapnia.
Methods: Among 25 patients who were hospitalized for an exacerbation of COPD with moderate hypercapnia, 10 were randomly selected to receive NNPPV (NNPPV group) and then compared to the 15 patients who received only an optimal medical treatment without ventilation support (control group). However, the role of NIV as a palliative measure in dying patients with COPD remains unclear.
Aim: To investigate the usefulness of NIV as an end-of-life measure in patients with COPD.
Patients and methods: We retrospectively reviewed the medical records of COPD patients who died of respiratory failure and had been receiving NIV at the end of life in a university-affiliated medical center.
Results: In 683 COPD patients who died, only 47 (7%) was under NIV support as a palliative measure before death. Most patients (79%) died in general ward, while the minority of patients had a preexisting "do-not-inhabit" (DNI) will, 76% placed a DNI documentation after initiation of NIV. There was no significant increase of respiratory rate or worsening of other vital signs 24 hours after starting NIV, suggesting the usefulness of NIV to prevent progression of distress. The consciousness significantly deteriorated (p=0.001) after the starting of NIV, which prevented the use of opioids or sedative agents. The mean length of NIV was 8.7±7.3 days and most of the patients (79%) were maintaining the NIV until they died, suggesting the tolerability.
Conclusions: Our study results suggest that NIV might be useful for dying COPD patients, who might experience a comfortable dying process. For relieving distress caused by respiratory failure, NIV may be a useful alternative measure to alleviate the dyspnea or discomfort. Further prospective study might be required.

P2034
Acetazolamide for reversing metabolic alkalosis during NIV treatment for AECOPD
Laura Borroengoa, Mattia Internullo, Liborio Sardo, Paolo Marinielli, Caterina Antonaglia, Alessia Steffania, Giovanni Alessandri, Matteo Bonini, Elena Angelici, Francesca Vaccaro, Paolo Palange. Department of Public Health and Infectious Diseases, Lang Function Unit, "Sapienza" University, Rome, Italy

Background: COPD is a leading cause of morbidity and mortality. Hypercapnic respiratory failure during acute exacerbation of COPD (AECOPD) strongly influences the prognosis. Non invasive ventilation (NIV) is an effective treatment for AECOPD. NIV may be less successful in the presence of metabolic alkalosis (MAK), due to the associated reduced ventilator drive. This study aimed to assess the effect of acetazolamide (ACET) on the correction of MAK, as well as of hypercapnia, during NIV for AECOPD.
Methods: Among patients referred to our clinical ward and treated with NIV, seven subjects (78.7±8.3 years) with AECOPD hypercapnic (PaCO2 >45mmHg) respirator failure (PaO2 <60mmHg), and MAK (pH = 7.40 and HCO3- <30mmol/L).
were enrolled in the study. Twenty-four hours (Day 0) from starting NIV treatment, ACET 500mg p.o. daily for two consecutive days (Day 1 and 2) was adminis-

tered. The following parameters were measured: arterial PO2, PCO2, pH, HCO3–, chloride and urinary pH. Results are expressed as mean±SD. Student t-test with Bonferroni’s correction was used for statistical analysis.

Results: Both at Day 1 and 2, pH and PaCO2 were significantly reduced compared to Day 0: pH 7.42±0.04 vs 7.45±0.04, p= 0.02; PaCO2 58±4mmHg vs 68±10, p= 0.03. HCO3– decreased with ACET, being the reduction more pronounced at Day 2 compared to Day 0 (36.2±4.8mmol/L vs 45.9±6.2, p= 0.0006). Conversely, urinary pH significantly increased during ACET. No drug adverse events were observed.

Conclusions: ACET may be useful for the correction of MAalk during AECOPD that requires NIV. A reduction in both pH and PaCO2 can be obtained in the first 24-48 hours of treatment. Further studies are needed on its long term efficacy.

P2035
Arterial bicarbonate as a determinant of the length of non-invasive ventilation (NIV) in COPD patients with acute hypercapnic respiratory failure (AHRF)

Sushil Agarwal1, Vikas Punamiya1, Shiva Bikmalla1, Christopher Bond 1, Biman Chakraborty1, Harjevan Gill1, Ben Beauchamp1, Rahul Mukherjee1.

1Department of Respiratory Medicine & Physiology, Heart of England NHS Foundation Trust, Birmingham, United Kingdom; 2School of Mathematics, University of Birmingham, United Kingdom

Introduction: Factors related to length of stay are complex and related to many non-medical factors, however length (duration) of NIV treatment is not. Although the associations of mortality of patients requiring NIV are well-documented (Thomas A et al Thorax 2010; 65:4. A33.), the determinants of the length of NIV have not been clearly elucidated, which we decided to investigate.

Methods: A retrospective analysis of the initial arterial blood gas bicarbonate (HCO3–)values on 115 consecutive episodes of NIV for at a dedicated respiratory NIV unit from 01 Jan to 31 Oct 2011 was carried out. Analysis of blood gases and duration of use of NIV (in days) was documented and analyzed.

Results: There were 115 patients admitted with AHRF with COPD. Plotting a graph with HCO3– and length of NIV we see that it has a linear relationship.

The p-value for HCO3– as a determinant of length of NIV is 0.00084, which suggests that it is significant.

Conclusion: This scientific survey indicates that the length of NIV therapy in patients in AHRF increases with a higher HCO3–. Though outcome and mortality is closely linked to the pH, length of NIV is more closely linked to the HCO3–. This is explained by the fact that people with higher HCO3– are likely to have had chronic respiratory failure for longer and are likely to take longer to recover from the respiratory failure.

P2036
Acidotic hypercapnia: Beyond type 1 and type 2 respiratory failure

Ambika Talwar1, Vikas Punamiya1, Shiva Bikmalla1, Sushil Agarwal1, Ben Beauchamp2, Rahul Mukherjee1.

1Department of Respiratory Medicine & Physiology, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; 2Department of Physiotherapy, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom

Introduction: The indications of non-invasive ventilation (NIV) have widened in the recent years, which is now used in treating hypercapnia with acidosis in a variety of patients. However, in many of the patients treated with NIV, the acidosis may have preceded the hypercapnia. The current case series from our 11-bedded ward based NIV unit describes such acidotic hypercapnia: hypercapnic respiratory failure following metabolic acidosis.

Methods: Time series of Arterial Blood Gas (ABG) findings in 4 patients with acidotic hypercapnia with a background of COPD confirmed with spirometry.

Results: The ABGs for cases 1 and 2 showed a rising CO2 following the onset of a metabolic acidosis; a mixed metabolic and respiratory acidosis in patients 3 & 4 - with the acidosis preceding hypercapnia (Case 3) or being out of proportion to CO2 rise (Case 4). All four patients improved with initiation of NIV combined with active fluid/electrolyte management. A sample ABG time series (Case 3) showing initial eucapnia with acidosis leading to hypercapnia is shown:

The classic Acidotic Hypercapnic picture:

Discussion: Acidotic hypercapnia could be a further subtype of respiratory fail-
ure (akin to previously described Type 4 or shock-muscle hypoperfusion related respiratory failure) for which larger confirmatory studies and prospective trials to establish the efficacy and timing of NIV are required.

P2037
A cohort study for improvement of asthma attack by noninvasive positive pressure ventilation (NPPV)

Tomoya Katsuta1, Toshimitsu Suwaki2, Takayuki Kamo2, Shuzi Okahara3.

1Respirology, Sumitomo Bexchi Hospital, Nishanuma, Japan; 2Internal Medicine, Kanda Hospital, Minowas, Japan; 3Critical Care Medical Center, Tsuayama Central Hospital, Tsuyama, Japan

Objective: A few study of efficacy of NPPV therapy in asthmatic patients have been reported. We studied efficacy and incidence rate of NPPV therapy.

Method: This prospective cohort study was performed in two hospitals in Okayama prefecture, Japan. All of the patients admitted because of asthma attack between January 2005 and June 2010 had to fulfill the following criteria before hospitalization. 1. The patients’ peak flow is less than 200L/min or 30% of his or her best peak flow 2. Borg scale is nine or ten. Hospitalization patients had to fulfill the following criteria for NPPV therapy. 1. Patients received PaCO2 >45mmHg and pH<7.351. 2. His or her Borg scale is ten.

Results: 94 patients were included in the study. Fourteen patients were received NPPV therapy. All patients avoided receiving mechanical ventilation.

Figure 1 shows profile of pH in the patients receiving NPPV. Figure 2 shows profile of Borg scale in the patients receiving NPPV.

Conclusion: The proportion of patients need NPPV therapy is 15%. In asth-
matic patients NPPV therapy appears highly effective in correcting gas exchange abnormalities and severe dyspnea.
P2038 Should teaching about non-invasive ventilation be made mandatory to all grades of general medical doctors? An audit of junior doctor knowledge regarding the management of patients on NIV before and after teaching sessions

Maria Aisha McClintock-Tiongco, Jane Evans, Yee-Ean Ong. Respiratory Medicine, St. George’s Hospital, London, United Kingdom

Introduction: Patients on non-invasive ventilation (NIV) are usually looked after out of normal working hours by general medical doctors.

Aims and objectives: We sought to determine the level of knowledge about NIV amongst general medical foundation (F1) doctors, core medical trainees (CMT) and specialist registrars (SpRs) before and after teaching.

Methods: Junior doctors were asked to complete a questionnaire covering knowledge about the criteria for commencing NIV, initial settings and appropriate manipulation of NIV machines according to patient response before and after mandatory teaching for F1 and CMT trainees and a voluntary attendance session for SpRs.

Results: Forty-nine doctors completed the questionnaire pre-teaching and all F1 and CMT doctors attended training but only 5/16 SpRs attended teaching.

Some of the most concerning findings were that all grades were poor at defining type II respiratory failure pre- and post-teaching. Knowledge about initial ventilator settings, alteration of pressure settings and target oxygen saturations on NIV were poor before teaching (although better in SpR group than more junior doctors).

Majority would have aimed for pressure settings too low to be effective. However, knowledge improved substantially after teaching amongst those who attended.

Conclusion: Baseline knowledge of all grades of junior doctors about practical NIV care is poor risking ineffective treatment but this can be improved by teaching. However, sessions need to be mandatory to ensure attendance.

P2039 Short and long-term outcomes after the first episode of non-invasive ventilation (NIV) for an acute exacerbation of COPD (AECOPD) on a general ward

K.H.M. Walraven, M. van Vliet, J.A. van Noord. Department of Respiratory Diseases, Atrium MC Parkstad, Heerlen, Limburg, Netherlands

Background: NIV is an evidence based treatment for acute respiratory acidosis due to AECOPD. However, less data exist on long-term prognosis after the first episode of NIV.

Aim: To investigate the short and long-term outcomes after the first episode of NIV for AECOPD.

Method: A retrospective, observational, cohort study of 183 patients admitted to the hospital between 2008-2011 for an acute respiratory acidosis due to AECOPD treated with NIV on a general ward. Potential prognostic factors were recorded.

Results: During a 3-year period 275 admissions involving 183 patients were analysed. Included were 72 (39%) men and 111 (61%) women, with a mean age of 70 years (range 45-93y) and a mean FEVI of 33% (range 12-74%). 34 (19%) patients were readmitted for NIV with an average of 3 admissions (range 1-9).

Success rate of NIV was 76% (211 of 275 episodes). In 24% (64 episodes) NIV failed: 32 patients died during NIV (all prior Do-Not-Intubate patients), 7 did not tolerate NIV and died (all prior DNI patients), 16 needed invasive ventilation at the ICU (2 died), 9 died because of a non-respiratory cause.

In-hospital mortality during the first admission was 21%. The mortality rate at 1 hour and 5.12±3.42h: 0/22/78, p<0.001.

Conclusion: Success rate of NIV on a general ward is high (76%), but survival after 1 year is poor.

P2040 Outcome of respiratory critical care patients treated with noninvasive ventilation as a maximal intervention strategy

Elsa Fragoso, Filipe Monteiro, Carlos Lopes, Pilar Azvedo, Jorge Monteiro, Gabriela Brun, António Bugalho de Almeida. Pulmonology, Hospital de Santa Maria, Lisboa, Portugal

Background: End-of-life decisions are an important part of day-to-day medical practice in Respiratory Intensive Care Units (RICU), reflecting the need to prevent unreasonable therapeutic interventions. Noninvasive ventilation (NIV) can be used in the do-not-intubate patient and in palliative care setting.

Aim: To determine the outcome of patients with respiratory failure (RF) in whom NIV was suggested as a maximal intervention strategy. Noninvasive ventilation (NIV) can be used in the do-not-intubate patient and in palliative care setting.

Methods: Prospective study of 369 patients admitted to our RICU for 18 months. Age, gender, APACHE II, diagnosis, comorbidities, inpatient days, NIV duration, type of respiratory failure, PaCO2 on admission, NIV dependence (quantified in hours/day as follows: ≤15, 16-23 and 24) and ICU mortality were evaluated. Patients were divided in 2 groups based on outcome (alive/dead) and variables were compared between groups.

Results: Among patients in need of ventilatory assistance (n=242), 60 had a decision to forego tracheal intubation (24,8%). Age (y): 70±16. Males: 60%. APACHE II: 16±8. Inpatient days: 14±10. Diagnosis, %: chronic respiratory disease 50, heart failure 11, cancer 10, pneumonia 10, neuromuscular disorders 7, others 12. Thirty percent had at least two comorbidities (considering chronic heart failure, chronic renal failure, pulmonary hypertension and dementia). ICU mortality 73%. Mortality, % (hypoxemic RF/hypercapnic RF): 100/64, p=0,007. PaCO2, mmHg (alive/dead): 62±15/5±1,7, p=0,03. Mortality, % (NIV<15/16-23/24h): 0/22/78, p=0,001.

Discussion: The presence of hypercapnic RF had better prognosis, as opposed to hypoxemic RF. Greater NIV dependence was correlated with higher mortality. The mortality rate observed was high, as expected in this subset of patients.

P2041 Elective early noninvasive ventilation as a weaning method of COPD patients

Ahmed Sh. Mohamed 1, Ibrahim Ibrahim 1, 2. Chest Department, Tanta University Hospital, Faculty of Medicine, Tanta, Qalubia, Egypt; 1 Chest Department, Tanta University Hospital, Faculty of Medicine, Tanta, Qalubia, Egypt

Patients with acute exacerbations of COPD represent a large portion of critically ill patients that mechanically ventilated. The rate of weaning failure is high in these patients. Prolonged mechanical ventilation (MV) increases intubation associated complications.

Objective: To determine the efficacy of early non-invasive mechanical ventilation as a weaning method in COPD patients with acute hypercapnic respiratory failure compared with the conventional-weaning approach.

Methods: Study was conducted on a 30 mechanically ventilated COPD patients who had infective exacerbations. Patients were randomly extubated, receiving non-invasive ventilation (n=15), or weaned following a conventional-weaning approach (n=15).

Results: Compared with the conventional-weaning group, the noninvasive-ventilation group had shorter periods of invasive MV, total ventilator support, ICU stay, less incidence of ventilator associated pneumonia and less mortality.

P value less than 0.001 was considered significant.

Conclusion: Patients with chronic obstructive pulmonary disease who had respiratory failure and were starting to breathe spontaneously, showed that noninvasive ventilation could decrease pneumonia, length of stay in the intensive care and the duration of ventilatory support.

242. Application of noninvasive ventilation in non-obstructive patients

P2042 Results of noninvasive ventilation in patients with acute hypercapnic ventilatory failure and obesity hypventilation syndrome (OHS)

Jesus Fernando Sanchez Gomez, Virginia Almadana Pacheco, Ana Gomez Bastero Fernandez, Patricia Guerrero Zamora, Jose Maria Benitez Moya, Agustin Valido Morales, Teodoro Montemayor Rubio. Clinical Unit of Pneumology, Hospital Universitario Virgen Macarena, Seville, Spain

Background: The NIV is used in patients with OHS presenting with hypercapnic respiratory failure. Few studies examine the evolution and impact after starting this therapy in this patient group.

Objective: To determine the efficacy of NIV in obtuse patients with acute hypercapnic respiratory failure and its prognosis consequences.

Methods: A prospective study with consecutive inclusion of obtuse patients with acute hypercapnic respiratory failure treated with NIV from Feb 08 to Jun 11.

Results: See Tables 1 and 2.

At the moment of discharge no differences were observed in comorbiddities, clinical data an blood gases between patients with or without NIV treatment. Patients discharged with NIV had tolerated better and had more total hours of use with BiPAP than those discharged without it.

Compliance measured at 3 months of onset and the last recorded was 4.5±1.3, 30 hours and 5.1±3.42 hours daily.

359s
Introduction: Patients with amyotrophic lateral sclerosis (ALS) and severe bulbar muscle impairment may be at respiratory failure risk during percutaneous endoscopic gastrostomy (PEG). Noninvasive ventilation (NIV) might reduce the risk of respiratory complications in patients with severe ventilatory impairment (SVI).

Objective: To report the outcomes of PEG placement with NIV in ALS patients with SVI.

Methods: Retrospective study including ALS patients with severe bulbar muscle impairment and indication for PEG placement. Pre-PEG pulmonary data was analyzed. Procedure was performed under nasal NIV using patients home bi-level ventilator. Vital signs, estimated tidal volumes and air-leaks were monitored. Due to increases in mouth air-leaks during the procedure ventilator parameters were readjusted. Low flow oxygen was only for SpO2 ≥ 95% despite NIV optimization. If SpO2 < 95% could not be reached the procedure was cancelled. NIV was maintained for 3h after.

Results: Ten patients (mean age 68.2 years) were included. Six patients didn’t require hospital admission. Patient’s pre-PEG pulmonary assessment is in Table 1.

Table 1

Conclusion: NIV allows successful PEG placement in ALS patients with severe ventilatory impairment.

P3044
Training and confidence in the use of NIV/BiPAP amongst front-line medical staff in a teaching hospital setting
Imran Mahmud, Azhar Hussain, Ahmad Moinie, Ari Manuel, Hossam Fayed, Najib Rahman, Oxford Centre for Respiratory Medicine, Oxford University Hospitals, Oxford, Oxfordshire, United Kingdom

Background: Non-invasive ventilation is an evidence-based and validated treatment for patients with type II respiratory failure, and is widely used in acute and chronic settings. Poor training/preparedness have been linked with poor patient outcomes.

Aims and objectives: Staff confidence in managing patients on NIV is poorly described in the literature. Medical interns (with basic medical training) frequently care for patients on NIV during and outside normal working hours. We aimed to assess the preparedness and confidence of year 1 interns in managing patients on NIV within a teaching hospital in the UK. A structured questionnaire probed doctors’ understanding, confidence and practical skills in administering NIV.

Methods: 30 interns completed the questionnaire at a weekly mandatory teaching session. Answers were collated and analysed.

Results: 43% of interns did not know what “BiPAP” stands for; 33% described their knowledge of NIV indications as inadequate; 87% had no formal teaching in the use of NIV; 87% described their practical knowledge of NIV as inadequate, and 70% felt their confidence in managing patients on NIV was inadequate. The overwhelming majority (90%) of respondents felt they needed formal training in the use of NIV to ensure patient safety.

Conclusion: Our study illustrates worrying shortfalls in the training and confidence of front-line medical staff in the use of a medical intervention frequently found on hospital wards. This suggests a role for formal training at either the undergraduate or early postgraduate stage.

P2045
Introduction of a non invasive ventilation (NIV) care bundle in a district general hospital
Huw Ellis, Reham Nasser, Alan Hart-Thomson, Annika Graham. Respiratory Medicine, Huddersfield Royal Infirmary, Huddersfield, West Yorkshire, United Kingdom

Introduction: A care bundle is a group of evidence based actions needed to deliver optimal care in a clinical setting. It takes the form of a simple checklist, placed in the notes, which serves as a reminder to clinicians. It aims to ensure consistent delivery of care leading to safe and reliable care. Compliance with all elements is needed for optimum benefit.

Method: A 7 item bundle was created for acute NIV. It was introduced to coincide with the 2011 British Thoracic Society (BTS) NIV audit so that the impact could be assessed by comparison with the 2010 audit. The bundle was provided in the form of a sticker to be inserted in the case notes when NIV was commenced. Bundle elements not included in the table below were (1) NIV only to be delivered in areas where nursing staff are trained (2) arterial blood gases checked at 1 hour (3) at 4 and 4 hours review by a physician within 24 hours (4) Mon – Fri.

Results: 13 of 19 patients (67%) had a bundle in the notes. 11 of 13 (85%) had all 7 elements completed. The impact of the bundle on key measurements are summarised in the table (bundle items highlighted).

Conclusion: Implementation of an NIV bundle is possible in a DGH and coincided with improved audit outcomes, patient safety documentation of ventilation plans and increased pressures. Numbers are small but it may have contributed to reduced mortality and length of stay.

P2046
Efficacy and safety of continuous sedation for agitated patients under noninvasive ventilation
Takashi Matsumoto, Takahisa Kawamura, Koji Taimai, Junpei Takeshita, Kosuke Tanaka, Kazuya Monden, Kazuma Nagar, Kyoko Ootuka, Ashoki Nakagawa, Ryo Tachikawa, Kojuro Ootuka, Keisuke Tomi, Department of Respiratory Medicine, Kobe City Medical Center General Hospital, Kobe, Japan

Introduction: Sedation is often required for agitated patients under noninvasive ventilation (NIV). However, there have been few reports on use of continuous sedation in these patients. Aim: To evaluate the efficacy and safety of continuous sedation for agitated patients under NIV.

Methods: We retrospectively reviewed 110 patients receiving NIV for acute respiratory failure from May 2007 to December 2011, who needed sedation for treatment of agitation. Difference in clinical outcomes was compared between continuous use group and intermittent use group, according to do-not-intubate (DNI) status (n=73) or non-DNI status (n=37).

Results: In non-DNI patients, the severity assessed by baseline PaO2/FiO2 and mortality were similar between continuous use group (n=10) and intermittent use group (n=27) (117±66 mmHg vs. 116±50 mmHg, p=0.95 and 10% vs. 22%, p=0.40). No patient in continuous use group required intubation due to agitation, while three patients in intermittent use group required intubation due to failure of sedation (0% vs. 11%, p=0.54). In DNI patients, baseline PaO2/FiO2 ratio was lower and the mortality was higher in continuous use group (n=53) compared with intermittent use group (n=40) (131±51 mmHg vs. 151±42 mmHg, p=0.017, and 85% vs. 58%, p=0.011). Only one patient in continuous use group failed to continue NIV due to agitation. Patients with continuous sedation were safely managed under NIV with the level of sedation assessed by Richmond Agitation Sedation Scale, except only one adverse event of hypotension caused by midazolam.

Conclusions: Continuous sedation could be safely administered, and potentially prevent undesirable intubation due to persisting agitation under NIV.

Effects of a high-flow nasal cannula system (nHF) on ventilation in healthy volunteers and patients with IPF

Jens Brandmuller, Marcus Keckler, Hans-Jurgen Seyfarth, Stefan Hammerschmidt, Hubert Wenz. Department Pneumology, University of Leipzig, Germany

**Introduction:** Treatment with a nHF-system is able to improve symptoms of acute and chronic respiratory insufficiency. The method uses a warmed and humidified high flow of air/oxygen with 10-50 liter per minute (lpm). By using these devices an increase in mean pressure, pressure amplitude and a decrease in pCO2 is observable.

**Method:** Healthy volunteers and patients with IPF were included in this study. For detection of volume changes, frequency variations and I/E-ratios we used impedance measure bands. The bands were placed 10 cm below jugulum and 10 cm below xiphoid. The signal was relayed to a polysomnography device. Flows from 10 lpm up to 50 lpm with small, medium and large nasal prongs were tested. To compare the results with a closed ventilation support system, the measurements were also performed with CPAP 6 and 10 mbar and BiPAP 14/6 mbar. We compared the results with values measured during spontaneous breathing.

**Results:** Results were compared with the standard deviation (SD) and with the t-test.

- **Discussion:** HFNC led to no changes in tidal volume in patients with IPF and a decrease in healthy volunteers. The breathing rates in healthy volunteers and patients with IPF in comparison with spontaneous breathing were decreased. The I/E-ratio results in no significant changes in healthy volunteers and patients with IPF. In both groups, the minute volume was decreased. In comparison with CPAP and BiPAP, the measuring results showed different effects like HFNC.

**Conclusion:** HFNC led to no significant changes in respiratory parameters of healthy volunteers and in patients with restrictive pulmonary diseases. The changes in healthy volunteers and IPF will support respiratory efforts and will finally result in a reduction of breathing-related work.

Acute repercussions of noninvasive ventilation in patient with severe heart failure

Andrea da Nobrega Céron Nogueira, Francisco Delano Campos Macedo, Vaso Pinheiro Diógenes Bastos, Leiana Silveira Marinho, Nathalia Parente de Sousa, Soraya Maria do Nascimento Rebonças Viana, Luz Henrique de Paula Melo, Raimundas Herzminda Maia Macedo, Maria do Socorro Quintino Farias, Juniora Maria de Oliveira Lima, Roberto Martins Rodrigues Sobrino, Marcelo Alcantara Holanda. Laboratory Respiration, Department of Medicine, Federal University of Ceará, Fortaleza, Brazil

**Objective:** To analyze the acute effects of noninvasive ventilation (NIV) on cardiac function in patients with severe heart failure (HF).

**Methods:** The study involved 10 patients with HF functional class III and IV (NYHA), ejection fraction (EF) ≤ 40%. Shan CPAP was used and CPAP 10 cm H2O for 60 minutes with an interval of 20 minutes. We analyzed Simpson ejection fraction (EF SIMP), cardiac output (CO), pulmonary artery pressure (PAP), heart rate (HR) and mean arterial pressure (MAP) by echocardiography and oxygen saturation (SaO2) monitored every 30 minutes.

**Results:**

<table>

**P2049**

Predictors of failure of non-invasive ventilation in patients with respiratory failure

Sanjay Sotai, Ravinder Shekhar Jha, Eema Chaudhary. Respiratory, Critical Care and Sleep Medicine, Indraprastha Apollo Hospital, Delhi, India

**Introduction:** In patients with respiratory failure, randomized studies have shown noninvasive ventilation (NIV) to be associated with lower rates of intubation. In these patients, predictors of NIV failure are not well characterized. We conducted this study to investigate variables predictive of NIV failure in patients with respiratory failure.

**Materials and methods:** This prospective study was conducted at a tertiary care hospital in India. Fifty patients were included in the study, and were then followed up to discharge/expiry.

**Result:** Patients matched on baseline characteristics. Most of the patients (68%) did not have any pre-existing lung disease while 8 out of 50 (16%) had COPD. 4 patients (8%) had bronchial asthma; 2 patients had malignancy and 2 patients (4%) had history of previous Tuberculosis. In associated co-morbidities, 17 patients (34%) had Diabetes and 24 patients (48%) had hypertension.

**Conclusion:** With prudent case selection, NIV is successful in more than 60% of cases. Failure of NIV may be related to the primary diagnosis. Association of co-morbidities as independent predictor of NIV failure needs further study.

**P2050**

The use of non-invasive ventilation in paediatric lung transplantation

Surendran Thavagnanam, Hartmut Graesemann, Melinda Solomon, Indra Narang. Respiratory Medicine and Transplant Centre, Hospital for Sick Children, Toronto, ON, Canada

**Introduction:** Progressive deterioration in paediatric patients (pts) with end-stage lung disease may result in diurnal hyperventilation. There are paucity of data describing polysomnography (PSG) & the benefits of Bilevel Positive Airway Pressure (BiPAP) therapy in these children.

**Aim:** To evaluate cardiorespiratory data & gas exchange using PSG in children awaiting lung transplantation (LTx) prior to & after BiPAP therapy.

**Methods:** Retrospective review of PSGs on these patients between 2005 & 2012 was performed. Change in cardiorespiratory parameters during PSG following BiPAP initiation was assessed & analysed using a paired t-test.

**Results:** Of the 31 pts identified, 24 underwent LTx & 7 were on a wait list (WL). 13 were male pts with mean age of 12 years (9 to 15). 9 LTX & 3 WL pts had PSGs; 10 pts were on supplemental oxygen. 9 pts had cystic fibrosis, 2 had interstitial lung disease & 1 had pulmonary venous occlusive disease (PVOD). 10 pts had evidence of nocturnal hyperventilation in the absence of obstructive or central apneas & were initiated on BiPAP. After titration of BiPAP to optimal settings, there was a significant increase in mean SaO2 [91% (SD 2.4) to 96% (SD 0.9); p=0.0001], decrease in heart rate [111 (SD 18.3) to 96 (SD 15) beats per minute, p=0.02]; respiratory rate [35 (SD 5) to 28 (SD 6) breaths per minute, p=0.03] and transcutaneous carbon dioxide recordings [74 (SD 17) to 67 (SD 14) mmHg, p=0.006] from baseline.

**Conclusion:** All pts had significant nocturnal hyperventilation with improved clinical parameters & gas exchange abnormalities following BiPAP. Further research is needed to assess the role of PSG & BiPAP therapy as a bridge to transplant in children with severe chronic lung disease.

**P2051**

Ventilatory management in patients after intestinal transplantation

Man-Ju Ting1, Yun Chen2, Shih-Lung Cheng.1 Department of Chest Medicine, Far Eastern Memorial Hospital, Taipei, Taiwan; 1Department of Pediatric Surgery, Far Eastern Memorial Hospital, Taipei, Taiwan

Intestinal transplantation (IT) is a life-saving therapy for the patients with intestinal failure. However, ventilatory management of intestinal transplant recipients in the immediate post-operative period is difficult and challenging. Therefore, our aim was to establish the criteria for postoperative extubation, identify risk factors for prolonged ventilator needs.

We conducted an observational, prospective clinical trial and performed retrospective chart reviews of 7 patients receiving IT between 2007 and 2012 at the Far Eastern Memorial Hospital. The patients were divided into two groups; 3 patients were not successfully extubated within 72 hours of the IT operation (ventilated, V) and 4 were (extubated, E). The median age and weight in the V group were significantly lower than the E group, 9.67 yrs vs. 28.25 yrs and 23.33 kg vs. 36.75 kg respectively. When compared to the E group, congenital Hirschprung’s disease was cause of intestinal failure, preexisting respiratory disease, severe acute rejection, immunosuppressive level and longer operation time were more common in the V group. The consequences of not being extubated within 72 hours were increased.
Correspondence between clinical prediction and outcome in patients with AHRF due to RLD - further prospective studies are needed to establish this in detail. As NIV is increasingly used acutely on critically ill patients beyond the originally supposed indication of AHRF in selected patients (and even in palliative care), the use of NIV as the “ceiling of care” needs consistent monitoring.

High-flow nasal cannulae oxygen in acute respiratory failure: effectiveness and predictors of failure

Introduction: To determine the effectiveness of high flow nasal cannula (HFNC), and the factors predicting from failure of HFNC in acute respiratory failure.

Method: We retrospectively evaluated acute respiratory failure patients who received HFNC at Chungcheon Sacred Hospital, between August 2011 and January 2012.

Result: In all, 33 patients were included in the study. Their median age was 73 years (49-89). Majority of the patients were male(22 patients, 67%). The most common cause of acute respiratory failure was pneumonia followed by COPD acute exacerbation, acute pulmonary edema due to congestive heart failure, cancer progression, and lung fibrosis. The hospital mortality was 24%. In the unadjusted model, (P=0.03), APACHE II score (P=0.04), BNP (P=0.03) and higher respiratory rate (P=0.04) were associated with HFNC failure. However, in the adjusted model, higher respiratory rate (P=0.04) were associated with HFNC failure (P=0.04, OR 3.36).

Conclusion: HFNC has beneficial effect on clinical sign and oxygenation in ICU patients with acute respiratory failure. Predictors of high flow nasal cannula failure might be used to guide decisions regarding intubation.

Treatment of preterm infants with high-flow nasal cannulae: A review of the evidence

Charles Roeke1, Brett Manley2,3,4, Simone Dold1, Peter Davis2,3,4. 1Department of Neonatology, Charity University Medical Center, Berlin, Germany; 2Department of Newborn Research, The Royal Women’s Hospital, Melbourne, Australia; 3Department of Obstetrics and Gynaecology, The University of Melbourne, Melbourne, Australia; 4Murdoch Childrens Research Institute, Melbourne, Australia

Background: High-flow nasal cannulae (HFNC) are gaining popularity as a form of non-invasive respiratory support for preterm infants, and are proposed as an alternative to nasal continuous positive airway pressure (NCPAP) in a variety of clinical situations.

Objectives: We critically examined the published evidence for the mechanism of action, efficacy and safety of HFNC as a treatment for preterm infants.

Methods: Internet-based literature search for relevant, original research articles on use of HFNC in preterm infants. PubMed, Medline, and the Cochrane Library were searched, search terms [high flow OR high-flow] AND nasal cannula(e), without language restriction.

Results: The search produced a total of 73 articles; 15 studies were included in the review. Distending pressure generation from HFNC increases with increasing flow rate and decreasing infant size, and varies according to the amount of leak around the prongs. HFNC may be as effective as NCPAP at improving respiratory parameters such as tidal volume and work of breathing in preterm infants, but perhaps only at flow rates above 2 Litres/minute. Only four published randomized controlled trials (RCTs) of HFNC use in preterm infants were found; only two of these compare HFNC to NCPAP, and all are small. Based on the current, limited evidence, HFNC appears to be inferior to NCPAP as post-extubation support, and ineffective when used to wean from NCPAP. There are no RCTs of HFNC as a treatment for early respiratory distress.

Conclusions: The efficacy and safety of HFNC in preterm infants remain to be determined, and further RCTs in the settings of primary support from birth, post-extubation support, and weaning from NCPAP are required.
P2057
Respiratory depressants among patients undergoing noninvasive ventilation for hypoxemic-hypercapnic acidosis: Prevalence and impact on prognosis
Angélica Ortega-González1, Diego Germán Rojas-Tula1, Marcelino Sánchez-Casado1, José Carlos Serrano-Rebolledo1, José Javier García-López1, Máximo Gómez-Fernández1, 1Respiratory Monitoring Unit, Pulmonology Department, Hospital General Nuestra Señora del Prado, Talavera de la Reina, Toledo, Spain; 2Intensive Care Unit, Complejo Hospitalario de Toledo, Toledo, Spain
Medical records show frequent psychoactive drug treatments among the elderly with respiratory depression as a potential side effect. We evaluate their impact in patients undergoing noninvasive ventilation (NIV) for acute hypercapnic respiratory failure (AHRF) with acidosis.
Methods: Prospective study in 103 consecutive admissions (71 M, age 74.9±9.9 yrs) starting NIV for AHRF with acidosis in a Monitoring Unit (Oct 08-Jan 12). Two groups based on previous therapy with psychoactive drugs and significant sedative effect. Variables: pH, PaO2, PaCO2, PaO2/PaCO2 at admission (1), of NIV (2) and 24h of NIV (3); in-hospital mortality and combined in-hospital and 30-day post-discharge mortality, length of stay (LOS) and intubation %. We recorded main diagnosis and thoracic comorbidities. Stat. analysis: = 7.02MW.
Results: 39 pts (37,9%) received sedatives: M 22,5%.F 77.5%; BZD 89.9%. Main diagnosis (% sedatives): COPD 48 (25%), OHS 20 (55%).Acute heart failure 16 (56,2%), Pneumonia 7 (28,6%). Acute pulmonary edema 6 (66,7%). Chest wall deformities 4 (25%).Comorbidity 55,3%. Group analysis (sedatives vs no sedatives): Sex (M) 41% vs 85,9% (p <0,001); age 77,4±8,1 vs 73,5±4,3 (p <0,05). In-hospital mortality 17,9% vs 10,9% (NS), In-hospital 30-day mortality 23,1% vs 14,1% (NS), COPD prevalence 30,8% vs 56,2% (p <0,05). NS differences in LOS, intubation %, pH and PaCO2; evolution between groups: pH 7,27±0,08 vs 7,29±0,58; PaCO2 37,3±10,09 vs 73,2±2,07; pH <7.3±3.5 (both groups).
Conclusions: We found a high prevalence of respiratory depressants in patients with AHRF. Sedatives may worsen prognosis and early response to NIV, especially in elderly female patients without COPD.

P2058
Effect of non-invasive ventilation on pH, carbon dioxide and bicarbonate, in acute, hypercapnic, respiratory failure
Diana Dolgova1, 1Cardiac Surgery, Kiev City Heart Centre, Kiev, Ukraine
Acute, hypercapnic, respiratory failure is defined by the presence of PaCO2>6.6 kPa and pH <7.35. Non-invasive ventilation is an established treatment for this condition. The improvement in alveolar ventilation leads to a lowering of the PaCO2 with normalisation of the pH. The role of renal buffering in the treatment of acute respiratory failure using NIV has not been reported in the literature. We undertook an audit of patients admitted to a high dependency unit in a large teaching hospital setting. The patients were in acute type II respiratory failure as defined above. They had an arterial blood gas (ABG) recorded before initiation of NIV, after 1-2 hours, after a further 4 hours and at discharge from NIV. We have shown the data for pre NIV and at the end of NIV treatment. The data is therefore for patients who successfully completed NIV therapy. The study was carried out over a twelve month period. The data was entered into the database by the ward junior doctor at the time of the patient’s admission and subsequent discharge.

We had complete data for 44 patients. The p value was derived from the t-test for paired data. This study confirms the findings of previous studies that the successful use of NIV in acute, hypercapnic, respiratory failure leads to significant improvements in both the pH and PaCO2. This improvement appears to be directly due to improved alveolar ventilation leading to a reduction in PaCO2; from this data there does not appear to be a significant contribution from renal buffering.

P2059
Noninvasive ventilation in acute cardiogenic pulmonary edema with haemodynamic instability
Irina Martyniuk1, 1Intensive Care, Kiev City Heart Centre, Kiev, Ukraine; 2Cardiac Surgery, Kiev City Heart Centre, Kiev, Ukraine
Background: Although noninvasive ventilation (NIV) in acute cardiogenic pulmonary edema (ACPE) is widely used, its use in patients with unstable hemodynamics is contradictory. Aims: To evaluate NIV use in ACPE with low systolic blood pressure (SBP) and search for the correlates of its success.
Methods: Prospective interventional trial of all 22 patients with ACPE with SBP 75-90 mm Hg, with no acute arhythmia, SaO2 90% on spontaneous breathing with 10 l per minute oxygen, cooperative, not hypercapnic, with low cardiac output due to acute myocardial infarction, mitral regurgitation or congestive heart failure, was done from July 1, 2010 through December 31, 2011. All patients were immediately started on conventional therapy (dobutamine and/or dopamine, morphine, furosemide, nitroglycerin) and NIV through a face mask with FiO2=1.0, initial PEEP 5 cm H2O and pressure support (PS) 5 cm H2O. Hemodynamic parameters, SaO2, central venous saturation (ScvO2), respiratory rate (RR) and end tidal volume (Vt) were documented every 3 minutes. If no relief in 3 minutes, PEEP was enhanced to 7 cm H2O and after next 3 minutes PS added to 7 cm H2O. Results: All patients had SaO2 90% and SBP>90 mm Hg after 10 minutes. If at this moment RR was 30 and Vt 5 ml/kg of body weight, or more than low doses of cardiotonics were needed, the patient was intubated (4 patients). After 30 minutes, those who needed FiO2 60% on NIV, were oliguric and failed to rise ScvO2 above initial, were intubated (2 patients). No intubation was needed in 16 patients. No factors correlated with NIV failure. Conclusion: In selected hemodynamically unstable patients with ACPE NIV helps avoid intubation.

P2060
Effects of use of Boussignac CPAP on development of post-operative atelectasis
Serife Savas Bozdogan1, 1Balam Er Dedekargioglu1, Serap Cakir2, Feza Yarbug 1, Karakaya1, Fuusan Onur Eyuboglu1, 1Pulmonary Medicine, Baskent University Faculty of Medicine, Ankara, Turkey; 2Pulmonary Disease, Corlu Public Hospital, Tekirdag, Turkey; 3General Surgery, Baskent University Faculty of Medicine, Ankara, Turkey
Background: Boussignac CPAP is a method to apply CPAP through a special valve system. Aims: Patients who had a high likelihood of postoperative atelectasis undergoing abdominal surgery were included in the study. It was aimed to evaluate the development of atelectasis and its effects on PFT parameters through utilisation of Boussignac CPAP system.
Patients and method: A total of 28 patients were included in our study and were randomized into two groups. Conventional methods (incentive spirometry, respiratory physiotherapy) were scheduled for the first group and Boussignac CPAP treatment in addition to conventional methods was scheduled for the second group. Boussignac CPAP system was applied to patients with spontaneous respiration for 3 days as 6 times and 15 minutes on each session. Pre and post application pulmonary function tests(PFT) parameters, chest X-ray findings and radiological atelectasis scores were evaluated.
Findings: Mean age was 65.4 years and 57.1% were male. There was not any significant differences in the Boussignac CPAP group and control group between location of incision, operation time and presence of pulmonary disease. Preoperative chest X-ray findings were similar(=0.05). In the Boussignac CPAP group, postoperative radiological atelectasis score was significantly lower than control group(p<0.05). In CPAP group, no decline in oxygen saturation and oxygen partial pressure was observed unlike control group. Significant decrease was observed in FVC that is one of PFT parameters in postoperative period.
Conclusion: Our findings suggest that development of post-operative atelectasis might be decreased, thus oxygenation might be improved by use of Boussignac CPAP.

P2061
Noninvasive ventilation in the emergency department: Early predictors of outcome in acute cardiogenic pulmonary oedema
Rodolfo Ferrari1, Fabrizio Gistro1, Roberto Lazzari1, Mario Cavazzza1, 1Unità Operativa di Medicina d’Urgenza e Pronto Soccorso. Dipartimento Emergenza - Urgenza, Chirurgia Generale e dei Trapianti, Policlinico Sant’Orsola - Malpighi. Azienda Ospedaliero Universitaria di Bologna, Italy; 2Unità Operativa di Medicina d’Urgenza e Pronto Soccorso. Policlinico Sant’Orsola - Malpighi di Bologna, Scuola di Specializzazione in Medicina d’Emergenza Urgenza, Università degli Studi di Modena e Reggio Emilia
Introduction: The application of early continuous noninvasive ventilation (NIV) is well established in the Emergency Department (ED) for the treatment of acute respiratory failure (ARF) due to Acute Cardiogenic Pulmonary Oedema (ACPO). Aims and methods: To critically analyse the impact of NIV in ACPO, about ARF presentation and the treatment efficacy or failure (defined as hospital mortality or need for invasive mechanical ventilation). Observational clinical study in the real life practice of the ED of a University teaching Hospital, during 5 months, including every patient emergently admitted and treated for ACPO according to inclusion criteria referring to an institutional protocol. Results: 214 patients (media 1.42/day). Failure rate 15.5%. Failure versus success groups were similar in many characteristics and parameters. They were mainly different in: comorbid diseases, neurologic status, arterial blood pressure, rates of paliative or “ceiling” NIV, leukocytosis, AST, CPKMB, troponinI, LDH, PCR, changes in blood gas analysis parameters after 120 minutes. Conclusion: We identified early predictors of outcome in the ED: clinical parameters, biomarkers and arterial blood gas analysis data to recognize severe conditions and the response to treatment. Unnecessary delaying tracheal intubation remains
the major hazard of NIV in ARF; the overutilization of NIV is also a concern. A pivotal unresolved question is about selection criteria and early choices for patients having preset therapeutic and prognostic limits and acutely reversible processes. RCTs in the ED are necessary to define the subgroups of patients who are most likely to benefit for the early application of NIV.

A randomised controlled trial comparing stepwise versus immediate withdrawal from non-invasive ventilation in chronic obstructive pulmonary disease patients recovering from acute hypercapnic respiratory failure

Chung Tat Lam, Chung Ming Chu, Veronica Lee Chan, Wai Shing Leung, Pik Shan Cheung, Suet Lai Cheng, Miranda Tsui. Department of Medicine, The United Christian Hospital, Kwun Tong, Hong Kong, Hong Kong

**Background:** COPD patients who suffer from exacerbation with acute hypercapnic respiratory failure (AcHRF) benefit from non-invasive ventilation (NIV). The best withdrawal method of NIV is not known.

**Aim and objectives:** To compare the success rate of withdrawal in NIV between stepwise withdrawal and immediate withdrawal in COPD patients with AcHRF.

**Method:** This was a prospective, single-centre, open-labelled randomised study comparing stepwise and immediate withdrawal of NIV. The primary end-point was the success rate of NIV withdrawal. The secondary end-points were hospital length of stay and duration of NIV use.

**Results:** Sixty patients were randomised: 35 patients to the stepwise withdrawal group and 25 patients to the immediate withdrawal group. There was no statistically significant difference in the success rate of withdrawal of NIV and length of stay after randomisation, with the success rate of 74.3% and 50% in stepwise and immediate withdrawal group respectively (p = 0.139). There was statistically significant difference in the duration of NIV with median duration of 5 days and 3 days in stepwise and immediate withdrawal group respectively (p = 0.001). The post-hoc analysis showed the use of LAMA, higher inhaled steroid dosage and higher arterial pH value on randomisation were the factors associated with success in withdrawal in the immediate group.

**Conclusion:** Our study showed no significant difference in the success rate and length of stay between stepwise withdrawal and immediate withdrawal of NIV. Duration of NIV was significantly shorter in the immediate withdrawal group.

#### P2063
Automatic tailoring of positive end-expiratory pressure (PEEP) by forced oscillation technique (FOT) during non-invasive ventilation: Effects of posture and exertion in COPD

Raffaele Dellaca,1 Bob Romano2, Joe Garuccio3, Cherian John3, Ramesh Thimmiah3, Melvin Saludes4, Charles Cant5,1 Departmento di Bioingenieria, Politecnico di Milano, Milan, Italy; 2Home Respiratory Care, Philips Respironics, Monroeville, PA, United States; 3Cardio-Pulmonary Medicine, Regional Medical Associates, Beaverstown, PA, United States

**Expiratory Flow Limitation (EFL) promotes the development of intrinsic PEEP (PEEPi) which can lead to hypercapnia and respiratory failure.** In mild to severe COPD, the development of EFL is greatly affected by posture and exertion and this results in major adjustments in the PEEP required to counteract intrinsic PEEP within the same patient.

Eleven COPD patients (GOLD stage 2-4, BMI 30±10, FEV1/FVC 56±8) were initiated to nasal BiPAP with automatic PEEP adjustment. After adaptation, ventilation was applied for 10 minutes in the seated and supine positions and during a 6MWT. Data were recorded in the last minute for each condition.

At PEEP=2cmH2O, 8 patients showed EFL in the seated position, 10 in the supine and 9 in the last minute of the 6MWT. The average PEEPopt is reported in figure. In mild to severe COPD, the development of EFL is greatly affected by posture and exertion and this results in major adjustments in the PEEP required to counteract EEPi within the same patient.

**Conclusion:** PEEPopt is adaptive and should be modified to posture and exertion in severe COPD.
P2066

Respiratory events during long term noninvasive positive pressure ventilation in children: Clinical implications and detection of events

Valeria Calderelli1,2, Jean Christian Borel1, Sonia Khiarani3, Adriana Ramirez1, Renato Cutrera7, Jean Louis Pepin7, Brigitte Faure4,5,14,15,16, Department of Clinica Pediatrica, Universita degli Studi di Ferrara, Italy; 2Pediatric Pulmonary Department, AP-H, Armand Trousseau Hospital, Paris, France; 3INSERM ER17, HPZ Laboratory, Grenoble University Hospital, Grenoble, France; 4InsERM UMR S-938, UPMC University Paris 06, France; 5Technical Department, ADEP Assistance, Suresnes, France; 6UCO Broncopenneumologia, Ospedale Pediatrico Bambino Gesù, Rome, Italy

Objective: The aims of the study were (1) to describe the respiratory events during noninvasive positive pressure ventilation (NPPV) and, (2) to analyze the clinical consequences.

Method: Nocturnal polygraphic (PG) recordings were performed in stable patients. Respiratory events were scored using the SomnoNIV Group definitions [1]. The consequences of an event i.e. a fall of ≥ 3% of pulse oximetry (SpO2) and/or a ≥ 30% decrease in pulse rate amplitude (respiratory auto-micro-arousals) were described.

Results: PG tracings of 27 patients (13 boys, age range 1-18) were analyzed: neuromuscular disease (n=7), obstructive sleep apnea (n=8) and lung disease (n=12). Unintentional leaks, partial or total upper airway obstruction without reduction of ventilatory drive, a decrease in ventilatory drive, mixed events, and patient ventulator asynchronies were observed in 61%; 37%; 28%; 7%; 55% of the patients, respectively. These events were associated with a decrease of SpO2 in 21%; 37%; 18%; 12% of the patients and with a RAM in 38%; 27%; 8%; 3%; 32% of the patients respectively. The mean number of type of events per patient was 1.8±1.1. For a given patient, there was a predominant event representing 87±10% of total time with respiratory events. The median duration spend in respiratory event was 39% (range 0.7 to 92%) of total recording time. Of the patients, respectively. These events were associated with a decrease of SpO2 ≥ 3% of pulse oximetry (SpO2) and/or a ≥ 30% decrease in pulse rate amplitude (respiratory auto-micro-arousals) were described.

Conclusion: Respiratory events are common in stable children treated with long term NPPV and can be associated with desaturations and/or RAM. 1. Gonzalez J et al. Thorax 2011.

P2067

Polysonomographic criteria to assess the efficacy of noninvasive ventilation in chronic respiratory failure

Roozma Naeck1, Adriana Portmann2, Ubistan Freitas1, Donnia Boumonaire1, Florence Portier2, Christophe Letellier1, Jean-François Muir2, Antoine Cuvelier3,1, COPRA UMR CNRS 6614, Rouen University, St Etienne du Rouvray, France; 2Pulmonary & Respiratory Intensive Care Department, Rouen University, Rouen, France

Aim: We performed successive polysomnographies (PSG) under spontaneous breathing (SB) and under noninvasive ventilation (NIV) in order to assess the improvements of ventilation and sleep in patients with severe chronic respiratory failure.

Methods: 12 patients indicated to domiciliary NIV because of chronic respiratory failure (neuromuscular disease (n=4), obesity-hypventilation syndrome (n=6) or thoracic deformation (n=2)) have performed a PSG under SB at day 1, another PSG with the newly implemented NIV at day 2 and therefore a third PSG under NIV two weeks after (day 15). NIV titration was performed according to local protocols, based on nocturnal oximetries and morning arterial blood gas assessments.

Results: As compared to SB, the oximetric parameters significantly improved during the first night under NIV. Pco2 values, early-morning and diurnal arterial blood gases slightly improved during the first night under NIV but the differences were statistically significant only at day 15. We observed a rapid increase of time spent in REM sleep (9.1±2.1 vs 15.2±4.2% of total sleep time, p=0.0148), a reduction of obstructive apnea index (28.4±8.6 vs 9.7±4.2, p=0.0175) and the micro-arousal index (40.1±8.5 vs 25.7±1.9, p=0.0258). Heart rate and cardiac variability were significantly reduced under NIV. Patient-ventilator asynchronies were less in all patients except two and did not significantly vary between day 2 and day 15.

Conclusion: NIV efficacy is associated with a rapid and objective improvement of sleep quality, in parallel with a slower improvement of diurnal and nocturnal hypercapnia. Cardiac variability may be also a pertinent parameter to evaluate these patients.

Mean hours of use between VAPS and PCV were not significantly different (6.0 (±2.7) vs 5.9 (±2.4) hours respectively). There was a trend towards shorter time to initiate VAPS compared to PCV (3.4 vs 4.7 days respectively, p=0.071). During the trial period 2 patients from each arm died.

Conclusion: In patients with COPD and chronic ventilatory failure, VAPS achieves similar improvements in overnight oximetry and daytime PaCO2 compared to PCV. VAPS is a well tolerated and effective treatment for chronic ventilatory failure in this patient group. A longitudinal trial investigating survival may now be warranted.

P2069

Effect of transnasal “high-flow oxygen insufflation” in patients with severe COPD

Johannes Cleven1, Helene Vogelsinger1, Sebastian Ott2, Thomas Geiser2, Michael Halank2, C.M. Kahler2, 1Department of General Internal Medicine I, Medical University of Innsbruck, Tyrol, Austria; 2Medizinische Klinik und Poliklinik I, University Hospital Carl Gustav Carus, Dresden, Germany; 3Klinik und Poliklinik für Pneumologie, Universitätsklinikum, Switzerland

Introduction: Long-term oxygen therapy is one of the established treatment strategies. Nasal insufflation of warm, humidified air at a high flow rate is a new and simplified method in non-invasive ventilation.

Until now, no data on the safety, effects and efficacy of in COPD patients are available. Our multicenter, controlled study has been approved by the national ethic committees.

Aim: It was designed to examine the safety and effects of high flow therapy in patients with COPD IV and to explore possible changes in efficiency in ventilation and parameters of the lung function.

Method: Patients with COPD IV with indication for LTOT are enrolled. The following inclusion criteria have to be met: age 30-80, stable disease for 14 days, Hb>100g/l, and no current participation in another study.

Results: So far 38 subjects were recruited: 32 males, 6 females, age 67.5±6.64 yr; FEV1 14-49% predicted. Oxygen supplementation was performed in 10 min intervals each with an augmentation of 0.5-1 L/min until a pO2 >60mmHg was achieved. Using [TNI], oxygen was mixed with warm and humidified air at a constant flow rate of 15 L/min. Concerning safety high flow delivery was well tolerated in all patients and no significant differences were found for several spirometric parameters tested. Furthermore a highly significant decrease of CO2 in arterial blood after short-term treatment could be measured (-2.87 mmHg; p<0.0001) compared to conventional oxygen administration.

Conclusion: In conclusion, we can postulate that short-term treatment with high flow [TNI] seems to be safe in patients with COPD IV with a reduced oxygen saturation.

P2070

Uptake of NIV treatment in MND is dependent upon caregiver variables

Rosanna Cousins1, Hikari Ando1, Carolyn Young2, Biswajit Chakrabarti1, Robert Angus3, 1Health Sciences, Liverpool Hope University, Liverpool, United Kingdom; 2The Walton Centre, NHS Foundation Trust, Liverpool, United Kingdom; 3Attendance Chest Centre, Attendance University Hospitals NHS Foundation Trust, Liverpool, United Kingdom

There is robust evidence that NIV relieves respiratory symptoms and improves quality of life in MND. Nevertheless, about a third of those who would benefit

MONDAY, SEPTEMBER 3RD 2012

3658
from NIV decline the treatment. It is important to understand why the most effective treatment available for MND patients [1] is refused. To investigate this phenomenon, we undertook a cross-sectional quantitative analysis of 27 patient and caregiver dyads offered ventilatory support based on physiological markers, including forced vital capacity and nocturnal pulse oximetry. The analyses indicated that there were no differences between the patients who went on to accept NIV treatment (n=17) and those who declined (n=10) in terms of age, sex, MND symptomatology (ALS-FRS-R, ALSAQ-40, MND Dyspnoea Rating Scale, daytime sleepiness) and psychological measures (hopelessness, anxiety and depression). The similarity of the scores in the two groups is such that we are confident that we do not simply have a power issue. In view of assertions that uptake of NIV treatment increases caregiver burden, which suggests caregiver input in NIV treatment, we also analysed caregiving variables. There were no differences in general physical or mental health but caregivers who supported NIV treatment were significantly more emotionally stable and less anxious, and in terms of coping style more resilient, more committed and more in control. A regression analysis focusing MND symptoms to enter before caregiving variables still indicated that resilience: commitment alone explained 24% of the variance.

We will discuss these findings, and implications for clinicians.

P2070
Triple O – A new respiratory syndrome?
Maria Drummond1,2, Ana Santos1,2, Tiago Pinto1, Miguel Gonçalves1,2, AnaBela Manrho1, Maria Sucena1, Joao Almeida1, Joao Winck1,2.
1 Pulmonology Department, Centro Hospitalar Sao Joao, Porto, Portugal; 2Medicine Department, Centro Hospitalar Sao Joao, Porto, Portugal.

Introduction: There is a growing number of patients needing nocturnal ventilatory support, presenting with Obesity-Hyperventilation Syndrome (OHS). Chronic Obstructive Pulmonary Disease (COPD) and Obstructive Sleep Apnea (OSA). As these three entities seem to coexist we are using them to propose the Triple O Syndrome (TOS).

Objective: To characterize TOS patients and compare their demographic characteristics and ventilatory needs with OHS patients.

Materials and methods: Forty-four patients with obesity (BMI >30 kg/m²), COPD (FEV1/FVC ratio <70%), and OSA (AHI>5/h) were included. Exclusion criteria were pulmonary diseases others than COPD, OSA, data entry delay, bronchiectasis, Cheyne-Stokes Breathing, Complex OSA and Central Sleep Apnea. These patients were compared to 46 OHS patients. Both groups started ventilatory support between 2009 and 2011.

Results: TOS patients: mean age 69.4±9.1 years, 84% were male, BMI mean 35.8±4.4 kg/m², mean Epworth 11.4±4.8, mean FEV1 57.9%±19.5% predicted, median AHI 36.3h, median PaCO2 47.2 mmHg, median PaO2 18.0 cmH2O, median PaCO2 10.0 cmH2O, median RR 14 cycles per minute, 23% needed oxygen complement.

Conclusion: Compared to OHS patients, TOS patients were older, leaner, the percentage of male gender was higher, had less severe OSA and lower RR when adapted to ventilatory support.

Conclusions: Triple O patients seem to be an individualized group, with different demographic characteristics when compared to OHS patients. The ventilatory needs were similar between both groups, but the RR and the mask used, mainly nasal, in TOS patients.

P2071
Thoracoabdominal contribution to tidal volume after an inpatient cardiac rehabilitation program associated to continuous positive airway pressure (CPAP)
Camila R E Damon1, Luciana Di Thommmoz1, Renata G Mendes1, Flavia C.R. Caruso1, Daniel Mezzalira2, Aparecida M. Cati1, Othol Amaral Neto2, Audrey Borgo-Silva1,2, Physical Therapy Department, Federal University of Sao Carlos, Brazil; 2Cardiovascular Department, Santa Casa Araquara Hospital, Araquara, Brazil.

Background: Continuous positive airway pressure (CPAP) is an important strategy for improvement of gas exchange and breathing work in post operative of coronary artery bypass grafting surgery (CABG). However, it's unknown the breathing pattern (BP) behaviour after inpatient cardiac rehabilitation (CR) program associated to noninvasive ventilation (NIV) during exercises.

Aim: To evaluate the BP of post-CABG patients engaged in CR associated to NIV.

Methods: Nineteen patients submitted to twice-daily supervised postoperative CR program. The criteria to include the patients in the CPAP group were: (a) no history of respiratory and cardiology maladies; (b) no history of COPD; (c) no history of thoracoabdominal contributions to tidal volume. The measurements were recorded with a flexible fiberoptic bronchoscope, with volume analysis and pressure measurement software, with special app. The patients were divided in 2 groups: patients in the CPAP group and patients in the control group. The objective was to compare both groups through a noninvasive ventilator, electronically controlled, with fixed pressure of 10 cmH2O. The cotton masks were used to avoid desaturation in the CPAP group.

Results:
- In the CPAP group: observed a respiratory rate of 15, mean arterial pressure of 114/73 mmHg. The patients were able to perform the ventilatory recruitment manoeuvre with tidal volume of 600 ml and BBUs of 15, in 15 min.
- The ratio of inspiratory to expiratory times was 1:1, with a tidal volume of 1500 ml. The mean arterial pressure was 114/73 mmHg, with a respiratory rate of 15. The patients were able to perform the ventilatory recruitment manoeuvre with tidal volume of 600 ml and BBUs of 15, in 15 min.

Conclusion: The results showed that the ventilatory pattern (BP) was improved in the CPAP group compared to the control group, with a significant reduction of respiratory work.

P2072
Adherence and tolerance of an auto-CPAP (APAP) device specially designed for occidental way of life and bedroom: Beyond technology, medical appearance is obsolete
Erich Hazouard1, Jean-Philippe Maffe1, Violaine Kubiszewski1,2,1 Sleep Laboratory, Clinique de l’Alliance, Saint Cyr sur Loire, France; 2EA-2114, Laboratory, Clinique de l’Alliance, Saint Cyr sur Loire, France.

Observance up than 3hr/night, only is required in France to allocate reimbursement of CPAP treatment for Sleep Apnoea Syndrome. But control of hypertension requires up than 4hr/night. Breat-sleep, or Fisher&Pakell ICON are clearly designed to look as a clock or a radio-alarm-clock without external electric transformer.

Aim: Define if such CPAP device is associated with a mean sleep use up than 4hr/30, achieving 3 sleep’s cycles. Data collection [comfort, residual AHI, respiratory pressure, etc.]

Methods: Two HomeCare HealthCareProviders (no financial or material conflict of interest), Noncomparative observational study. We collect use’s duration of a month from 25 consecutive OSA patients, all ventilated by ICON. APAP mode, 4/16 cmH2O, no ramp with optimal subjective comfort humidification setting.

Results: 108 consecutive symptomatic OSA patients (IAH > 30/hr), evaluation time of 4 months delay treatment, 6% 65±4.6 y/o; residual AHI = 4.8±3.9/hr and P95% = 9.3±3.7 cmH2O

Observance: 34±2.4 min, comfort’s evaluation through a modified Analogic Visual Scale (AVS) 7.4±1.2, Design’s evaluation through a modified AVS 8.7±4.3.

Conclusions: A pretty bedroom designed CPAP device is associated with a therapeutic duration up than 2hr/30. An affective-based customer societal approach of such treatment seems relevant to enhance patient adherence. Comparative studies are required to confirm this monocentric and limited non comparative descriptive study.

Our experience in home mechanical ventilation
Vesna Bukumirovic1, Zorica Stevic2, Vladimir Zugic1, Branka Balajac-Subotic1, Miodrag Vukcevic1.
1 Center for Neuromuscular Diseases, University Clinical Center of Serbia, Belgrade, Serbia; 2Clinic for Neurology, University Clinical Center of Serbia, Belgrade, Serbia.

Home mechanical ventilation (HMV) increases survival of patients with chronic respiratory failure. National center in Serbia for HMV in neuromuscular patients was established in 2007.

Aim: We aimed to evaluate our practice

Method: We retrospectively analyzed clinical history of patients receiving HMV in our center from 2007-2012.

Results: 146 patients were started on HMV (71 M/55 F) mean age 46±20 years. Most of the patients were treated with non invasive ventilation. Twelve percent of patients were ventilated invasively via tracheostomy. Three patients were converted from invasive to noninvasive ventilation. Most frequent diagnosis was motor neuron disease (MND) 78, mean FCV% 33±8,7 and spinal muscular atrophy (SMA) 15. Overall survival was 59% of patients. In MND group, mean survival was10 months, and all dystrophin patients are still in follow up.

Conclusion: In our country HMV in last years is increasingly used but its prevalence is still low compared with other countries.

P2074
Multidisciplinary MND clinics – Should every hospital have one?
Anthony Carver1, Tracy Ellimah1, Thomas Sanctuary 1, Mohamed Sakel 2, Andy Bell1,2.
1,2 Respiratory Medicine, East Kent Hospitals University NHS Foundation Trust, Ashford, Kent, United Kingdom; 1Neurorehabilitation, East Kent Hospitals University NHS Foundation Trust, Ashford, Kent, United Kingdom.

Motor neuron disease (MND) is best managed by a multi-disciplinary team, including a respiratory physician to assess for respiratory failure, for which non-invasive ventilation (NIV) is indicated. East Kent Hospitals University Foundation Trust has recently developed a regional neurology centre and has well established domiciliary ventilation services. The multi-disciplinary MND team was developed in 2008.
Aim: To review the management of MND in East Kent and the changes since the establishment of a multi-disciplinary MND team.

Methods: A retrospective analysis of the clinical notes of all patients diagnosed with MND over the last 10 years.

Results: Total number of patients with a diagnosis of MND was 65. 3 had familial disease (4.6%).

Methods: We prospectively studied a group of tracheotomized and chronically ventilated patients admitted to a weaning centre who could be suitable for decannulation and conversion to NIV because of absence of airway stenosis, normal swallowing function, preserved cough mechanism but unable to sustain a spontaneous breathing for more than 16 hours without increasing PaCO₂. Data collected for follow-up were: demographic, functional, severity score (SAPSII), need to re-trachecotomy, survival, hospital admissions/year, maintenance of adequate gas exchange. The Fisher exact test and the log-rank test have been employed for statistical analysis.

Results: 176 patients with tracheotomy and prolonged IV were evaluated: 26 patients (14 men) met the criteria and were decannulated and converted to NIV (16 obstr. 10 restr.). Mean age was 67.46 years, mean SAPSII score was 26.8, mean follow-up time was 24.8 months; 12 patients had at least 1 new episode of exacerbation, in 5 cases requiring ICU admission, and 2 patients needed re-tracheotomy. Two-years-mortality rate was 26%. Age and severity score turned out to be statistically significant predictors of survival.

Conclusions: Long-term maintenance of tracheotomy and invasive ventilation makes the patient more fragile and difficult to manage in the domiciliary setting. Decannulation and conversion from IV to NIV is a safe and feasible technique and should be attempted in selected hypercapnic patients.

P2078

Use of home non-invasive ventilation (NIV) in patients with ankylosing spondylitis (AS)

Martina Mason, Rebecca Chadwick, Ian Smith. Respiratory Support and Sleep Centre, Papworth Hospital NHS Foundation Trust; Papworth Everard, Cambridge, United Kingdom

Background: Ventilatory impairment is a recognised extra-articular manifestation of AS. To our knowledge there are no published data describing home NIV in this condition.

Aims and objectives: Retrospective assessment of home NIV in AS patients at a tertiary UK ventilatory support centre to determine i) indications for NIV, ii) physiological response to treatment and iii) compliance and survival.

Methods: Case records of patients referred for consideration of NIV between 1993 and 2011 were retrospectively reviewed and information regarding the indication for NIV, demographics, co-morbidities, arterial blood gas analysis, pulmonary function, mean overnight oxygen saturation (SpO₂), compliance and survival recorded.

Results: The case notes of 18 patients (15 male, 64±9.2 yrs) were reviewed. Most commenced NIV in the context of acute respiratory decompensation (n=11; 61%). The most frequent indication for NIV was hypercapnia (PaCO₂ ≥ 6.5, n=14; 78%). NIV led to a sustained decrease in PaCO₂ from the baseline (p<0.05) and rise in the mean overnight oxygen saturation (p<0.05). Twelve patients have died (68%) with the median time to death from starting NIV of 31 months (range 1-98). The mean duration of treatment was 33 months (range 1-99).

Home mechanical ventilation the Netherlands; an overview

Anja Hoozenberg1, Nicolle Cobben2, Mike Kappelmacher3, Jacqueline Rispens-Vos4, Peter Wijkerstra4. 1Home Mechanical Ventilation, University Medical Center, Groningen, Netherlands; 2Home Mechanical Ventilation, University Medical Center, Maartenskliniek, Limburg, Netherlands; 3Home Mechanical Ventilation, University Medical Center, Utrecht, Netherlands; 4Home Mechanical Ventilation, University Medical Center, Rotterdam, Zuid-Holland, Netherlands

Background: Home Mechanical Ventilation (HMV) is well known as a cost-effective treatment which significantly improves quality of life. In this abstract we give an overview of the development of HMV in the Netherlands.

Methods: Since 1991 we have been collecting data regarding all patients treated with HMV the Netherlands.

Results: Over the last 20 years, the number of Dutch patients treated with HMV increased from 200 to 2000. There is a significant growth in number of patients treated with non-invasive ventilation. Mask and mouth-piece ventilation in combination with the progress in technical abilities of the equipment, allows patients to use the non-invasive ventilation up to 24 hours a day. Patients were divided in four categories: neuromuscular disease (NMD), thoracic cage restriction (TCR), lung disease and obstructive or central sleep apnea syndrome. Patients with NMD have been always and still remain the largest category in the Netherlands. The rise in NMD is especially due to patients with ALS; almost 100 patients with ALS started HMV last year. The 2nd largest group includes patients with TCR. Patients with
Obesity hypoventilation syndrome (OHS) are primarily responsible for the growth in this group. Patients with obstructive lung disease are a fairly stable group. Of all patients, 68.3% lives at home.

**Conclusion:** Most patients on HMV are currently treated non-invasively. The growth of these patients is specifically seen in patients with ALS or OHS. Despite this enormous rise of patients treated with HMV, 83% of the patients still live at home.

P2080
Home NIV for patients with stable COPD
Kasper Ankiærgaard1, Sophia Maibom, Jon Torgny Wilcke. Dept. of Pulmonary Medicine, Gentofte Hospital, Hellerup, Denmark

**Background:** Non invasive ventilation (NIV) is shown to be effective in the treat-ament of acute respiratory failure in patients with chronic obstructive pulmonary disease (COPD) and as treatment at home in patients with chronic respiratory failure due to e.g. neuromuscular disease. Previous studies in patients with COPD have shown conflicting results of home NIV.

**Aim:** Audit of home NIV treatment initiated due to repeated admissions with NIV treated acute hypercapnic respiratory failure (AHRF).

**Method:** Retrospective study of acutely NIV treated patients in our dept. of lung medicine. Frequency and duration of hospital admissions respectively 12 and 6 months before and 6 months after the initiation of home NIV were compared.

**Results:** Figure shows a significant reduction in number of admissions 6 months after initiation of home NIV compared to 12 (avg 2.4 to 0.75 (p=0.05)) and 6 months before initiation (avg 4 to 0.75 (p=0.046)).

**Conclusion:** The study shows that home NIV is effective to reduce admissions with respiratory problems in a highly selected group of COPD patients with previous repeated AHRF and need of acute NIV treatment.

P2081
The evaluation of the efficacy and safety of phospholipids’ inhalation in patients with bronchial asthma (BA): A prospective randomized placebo-controlled study
Alexander Lisitsin1, Igor Kilmanov2, Svetlana Soodaeva3.

**Background:** The aim of the study was to evaluate the efficacy and safety of phospholipid’s inhalation (PhLi) in BA patients during the 24-week course of treatment.

**Materials and methods:** The prospective, single-blind, randomized, placebo-controlled, parallel-group study was performed. 38 patients (age 67.5±6.13, male 68.5%) with partly controlled and uncontrolled BA were enrolled (FEV1<50%). Group1 contains 30 patients who received a PhLi by compressor nebulizer once a day in addition to traditional therapy; group2 - 28 patients who received a traditional therapy only (control). The lung function test was performed in each clinical visit, as well as PEF measurements were performed twice daily by the patient itself. Usage of short-acting β-agonists and the asthma symptoms score were also determined.

**Results:** It was shown the statistically significant increase of FEV1 level in group1 compared with control (78.3±7.7 vs 72.9±9.2; p=0.01). The PEF increase was also determined in group 1 (570.1±206. vs 486.3±98.3 l/min; p=0.03). The strong correlation between these two parameters was observed (r=0.94; p<0.005).

**Conclusion:** The number of inhalations of bronchodilator reliever medication was significantly lower in group 1 (1.7±0.8 vs 2.9±1.6; p=0.027) as well as asthma symptoms score (4.2±1.1 vs 6.3±1.0; p=0.01).

**Conclusion:** The results obtained demonstrate that a phospholipids’ inhalation in addition to traditional therapy of BA has a significant positive effect both in clinical status and lung function test in patients with BA.

P2082
Onset of bronchodilation with fluticasone/formoterol versus fluticasone/salmeterol
Guy Brusselle1, René Aalbers2, Tammy McIver3, Birgit Grothe4, Anna Bodzenta-Luksyzyk4, Longziczen - Laboratory for Translational Research of Obstructive Pulmonary Disease, Gent University Hospital, Gent, Belgium; 2Department of Pulmonary Diseases, Marmi Hospital, Groningen, Netherlands; 3European Medical Science, Mundipharma Research Ltd., Cambridge, United Kingdom; 4Department of Allergology and Internal Medicine, Medical University of Bialystok, Poland

**Background:** Rapid bronchodilation has been identified as a key attribute of ICS/LABA combination therapy for asthma. This post-hoc analysis assessed the onset of bronchodilation with fluticasone propionate/formoterol fumarate (FLUT/FORM) and fluticasone propionate/salmeterol xinafoate (FLUT/SAL).

**Methods:** 202 adults with asthma (forced expiratory volume in 1 sec [FEV1] reversibility of ≥15%) were randomized to 12 weeks’ treatment with either FLUT/FORM (pMDI, 100/10 or 250/15 g b.i.d. [treatment doses]; n=101) or FLUT/SAL (pMDI; 100/50 or 250/50 g b.i.d. [treatment doses]; n=101) in a double-blind, parallel-group study. The percentage of patients with onset of bronchodilation within 5 min and 120 min post-dose was assessed on days 0 and 84. Onset of bronchodilation was defined as the first time point post-dose with ≥12% increase in FEV1 versus pre-dose.

**Results:** Baseline mean FEV1 was 2.1±0.6 L (reversibility 27.6±12.8%) and 2.1±0.5 L (reversibility 24.9±9.9%) in the FLUT/FORM and FLUT/SAL groups, respectively. On day 0, a significantly greater proportion of patients had an onset of bronchodilation with FLUT/FORM than FLUT/SAL within 5 min (38.6% vs 14.0%; odds ratio [OR] 1.0; 95% CI 2.0, 8.0) and within 120 min post-dose (78.0% vs 64.0%; OR 2.0; 95% CI 1.1, 3.9). This was sustained over 12 weeks; on day 84, the percentage of patients with an onset of bronchodilation was greater with FLUT/FORM than FLUT/SAL within 5 min (16.3% vs 2.0%; OR 9.6; 95% CI 2.1, 42.9) and within 120 min post-dose (51.0% vs 35.1%; OR 1.9; 95% CI 1.1, 3.4).

**Conclusion:** FLUT/FORM consistently provided more rapid bronchodilation than FLUT/SAL in patients with asthma over 12 weeks of therapy.

P2083
Intermittent versus daily inhaled corticosteroids (ICS) in children and adults with mild persistent asthma: A Cochrane review
Francisco Dieguez1, 2, Blureen Essawi2.

**Introduction:** Although guidelines recommend daily ICS in mild persistent asthma, most patients use, and many physicians prescribe, intermittent ICS.

**Objectives:** To compare the safety and efficacy of intermittent versus daily ICS in mild persistent asthma.

**Methods:** Randomised trials comparing intermittent vs. daily ICS in children and adults were eligible. Outcomes included: patients requiring rescue oral steroids (primary efficacy), serious adverse health events (primary safety), hospitalisations, lung function, asthma control, adverse effects, and withdrawals.

**Results:** Six (4 children; 2 adults) parallel-group trials using beclomethasone or budesonide, were included. There was no significant group difference in patients requiring rescue oral steroids (RR=1.07, 95%CI 0.87, 1.32) and serious adverse events (RR=0.82, 95%CI 0.33, 2.03). Compared to daily ICS, intermittent ICS was associated with lower change in FEV1, fewer control days, more PEF-agonists use, and higher exhaled nitric oxide. There was no group difference in acute care visits, hospitalisations, FEV1, adverse effects, and withdrawals. Compared to intermittent, daily budesonide was associated with lower growth in children (MD0.41cm, 95%CI 0.13, 0.69).

**Conclusions:** Intermittent and daily ICS strategies did not significantly differ in the use of rescue oral steroids, nor did they reach equivalence. Daily ICS was superior to intermittent ICS in several indicators of lung function, airway inflammation, control, and reliever use. The findings would support the greater efficacy of daily ICS in children and adults with mild persistent asthma, while using the safest, and lowest effective dose of, ICS in children.

P2084
Oral polyunsaturated fatty acid supplementation as adjuvant therapy for asthmatic children
Malak Shaheen1, Magdy Mahmoud2, 3, Eman Elshinawy2, 3.

**Introduction:** The feeding of long-chain polyunsaturated fatty acids (PUFA) competitively inhibit the formation of leukotrienes and prostaglandins produced from omega-6 fatty acids and thus provide anti-inflammatory effect. However, the precise impact of
omega-3 fatty acid oral supplements for asthmatic children has not been established. The aim of this study was to assess safety and efficacy of omega-3 PUFA supplementation for asthmatic children.

Method: In a prospective study, 44 known asthmatic children and 15 matched healthy children received oral supplementation with omega-3 PUFA for 5 weeks during all children underwent; history taking, clinical examinations, pulmonary function testing and assessment of omega-3 PUFA serum levels, total IgE (TiGE) levels and interleukin 4 (IL4) levels before and after the supplementation. Result: Basal omega-3 PUFA serum levels were significantly lower in asthmatic children compared to controls (p = 0.03) and much lower with severe grades of asthma (r = 0.25, p = 0.03). Three folds rise was documented in the mean omega-3 PUFA level of asthmatic children compared to eight folds increase in healthy children after PUFA supplementation (p = 0.0004). Clinical asthma scores showed one step down improvement only in 13.5% of asthmatic children (6:44). Mean values of TiGE serum levels in asthmatic children showed a significant reduction after supplementation (p = 0.04) while IL4 serum levels showed a rise after supplementation.

Conclusion: Significant difference exists between healthy children and asthmatic children regarding the impact of oral PUFA supplementation. However; it showed some positive effects for asthmatics, its safety is questionable in children.

P2085

Does a formal prednisolone absorption test lead to improved control in difficult-to-treat asthma?
Lisa Midgley1, John Blakey2, Adel Mansour1.1 Severe and Brittle Asthma Unit, Heart and Lung Tract, Birmingham, United Kingdom; 2 Respiratory Medicine, University of Nottingham, United Kingdom

Patients with disabling asthma may have poor concordance with prescribed therapy and admit this only when confronted with firm evidence. Control may then improve through greater concordance with agreed management. Hypothesis: In individuals prescribed long term prednisolone, an absorption test may provide formal evidence of poor concordance and thus lead to improved clinical outcomes.

Design: Observational cohort

Population: 27 patients (22 female) with asthma and poor control despite specialist review, regular prednisolone, and reported concordance.

Intervention: 0.5mg/kg prednisolone orally. Prednisolone, prednisone, cortisol and cortisone levels every hour for 3 hours.

Assessment: First visit to the asthma service, appointment at which test requested, test day, and 6 months thereafter.

Outcomes: ACQ, FEV1% predicted, FeNO, peripheral blood eosinophil count, and reported prednisolone dose.

Analysis: Paired t tests. Results = mean ± SEM (2df).

Results: Patients had impaired lung function (FEV1 65% predicted ±6.0) and poor control (4.4±0.5) at time of test request despite prednisolone (30mg ±3.9).

12 (44%) patients had suppressed cortisol attest baseline. All tests showed adequate absorption of prednisolone.

FEV1, FeNO, prednisolone dose and ACQ did not change significantly across the four time points. Eosinophil count fell by a mean of 0.30 (CI 0.02-0.58, p=0.037) between request and test. This improvement was sustained from request to follow up (mean ±0.50, CI 0.11-0.90, p=0.016).

Conclusion: In this small study a prednisolone absorption test was associated with a sustained fall in eosinophil count. This was not reflected in improved exhaled, spirometric or clinical markers.

P2086

Patient characteristics that can predict response to omalizumab (an anti-IgE antibody) for achieving better control of asthmatic patients
Nancy Abdelaty, Chest, Sue: Canad University, Imsailia, Egypt

Background: Omalizumab is a monoclonal anti-immunoglobulin E (IgE) antibody indicated for the treatment of inadequately controlled severe persistent asthma despite optimal controller therapy. It is an expensive medication so there is a need to identify those patients most likely to benefit.

Aim of the study: To investigate characteristics associated with response to omalizumab in difficult asthma.

Patients and methods: The study enrolled 42 patients (15 female, 27 male) with age range (20y-52y) with severe asthma that was inadequately controlled despite step-4treatment as described in (GINA) guidelines. Omalizumab was given as add-on therapy to concomitant asthma treatment and administered subcutaneously every 2 or 4 weeks according to patients’ pretreatment bodyweight and baseline IgE levels, for at least 16 weeks, those who showed better asthma control, were analyzed to investigate whether pre-treatment patient baseline clinical characteristics could be reliably identified and to be predictive of a superior response to omalizumab.

Results: 12/42 (28.6%) of enrolled patients showed better asthma control. Using univariate and multivariate regression analysis, many variables showed significant effect on response to omalizumab including; age, duration of asthma, history of allergic Rhinitis, history of allergic dermatitis, bronchial reversibility, no of positive results to common allergen, in immediate skin-prick, sputum eosinophilia and baseline total (IgE).

Conclusion: Omalizumab is an expensive medication so it is recommended to target its use to patients most likely to benefit rather than recommend widespread use. Further studies are needed to confirm these data.

P2087

Physician assessment of asthma control in patients receiving omalizumab in a real-world setting
Melinda Szabo1, Jan Chlumsky2, Robert Maykut3, Panayiotis Georgiou4.

1 Severe and Brittle Asthma Unit, Heart and Lung Tract, Birmingham, United Kingdom; 2 Pulmonary Medicine, Koch Robert Hospital, Edeby, Hungary; 3 Critical Care, Novartis Pharma AG, Basel, Switzerland; 4 Critical Care, Novartis Pharmaceuticals Corporation, East Hanover, United States.

GINA guidelines define controlled, partly controlled and uncontrolled asthma based on a number of individual components (symptoms, activity limitation, rescue medication use, lung function and exacerbations).

The 2-year, global, single-arm, observational eXpErience registry evaluated the efficacy and safety of omalizumab (OMA) in patients with allergic asthma in a ‘real-world’ setting. Investigators were instructed to assess asthma control using the GINA 2006 definitions. A post-hoc analysis compiled the individual components of control recorded by physicians and applied these to the GINA definitions. The intent-to-treat population consisted of 916 patients. Investigators’ assessment (IA) of control increased from 1.4% at baseline to 41.1% after 2 years of treatment (Table). Asthma control by strict GINA definitions increased from 0.8% at baseline to 21.0% over the 2 year treatment period (Table).

These data show differences between physician’s assessment of asthma control and control as determined by strict application of GINA 2006 definitions. This study did not explore what determined the differences in assessment, which may be of interest for future study. Regardless of method, asthma control improved over time in patients receiving OMA in this real-world study.

P2088

Effects of inhaled corticosteroids on asthmatic inflammation: The FeNoType trial
William Anderson, Philip Short, Peter Williamson, Brian Lipworth. Asthma and Allergy Research Group, University of Dundee, Scotland, United Kingdom.

Background: Personalised treatment for inflammatory asthma phenotypes confers superior benefits. The elevated exhaled nitric oxide (FeNO) inflammatory phenotype requires evaluation of dose-response to inhaled corticosteroids (ICS).

Methods: Randomised, crossover trial in mild-to-moderate asthmatics receiving ICS with elevated FeNO—40ppb after ICS washout. Patients received 2 weeks of: fluticasone propionate 50ug twice-daily (FP100) or 250ug twice-daily (FP500). Primary outcome: response in diurnal domiciliary FeNO levels. Secondary outcomes included: mannitol challenge; serum eosinophilic cationic protein (ECP); blood eosinophil count; and asthma control questionnaire (ACQ).

Results: 21 patients completed. We found significant dose-related reductions of diurnal FeNO compared to baseline: am: FeNO: baseline=71ppb, FP100=34ppb, p<0.001, FP500=27ppb, p<0.001; and significant dose separation for am, p<0.05, and pm, p<0.001. Time series FeNO displayed exponential decay:

\[ \text{FeNO} = \text{FeNO}_0 \times (1 - e^{-kt}) \]

where k is the decay constant, and FeNO0 is the initial concentration.

ACQ significantly improved exceeding the minimal important difference (>0.75) with values in keeping with controlled asthma (>0.75) after each dose: FP100=0.48, p=0.004; FP500=0.37, p=0.001. All other secondary inflammatory related outcomes showed significant improvements from baseline but no dose separation.
Conclusion: There is significant, dose-response of diurnal FeNO to FeNO in patients with a high FeNO phenotype, also associated with well controlled asthma.

P2089
Effects of Arg16Gly polymorphism in ADRB2 gene on responses to salmeterol: a multi-centre study added to inhaled corticosteroids in Japanese asthmatic subjects
Satoshi Kimura1, Hiroshi Makita1, Nobuyuki Hizawa2, Kaoru Shimizu3, Fumio Kokubu3, Takerumi Sato4, Toku-aki Okumura5, Hiroki Ninomiya6, Hisashi Shionoura1

Methods: The primary endpoint was the difference of the change in morning PEF at 16 weeks [(APEF (Sal) – APEF (Mon)] between the two genotypes. Results: The mean difference in [(APEF (Sal) – APEF (Mon)] was 162mL (p=0.006), but no other significant differences were observed. The least significant differences were 36mL (p=0.05). Conclusion: It is likely that the Arg16Gly polymorphism does not influence the preferential bronchodilator effect of Sal or Mon in mild to moderate persistent asthma patients, at least, in 16 weeks follow-up.

P2090
The efficacy of inhaled fluticasone furoate (FF) and vilanterol (VI) administered in combination in asthma is comparable when administered in the morning or evening
Kozer Keensma1, Amanda Oliver2, Lee Tombs3, Jo Balfour4, Ludovic Apoux5, Eric D. Bateman6, Hilary Medley7, Carol Nunn7

Methods: Single centre, randomised, double-blind, placebo-controlled, three-way crossover study. Subjects with persistent asthma (N=26; 24-64 years) received FF/VI (AM or PM) or matching placebo (P) once daily for 14±2 days. FEV1 (0-24h weighted mean and pre-treatment [AM and PM]) was determined after the Day 14 PM dose together with pre-treatment [AM and PM] PEF on Days 1–12. Results: FF/VI administered AM or PM produced clinically significant increases in weighted mean FEV1; the differences [95% CI] from P were 37mL [293, 462] and 422mL [337, 507], respectively; the difference between AM and PM dosing was 44mL [−135, 36]. Pre-treatment AM FF/VI differences [95% CI] from P were 403mL [272, 533] and 496mL [369, 624] after AM and PM dosing, respectively; the treatment difference was −94mL [−221, 34]. Pre-treatment PM FEV1 differences [95% CI] from P were 275mL [169, 380] and 309mL [205, 413] after AM and PM dosing, respectively; the treatment difference was −34mL [−138, 70]. FF/VI (AM or PM) produced rapid increases in PEF with the full effect apparent after the first dose and maintained throughout the 14 day treatment period. Conclusion: The efficacy of FF/VI (100/25mcg) was comparable when dosed in the morning or evening in subjects with persistent asthma. Funded by GSK (HZA114624, NCT01287005).

P2091
Efficacy of fluticasone furoate (FF) as a monotherapy and in combination with vilanterol (VI) over 12 weeks in patients with persistent asthma
Eugenie R. Bleeker1, Jan Lowitt1, Paul M. O’Byrne2, Ashley Woodcock4, William W. Busse3, Richard Forth4, Hilary Medley1, Carol Nunn7, Loretta Jacques4, Eric D. Bateman6, 1Center for Genomics and Personalized Medicine, Wake Forest School of Medicine, Winston-Salem, United States; 2Krefting Research Centre, University of Gothenburg, Sweden; 3Michael G DeGroote School of Medicine, McMaster University, Hamilton, Canada; 4School of Translational Medicine, University of Manchester, United Kingdom; 5Department of Medicine, University of Wisconsin, Madison, United States; 6Quantitative Sciences Division, GlaxoSmithKline, Research Triangle Park, United States; 7Respiratory Medicines Development Centre, GlaxoSmithKline, Uxbridge, United Kingdom; 8Respiratory Medicines Development Centre, GlaxoSmithKline, Uxbridge, United Kingdom; 9Department of Medicine, University of Cape Town, South Africa

Introduction: The inhaled corticosteroid FF in combination with the long-acting beta2 agonist VI is under development for the treatment of asthma and COPD. Objectives: To compare the efficacy and safety of FF/VI and FF in patients (aged ≥12 years) with persistent asthma. Methods: In a randomised, double-blind, parallel-group study, patients (N=460; ITT) received FF/VI 100/25mcg, FF 100mcg or placebo once daily in the evening via a new dry powder inhaler. Co-primary endpoints: change from baseline in trough FEV1, and weighted mean (w) 0-24h FEV1. Rescue-free 24-h periods and safety were also assessed. Results: Placebo increased trough FEV1 (196mcL and wFEV1; [212mL vs baseline. FF/VI and FF, respectively, significantly improved compared with placebo trough FEV1 (172mL [p<0.001] and 136mL [p=0.002] and wFEV1 (302mL [p<0.001] and 186mL [p=0.003]), Treatment differences between FF/VI and FF approached significance for wFEV1 (160mL [p=0.06], but not for FEV1 (160mL, p=0.060), but not for FEV1 (302mL, p=0.405). Percent of rescue-free 24-h periods with FF/VI was 10.6% greater than FF and 19.3% greater than placebo. Statistically significant (p=0.032) urinary cortisol suppression was seen with FF/VI (ratio=0.82) relative to placebo, but not for FF Adverse event and safety profiles were similar across treatment groups. Conclusions: Significant improvement in lung function was observed with FF/VI and FF in patients with persistent asthma. Addition of VI to FF did not significantly improve FEV1, but a numerical increase was seen. The high placebo response in evening trough FEV1 may have influenced the assessment of efficacy in this study. Funded by GSK (HZA108627, NCT01165138).

Introducing the novel corticosteroid FF in combination with the long-acting beta2 agonist VI

William W. Busse1, Paul M. O’Byrne2, Eugene R. Bleeker1, Jan Lowitt1, Ashley Woodcock4, Leslie Andersen, Jody West3, Loretta Jacques4, Ludovic Apoux5, Eric D. Bateman6, 1Department of Medicine, University of Wisconsin, Madison, United States; 2Krefting Research Centre, University of Gothenburg, Sweden; 3Michael G DeGroote School of Medicine, McMaster University, Hamilton, Canada; 4School for Genomics and Personalized Medicine, Wake Forest School of Medicine, Winston-Salem, United States; 5Krefting Research Centre, University of Gothenburg, Sweden; 6School of Translational Medicine, University of Manchester, United Kingdom; 7Respiratory Medicines Development Center, GlaxoSmithKline, Research Triangle Park, United States; 8Quantitative Sciences Division, GlaxoSmithKline, Uxbridge, United Kingdom; 9Respiratory Medicines Development Centre, GlaxoSmithKline, Uxbridge, United Kingdom; 10Global Clinical Safety and Pharmacovigilance, GlaxoSmithKline, Uxbridge, United Kingdom; 11Department of Medicine, University of Cape Town, South Africa

Introduction: The FF in combination with the LABA VI is in development for asthma and COPD. Objectives: To assess the safety and tolerability of the novel inhaled corticosteroid (ICS) fluticasone furoate (FF) in combination with the long-acting beta2 agonist (LABA) vilanterol (VI) administered once daily (OD) in patients with asthma William W. Busse1, Paul M. O’Byrne2, Eugene R. Bleeker1, Jan Lowitt1, Ashley Woodcock4, Leslie Andersen, Jody West3, Loretta Jacques4, Ludovic Apoux5, Eric D. Bateman6, 1Department of Medicine, University of Wisconsin, Madison, United States; 2Krefting Research Centre, University of Gothenburg, Sweden; 3Michael G DeGroote School of Medicine, McMaster University, Hamilton, Canada; 4School for Genomics and Personalized Medicine, Wake Forest School of Medicine, Winston-Salem, United States; 5Krefting Research Centre, University of Gothenburg, Sweden; 6School of Translational Medicine, University of Manchester, United Kingdom; 7Respiratory Medicines Development Center, GlaxoSmithKline, Research Triangle Park, United States; 8Quantitative Sciences Division, GlaxoSmithKline, Uxbridge, United Kingdom; 9Respiratory Medicines Development Centre, GlaxoSmithKline, Uxbridge, United Kingdom; 10Global Clinical Safety and Pharmacovigilance, GlaxoSmithKline, Uxbridge, United Kingdom; 11Department of Medicine, University of Cape Town, South Africa

Methods: Patients (N=503) were randomised (2:2:1) to FF/VI 100/25mcg or FF/VI 200/25mcg OD in the evening, or fluticasone propionate (FP) 500mcg twice daily. Safety evaluations included adverse events (AEs), non-fasting glucose and potassium, urinary cortisol (UC), heart rate (HR), pulse rate and ophthalmic assessments. Results: Statistically significant UC suppression was seen with FP compared with both FF/VI groups at Weeks 12 and 28 (p<0.006), but not at Week 52. Potassium and glucose values were similar across groups. Increases in pulse rate (10min post dose: Week 25) were reported with FF/VI vs FP (100/25mcg: 3.4bpm, p=0.002; FF/VI 200/25mcg: 3.3bpm, p=0.003). No significant differences with FF vs FP were observed on QTc(F) outputs or HR with Holter monitoring. AEs were reported by 66-69% of patients on FF/VI and by 73% on FP. Oral/oropharyngeal candidiasis (AEs: FF/VI 6.7%, FP 9%). Twelve SAEs were reported; one (worsening hepatitis on FP) was considered drug related. Low number of ‘special interest’ AEs (including ocular effects and pneumonia). Conclusions: FF/VI (100/25mcg or 200/25mcg) administered once daily over 52 weeks was well tolerated by patients aged ≥12 years with asthma. The overall safety profile observed for FF/VI did not reveal any findings of significant clinical concern and was similar to FP. Funded by GSK (HZA108639, NCT01018186).
QMFiS is an investigational once-daily (QD), fixed-dose combination of indacaterol (IND) and mometasone furoate (MF). This study assessed the long-term safety of QMFiS in patients (pts) with persistent asthma.

In this randomized, double-blind, multi-centre, Phase II study, pts (12–70 y) received QMFiS (IND maleate 500 μg/MF 400 μg) or MF (400 μg), both administered QD via the Twiskhaler® for 6–21 months. Systemic exposure data show that this QMFiS dose is comparable to 150 μg IND/160 μg MF in the Concept® (Breezhaler®) inhalation device, the delivery device that will be used in future studies. The primary endpoint was time to first serious exacerbation (resulting in hospitalisation, intubation or death). A key secondary endpoint was the cumulative incidence of serious exacerbations. AEs and SAEs were recorded.

Of 8 of 1519 randomised pts (QMF, 756; MF, 763) were hospitalised for a serious exacerbation (QMFiS, 2; MF, 6); none required intubation or resulted in death. QMFiS reduced the risk of a serious exacerbation vs MF by 69% (hazard ratio=0.31; 90% CI 0.21, 0.46; p=0.0076). The difference in cumulative incidence was 0.52 percentage points (90% CI 0.14, 1.14, 0.09) in favor of QMFiS, meeting the pre-specified, non-inferiority margin of difference of 1 percentage point. Similar proportions of pts experienced AEs and SAEs in both groups (QMFiS, 74.0% and 4.0%; MF, 73.4% and 5.8%). Most frequent AEs with QMFiS and MF were cough and asthma, respectively. There was one death (MF group), which was not treatment or asthma related. Mean plasma MF concentrations were similar in both groups.

QMFiS QD was not associated with additional safety concerns vs MF monotherapy in pts with persistent asthma.

Asthma control remains suboptimal in many patients as indicated by exacerbations and deteriorating symptoms. This pooled analysis of up to 5 randomized double-blind studies assessed the effects of fluticasone propionate (FP) and formoterol fumarate (FORM) in a single aerosol inhaler (FLUT/FORM) in asthma exacerbations.

Methods: Adults and adolescents with asthma (all severities) were randomized to FLUT/FORM (100/5, 250/5 or 500/20 μg bid), or equivalent nominal doses of FLUT (100, 200 or 500 μg bid; 5 studies) or FORM (10 μg bid; 3 studies) for 8 or 12 weeks. The proportion of patients with an exacerbation was assessed. Mild-to-moderate exacerbation was defined as peak expiratory flow rate >30% below baseline, awakening at night due to asthma symptoms, ≥4 times/day (each on ≥2 consecutive days); severe exacerbation was need for additional therapy, or emergency visit/hospitalization due to asthma.

Results: Significantly fewer patients reported exacerbations with FLUT/FORM than FLUT (27% [172/641] vs 33% [211/643]; odds ratio [OR] 0.75; 95% CI 0.59, 0.96) or FORM (18% [62/341] vs 31% [108/345]; OR 0.49; 95% CI 0.34, 0.70). The annualised exacerbation rate was significantly lower with FLUT/FORM than FLUT (ratio 0.66; 95% CI 0.61, 0.79; p<0.001) or FORM (0.55; 95% CI 0.44, 0.68; p<0.001). The risk of severe exacerbation was similar for FLUT/FORM and FLUT (2% [18/1264] vs 3% [18/643]; OR 0.66; 95% CI 0.32, 1.39), but lower with FLUT/FORM than FORM (2% [8/341] vs 10% [33/345]; OR 0.23; 0.10, 0.50).

Conclusion: FLUT/FORM significantly reduces the risk of reported asthma exacerbations (any severity) compared with its individual components.
P2098

Efficacy and safety of ciclesonide in the treatment of patients with persistent allergic or non-allergic asthma

Otto Chris Burgjaeger1, Gerhard Köberl1, Susanna Lenk-Feik3, Monika Schantl4, Alexandra Hammer4, Gerhard Köberl2, Alexander Hummers1, Internal Department, Otto Wagner Hospital, Vienna, Austria; 1Pneumology Practice, Feldkirch, Austria; 2Pneumology Practice, Baden, Austria; 3Pneumology Practice, Graz, Austria; 4Medical Department, Nymomed Deutschland GmbH, Konstanz, Germany; 5Medical Department, Nymomed Pharma GmbH, Vienna, Austria

Aim: To evaluate the efficacy and safety profile of ciclesonide (CIC) in the treatment of persistent allergic or non-allergic asthma in a real-life setting in Austria.

Methods: 307 patients suffering from persistent asthma of any severity grade (42% treatment-naive) were enrolled in this non-interventional study (NIS). All patients used CIC for at least 3 months. Of the patients, 43.4% were prescribed concomitant medication, primarily short-acting β2-agonists. Efficacy was evaluated by FEV1, Asthma Control Questionnaire (ACQ), Asthma Quality of Life (AQLQ/S), asthma symptoms, physical activity limitations and use of rescue medication.

Results: Mean FEV1 % predicted increased from 75.1 ± 15.4% to 83.7 ± 14.9%. At the end of the observation period, the percentage of patients with daily symptoms that had declined from 33.2% to 3.9%, nighttime symptoms from 21.8% to 5.2%, physical activity limitations from 73.9% to 24.4%, and rescue medication usage from 70% to 29.3%. The mean total ACQ score was 2.32 ± 1.14 at baseline and 1.08 ± 0.88 at study end. The number of patients with well-controlled asthma (ACQ-score <1) increased considerably from 11.0% to 52.2%. Accordingly, clinically important mean improvements were observed in the total self-assessed AQLQ/S score. A low incidence of adverse drug reactions (ADR) was observed (4 ADRs in 3/307 patients).

Conclusion: This NIS in patients with persistent asthma confirmed the efficacy and safety of CIC in routine clinical care showing improvements in symptom control, lung function, and quality of life. CIC was well tolerated in this heterogeneous patient population.

P2099

Safety of formoterol in asthma clinical trials

Malcolm Sears1, Finn Radner2,3, Medicine, McMaster University, Hamilton, ON, Canada; 1AstraZeneca R&D, AstraZeneca R&D, Molndal, Sweden

Background: We have previously reported safety data through 2006 from all AstraZeneca-sponsored, randomised, controlled, parallel-group trials with 3-12 months duration with formoterol. Data from 2007-2011 trials have now been added.

Methods: Risks associated with formoterol relative to non-LABA-treatments (ICS, SABA, placebo, salmeterol treatments, and conventional best practice, were assessed using rate and ratio measures for multiple safety endpoints.

Results: The 2007-2011 data added 15 trials and 22,599 patients including 17,447 treated with formoterol (with all concomitant ICS), increasing the combined dataset to 79 trials and 94,683 patients, of whom 67,380 received formoterol (94% using ICS). There were no asthma-related deaths in the new trials. In total, there were 8 asthma-related deaths among the formoterol-treated patients (exposure 33,700 years). No increased risk was observed for formoterol vs. non-LABA treatments for all-cause mortality (RR 0.94; 95% CI: 0.52-1.80), cardiac mortality (RR 0.47; 95% CI: 0.19-1.22), or cardiac-related SAEs (RR 0.94; 95% CI: 0.32-1.80). Asthma-related SAEs were significantly reduced for formoterol vs. non-LABA treatment (RR 0.63; 95% CI: 0.53-0.75). The new trials added a substantial number of black patients to the dataset, but no increased risk for asthma-related SAEs was observed for this subgroup in the combined dataset.

Conclusion: Use of formoterol in asthma patients, most using ICS, is not associated with any increased risk of asthma- or cardiac-related deaths or SAEs.

P2100

Prospective follow-up of novel bone turnover markers in asthmatics exposed to low or high doses of inhaled ciclesonide over 1 year

William Anderson, Lesley McFarlane, Brian Lipworth, Asthma and Allergy Research Group, University of Dundee, Scotland, United Kingdom

Background: There is concern that asthmatics receiving long-term inhaled corticosteroids could develop systemic adverse effects on bone metabolism. We investigated if exposure to inhaled ciclesonide at high vs low doses over 1 year caused any adverse effects on sensitive biomarkers of bone turnover in asthmatics.

Methods: Post hoc analysis of stored bone marker samples in a subgroup from a prospective, randomised parallel group trial (Lipworth et al. Chest DOI:10.1378/chest.11-1748) where ciclesonide was titrated to control asthma against either mannitol airway hyper-responsiveness (AHR strategy) or control (based on symptoms, reliever use and lung function) over 1 year. 100 mild-moderate asthmatics, 18-65 years, with AHR to mannitol challenge had been bone marker samples available for analysis. Outcome measures: bone formation (PINP, PIIINP), resorption (ICTP, CTX) and adrenal suppression (overnight urinary corticosteroids). We divided patients into two groups at baseline based on their inhaled corticosteroid exposure (AHR strategy vs control group).

Results: There were 100 mild-moderate asthmatics, 18-65 years, with AHR to mannitol challenge. Bone formation (PINP, PIIINP) was significantly higher in the AHR strategy group compared to the control group. Bone resorption (ICTP, CTX) was significantly lower in the AHR strategy group compared to the control group. Adrenal suppression was not significantly different between the two groups.

Conclusion: Exposure to inhaled ciclesonide at high vs low doses over 1 year caused significant differences in bone turnover markers in asthmatics exposed to high doses of inhaled corticosteroids.
Results: In pts with mMRC ≤2 (respectively COPD 1425/1752), mean age was 63.1/63.9 years, FEV1 57.6/51.8% predicted, FEV1/FVC 53.9/51.6%. Differences of the GLOW1 and GLOW2 studies of notable pulse rate (FVC) at Day 1 and Wks 12, 26 and 52, 24-hr serial spirometry in a subset of patients for NV A237 and TIO, respectively, with no deaths. There were no reports of notable pulse rate (>130 bpm, or >120 and >90 bpm from baseline) and QTc interval (Flickerca) >500ms over 52 wks. Dry mouth incidence was less frequent with NV A237 (1.6%) vs TIO (5%). A clinically significant increase from baseline in pre-dose FEV1 was observed for NVA (101 mL) and TIO (173 mL) at Wk 12. The event-free rate for moderate or severe COPD exacerbation was 78.9% for NV A237 and 76.6% for TIO at Wk 52.

Conclusion: NV A237 once daily had a safety and tolerability and efficacy profile similar to tiotropium in Japanese patients with moderate-to-severe COPD over 52 weeks.

P2104

Sputum neutrophil monitoring is useful for long-term oxygen therapy in patients with COPD

Masahide Miyagome1,2, Ken Takao1, Yohko Okuda1, Minako Manzuma1, Eri Turugui1, Yohko Nakazato1, Misuru Adachi1,2, Respiratory Medicine, IMS Group, Ohta Fukushima General Hospital, Ohta City, Japan;1 Respiratory Medicine and Allergology, Showa University Hospital, Japan

Long-term oxygen therapy (LTOT) is the treatment proven to improve survival in chronic respiratory failure patients, especially chronic obstructive pulmonary disease (COPD). Participation of airway neutrophil inflammation is suggested to be a part of illness, such as COPD. The aim of this study is to evaluate whether sputum neutrophil monitoring is useful for LTOT in patients with COPD exacerbations.

Twenty two patients, mean age were 72 years, were participated in this study. Twenty patients survived to the follow-up after 14 months of this study. Before receiving LTOT, mean sputum neutrophil was 8%. However, after LTOT administrations, sputum neutrophil was decreased to approximately 3% and reduced the number of hospitalizations including outpatient service. Also St George's Respiratory Questionnaire score (SGRQ) was significantly improved. In peripheral blood, downward tendency was seen, but not so significant. Before outpatient service in COPD patients, average neutrophil percentage in the sputum was gradually raised up to 19%±6%. So we could respond for COPD exacerbations at an early stage using corticosteroid and antibiotic drugs. While this neutrophil partciapate mechanism is still unknown, further study should be needed including cytokine evaluation. However, this study indicates that in patients with COPD, long-term oxygen therapy is associated with airway sputum neutrophil reduction.

P2105

The effect of high dose N-acetylcysteine (1200mg daily) on airway function and airway trapping in COPD patients – A double blinded randomized placebo controlled trial

Hoi Nam Tse1,2, King ying Wong1,2, Kwk Sang Yee1,2, Lai yun Ng1,2, 3Medical Department, Kwong Wah Hospital, Hong Kong, Hong Kong; 2Department of TB and Chest Unit, Wong Tai Sin Hospital, Hong Kong, Hong Kong

Introduction: High dose N-acetylcysteine (NAC) has both antioxidant and mucoytic effect. However, there was a lack of study to demonstrate its beneficial use in COPD patients.

Aims: To investigate the effect of high dose NAC (1200mg daily) on airway function in stable COPD patients

Methods: This is a 16-week double-blinded randomized placebo-controlled trial conducted in a government hospital in Hong Kong. Spirometry confirmed COPD patients (FEV1/FVC <70%) were recruited and randomized into treatment (NAC 1200mg daily) and placebo groups. Both patients and doctors were blinded for

| MONDAY, SEPTEMBER 3RD 2012 | 373s |
the group allocation. Lung function tests were measured at the beginning and at the end of the treatment period. Primary outcome variable: change from baseline over the treatment period in predose FEV1; secondary outcome variables included lung function time to first exacerbation, tolerability.

Results: 1293 patients were randomized. Both BUD/FORM and FORM improved predose FEV1 (improvements of 4.6% and 1.5%, respectively), the change from baseline was significantly greater with BUD/FORM vs FORM for 12-week period (p=0.001). Both treatments were well tolerated. The incidence and type of adverse events were similar in both groups; most commonly reported adverse events (BUD/FORM vs FORM) were COPD exacerbation 7.9% vs 4.6%, nasopharyngitis 5.1% vs 4.9% and bronchitis 2.0% vs 2.3%.

Conclusions: BUD/FORM 160/45 μg two inhalations daily was more effective than FORM 4.5 μg two inhalations daily in patients with moderate to severe COPD. Both treatments were well tolerated. Funding: AstraZeneca.

Budesonide/formoterol vs formoterol, both via Turbuhaler®, in patients with moderate to severe COPD: Phase III study results
Masakazu Ichinohe1, Ronnie Samoro2, Rustem Fassakhov3, Mitsuori Oguri4, Jan Ekelund5, Lars-Goran Carlsson6, Yoshinosuke Fukuchi7, 1Third Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan; 2Department of Medicine, Institute of Epidemiology and Microbiology, Kazan, Russian Federation; 3Department of Medicine, Oji General Hospital, Hokkaido, Japan; 4Clinical Sciences, AstraZeneca R&D, Molndal, Sweden; 5Department of Respiratory Medicine, Juntendo University, Tokyo, Japan

Background: This study evaluated the efficacy and tolerability of budesonide/formoterol (BUD/FORM) vs formoterol (FORM) in patients with moderate to severe COPD.

Methods: In this randomised, double-blind, parallel-group, phase III study (NCT01069289) patients with moderate to severe COPD for ≥2 years received either BUD/FORM 160/4 μg 2 inhalations twice daily via Turbuhaler® or FORM 4.5 μg 2 inhalations twice daily via Turbuhaler® for 12 weeks. Primary endpoint: salbutamol 100 μg via pMDI. Primary outcome variable: change from baseline over the treatment period in predose FEV1; secondary outcome variables included lung function time to first exacerbation, tolerability.

Results: 1293 patients were randomized. Both BUD/FORM and FORM improved predose FEV1 (improvements of 4.6% and 1.5%, respectively), the change from baseline was significantly greater with BUD/FORM vs FORM for 12-week period (p=0.001). Both treatments were well tolerated. The incidence and type of adverse events were similar in both groups; most commonly reported adverse events (BUD/FORM vs FORM) were COPD exacerbation 7.9% vs 4.6%, nasopharyngitis 5.1% vs 4.9% and bronchitis 2.0% vs 2.3%.

Conclusions: BUD/FORM 160/45 μg two inhalations daily was more effective than FORM 4.5 μg two inhalations daily in patients with moderate to severe COPD. Both treatments were well tolerated. Funding: AstraZeneca.

P2107
Effect of once-daily indacaterol in a predominantly Chinese COPD population: A 26-week Asia-Pacific study
Wanzhen Yao1, Changzheng Wang2, Nanshan Zhong3, Wei Yang4, Michelle Henley5, Benjamin Kramer5, 1Department of Respiratory Medicine, Peking University Third Hospital, Beijing, China; 2Institute of Respiratory Diseases, Xiangya Hospital, 3Military Medical University, Chongqing, China; 4State Key Lab of Respiratory Disease, 1st Affiliated Hospital Guangzhou Medical College, Guangzhou, China; 5Primary Clinical Science Unit, Novartis Pharmaceuticals UK Ltd, Horsham, United Kingdom

Background: Severe exacerbations of COPD require hospitalization and have serious long-term consequences for patients. Roflumilast (ROF) is a PDE4 inhibitor that significantly reduced moderate-to-severe exacerbations in clinical studies. Its effects on severe exacerbations and any adverse events leading to hospitalization have not been described previously.

Aim: To investigate the effects of ROF on the rate of hospitalizations resulting from severe exacerbations or any other adverse events in two 1-year studies (M2-124 and M2-125).

Methods: In a post-hoc pooled analysis of the pivotal studies of ROF 500 μg (n=1537) vs placebo (n=1554), statistical analyses were performed on the overall population and in patient subgroups with: A) severe/very severe COPD; B) frequent COPD exacerbations; and C) severe/very severe COPD and frequent COPD exacerbations. Negative binomial regression analyses were used to investigate the rate reduction for hospitalizations.

Results: In the overall population, ROF decreased the rate of hospitalizations resulting from severe exacerbations vs placebo by 21.6% (rate ratio 0.784; 95% CI 0.619, 0.993, p=0.0439), and overall there were trends towards extended times-to-onset of severe exacerbations leading to hospitalization. Although not statistically significant, ROF reduced hospitalizations resulting from any adverse event compared with placebo. In all subgroups analyzed, ROF had a positive numerical but not statistically significant effect on rate reduction of all-cause hospitalizations, time to hospitalization and risk of hospitalizations.

Conclusions: Roflumilast significantly reduced the rate of severe exacerbations leading to hospitalization vs placebo.
P2110

The effect of tiotropium on lung dynamic hyperinflation and treadmill exercise capacity in mild to moderate COPD

Richard Casaburi1, Francois Malais1; Janos Porszasz1, Frank Albers1

Qing Deng1, Afshar Iqbal1, Heather Padlen1, Denis O’Donnell1.

Division of Respiratory and Critical Care Physiology and Medicine, Rehabilitation Clinical Trials Center, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States; 2Centre de Recherche, Institut Universitaire de Cardiologie et de Pneumologie de Quebec, Université Laval, Quebec, Canada; 3Medical Affairs Respiratory, Pfizer Inc, New York, NY, United States; 4Department of Medicine, Queen’s University & Kingston General Hospital, Kingston, ON, Canada.

Rationale: In previous studies tiotropium improved cycle exercise duration in GOLD II-IV COPD patients. This double-blind crossover study (NCT01072396) compared tiotropium with placebo in GOLD I and II COPD using treadmill exercise testing.

Methods: Patients were current or ex-smokers aged >40y with post-bronchodilator FEV1/FVC <70%, FEV1 ≥50% predicted, and dynamic hyperinflation (>100 mL inspiratory capacity [IC] decrease during incremental treadmill exercise). Patients received tiotropium 18 μg bid and placebo for 6 weeks each (random order, 4-week washout). Patients performed constant work rate treadmill exercise at 80% of peak incremental work rate before and after each treatment period. The primary endpoint was the difference in exercise isotime IC change from baseline to Week 6 between tiotropium and placebo. Secondary endpoints included change in exercise duration.

Results: Patients (n=126, 52% male) had mean age 61 y, post-bronchodilator FEV1/FVC 59% and FEV1 77% predicted. Baseline IC was 2.27 L and exercise duration 447 s. The difference in change in exercise duration between tiotropium and placebo was statistically significant (65 mL, P<0.009). The difference in change from baseline in exercise duration between tiotropium and placebo was a non-inferiority in the combined GOLD II+III (29.3 s, P=0.109) and GOLD I (23.5 s, P=0.415) groups, but was statistically significant for GOLD II (65.0 s, P=0.007).

Conclusions: Tiotropium was associated with reduced lung hyperinflation at rest and during exercise in GOLD I and II COPD patients. Significantly improved exercise duration was observed in GOLD II patients but not the combined or GOLD I groups.

Safety of fluticasone furoate (FF), an inhaled corticosteroid in combination with vilanterol (VI), a long-acting beta agonist in management of COPD exacerbations

Peter M.A. Calverley1, Mark T. Dransfield1, Jean Bourbeau2, Paul Jones3,4, Nicola A. Hannam1, Donald A. Mahler1, Jürgen Votho1, Andrew Wachsted5, Fernando Martinez2, Frank Barnhart3, Lisa Sanford4, Sally Lettis5, Courtney Crim3, 1Clinical Science Centre, University Hospital Aintree, Liverpool, United Kingdom; 2Division of Pulmonary, Allergy and Critical Care Medicine, University of Alabama at Birmingham, United States; 3Medicine, McGill University Health Centre, Montreal, Canada; 4Division of Clinical Science, St. George’s University, London, United Kingdom; 5Pulmonary and Critical Medicine, Baylor College of Medicine, Houston, United States; 6Section of Pulmonary & Critical Care Medicine, Darmouth Medical School, Hanover, United States; 7Respiratory Research Group, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; 8UCCLA School of Medicine, UCLA, Los Angeles, United States; 9Department of Internal Medicine, University of Michigan, Ann Arbor, United States; 10Respiratory Medicine Development Center, GlaxoSmithKline, Research Triangle Park, United States; 11Quantative Sciences Division, GlaxoSmithKline, Uxbridge, United Kingdom.

INTRODUCTION: FF and VI are in development as combined once-daily (OD) therapy for COPD.

Objectives: Assess the safety of FF/VI (3 strengths) and VI in COPD.

METHODS: In two replicate 1 year studies, after a 28 day run-in with ADVAIR DISKUS® 250/500mcg, subjects received FF/VI 50/25, 100/25, 200/25mcg or VI 25mcg OD. Primary endpoint: annual rate of moderate/severe exacerbations (described separately). Safety endpoints included all, serious and fatal Adverse Events (AEs), Local Steroid Effects (LSE, including candidiasis), bone disorders (BD, including fractures) and pneumonia.

RESULTS: Pooled safety findings are shown in the table.

HR, Hazard Ratio. "On-treatment." *On-/Post-treatment. HR for LSE and BD were significantly higher for FF/VI vs VI in all comparisons except LSE at 0.025 (p=0.065).

Conclusions: In COPD patients FF/VI exhibited similar rates of serious and fatal AEs to VI, although rates of AE, BD, LSE and pneumonia were greater with FF/VI than VI alone. The efficacy of the combination is currently being funded by GSK. HZC102871:NCT01009463, HZC102970:NCT01017952.
P2114 Inhaled corticosteroid/long-acting beta-2 agonist (ICS/LABA) combination can decrease mortality of COPD patients, a nationwide population-based cohort study in Taiwan

Ming-Chen Chuang, Gin-Hen Lin. Section of Chest Medicine, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan

Department of Medical Research, Taichung Veterans General Hospital, Taichung, Taiwan

Background: Chronic Obstructive Pulmonary Disease (COPD) remains a major public health problem. Current treatments, including pharmacological and non-pharmacological, can only alleviate symptoms, prevent exacerbation and improve quality of life. Previous large-scale studies failed to demonstrate benefit of mortality reduction which is also important for a chronic illness.

Objective: The aim of this study is to determine whether ICS/LABA combination can reduce mortality of COPD by using Taiwan National Health Insurance Database.

Method: This was a nationwide population-based cohort study. A total of 1989 COPD patients were identified from one million sampling cohort dataset between January to December in 2005. Patients with diagnosed in 2005 as COPD were grouped as non-controller user (n=638), ICS/LABA (n=265) and LAMA (n=86). Cox regression model was used to evaluate the incidence of mortality and pneumonia in the following 3 years to December 2008.

Result: The incidence of pneumonia was not different among three groups. However, COPD patients with older age (H.R. 1.398 for every increase of 10 years, p < 0.0001) and male gender (H.R. 1.414, p < 0.001) had higher incidence to have pneumonia. The mortality rate was lower in patients who used ICS/LABA combination as compared with non-controller group (H.R. 0.694, p = 0.0165)

Conclusion: In the selected Taiwanese population, COPD mortality was lower among patients who used ICS/LABA. Incidence of pneumonia was not increased with ICS/LABA, but significantly related increased age and male gender.

P2116 Effect of formoterol alone and in combination with aclidinium on electrocardiograms in dogs

Amadeu Gavaldà, Marna Vinyals, Jordi Aubets, Jordi Gras. R & D, Almirall, Barcelona, Spain

Introduction: Co-administration of a long-acting β-agonist with an anticholinergic is common clinical practice for the management of COPD, but there are concerns that systemic exposure to both drugs could cause undesirable pharmacodynamic effects on the heart.

Aims: To evaluate the cardiovascular safety of formoterol alone and in combination with aclidinium in conscious dogs.

Methods: Formoterol (1, 3, 10 μg/kg iv), aclidinium (50, 167 μg/kg iv) and formoterol/aclidinium (1+17, 3+50, 10+167 μg/kg iv) were administered to fasted male Beagle dogs (n=4; 13–16 kg) in a 3-min perfusion. Each dog received each dose with >6-day washout. Electrocardiograms were recorded at baseline (for 1 h) and 24 h post-administration (for 90 min) and assessed for ventricular tachycardia (VT) and premature ventricular complexes (PVC).

Results: Formoterol alone showed a dose-dependent trend to induce VT. VT was observed in 0, 1 and 4 animals treated with formoterol 1, 3 and 10 μg/kg, respectively. Aclidinium alone (both doses) did not induce VT. The combination of formoterol/aclidinium resulted in VT in a similar number of animals as formoterol alone (2 and 3 animals with 3±50 and 10±167 μg/kg, respectively). Similar results were observed for PVC. At the highest doses of formoterol and aclidinium, plasma concentrations corresponded to 32 and 4000 times those reported in human plasma after clinically relevant doses.

Conclusions: Addition of aclidinium does not alter the incidence or rate of formoterol-induced VT or PVC in dogs. These results suggest that aclidinium has no synergistic interaction on cardiac function with β-agonists.

This study was supported by Almirall S.A., Barcelona, Spain.

P2117 Risk of pneumonia related to budesonide use in COPD: An updated pooled analysis

Don Sin,1 Donald Tashkin2, Finn Radner3, Ulf Sobiraj,4 Anders Thoren,5 Peter Calverley6, Stephen Kennard7,1 Department of Medicine, University of British Columbia, Vancouver, Canada; 2Division of Pulmonary and Critical Care Medicine, David Geffen School of Medicine at UCLA, Los Angeles, United States; 3Clinical Sciences, AstraZeneca R&D, Molndal, Sweden; 4School of Clinical Sciences, University of Liverpool, United Kingdom; 5Internal Medicine Section of Pulmonary and Critical Care, Nebraska Medical Center, Omaha, United States

Background: A meta-analysis of 7 clinical trials reported no increase in the risk of pneumonia as an adverse event (AE) in COPD patients taking the inhaled corticosteroid (ICS) budesonide; however, others have reported a numerical increase. Recently, an eighth trial (NCT00419744) fulfilling the meta-analysis inclusion criteria has been completed. This updated meta-analysis includes data from all 8 clinical trials of budesonide.

Methods: Patient data were pooled from 8 clinical trials of inhaled budesonide (320–1280 μg/day), with or without formoterol, vs control (placebo or formoterol alone) in patients with stable COPD and ≥6 months of follow-up. The primary analysis compared treatment groups for the risk of pneumonia as an AE or serious AE (SAE) during the trial or within 15 days of the trial end. Cox proportional hazards regression was used to analyse the data on an intention-to-treat basis.

Results: Data from 8260 patients were included; 4616 received budesonide and 3644 received control treatment, with 3395 and 2647 patient-years of exposure to treatment, respectively. No statistically significant difference was found in the incidence of budesonide compared with non-ICS treatment groups for the occurrence of pneumonia as an AE (3.9% [n=179 patients] vs 3.3% [n=120]; HR 1.13, 95% CI 0.89–1.43) or a SAE (1.8% [n=82] vs 1.6% [n=59]; HR 1.02, 95% CI 0.72–1.43). Similarly, there was no statistically significant difference between the budesonide and non-ICS treatment groups for time to pneumonia as an AE (log-rank test 0.30) or a SAE (log-rank test 0.56).

Conclusion: The updated pooled analysis shows that budesonide (320–1280 μg/day) does not increase the risk of pneumonia over 12 months in patients with COPD.

P2118 Long-term safety of twice-daily aclidinium bromide in COPD patients: A one-year, double-blind study

Arthur Geh1, Donald Tashkin2, Barry Make3, Xiaoyan Zhong4, Esther Garcia Gómez5, Cynthia Caracta6, Southern California Clinical Trials, Lakewood, United States; 2Division of Pulmonary & Critical Care Medicine, David Geffen School of Medicine at UCLA, Los Angeles, United States; 3Department of Medicine, National Jewish Health, Denver, United States; 4Biostatistics, University of California, Irvine, City, United States; 5R&D Centre, Almirall, S.A., Barcelona, Spain; 6Clinical Development, Forest Research Institute, Jersey City, United States

Introduction: Aclidinium bromide is a novel, long-acting muscarinic antagonist currently under investigation for the maintenance treatment of COPD. Safety data from a long-term efficacy and safety trial of twice-daily (BID) aclidinium are presented here.

Methods: In this 52-week study, moderate-to-severe COPD patients were randomised (1:1) to receive aclidinium 200 μg or 400 μg BID. Safety was assessed via adverse events (AEs), vital signs, and 12-lead ECG.

Results: A total of 605 patients were randomized, and 602 (99.5%) were included in the safety population. Postbronchodilator FEV1, and percent predicted at screening were (mean ±SD) 1.55±0.54 L and 52.3±13.2 L. The incidence of AEs was similar across the aclidinium 200 μg and 400 μg groups and most were mild or moderate. The most common AE and most frequently reported AE leading to discontinuation was COPD exacerbation, with a similar percentage of patients between groups who discontinued due to exacerbations (200 μg, 9 (2.9%); 400 μg, 8 (2.7%)).

The incidence of typically expected anticholinergic AEs was low and similar between groups (e.g. dry mouth: 200 μg, 1.3%; 400 μg, 2.7%; constipation: 200 μg, 2.9%; 400 μg, 1.7%). Cardiac and cerebrovascular AEs did not occur in a dose-related manner. The 200 μg and 400 μg groups had similar incidences of serious AEs, with values (n (%)) of 29 (9.3%) and 29 (10.0), respectively. One patient in each treatment group died during the study (200 μg, biliary sepsis; 400 μg, subarachnoid hemorrhage), but neither death was deemed to be related to treatment.

Conclusions: Twice-daily aclidinium 200 μg and 400 μg were safe and well tolerated over 52 weeks with a similar safety profile for both doses.

P2119 Effect of augmentation therapy on immune function of patients with severe Alpha-1-antitrypsin deficiency

Ilaria Ferrarotti1, Tomas P. Carroll2, Simona Inghilleri3, Stefania Ottaviani4, Maurizio Luissi5, Noel G. McElvaney6, 1Dept of Molecular Medicine, Pneumology, IRCCS San Matteo Hospital Foundation, University of Pavia, Italy; 2Dept of Medicine, Respiratory Research Division, Royal College of Surgeon on Ireland, Education and Research Centre, Beaumont Hospital, Dublin, Ireland

Alpha-1 antitrypsin (AAT) deficiency is a hereditary disorder caused by mutations in the SERPINA1 gene. Individuals homozygous for the most common mutation Z have markedly reduced AAT concentrations and are predisposed to developing early-onset emphysema. Approximately 3% of AATD individuals have other deficiency alleles including Null alleles which do not express AAT. Although AAT production in monocytes is relatively small in comparison with hepatocytes, local regulation of the antiprotease shield represents an important first line of defence in times of infection and inflammation.

Our aim was to investigate the anti-inflammatory properties of AAT by studying individuals homozygous for Null mutations who were receiving augmentation therapy with human plasma derived AAT, and comparing them to ZZ individuals and MM healthy controls.

We isolated peripheral blood monocytes from Null/Null and ZZ patients (with/without therapy), and comparing them to ZZ individuals and MM healthy controls.

Augmentation therapy was used to alternate IL-4 and IL-8 production from ZZ monocytes at both. Moreover, we noted a reduced chemotactic activity and superox-
ide production in AATD individuals receiving augmentation therapy in comparison to untreated AATD patients.

Augmentation therapy in AATD individuals (ZZ and Null/Null) appears to modulate immune function and may provide a rationale for reduced exacerbations in subjects receiving augmentation therapy.

P2120 NFAT subtypes in regulating Th2 lymphocytes

Xin Yao1, Yue Teng1, Hao Huang1, Ian Adcock2, Peter Barnes1. 1Respiratory Medicine, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; 2Asthma Disease, NHLL, Imperial College, London, United Kingdom

Methods: Nuclear factor of activator T cells (NFAT), consists of five members and plays a pivotal role in regulating T lymphocyte activation. Among the five subtypes of NFAT, NFAT1, NFAT2, and NFAT4 were recognized as the key family members associated with allergic diseases. However, evidence regarding the functions of NFAT1 and NFAT2 in Th2 cells are still conflicting.

Aims and objectives: Therefore, we explored the functions of NFAT1 and NFAT2 on Th2 lymphocytes.

Methods: Knockdown of NFAT1 and NFAT2 using small interfering RNA (siRNA) was performed in the murine Th2 lymphocyte cell line (D10.G4.1). Real-time qPCR, Western Blotting and ELISA were performed to test the relative expression of Th2 cytokine mRNA and protein in cells and culture supernatant.

Results: D10 cells express IL-4, IL-5, IL-13 and GATA3 mRNA level. NFAT1 siRNA and NFAT2 siRNA selectively suppressed the expression of NFAT1 and NFAT2 respectively at both the mRNA and protein level. Higher levels of IL-4, IL-5 and IL-13 were seen in NFAT1 siRNA treated Th2 cells. This suggests that NFAT1 may play a negative role in Th2 cytokine expression. Interestingly, the opposite effect was seen with NFAT2 siRNA. NFAT2 siRNA down-regulated the expression of IL-4, IL-5 and IL-13 mRNA levels. This was associated with a reduction in the expression of GATA3 mRNA and protein.

Conclusions: NFAT1 may play a negative role in regulating Th2 cytokines whilst NFAT2 may have the opposite effect.

P2121 Umeclidinium (GSK573719) dose response and dosing interval in COPD

Akison Church1, Misha Beerahare2, Jean Brooks2, Rashmita Mehta2, Palvi Shah1. 1GlaxoSmithKline, Research Triangle Park, Durham, NC, United States; 2GlaxoSmithKline, GlaxoSmithKline R&D, Stevenage, United Kingdom

Introduction: Dose differentiation is important in selecting COPD treatments.

Objective: Characterize Umeclidinium (UMEC), a long-acting muscarinic antagonists, dose response in COPD patients.

Methods: Randomized, double-blind, placebo-controlled, crossover study. Subjects were randomized to a sequence of 3 treatments for 7 days separated by a 10-14 day washout. Four once-daily (OD) UMEC doses (15.6, 31.25, 62.5, 125mcg) or two twice-daily (BID) doses (15.6, 31.25mcg) were administered via dry powder inhaler: Tiotropium (18mcg) was an active control. Primary endpoint was morning trough FEV1; on Day 8; population model analysis was applied with ANCOVA. Population model analysis was applied with ANCOVA.

Results: 163 subjects (mean age 59.5yrs, 52% female) were randomized. Emax results were similar. 125mcg OD had more improvement in trough FEV1, was characterized with OD dose ordering of UMEC compared to placebo (n=115) for 24 weeks. Primary endpoint: trough FEV1 at 24 weeks. Powered secondary endpoint: change from baseline in % rescue-free 24h periods over 24 weeks. Safety assessments included adverse events (AEs), incidence of severe exacerbations and 24h urinary cortisol (UC) excretion.

Results: FF and FP significantly improved trough FEV1 compared with placebo (diff. 146mcL [p=0.009] and 145mcL [p=0.011], respectively). Significantly more % rescue-free 24h periods were reported for FF (44.8%) and FP (17.9%) than placebo (both p<0.001). Incidence of on-treatment AEs: FF 53%, FP 42%, placebo 40%. Incidence of on-treatment severe exacerbations: FF 3%, FP 2%, placebo 7%. Statistically significant UC suppression was seen with FF (t7=0.76, p=0.030) and FP (t7=0.77, p=0.036), relative to placebo.

Conclusions: FF 100mcg OD significantly improved trough FEV1 to a similar extent to FP 250mcg BD and reduced rescue use relative to placebo. FF was well tolerated with a similar AE profile and effect on 24h UC to FP. Funded by GSK (FAA1205P). NCT01159912.

P2122 Apolipoprotein A1 (ApoA1) abrogate cigarette smoke induced emphysema in mice

Dojin Kim1, SsongWoo Park1, Jae Jeong Shim2. 1Pulmonary, Soonchunhyang University Bucheon Hospital, Bucheon, Gyeonggi, Republic of Korea; 2Pulmonology, Korea University Guro Hospital, Seoul, Republic of Korea

Rationale: Apolipoprotein A-1 (ApoA1) have anti-inflammatory and antioxidant properties as well as cholesterol efflux.

Objectives: To determine if the expression of human ApoA1 within the lung protect against the development of emphysema.

Methods: Transgenic human ApoA1 mice (ApoA1 TG) were exposed to CS for 6 month and compared to control transgenic mice. Other ApoA1 TG mice were treated with intratracheal elastase in order to generate emphysema. Measurement; Lung inflammation, oxidative injury was measured in the lung. Emphysema was determined by measuring the mean intercept (Lm). Proinflammatory cytokines in the BALF were measured by ELISA and analysis of apoptosis using the TUNEL assay.

Results: Compared with control TG mice, ApoA1 TG mice had significantly less lung inflammation, oxidative damage and apoptosis as well as decreased levels of proinflammatory cytokines. ApoA1 attenuated the development of emphysema in both the smoke-induced and elastase-generated models.

Conclusions: Overexpression of ApoA1 prevents CS and elastase induced emphysema in mice. Augmentation of ApoA1 in the lung could be effective for the prevention or treatment of emphysema/COPD.

P2123 Efficacy and safety of once-daily (OD) fluticasone furoate (FF) in patients with persistent asthma: A 4-week randomised trial

Ian Lovel1, Eugene Bleecker2, William Buse3, Paul O’Byrne4, Ashley Woodcock5, Eric Bateman5, Edward Kerwin6, Sally Stone7, Richard Forth8, Loretta Jacques8, 1Krafting Research Centre, University of Grothenburg, Sweden; 2Center for Genomics and Personalized Medicine, Blake Forest University Health Sciences, Winston-Salem, NC, United States; 3Department of Medicine, University of Wisconsin, Madison, WI, United States; 4Department of Medicine, University of Michigan, Hamilton, ON, Canada; 5School of Translational Medicine, University of Manchester, United Kingdom; 6Department of Medicine, University of Cape Town, South Africa; 7Allergies & Asthma Center, Clinical Research Institute of Southern Oregon, Medford, OR, United States; 8Respiratory Medicine Development Centre, GlaxoSmithKline, Uxbridge, United States; 9Quantitative Sciences Division, GlaxoSmithKline, Research Triangle Park, Durham, NC, United States

Introduction: The inhaled corticosteroid (ICS) CS is under development as a OD monotherapy for asthma and in combination with the OD long-acting beta antagonist montelukast for asthma and COPD.

Objectives: To evaluate the efficacy and safety of FF in patients ≥12 years with persistent asthma uncontrolled on a stable low-to-mid dose of ICS (≤500mcg fluticasone propionate [FP] equivalent total daily dose).

Methods: In this double-blind, double-dummy, placebo-controlled study, patients (N=343; ITT) received FF (100mcg OD in the evening via a new dry powder inhaler; n=114), FP (250mcg twice daily [BD] via DISKUS™; n=114) or placebo (n=115) for 24 weeks. Primary endpoint: trough FEV1 at 24 weeks. Powered secondary endpoint: change from baseline in % rescue-free 24h periods over 24 weeks. Safety assessments included adverse events (AEs), incidence of severe exacerbations and 24h urinary cortisol (UC) excretion.

Results: FF and FP significantly improved trough FEV1 compared with placebo (diff. 146mcL [p<0.009] and 145mcL [p<0.011], respectively). Significantly more % rescue-free 24h periods were reported for FF (44.8%) and FP (17.9%) than placebo (both p<0.001). Incidence of on-treatment AEs: FF 53%, FP 42%, placebo 40%. Incidence of on-treatment severe exacerbations: FF 3%, FP 2%, placebo 7%. Statistically significant UC suppression was seen with FF (t7=0.76, p=0.030) and FP (t7=0.77, p=0.036), relative to placebo.

Conclusions: FF 100mcg OD significantly improved trough FEV1 to a similar extent to FP 250mcg BD and reduced rescue use relative to placebo. FF was well tolerated with a similar AE profile and effect on 24h UC to FP. Funded by GSK (FAA1205P). NCT01159912.

P2124 RC kinase: A novel kinase expressed by alveolar macrophages that may play a role in COPD and IPF

Stefan Boegh1, John Ludvik1, Danielle DiTrillo2, Ana Lucia Coelho3, Cory Hogaboam4, Tai Wei Ly5, Kevin Bacon1. 1Department of Biology, Axikon Pharmaceuticals, Inc., San Diego, CA, United States; 2Department of Pathology, University of Michigan, Ann Arbor, MI, United States; 3Department of Medicine, Michael G DeGroote School of Medicine, Hamilton, ON, Canada; 4Department of Medicine, University of Cape Town, South Africa; 5Allergies & Asthma Center, Clinical Research Institute of Southern Oregon, Medford, OR, United States; 6Analysis & Asthma Center, Clinical Research Institute of Southern Oregon, Medford, OR, United States; 7Allergy & Asthma Center, Clinical Research Institute of Southern Oregon, Medford, OR, United States

We have characterized a novel serine/threonine protein kinase, called RC kinase, that revealed expression in CD68+ alveolar macrophage and bronchial epithelial cells. Various cell lines upregulated RC kinase expression upon exposure to cigarette smoke extract, or conditions of oxidative or endoplasmic reticulum stress, and this
correlated with the production of IL-8. In acute (4 day) and sub-chronic (14 day) cigarette smoke-induced murine models of COPD, treatment with either intra-tracheally delivered KC kinase siRNA or orally administered novel and specific small molecule inhibitors caused a significant reduction in BAL neutrophilia, as well as decreased levels of KC and CCL-20. There was also a marked reduction in the amount of pulmonary inflammation. In a murine adoptive transfer model of idiopathic pulmonary fibrosis, both siRNA and small molecule antagonist treatment significantly inhibited hydroxyproline production, inflammation and cellular and biochemical markers of fibrosis. Taken together, these results strongly suggest that inhibition of TNF-α may provide a novel therapeutic approach for the treatment of COPD and IPF.

P2125
Statins worse pulmonary fibrosis through enhancing NLRP3 inflammasome activation

Jin-Fu Xu1,2, George R. Washko3, Hui-Ping Li1, Augustine M.K. Choi2, Gary M. Hunninghake1,3,4,5.
1Department of Pulmonary Medicine, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; 2Pulmonary and Critical Care Division, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, United States

The role of statins is controversial. To evaluate the association between statin use and interstitial lung abnormalities (ILA) in a large cohort of smokers from COPDGene. Next, we evaluated the effect of statin pretreatment on bleomycin-induced fibrosis in mice and explored the mechanism behind these observations in vitro. In COPDGene, 38% of subjects with ILA were taking statins compared to 27% of subjects without ILA. Statin use was positively associated in ILA (odds ratio [OR] 1.60, 95% confidence interval [CI] 1.03-2.50, P=0.04) after adjustment for covariates including a history of high cholesterol or coronary artery disease. This association was modified by the hydrophilicity of statin and the age of the subject. Next, we demonstrate that statin administration aggravated lung injury and fibrosis in bleomycin-treated mice. Statin pretreatment enhances caspase-1-mediated immune responses in vivo and in vitro; the latter responses were abolished in bone marrow-derived macrophages (BMDM) isolated from Nlx-1-KO and Lpr-Gld mice. Finally, we provide further insights by demonstrating that statins enhance NLRP3-inflammasome activation by increasing mitochondrial reactive oxygen species generation in macrophages. Statin use is associated with ILA among smokers in the COPDGene study and enhances bleomycin-induced lung inflammation and fibrosis in the mouse through a mechanism involving enhanced NLRP3-inflammasome activation. Our findings suggest that clinicians should be aware that radiological evidence of ILD can develop in some COPD patients treated with statins.

P2126
Effects of combination of PI3Kδ and δ inhibitors on airway hyperresponsiveness in tobacco smoke-exposed mice

Yasuo Kurosawa1,2, Kenji Kikutani3,4, Keitaro Usuda5, Yuji Watanabe5, Shouichi Eto6,7, Tadashi Kusama1,2, Imperial College, London, United Kingdom

PI3Kδ and γ are known to be involved in inflammatory cell functions. We recently found upregulation of PI3Kδ in lung tissue of COPD patients and ability of a PI3Kδ inhibitor to restoration of steroid sensitivity in airway inflammation in tobacco-smoke (TS) exposed mice. Superior effects of combination of PI3Kγ and δ inhibitors to each inhibitor alone on airway inflammation in TS-exposed mice were also observed. The aim of this study is to evaluate role of PI3Kγ and δ in lung hyperresponsiveness (AHR) in TS-exposed mice. A/J mice were exposed to TS for 11 days and C57BL/10ScSn (C57) and/or fluticasone propionate (FP) were administered intranasally twice a day for 3 days after the last TS exposure. Airway responsiveness was determined as the increment of airway resistance (Δ(Raw)/Tdy) before and 1 min after histamine at 24 h after the last drug dosing. The effects of the PI3Kδ inhibitors on the contractile response to carbachol in guinea-pig tracheal smooth muscle preparation were also evaluated by the isometric tension recording. The concentration-response curve of carbachol was shifted to rightward and reduced the maximal response by AS (10-100 μg/ml) was limited in the tracheal smooth muscle. The AHR induced by TS was significantly reduced by AS (4 mg/ml; by 56% inhibition) and IC (4 mg/ml; 43%) alone. The inhibitory effects were enhanced by combination treatment of AS and IC (69%). Moreover, the combination of IC and FP showed stronger inhibition (96%) on the AHR. Considering with our previous findings, the combination of a PI3Kδ or PI3Kδ/δ inhibitor with corticosteroid may offer potential treatment of COPD.

P2127
A robust translational model of acute exacerbations in the tobacco-smoke and pol IC treated mouse

Vincent Russell1, Paul Woodman, Andrew Connolly, Diagne Spicer, Joanna Dlugozma, Alan Young. Pharmacology, Astranka, Stoke Court, Slough, United Kingdom

Exposure to tobacco smoke (TS) for 4 days induces steroid-insensitive lung inflammation in mice. The effect of adding the viral mimetic poly IC (PIC) to TS-exposed mice was examined.

Methods: Mice were exposed daily to either TS or air for 4d. Saline or PIC was administered intra-nasally. The time course of lung inflammation was examined 4-120hrs after the last exposure and cell numbers measured in the BAL fluid. The acute effects of oral Dexamethasone (DEX) 0.3mg/kg) or Rosflumilast (ROF 5mg/kg) on the peak inflammation were examined. The effects of DEX on the kinetics of the enhanced inflammation were also examined.

Results: TS caused a lung inflammation which was inhibited by ROF but not by DEX. PIC alone induced an inflammation that was not inhibited by DEX or ROF. Dosing PIC in addition to TS induced an exaggerated response that was significantly greater than the additive effect of the two stimuli. The enhanced response peaked 24hrs after the last exposure then slowly declined. Neutrophils were predominant over the first 48 hrs. Macrophage numbers increased at 24-72hrs and lymphocyte numbers peaked at 48-72hrs. The peak inflammation after TS/PIC exposure was significantly inhibited by ROF (56%, p<0.05) and DEX (56%, p<0.05), in contrast to the lack of efficacy of DEX against TS or PIC alone. A single dose of DEX after the last exposure reduced the exaggerated response over the entire 120hr study period, but did not fully resolve the inflammation.

Conclusions: TS exposure for 4 days induced a steroid-insensitive lung inflammation. Addition of PIC markedly enhanced the inflammatory response which was sensitive to both steroids and roflumilast, mimicking features of human COPD.

P2128
Inhaled cationic salts modulate macrophage function to reduce inflammation during LPS induced lung injury

S.P. Arold1, E.L. Berry, D. Rosa, P.A. Satu, S. Kong, P.L. Wright, R.W. Clarke1, D.L. Hava2, Research, Pulmatrix, Lexington, MA, United States

Pulmatrix is developing PUR118 as a host-targeted, dry powder therapy based on the inhalation of calcium salts for acute exacerbation (AE) control in chronic obstructive pulmonary disease and other inflammatory lung disease. Preclinical data suggest that this approach is effective against an array of pathogens and also reduces inflammation resulting from environmental stimuli such as tobacco smoke. We hypothesized that this treatment could have a beneficial effect in reducing lipopolysaccharide (LPS) induced lung inflammation by modulating the function of pulmonary macrophages. Mice were exposed to nebulized LPS (Pseudomonas aeruginosa) and PUR118, was delivered via a whole body exposure 1h post-LPS challenge. Four hours after LPS exposure inflammatory cell counts and chemokine and cytokine concentrations were determined in BAL. PUR118 treatment decreased total inflammatory cell counts and neutrophils in the BAL fluid of LPS challenged mice and correlated with reduced KC, IL-6 and TNF-α in BAL fluid. Separately, peritoneal macrophages were isolated from naïve mice and challenged with LPS in media supplemented with calcium to simulate conditions thought to be found in lung fluid lining after PUR118 treatment. Inflammatory mediator secretion and gene expression were determined 2h post LPS exposure. Macrophages stimulated with LPS in the presence of calcium exhibited a dose dependent decrease in KC, IL-6 and TNF-α secretion as compared to LPS-stimulated cells. Preclinical data from in vivo and in vitro studies strongly suggest that clinicians can be used to reduce lung inflammation and may reduce the risk of AE caused by infections during chronic lung disease.

P2129
Inhaled calcium salts reduce expression of inflammatory mediators associated with tobacco smoke exposure to reduce airway inflammation

P.L. Wright1, 2, 3, P. Woodman1, 2, D. Spencer1, 2, K. Kenyon1, P. Okerholm1, V. Russell1, 2, R.W. Clarke1, D.L. Hava1, Research, Pulmatrix, Lexington, MA, United States; 1Respiratory, Asthma, Slough, United Kingdom

PUR118, an inhaled calcium based dry powder (DP) formulation exhibits preclinical anti-inflammatory and anti- infective activity. PUR118 may provide a novel approach for acute exacerbation control in patients with COPD and CF where the combination of underlying inflammation and pathogen infection results in reduced lung function and quality of life. The goal of this study was to evaluate the impact of PUR118 on gene expression in lung samples from a tobacco smoke (TS) exposure model. Mice were exposed to TS for 4d and treated with PUR118 or DP control 1h prior to TS. Mice were euthanized 4h after the last TS exposure and BAL and lung RNA were collected for cell counts, protein levels and QPCR analyses. Expression of 336 genes was evaluated using targeted QPCR arrays. TS exposure increased BAL cell counts that were reduced with PUR118 (79% reduction in neutrophils; p<0.005) and DEX (56%, p<0.05). Among genes found
downregulated with PUR118 treatment, many were associated with neutrophilic inflammation including: KC, MIP2, ENA78, IL-6, and MCP-1. BAL protein levels of several of these were similarly reduced by PUR118 compared to controls. Thus, PUR118 diminishes the inflammatory signals induced by TS exposure including many key drivers of neutrophilic inflammation at both the gene and protein level as a mechanism to reduce airway inflammation.

P2130

Protection against allergen-induced airway hyperresponsiveness (AHR) by olodaterol in guinea pigs is synergistically enhanced by tiotropium

Marieke Smits1,2, Annet Zoetelof2, Sophie Bos1,2, Harm Maarsingsh1,2, Renoud Gosens1,2, Johan Zsagka1,2, Herman Meers1,2, Department of Molecular Pharmacology, University of Groningen, Netherlands; 3Groningen Research Institute for Asthma and COPD, University of Groningen, Netherlands

The ultra-long acting β2-agonist olodaterol has shown to be effective in asthma and COPD. Increased cholinergic tone, common to these diseases, may reduce β2-agonist responsiveness. In a guinea pig model of asthma, we investigated the protective effect of olodaterol combined with tiotropium. AHR was measured in the whole lung after a single injection of ovalbumin (OA), 1 h before OA, an intravenous injection of OA (4.9-fold decrease in PC100 compared to baseline), which was fully protected by olodaterol (2.3-fold increase in PC100), and tiotropium (1.3-fold increase). When combined, a synergistic 4.8-fold increase in PC100 was observed. After the LAR, AHR (2.8-fold decrease), was also protected by olodaterol, tiotropium and their combination (1.5-, 1.3- and 1.6-fold increase in PC100, respectively). OA-induced infiltration of inflammatory cells, measured by BAL, after the LAR, was not affected by any treatment. In conclusion, in a guinea pig model of asthma olodaterol and tiotropium protect against allergen-induced AHR after the EAR and LAR, without affecting inflammatory cell influx. Synergism between the drugs was found after the EAR, indicating that acetylcholine reduces the effectiveness of the β2-agonist and that the combination of olodaterol and tiotropium may be beneficial in the treatment of allergic asthma. Effects of N-acetylcysteine on airway inflammation, airway hyperresponsiveness and abnormal lung function in chronic ozone-induced COPD model

Feng Li1, Cornelis Wiegman2, Joanne Seiffert3, Pankaj Bhavsar4, Fan Chung5

1Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom; 2Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom; 3Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom; 4Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom; 5Department of Clinical Sciences, Faculty of Veterinary Medicine, University of Tabriz, Islamic Republic of Iran; 6Department of Pathobiology, Faculty of Veterinary Medicine, University of Tabriz, Islamic Republic of Iran; 7Tuberculosis and Lung Disease Research Center, Faculty of Medicine, Tubriz Medical University, Tubriz, Islamic Republic of Iran; 8Department of Clinical Sciences, Faculty of Veterinary Medicine, University of Tubriz, Islamic Republic of Iran

Background: Chronic exposure to ozone in mice induces chronic lung inflammation and emphysema, features of COPD. We determined to examine the preventive and therapeutic effects of N-acetylcysteine (NAC) on airway inflammation, airway hyperresponsiveness (AHR) and abnormal lung function.

Method: C57BL/6 mice were exposed to air or ozone (3ppm, 3h), twice a week over 6 wk, and then ozone exposure was discontinued for 6 wk. NAC treatment (100mg/kg, i.p. twice a week; for 6 wk) was carried out during exposure period or cessation period. Pulmonary function and airway responsiveness were measured and total cells and neutrophils cell in BALF were counted.

Results: Compared with air exposed mice, lung volume indices TFC, FRC, FVC were increased and respiratory indices FEV25/FVC, FEV50/FVC were decreased in ozone exposed mice and continued after ozone cessation. NAC inhibited AHR during cessation period. Total cells and neutrophils in BALF were increased in ozone exposed mice and returned to normal after ozone cessation. NAC given during exposure period reduced the total cell counts, but not the neutrophil counts.

Conclusions: AHR and abnormal lung function persisted in ozone induced COPD model despite cessation of ozone exposure. Though NAC had no effect on neutrophilic inflammation or abnormal lung function in ozone-exposed mice, it did inhibit AHR during cessation period. NAC interferes with airway smooth muscle dysfunction caused by chronic oxidative stress.

P2132

Interaction of the glutamatergic and nitricergic signaling system in the airway hyperactivity

Anna Strapkova, Martin Antosova, Department of Pharmacology, Comenius University, Jessenius Faculty of Medicine, Martin, Slovakia (Slovak Republic)

It is only little information regarding a possible interaction of glutamatergic and nitricergic system in the airways hyperactivity (AHR). We investigated the effect of agents modulating the activity of these systems on the experimental ovalbumin-induced AHR as well as on the changes of exhaled nitric oxide (eNO) levels. We used the agonists of NMDA receptors - N-methyl-D-aspartic acid (NMDA) and monosodium glutamate (MSG), selective competitive antagonist (D,L-2-amino-5-phosphonovaleric acid – AP-5) and selective non-competitive antagonist (dizocilpine - MK-801) of these receptors. We used also non-specific inhibitor of NO synthases N-omega-nitro-L-arginine metylester (L-NAME). The AHR to histamine or acetylcholine was evaluated in in vitro conditions. NMDA administration caused the increase of tracheal smooth muscle response in ovalbumin-induced HR to acetylcholine. The effect of MSG was less pronounced. MK-801 as well as AP-5 provoked the decrease of reactivity mainly to acetylcholine in tracheal smooth muscle, while the former, non-competitive antagonist was more effective. We recorded the changes in eNO levels. The activation of NMDA receptor with NMDA or MSG increased eNO levels. The inhibition of NO synthesis with L-NAME caused the fall of eNO levels. We suppose here the participation of constitutive isoforms of NO synthases mainly. MK-801 shows the more expressive effect on the eNO levels lowering sensitivity than other studied drugs. These results bring a whole new look regarding the relationship of the glutamatergic and nitricergic system in the airway inflammatory diseases.
Conclusion: Doxofylline significantly reduced cell transmigration in response to LPS, supporting an anti-inflammatory action.

P2135
Protective effect of fenpirofene on bronchi in rats with COPD
Natalia Kurenkova1, Elena Lebedeva1, Anatoly Fedin2, Ivetta Dvorakovskaya1.
1Laboratory of Chronic Obstructive Lung Pathology, Research Institute of Pulmonology at I.P.Pavlov's State Medical University, St. Petersburg, Russian Federation; 2Laboratory of Comparative Respiratory Physiology, I.M.Sechenov’s Institute of Evolutionary Physiology and Biochemistry, St. Petersburg, Russian Federation

Corticosteroid resistance in COPD is urgent problem so the search for drugs that have bronchodilator and anti-inflammatory effect at all stages of COPD is needed.

Aim: To study effect of non-corticosteroid drug fenpirofene (F) on contractile activity of bronchial smooth muscle (SM) in rats with COPD.

Methods: Model of COPD was induced in rats by nitrogen dioxide (NO2) exposure (15 ppm, 1,5 h/day, 60 days). F (0.15 or 1.5mg/kg) was administered per os daily before exposure to NO2. Control rats received 0.9% NaCl. Isometric contraction of bronchial segments caused by electrical stimulation (st) of preganglionic nerve or SM was recorded by displacement electromechanical transducer.

Results: Treatment with F at the acute stage of COPD (15 days) prevented the bronchial constrictor effect of NO2. Contractile reactions of bronchi were lower than in control with st both nerve (89.4%; 107.2%; for 0.15 and 15 mg/kg, control 118.5%; p < 0.05) and SM (89.5%; 88.4%; for 0.15% and 3.3% respectively, p < 0.05).

Dilatation effect of low dose F was mediated by interaction with capsaicin sensitive C-fibers that prevented the initiation of neurogenic inflammation as evidenced by lack of COPD structural changes in lungs. At stage of COPD (60 days) bronchodiator effect of low dose F did not appear; high dose F caused a greater SM relaxation with st muscle st (70.3%; 63.4%) than nerve st (91.2%; p < 0.05). Effect of high dose F was mediated not only the afferent component but due to its direct relaxing effect on SM.

Conclusion: Mechanism of F action on bronchial SM depends on its dose. Revealed bronchodilator and anti-inflammatory effect of extremely low dose F can be used for prevention of COPD development in persons exposed to aggressive environmental factors.

P2136
Effects of corticosteroid and montelukast treatment in inflammation in guinea pigs with chronic allergic inflammation
Nahalia Gobba1, Flavia Souza1, Carla Prado2, Milton Martins1, Jolanda Tiberio2, Edna Leick1.
1Medicine, School of Medicine University of São Paulo, Brazil; 2Biological Sciences, Universidade Federal de São Paulo, Brazil

The effects of montelukast or dexamethasone in asthma pathophysiology are barely understood. We evaluated the inflammation and the eosinophilic recruitment in distal lung parenchyma and airway walls in guinea pigs (GP) with chronic allergic inflammation. GP were inhaled with ovalbumin (OVA group-2xweek/4weeks). After 4th inhalation, GP were treated with montelukast (M group-10mg/kg/PD/day) or dexamethasone (D group-5mg/kg/IP/day). After 72 hrs of 7th inhalation, GP were anesthetized, lung strips were submitted to histopathological evaluation. On distal parenchyma both montelukast and dexamethasone were effective in reducing the number of eosinophils, RANTES and NF-κB positive cells compared to OVA group (p < 0.05). Montelukast was more effective in reducing the eosinax positive cells compared to dexamethasone treatment (p < 0.05). There was a more expressive reduction of IGF-1 and RANTES positive cells compared to OVA group (p < 0.05). Dexamethasone was more effective in reducing the number of eosinax and NF-κB positive cells than Montelukast (p < 0.05).

Conclusions: In this animal model, both corticosteroid and montelukast treatments contribute to the control of the inflammatory response in distal lung parenchyma and airway walls. Dexamethasone treatment induced a greater reduction of NF-κB expression in airway walls which supports one of the mechanisms that explains the higher efficacy of this therapeutic approach. Acute lung injury (ALI) induced by lipopolysaccharide (LPS) exposure is characterized by cellular infiltrate, edema and altered airway responsiveness. Traditional treatments for ALI include strategies of mechanical ventilation and a variety of drugs such as, corticosteroids and other disease-modifying agents. However these conventional therapies may cause important side-effects that compromise long term therapies. In this sense, Low Level Light Therapy (LLLT) have already demonstrated promising data in reducing airway inflammation. Thus, in the present study we investigated the ability of LLLT to modulate neutrophil infiltration to the lungs. For that, Balb/c mice were submitted to daily doses of 10 mg of LPS for 3 consecutive days. LLLT group were submitted to irradiation daily at 2. 4 and 6 hours after LPS. CONTROL group received PBS and were not irradiated. On day 4, 24 hours after LPS exposure animals were sacrificed and LBA cellular, cytokine secretion and airway reactivity by FlexiVent were analyzed. Our results demonstrate a significant decrease in total cells and neutrophils recovered from the bronchoalveolar lavage (BAL) of LPS-treated animals after LLLT. We also detected reduced amounts of IL-6 but not IL-17 after LLLT. Airway reactivity to metacholine (MCh) also reduced. In conclusion, our data reveals a promising role for LLLT as an alternative therapeutic approach for acute lung inflammation.

P2138
Effect of CCR3 inhibitors on allergic airway responses in ascaris-sensitized cynomolgus monkeys
Edward Barrett1, Karin Rudolph1, Chris Royer1, T. Loy2, S. Boehm2, Kevin Bacon3.
1Respiratory Immunology, Lovelace Respiratory Research Institute, Albuquerque, United States; 2Laboratory of Comparative Respiratory Physiology, I.M.Sechenov’s Institute of Evolutionary Physiology and Biochemistry, St. Petersburg, Russian Federation

Aim: CCR3 has historically been associated with the functional responses of eosinophils in various models of allergic disease. The goal of this study was to determine whether pre-treatment with CCR3 inhibitors via oral and inhaled routes attenuates asthma responses in ascaris sensitized Cynomolgus monkeys.

Methods: Animals received either oral (AP0 5 mg/kg, BID 10 days) or by inhalation (AR1) once or twice a day for 10 or up to 21 days prior to inhalated ascaris challenge. Changes in airway function (immediate and methacholine [MCh]) and inflammation (BAL & blood cells) were evaluated.

Results: Oral (AP0 5 mg/kg; BID 10 days) or inhaled (AR1 860 μg; BID 7 days) treatment showed a trend towards a reduced immediate ascaris and MCh response but did not reach statistical significance. A longer oral treatment (AP0 3 mg/kg; QD 20 days) resulted in a significant additive or synergistic effect on airway function but did lead to a greater reduction in BAL and blood eosinophils than AP0 or fluticasone alone.

Conclusion: Treatment with a CCR3 inhibitor in the non-human primates, Ascaris model of asthma, shows that a number of critical parameters can be affected which are significantly different to alterations in the recruitment of eosinophils. Overall, these observations suggest that CCR3 inhibition may have more global beneficial responses in an asthmatic setting than previously appreciated.

P2139
PK/PD profiles of the CXCL8 decoy protein PA401 after intravenous and intratracheal administration in saline and LPS exposed mice
Faziana Adage, Angelika Falstone, Robert Dothoms, Mike Bartley, Andreas Kampf.
Pharmacology, Pharmazeutisches und Protein Engineering, ProAafia Biotechnologie AG, Graz, Austria

Neutrophils play a crucial role in acute and chronic lung diseases including ALI, COPD, and severe asthma, and their presence in the lung has been correlated to disease severity and progression. Among the mediators of neutrophil recruitment into the lung CXCL8 is considered the major player. CXCL8 exerts its chemotactic activity by binding to glycosaminoglycan (GAG) co-receptors on inhaled cells, thus creating a solid-phase haptotropic gradient and being properly presented to GPC receptors CXCR1/2 on neutrophils. We have engineered higher affinity for GAGs into human CXCL8 obtaining a protein-based competitor for the CXCL8/GAG interaction. By further knocking-out the GPCR domain, we have obtained a decoy protein (PA401) with potent anti-inflammatory characteristics.

PA401 has been tested in murine models of lung inflammation induced by lipopolysaccharide (LPS) showing strong dose-dependent neutrophil reduction in bronchoalveolar lavage fluid (BALF) after intravenous (IV) and subcutaneous (SC) administration. In the present study we have compared PA401 activity after IV and intratracheal (IT) administrations in the same model, using saline exposed mice as control. PA401 plasma levels were also measured to assess pharmacokinetic profiles. PA401 has strongly reduced BALF neutrophils number after IV and IT administration (up to ~76%). The blood cells increase due to LPS exposure was also partly normalized by IV, but not IT treatment, possibly due to the differences in plasma exposure. PA401 is a new biotherapeutic with a unique mode of action interfering with lung neutrophilic inflammation and with activity after systemic and local delivery to the lung.

Aerodynamic characteristics of dry powder inhaler (DPI) single-dose combination of budesonide with formoterol in vitro study validation
Ana Lucena Lima 1,2, Zaine Martha Andrade Lima 1,2, Leonardo Faria de Souza 1,2, Vinicius Matos dos Santos 1,2, Ana Lucinda Ribeiro 1,2, Ana Fernanda Siqueira 1,2, Laila Valéria Seijas Filho 1,2, Luis F. Pereira 1,2, Z. Medicine-Respiratory Division, Federal University of São Paulo, SP, Brazil; 2Pneumology, Hospital Pró-Cardáico, Rio de Janeiro, RJ, Brazil; 3Pneumologia, Hospital das Clinicas do UFMG, Belo Horizonte, MG, Brazil

Background: The aerodynamic properties of dry powder inhalers are essential for drug efficacy. Despite the availability of several devices, few studies have measured aerodynamic characteristics of the drug delivery using their proper device. Aim: To describe the aerodynamic characteristics of the combination dry powder inhaler (DPI) Alexina 1 single-dose AeroCops®(AA), which contains budesonide (BUD) and formoterol fumarate (FF) when compared with ForaSEF® Aerolizer®(FA) as the reference combination drug. Methods: They were assessed using quantitative sample analysis by high pressure liquid chromatography (HPLC), dose uniformity sampling apparatus (DUSA) and Andersen cascade impactor (ACI) to confirm the presence of active ingredients as well as the uniformity of released dose and the aerodynamic diameter of particles produced by their proper devices.

Results: Table 1 summarize the experiments.

Consider the turbulent energy not inhalation flow when patients use dry powder inhalers (DPIs)
Wahida Arozoo1, Philip Chetcuti2, Harold Hosker3, Dinesh Saralayas4, Anke Sichelstiel5, 6, 1Pharmacy, University of Huddersfield, United Kingdom; 2Pharmaceutics, Leeds General Infirmary, Leeds, United Kingdom; 3Respiratory, Bradford Royal Infirmary, Bradford, United Kingdom; 4Respiratory, Airedale General Hospital, Keeton, United Kingdom

During an inhalation the formulation of a DPI is de-aggregated by a turbulent energy created by the interaction between the DPI’s internal resistance and the patient’s inhalation flow. We have measured the inhalation profiles of asthmatic children (CHILD; n=16, FEV1 79% predicted), asthmatic adults (ADULT; n=53, FEV1 72%) and COPD (n=29, FEV1 42%) when they inhale through an Aerolizer® (AERÖ), Accuhaler® (ACC), Turbulhaler® (THB) and Easyhaler® (EASY) using their real life DPI technique. These are low, medium, high and high resistance DPIs. A summary of the inhalation characteristics is presented below.

The effect of airway alkalization by nebulized sodium bicarbonate on airflow blood flow
Adrian Kie1, Laura Andrea Toth1, Laszlo Komor1, Szilvia Vasas2, György Laszoczy1, Eiliana Mendes1, Adam Wanner1, Gaber Horvath1, 1Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Pulmonary Outpatient Clinic, Szent Janos Hospital, Budapest, Hungary; 3Division of Pulmonary, Critical Care and Sleep Medicine, University of Miami, United States

Background: The airway acidities in a variety of inflammatory lung diseases as measured by exhaled breath condensate (EBC). We have demonstrated in vitro that alkalization improves absorption of cationic bronchodilators, such as albuterol and tiotropium, both in airway epithelia and smooth muscle cells; however, the rationale of airway alkalization therapy is not fully understood.

Objective: The purpose of the study was to determine the effect of nebulized sodium bicarbonate (NaHCO3) solution on airway vascular smooth muscle function.

Methods: Ten healthy non-smoker volunteers participated in the study. To assess airway pH, EBC was collected pre- and post-administration of 4.2% NaHCO3 (pH4.8). NaHCO3 induced CO2 production was evaluated with a real-time mass spectrometer gas analyzer by measuring Phase 1 and end-tidal CO2 levels during normal breathing, and breath-hold maneuvers for 5 and 15 sec. Airway vascular smooth muscle responses were assessed by measuring airway blood flow (Qaw.).

Results: After NaHCO3 administration for 15 min using a heated ultrasonic nebulizer, EBC pH increased from 7.54±0.2 to 8.07±0.09 units (p<0.05). Pre- and post-treatment exhaled CO2 levels during normal breathing, and breath-hold maneuvers for 5 and 15 sec. Airway vascular smooth muscle responses were assessed by measuring airway blood flow (Qaw.).

Conclusion: Nebulized NaHCO3 can increase airway pH without significant effects on exhaled CO2 levels in healthy subjects. NaHCO3 induced increase in Qaw, together with elevated airway pH, could improve absorption of inhaled cationic bronchodilators.

The investigation of inhalation continuous duration for dry powder inhalers in asthmatic patients

Takashi Niimi 1, Yuko Shimia, 1, Yuriaki Sakurai 1, Takamitsu Asano 1, Akiko Hatala 1, Yuki Tomita 1, Yuko Takano 1, Shigeki Sato 1, Kenji Akita 1, Masashi Banno 2, Ryo Matsushita 3, Hidenori Ibata 2, Department of Respiratory Disease, Nagoya City East Medical Center, Nagoya, Aichi, Japan; 2Department of Medical Oncology and Immunology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan; 3Department of Respiratory Medicine, Nagoya Central Hospital, Nagoya, Aichi, Japan; 4Department of Pharmacology, Nagoya Central Hospital, Nagoya, Aichi, Japan; 5Clinical Pharmaceutics, Division of Pharmaceutical Sciences, Graduate School of Natural Science and Technology, Kanazawa University, Kanazawa, Ishikawa, Japan; 6Department of Respiratory Medicine, Mie Central Medical Center, Tsu, Mie, Japan

Background: Dry powder inhalers (DPIs) have been important for management of asthmatic patients. And instruction for use of inhaler devise was effectively for control of asthma. Although inhalation technique of DPIs that inhalating fast with maximum force from start to stopping was reportedly important, effective inhalation continuous duration was unknown. In this study, we evaluate effect of instruction considering inhalation continuous duration in asthmatic patients.

Methods: One hundred and thirty nine asthmatic patients who use fluticasone propionate discus or budesonide turbuhaler were studied. Insufficient peak inspiratory flow rate (PIF) and length of inspire continuous time were evaluated by discuss-trainer or turbuhaler-tester or In-Check. Of 139 patients, 22 without sufficient PIF were omitted from the study. InstructIon considering inhalation continuous time was done for 117 patients and effects for forced expired volume in one second (FEV1.0) and peak expiratory flow rate (PEF) was evaluated.

Results: In all patients groups distinguished by inhalation continuous duration before instruction, significant increase of inhalation continuous duration was found after instruction (p value of all groups were p<0.01). And Significant improvement of FEV1.0 and PEF was found after instruction in patients group with inhalation continuous time less than one second (both of FEV 1.0 and PEF, p<0.01).

Conclusion: In control of asthmatic patients, instruction considering inhalation continuous duration was useful and instructing not only inhale fast and forcefully, adding “continue inhalation with deeply breath more than one second” is considered to be recommend from our results.

P2145

Pharmacokinetics (PK) of single doses of mometasone furoate (MF) delivered via the Breezhaler® (BH) and Twisthaler® (TH) devices in healthy subjects

Sena Yavali 1, Sanjeey Khandri 1, Jess Robinson 1, Tom Smith 1, Balbir Magnus 1, Ulf Malmborg 1, Beverley Patterson 1

1Translational Sciences, Novartis Institutes for BioMedical Research, Cambridge, United States; 2Translational Sciences, Novartis Institutes for BioMedical Research, East Hanover, United States; 3Integrated Information Sciences, Novartis Pharma AG, Basel, Switzerland; 4Translational Sciences, Novartis Institutes for BioMedical Research, Basel, Switzerland; 5Clinical Research and Trial Centre, Skane University Hospital, Lund, Sweden

Background: QMF149 is being developed as a fixed dose combination of the long-acting β2 agonist indacaterol and the inhaled corticosteroid MF for treatment of asthma and COPD. Indacaterol is approved in the single dose dry power inhaler (DPI), BH for treatment of COPD (Onbrez® Breezhaler®). MF is approved in the multiple-dose DPI, TH for treatment of asthma (Asmanex® Twisthaler®). Due to its low oral bioavailability, systemic exposure after inhalation of MF reflects the amount of drug delivered to and absorbed from the lung.

Objective: To evaluate the PK of single doses of MF administered by oral inhalation via BH and to compare the systemic exposure to MF delivered via BH and TH devices.

Methods: This open-label, single-dose, crossover study recruited 24 healthy subjects to sequentially receive MF TH (400 μg) and escalating doses of MF BH (50, 100, 200, 400 μg). PK data were obtained up to 72h post-dose.

Results: Twenty subjects completed all treatments. Dose-normalized AUC last for all treatments (mean T 1/2: 12-13h). For the Visit 2 procedure, the mean number of inhalations to sequentially receive MF TH (400 μg) and escalating doses of MF BH (50, 100, 200, 400 μg). PK data were obtained up to 72h post-dose.

Conclusion: Systemic exposure of MF increased in a dose proportional manner over the dose range 50-400 μg for the MF BH. The estimated average dose of MF BH expected to provide systemic exposure comparable to the approved MF TH dose of 400 μg was 195 μg (90% CI: 175, 215).

P2146

An open-label trial to investigate the dose delivery and tolerability of inhalable dry powder mannitol (IDPM) using low output and high output Orbital® inhalers across defined flow rates in healthy volunteers

Gary Phillips 1, Andrew Reddien 2, John Crapper 1, Gallace Mirella 1, Brett Charlton 3

1Clinical Operations, Pharmaxis Ltd, Frensham Forest, NSW, Australia; 2Early Phase Trial Unit, Linear Clinical Research Ltd, Nealdon, WA, Australia

Introduction: Current dry powder inhalers (DPIs) typically deliver up to 30mg as the emitted powder mass. The Orbital® DPI is a disposable, single-use, pre-filled product being developed to deliver 400mg of mannitol to the lung via a number of inhalations. The assessment of emitted powder mass and tolerability is the focus of this trial.

Methods: Open-label trial in healthy subjects >18 years with baseline FEV1 >70% of predicted to determine the tolerability and dose delivery of IDPM across two defined flow rates using low and high output Orbital DPIS. Subjects who completed a full inhalation at any flow rate at Visit 1 progressed to Visit 2 at which time up to a maximum dosage of 400mg of IDPM was administered by sequential dosing.

Results: The single inhalation shot weights from the sequential assessments are shown in Table 1. For the Visit 2 procedure, the mean number of inhalations required to empty the DPI was 7.5 (SD 1.76; Range 5-12). The mean shot weight per inhalation was 43.9μg, mean cumulative shot weight after 5 inhalations was 300μg (SD 36). Visit 1 shot weights (μg)

Conclusion: Compared to conventional DPIS, the Orbital DPI is capable of delivering many-fold greater masses of dry powder over repeated inhalations. Further development is warranted to investigate the upper limits of dose delivery and to examine the utility of the device with other engineered particles.

P2147

Lung bioavailability of beclomethasone dipropionate and formoterol fumarate fixed dose combination administered using a pMDI or a novel DPI: NEXThaler®

Dave Singh 1, Germano Lucci 2, Daniela Acerti 2, Sergio Francesco 2, Isabella Montagna 2, Stefano Vezzoli 3, Shuniti Khurana 3, Gianluigi Poli 3

1Medicinal Evaluation Unit, MEU, Manchester, United Kingdom; 2Corporate Clinical Development, Chiesi Farmaceutici, Parma, Italy; 3Statistics, CROS NT, Verona, Italy

Introduction: NEXThaler® is a novel, easy to use, dry power inhaler (DPI) containing the fixed combination of beclometasone dipropionate (BDP) 100 μg and formoterol fumarate (FF) 6 μg, formulated for extrarne delivery. This will provide physicians and patients with an alternative inhaler device for treatment of asthma able to ensure delivery of the drugs to the lungs especially in patients with poor hand-breath coordination.

Objective: To compare the lung bioavailability of beclometasone monopropionate B17MP (active metabolite of BDP) and FF after administration of the fixed combinations using NEXThaler® or the pMDI Foster®

Methods: An open-label, two-way crossover, single-dose design was used. Activated charcoal was administered to block gastrointestinal absorption and pMDI use was optimized via space device. Adult asthmatic patients (n=24) were randomised to undergo two single dose treatment clinic visits, separated by a 7-day wash-out period. At each treatment visit, blood samples were collected over 24h for pharmacokinetic evaluation.

Results: The ratios (and 90% CI) for AUClast of B17MP and FF when comparing NEXThaler® to pMDI fell entirely within the bioequivalence region of 80-125%, showing that the lung bioavailability of both components was equivalent. No clinically significant trend to change in blood pressure or heart rate after dosing with either NEXThaler® or pMDI was observed.

Conclusion: BDP and FF lung bioavailability using the fixed dose combination NEXThaler® and pMDI was equivalent in the target population. Furthermore, treatment with NEXThaler® was well tolerated with no safety concerns.

P2148

Comparative in vitro performance of a new re-usable breath-actuated nebulizer (BAN) with other high performance systems intended for domiciliary use – 2: Portable battery-compressor

Jamie Mulea 1, Mark Nagel, Valentina Avvakoumova, Rubina Ali, Heather Schneider, Jolyon Mitchell

1Medical Aerosol Laboratory, Trudell Medical International, London, ON, Canada

Rationale: Treatments with home based compressor/nebulizer systems can of-
fer very different delivery characteristics. We evaluated a new, reusable BAN
(AeroEclipse-XL®, Trudell Medical International) in breath-actuated mode with
its portable (Ombra®) battery-compressor.
Methods: The nebulizer-on-test (n=5/group) was filled with 2.5–mL, 1.0 mg/mL
albuterol (Ventolin®, GSK Canada Inc.), and connected to a breathing simula-
tor (ASL5000, InMar Medical, Pittsburgh, PA) mimicking adult tidal breathing
(VT= 600 mL; duty cycle = 33%; rate = 10 cycles/min). Emitted aerosol was
captured on a filter at the mouthpiece, replaced at minute intervals until onset
of sputtering, defining run time. Recovery/assay of salbutamol was undertaken
by HPLC-UV spectrophotometry. Fine droplet fraction (FDF<4.7 μm) and mass
median droplet diameter (MMD) were determined by laser diffractometry. Total
fine droplet mass (FDM<4.7 μm) was the product of total mass and FDF<4.7 μm.
Comparative measurements were made with the Sprint® (PARI, Germany) and
MicroPlus® (Philips-Respironics, Germany) nebulizers using PARI BOY® Mobile
S® and Inspiration Micro Elite® portable compressors respectively.
Results: See Table

<table>

</tbody>
</table>

Conclusions: The BAN/Ombra® system provided highly respirable aerosol with
FDM<4.7 μm substantially greater than the benchmark systems. Its run time reflects
the fact that aerosol is only delivered during inhalation and not wasted to the
environment.

P2149
The absorption, distribution, metabolism and excretion (ADME) of single
oral doses of AZD5069, a novel CXCR2 antagonist, in healthy male
volunteers
Tim Mant1, Heather Wray1, Marie Cullberg2, Bengt Larsson2. 1Quintiles Drug
Research Unit, Guy’s Hospital, London, United Kingdom; 2Research &
Development, Astrazeneca, Molndal, Sweden

Background: AZD5069 is a CXC chemokine receptor-2 (CXCR2) antagonist with
potential as a novel COPD treatment. Initial studies have indicated an acceptable
safety profile for AZD5069. This study characterised the ADME of a single oral
dose of AZD5069.

Methods: In this phase I, open-label, non-comparative, single centre study, healthy
male volunteers received a single oral dose of 120 mg [14C]AZD5069. Blood and
urine samples (for radioactivity analysis, metabolite profiling, identification and
bioanalysis of AZD5069) and faeces samples (for radioactivity analysis and
metabolite profiling) were collected. Safety and tolerability were also assessed.

Results: Subjects (n=6) were white males (aged 50–65 years, mean BMI 25.6
kg/m²). The mean recovery of radioactivity in urine and faeces was 100% (range
98–103% [65% in urine, 35% in faeces]). 6.7% of the AZD5069 dose was re-
covered unmetabolised in urine. AZD5069 was rapidly absorbed and the apparent
terminal elimination half-life was 10 hours. There were no deaths, serious adverse
events (SAEs) or withdrawals due to AEs. Four subjects reported 6 AEs, with
terminology that is most commonly observed event. There were no clinically significant
safety and tolerability findings, other than the expected reversible reduction
in circulating neutrophil numbers.

Conclusion: Absorption of AZD5069 was rapid. Complete recovery of radioac-
tivity was attained, with the majority being excreted in the urine. Only a small
fraction was renally excreted as parent drug, suggesting that metabolism is the
primary route of elimination. No safety concerns were identified.

P2151
The pharmacokinetics (PK) and pharmacodynamics (PD) of the fluticasone
furoate (FF) and vilanterol (VI) combination in subjects with severe renal
impairment
Ann Allen1, Kelly Hardes2, Rodger Kempsford1, Lee Tombs3. 1Respiratory
Medicines Development Centre, GlaxoSmithKline, Stevenage, United Kingdom;
2Clinical Pharmacology Science and Study, GlaxoSmithKline, Uxbridge, United
Kingdom; 3Synergy, Statistics and Programming, GlaxoSmithKline, Uxbridge,
United Kingdom

Background: A combination of the novel corticosteroid FF and long-acting beta,
agonist VI (FF/VI) is being developed as a once-daily inhaled treatment for asthma
and COPD.

Objectives: To investigate the effect of severe renal impairment on FF and VI PK
and PD.

Methods: Open-label, parallel group study of repeat dose once-daily FF/VI
200/25mcg (7 days) in 9 subjects with severe renal impairment (CrCl<30mL/min)
and 9 matched control healthy subjects (by gender, ethnicity, age (±5 years) and
BMI (±15%)). FF and VI PK parameters were assessed on Day 7. PK parameter
point estimates (90% confidence interval [CI]) were constructed for the ratio of
geometric means (renally impaired:healthy subjects). Non-inferiority was to be
concluded if the upper 90% CI for the ratio was >2 for the Day 7 comparison.

Systemic PD effects of FF (0–24h serum cortisol) and VI (0–4h heart rate and
serum potassium) were assessed on Day 7.

Results: For FF AUC(0–24) and Cmax the geometric mean ratio [90% CI] for renal:
healthy was 0.91 [0.60, 1.38] and 0.96 [0.57, 1.61], respectively. For VI
AUC(0–24) and Cmax the geometric mean ratio [90% CI] for renal: healthy was
1.56 [1.27, 1.92] and 0.70 [0.49, 1.00], respectively. Administration of FF/VI
200/25mcg to subjects with severe renal impairment did not result in significantly
greater effects on serum cortisol, heart rate or serum potassium compared with
healthy subjects.

Conclusions: There was no evidence of clinically relevant increases in FF or VI
systemic exposure or systemic pharmacodynamic effects in subjects with severe
renal impairment compared with healthy subjects.

Funded by GSK (HZ1113970; NCT01266980).

Absorption, distribution, metabolism, and elimination (ADME) of umecilidinium (UCEM) in healthy adults

Dennis Kelleher1, Steve Hughes2, Rashmi Mehta3, Lee Tombs3, Kathryn Kelly4, Alison Church5, 1Respiratory Medicines Development Centre, GlaxoSmithKline, Research Triangle Park, United States; 2Drug Metabolism & Pharmacokinetics, GlaxoSmithKline, Ware, United Kingdom; 3Synergy, Statistics and Programming, GlaxoSmithKline, Slough, United Kingdom; 4Clinical Pharmacology & Study Science Operations, GlaxoSmithKline, Uxbridge, United Kingdom

Introduction: Umecilidinium (UCEM, GSK573719) is a new, long-acting muscarinic antagonist in development for treatment of chronic obstructive pulmonary disease (COPD).

Objectives: Evaluate the absorption, distribution, metabolism and elimination (ADME) of UCEM following single IV and oral doses of [14C]-UCEM.

Methods: This was an open, non-randomised ADME study of 6 healthy male subjects. There were two dosing periods: (1) a 65mcg IV dose of [14C]-UCEM (7.1mcCi) infused over 30min, and (2) a 1000mcg dose of [14C]-UCEM (50mcCi) administered orally. The dosing periods were separated by a washout of ≥28 days. Total radioactivity was measured in plasma, urine and faeces for 7–10 days following each dosing period.

Results: Following IV administration, the derived area-under-the-curve (0–∞) demonstrated that only ~20% of total radioactivity in plasma was parent UCEM, suggesting the predominance of UMEC metabolites. The geometric mean volume of distribution of IV UMEC was 86l, suggestive of tissue compartmentation. By day 8, approximately 58% and 22% of IV UMEC-associated radioactivity was excreted in the faeces and urine, respectively. Oral UMEC is poorly absorbed with <1% of administered parent drug detected in plasma (all concentrations non-quantifiable). Following oral administration, total radioactivity in the faeces and urine was 92% and 3% of the administered oral UMEC dose respectively, confirming negligible gut absorption.

Conclusions: Oral UMEC bioavailability is negligible. Intravenous UMEC is mainly removed from plasma by metabolism and subsequent biliary secretion, and to a lesser extent by urinary excretion.

Funded by GSK (AC4112014; NCT01362257).

P2154

Not all antistatic valved holding chambers have equivalent performance: An example of a packed holding chamber (VHC)-inhaller combination should be considered unique

Jamie Malpass, Mark Nagel, Valentina Arvakoumova, Rubina Ali, Heather Schneider, Jolyon Mitchell. Medical Aerosol Laboratory, Trudell Medical International, London, ON, Canada

Rationale: Electrostatic charge mitigation by the use of charge dissipative materials with VHCs is common, since initial pre-washing can be avoided. We provide a rationale for testing antistatic VHCs.

Methods: Charge was measured on samples of the VHCs with and without an actuator, with and without delay. Charge measurements were performed on 30 samples for 2 devices (ACFlow-Vu® , ACFlow-Vu® with Airdelay®) using an apparatus simulating in-use conditions. The following studies were performed to evaluate the stability of the drug product (DP: Aclidinium bromide 400μg formulation & inhaler).

Results: A highly-flexible 4-part protocol was designed, submitted to and approved by the MHRA and EC in 27 days. Parts 1 and 2 in HS is complete, Parts 3 and 4 are ongoing. Preliminary results show PUR118 is well tolerated in HS and subject 2% with COPD.

Conclusions: This multi-part dose-ranging protocol, developed and implemented in the UK, demonstrates its regulatory framework embraces innovative, highly flexible, multi-part trials in early clinical development strategies.

Drug product stability of aclidinium bromide in Genuair®,

Sebastian Kurz, Kathrin Block, Sonja Felgor, Thomas Pieper, Beatriz Fryms. Analytics, Almirall Sofotec GmbH, Bad Homburg, Hessen, Germany

Introduction: Aclidinium bromide is a novel, long-acting inhaled anticholinergic bronchodilator developed for the treatment of COPD. It is administered using a novel multidose dry powder inhaler called Genuair®, designed with an intuitive feedback system. The following studies were performed to evaluate the stability of the drug product (DP: Aclidinium bromide 400μg formulation & inhaler).

Methods: The stability of commercial scale batches were tested (Appearance, impurity, particle size, content of active, delivered dose (DD), fine particle dose (FPD) and microbial purity) as follows:

1. Packed DP: ≤24 months storage in 2 orientations at different climatic conditions.
2. Opened DP:
   - In use: 12 months packed storage at different climatic conditions, then open storage, without the protective cap during the in use period.
   - Effect of moisture: 4 weeks open storage at 20°C/34%R.H. versus 25°C/75%R.H.
3. Stability under extreme stress conditions was tested:
   - Temperature cycling study: 2 weeks storage at -10°C to 40°C (alternating every 24 h)
   - Vibrational stability: stressed at 50 Hz, amp. 1 mm using 3 durations.
4. Photo-stability evaluated according to ICH conditions.

Results: All tested samples and parameters confirmed the excellent stability of the packed and unpacked DP. Especially, the data for the pharmaceutical parameters DD (mean values: 362.4μg - 385.7μg) and FPD (mean values: 138.7μg - 164.3μg) were consistent and remained unchanged independent of storage time and conditions.

Conclusion: The advanced design and technological features of the Genuair® combined with the Aclidinium bromide inhalation powder guarantee a stable and robust product under various climatic, mechanical, and light radiation stress conditions.

P2157

The pharmacokinetics (PK) and pharmacodynamics (PD) of the fliucetasone furoate (FF) and vilanterol (VI) combination in subjects with hepatic impairment

Ann Allen1, Kelly Harries2, Rodger Kempfroid2, Lee Tombs3. 1Respiratory Medicines Development Centre, GlaxoSmithKline, Stevenage, United Kingdom; 2Clinical Pharmacology Science and Study, GlaxoSmithKline, Uxbridge, United Kingdom; 3Synergy, Statistics & Programming, GlaxoSmithKline, Uxbridge, United Kingdom

Introduction: A combination of the novel corticosteroid FF and long-acting beta2-agonist VI (FF/VI) is being developed as a once-daily inhaled treatment for asthma and COPD patients.

Objectives: To investigate the effect of hepatic impairment (HI) on FF and VI PK and PD.

384s
Methods: Open-label, repeat dose (7 day) study in subjects with mild, moderate or severe HI (Child-Pugh classification) and healthy subjects (HS) (matched with moderate HI). Subjects received FF/VI 200/25mcg or 100/12.5mcg (severe HI) once daily. FF and VI PK (Day 7) parameter point estimates and 90% confidence intervals (CIs) were constructed for the ratio of geometric means (HI/HS). Systemic PD effects of FF (0–24h weighted mean serum cortisol) and VI (0–4h heart rate and serum potassium) were assessed on Day 7.

Results: There was no effect of HI on dose-normalised VI Cmax or AUC(0–24) and no clinically relevant effects of FF/VI on heart rate or serum potassium compared with HS. Dose-normalised FF systemic exposure (AUC(0–24); Day 7) was higher in subjects with mild, moderate and severe HI (ratio vs. HS [90% CI]): 1.34 [0.82, 2.20], 1.83 [1.11, 2.99] and 1.75 [1.05, 2.91], respectively. Serum cortisol was only reduced in subjects with moderate HI (average 34% reduction [90% CI] 11%, 51%) compared with HS. A similar effect would be predicted in severe HI with FF/VI 200/25mcg.

Conclusions: In subjects with HI there was no increase in VI systemic exposure or systemic effects. FF exposure was increased by 3-fold in subjects with HI and was associated with a reduction in serum cortisol of approximately 30%.

Funded by GSK (HZA111789; NCT01266941).

No relevant drug-drug interaction between inhaled NVA237 and oral cimetidine
Romain Sechard1, Swati Dimitra1, Anton Drolmann1, Hisanori Hara1, Rajesh Karan2, Parasar Pal1, Sivakumar Vaidyanathan2, Guenther Kaiser1, Tina Roblek1, Katja Trobec2, Aleš Mrhar1, Mitja Lainsc1
1Translational Sciences, Novartis Institutes for BioMedical Research, Basel, Switzerland; 2Translational Sciences, Novartis Institutes for BioMedical Research, Basel, Switzerland; 2Translational Sciences, Novartis Institutes for BioMedical Research, Hyderabad, India; 3Biostatistics, Novartis Institutes for BioMedical Research, Hyderabad, India

Introduction: NVA237 (glycopyrronium bromide) is a once-daily long-acting muscarinic antagonist for the treatment of COPD. Renal clearance is a major elimination pathway of NVA237 and active tubular secretion in the kidneys contributes to this process. This study investigated the effect of inhibition of the organic cation transport in the kidneys on NVA237 disposition. Cimetidine was used as a probe inhibitor.

Methods: 20 healthy volunteers participated in this two-sequence crossover study. They inhaled a single 100 μg dose of NVA237 via the Breetherager® device on two occasions, i.e. alone (Treatment A) and on the 4th day of a 6-day treatment regimen with cimetidine 800 mg twice-daily (Treatment B). Treatments were separated by a washout period of 7 to 10 days. Plasma concentrations and urinary excretion of NVA237 were determined after each NVA237 dose. The primary PK parameters were plasma peak concentration (Cmax), AUC up to the last measured concentration (AUClast) and renal clearance (CLR) of NVA237. Trough plasma concentrations of cimetidine were determined throughout cimetidine dosing.

Results: Cimetidine trough concentrations indicated that the inhibitor drug had reached PK steady state prior to NVA237 inhalation in Treatment B. The concomitant administration of cimetidine resulted in an increase of total systemic exposure (AUClast) of NVA237 by 22%. This exposure increase correlated with a slight decrease of 23% in CLR. Cmax was not affected. Both treatments were safe and well tolerated.

Conclusions: Based on the magnitude of the PK changes, no relevant drug interaction is expected when NVA237 is co-administered with cimetidine or other inhibitors of the organic cation transport in the kidneys.

P2159
Drug-drug interactions in hospitalized patients with chronic obstructive pulmonary disease
Tina Roblek1, Katja Trobec2, Aleš Mrhar1, Mitja Laisinc
1The Chair of Biopharmaceutics and Pharmacoekinetics, Faculty of Pharmacy, Ljubljana, Slovenia; 2Pharmacy Department, University Clinic of Pulmonary and Allergic Diseases, Golnik, Slovenia; 3Division of Cardiology, University Clinic of Pulmonary and Allergic Diseases, Golnik, Slovenia

Aim: Chronic obstructive pulmonary disease (COPD) patients are treated with several drugs for their primary disease and comorbidity, which carries the risk of clinically relevant drug-drug interactions (DDIs). We aimed to evaluate DDI in hospitalized COPD patients.

Methods: This retrospective study included COPD patients hospitalized from January 2011 to July 2011 in a tertiary care clinic. Pharmacological therapy at admission and discharge was evaluated for DDI with electronic Lexi-Comp database:

- C: monitor therapy; D: consider therapy modification; X: avoid combination.

Results: We included 196 patients (68% male, age 71±9 years). The average number of prescribed drugs was significantly lower at hospital admission than at discharge (6±3 vs. 7.2±, p<0.01). Overall, more than 90% of patients had at least one interaction and Table 1 summarizes type C, D, and X interactions at hospital admission and discharge. The most prevalent type C interaction was between two β2-agonists (10% of cases) and the most prevalent type D interaction between β-blocker and α-blocker (9%). There were 15 type X interactions recorded at discharge, among which the most common was between non-selective β-blocker and β2-adrenoceptor agonist (8 cases).

Conclusions: DDI are common in hospitalized patients with COPD but few carry clinically relevant risk. Most type X interactions were between non-selective β-blocker and β2-adrenoceptor agonist which likely was indicated and should be safe in COPD patients.

P2160
Aerosol deposition in asthmatic subjects breathing helium-oxygen vs. air
Caroline Maja1, Ira Katz2, John Fleming3,5, Joy Conway4,5, Lesley Collier4, Marine Picchelin1, Livia Tossici-Bolt1, Georges Caillibotte1, Medical Gases Group - Centre de Recherche Claude-Delorme, Air Liquide Santé International, Jouy-en-Josas, France; 2Department of Mechanical Engineering, Lafayette College, Easton, PA, United States; 3Department of Medical Physics and Bioengineering, Southampton University Hospitals NHS Trust, Southampton, United Kingdom; 4Faculty of Health Sciences, University of Southampton, United Kingdom; 5Southampton NIHR Respiratory Biomedical Research Unit, Southampton University Hospitals NHS Trust, Southampton, United Kingdom

Introduction: Helium-oxygen (He/O2) mixtures are known to facilitate breathing due to their low density compared to air, and therefore, may be valuable to treat obstructive lung diseases such as asthma.

Objectives: The objective is to study the effect of air vs. He/O2 on the aerosol deposition of a nebulized radiolabel in stable, moderate asthmatic subjects.

Methods: 16 evaluable male subjects (6 asthmatics, 10 healthy volunteers) were studied. Each subject performed two inhalations which differed by a single controlled parameter (particle size, ventilation, or carrier gas). 2 of the asthmatics inhaled aerosols with either air or He/O2 (78%He/22%O2), and aerosol deposition was imaged with 3D-SPECT.

To characterize the sites of aerosol deposition, the 3D Central to Peripheral ratios, C/P, were calculated for right and left lungs.

Results: The effect of He/O2 on aerosol deposition was very visible for one of the asthmatic subjects (A06) with a large decrease in central deposition (Right C/P=9.1 and Left C/P=5.58 for air, vs. 1.32 and 1.37 for He/O2) when He/O2 was used to drive the nebuliser, but the other asthmatic did not respond to the change in carrier gas (Right C/P=3.87 and Left C/P=6.66 for air, vs. 3.87 and 7.53 for He/O2).

Figure 1. 3D-SPECT images of aerosol deposition superimposed with HRCT for subject A06 inhaling either air (top) or helium/oxygen mixture (bottom).

Conclusion: These results suggest that He/O2 can reduce aerosol deposition in central airways and increase deposition in peripheral airways in some asthmatic patients, but this response is not consistent among all patients.

248. Treatment of asthma, bronchiectasis and cough: inhaler use

P2161
Efficacy of fluticasone furoate (FF) and vilanterol (VI), separately and in combination (FF/VI), in an allergen challenge model
Amanda Oliver 1, Leif Bjørner 2, Dean Quinn 1, Parminder Saggu 1, Paul Thomas 2, Katy Yarnall 1, Jan Lovett 3. 1. Respiratory & Immuno-Inflammation MDC, GlaxoSmithKline, Uxbridge, United Kingdom; 2. Respiratory Medicine and Allergology, Institute for Clinical Science, Lund, Sweden; 3. Research Unit, PJ Research, Wellington, New Zealand; 4. Faculty of Medicine, University of NSW, Sydney, Australia; 5. Kerfingen Research Centre, University of Gothenburg, Sweden

Introduction: FF and VI are respectively, a novel inhaled corticosteroid and long-acting beta agonist. FF is efficacious in asthma over 24 h as monotherapy and combined with VI.

Objectives: Evaluate the effect of FF/VI on the allergen-induced early and late asthmatic response (EAR/LAR) and airway hyper-responsiveness (AHR) relative to placebo (PBO) and individual components.

Methods: Randomised, double-blind, 4-way crossover study of 27 mild asthma patients who received FF (100 mcg), VI (25 mcg), FF/VI (100/25 mcg) and PBO once daily for 21 days (4 periods). Allergen challenge was performed on Day 21 of each period 1 h post dose. AHR was assessed 24 h later by PC20 methacholine challenge.

Results: FEV1 maximum decline during EAR (0–2 h post-challenge) was significantly less with FF/VI and FF vs PBO. Treatment differences in minimum FEV1 (mL [95% CI]) vs PBO at 6 h post-challenge were 484 [332, 636], 484 [330, 638] and 168 [9, 638] for FF/VI, FF and VI, respectively. For LAR (4–10 h post-challenge) weighted mean (mL [95% CI]) vs PBO were 477 [282, 672], 265 [66, 463] and 135 [–72, 343] with FF/VI, FF and VI, respectively. For LAR (4–10 h post-challenge) weighted mean (mL [95% CI]) vs PBO were 477 [282, 672], 265 [66, 463] and 135 [–72, 343] with FF/VI, FF and VI, respectively. For LAR (4–10 h post-challenge) weighted mean (mL [95% CI]) vs PBO were 477 [282, 672], 265 [66, 463] and 135 [–72, 343] with FF/VI, FF and VI, respectively.

Conclusions: FF/VI and FF protected from all components of the asthmatic response. Overall FF/VI provided superior protection from the response to inhaled aeroallergens than monotherapy, with bronchoprotective effects lasting for over 24 h.

Funded by GSK (HZA113126; NCT01128595).

P2162
How frequent is bronchodilator reversibility in patients with stable asthma bronchiale and chronic obstructive lung disease (COPD) receiving maintenance therapy?
Veronika Muller, Gabriella Gallyf, Marta Orosz, Zsuzsanna Kovats, Gyogyi Lonczy, Lilla Tamasi. Department of Pulmonology, Semmelweis University, Budapest, Hungary

Lung function measurement is the most important tool in the diagnosis and differentiation of obstructive lung diseases. While asthma is characterized by variable bronchial obstruction, increase of airway resistance is mostly irreversible in COPD. As response to short acting bronchodilators seems highly variable, we tested bronchodilator reversibility in stable asthma and COPD patients receiving standard care.

In patients treated with stable COPD (N=77; male: female=43:57%; age: 62±3.5 years) or asthma (N=57; male: female=33:67%; age: 46±6.7 years) pre- and postbronchodilator values of bodyplethysmography measurements were analyzed using 400 μg salbutamol via easyhaler® (Buventol, Orion Pharma, Finland) during their regular out-patient visit.

Smoking was significantly more common in COPD patients than asthma patients (90 vs. 37%; p<0.05). Airway obstruction was more severe in COPD patients as compared to asthmatics (FFC: 2.38±0.26 vs. 3.14±0.43 L; FVC%: 72.6±5.1 vs. 87.4±6.4 L; FEV1/FVC: 1.45±0.21 vs. 2.13±0.31 L; FEV1%: 53.5±5.2 vs. 70.3±5.5, p<0.05). Reversible airway obstruction was present in 26% of COPD and 36% of asthma patients. Average response to salbutamol was similar in COPD patients compared to asthmatics (FFC: 195±22 vs. 189±25 mL; FVC%: 6.34±0.71 vs. 5.89±0.77), while smaller in FEV1 (FEV1: 126±17 vs. 254±30 mL; FEV1%: 4.97±4.08 vs. 8.67±0.88; p<0.01).

High proportion of COPD patients, whereas low proportion of asthmatics on regular treatment is showing ATS/ERS guideline defined reversibility using salbutamol easyhaler. Re-evaluation of diagnosis and/or therapy might follow these results.

P2163
Impact of age, age at diagnosis and duration of asthma on the risk of exacerbations in the EuroSMART study
Roland Ball, 1, Onno van Schaeyck, 2, Michel Aubier, 1, Juliette Ostinelli, 1, Leif Jørgensen, 1, John Haagensen 1, 3, 4. 1. Pulmonary Dept, Mainz; University Hospital, Mainz, Germany; 2. Maaschif University, CAPHRI Maastricht, Netherlands; 3. Service de Pneumologie A, Hôpital Bichat, Paris, France; 4. Medical Dept., AstraZeneca France, Bureil Malmaison, France; 1, 4Medical Dept., AstraZeneca Sweden, Södertälje, Sweden; 2Academic Primary Care, University of Aberdeen, United Kingdom

Background: Information about the influence of age and duration of asthma are limited.

Methods: EuroSMART, an open, randomised 6-month study (NCT00438368), compared two maintenance doses of budesonide/formoterol (BUD/FORM) (Symbi- smart® Turbuhaler®), 160/4 μg vs 1x2 and 2x2, plus as-needed BUD/FORM, in asthmatics ≥18 y with symptoms when treated with INH/LABA. Mean age of patients was 48 y, (range: 18–96 y) and 62% were females. The effects of biological age, age when asthma was first diagnosed, and duration of asthma were assessed. Among 8053 randomised patients, 4402 (54.6%) were ≥30 y of age when first diagnosed and 3411 (42.3%) had had asthma for ≥15 y. Data on allergic status (rhinitis, conjunctivitis) were collected. Severe asthma exacerbations were defined as: need for oral steroids for ≥3 days, emergency room treatment or hospitalisation.

Results: Presence of the allergic component decreased with increasing age at first asthma diagnosis. Patients >65 y had more exacerbations, and the risk of a first severe exacerbation was increased by 55.3% (p=0.0001; HR=1.533; 95% CI 1.249, 1.931). Severe asthma exacerbations were more frequent in patients diagnosed >30 y of age (p=0.0167; HR=1.248; 95% CI 1.040, 1.477) and more frequent in patients who had had the diagnosis for >15 y (p=0.0021; HR=1.289; 95% CI 1.107, 1.582). However, there were no differences in time to first exacerbation between the two randomised treatments 1x2 and 2x2 inclusions in any of the above three age measures.

Conclusion: Older patients, those with higher age at diagnosis and patients with long-term asthma have more exacerbations but did not show any difference between the 1x2 and 2x2 groups.

P2164
Patient and physician perspectives on asthma control and management strategies are discordant; a primary care study in Canada
Kenneth R. Charman 1, Jacques Bouchard 2, Renata M. Rea 3, Graham W. Bishop. 1. Asthma & Airways Centre, University Health Network, Toronto, ON, Canada; 2. Clin Med Fam de la Malbaie, Clin Med Fam de la Malbaie, La Malbaie, QC, Canada; 3. Medical Affairs, GlaxoSmithKline Canada Inc., Mississauga, ON, Canada; 4. Department of Medicine, Dalhousie University, St. John, NB, Canada

Background: Patients and physicians’ evaluations of asthma are often discordant.

We undertook this study to compare prescribed management strategies to patients’ actual strategies.

Methods: In 136 primary care practices, patients with asthma described their control using the asthma control test (ACT), current medication use, number of caregivers and health care utilization. Their physicians provided their understanding of each patient’s care while blinded to the patients’ responses.

Results: Of 904 patients (65% women, 21% current smokers), 54% had ACT scores < 20 although only 9% would describe their asthma as poorly controlled or uncontrolled. By contrast, 73% of physicians felt that the majority of patients had achieved control. In the 12 months prior, urgent care for uncontrolled asthma was obtained by patients in the following offices: 32% in their physicians’ offices; 19% at a walk-in clinic; 13% in the emergency room; and 3% in hospital. 21% of respondents had received at least one short course of prednisone. Of 247 patients described by their physicians as taking single maintenance and reliever therapy (SMART) only 60 (25%) used medications consistent with this regimen; 39% had separate relievers as well as their maintenance drug and 35% were not using a budesonide/formoterol inhaler.

Conclusion: Physicians overestimate the asthma control achieved by their patients; in Canada, patients are commonly uncontrolled and have frequent need for urgent asthma care. Physicians have not successfully implemented SMART therapy, either because prescribing is confounded by other caregivers or because physicians misunderstand the strategy.

P2165
Halotherapy – A possible method to enhance airway treatment on patients with obstructive pathology
Radu Cristian-Dahia 1, Traian Mihaescu 2, 1. Pneumology, Hospital of Respiratory Diseases, Iasi, Romania; 2. Pneumology, University of Medicine and Pharmacy, Iasi, Romania

Introduction: The clinical benefits of halotherapy is advocated, but the mechanisms are scarcely studied and there is not enough available clinical data. Halotherapy may influence mucociliary, antibacterial and anti-inflammatory actions, also the immunomodulator - hyposensibilizing agents. We conducted a perspective study where we use a dry-salt inhaler on patients with asthma and COPD.
P2166 Safety and efficacy of ectoin inhalation solution in patients with inflammation and airflow obstruction: The EFFECT study

Roman Berndt1, Ulrich Sydlik2, Andreas Bilstein1, Alessandra Marini2, Ursula Krammer1, Klaus Unfried1, R. & D, bitop AG, Witten, Germany, Leibniz Research Institute for Environmental Health, IFUP, Düsseldorf, Germany

Introduction: Ectoin is a compatible solute used for symptomatic treatment of chronic obstructive pulmonary disease (COPD), airway hyper-reactivity, and inflammatory epithelitis. Results from different studies demonstrated the efficacy of ectoin in reducing inflammation in the airways. Based on the positive results of a trial with asthmatic patients a study was set up to evaluate Ectoin Inhalation Solution (EIL) in subjects with mild airflow obstruction and inflammation.

Methods: The study was designed as double blind, placebo-controlled cross-over trial. Subjects were randomly assigned to EIL or placebo (0.9% saline). Primary endpoint was defined as reduction of inflammatory markers IL8 and neutrophilic granulocytes.

Results: Of the 52 patients enrolled, in the EIL treatment group and a patient in control group developed exacerbation and no patients in either group reported side effects. The microbiology results showed colonization of P. aeruginosa and K. pneumonia without any reported emerging antimicrobial resistance.

Conclusion: 12-week roxithromycin 300 mg once daily in symptomatic stable bronchiectatic patients did not show significant improvement of QoL, by SGRQ scores, reduced sputum volume nor improved lung function. Further long term study of anti-inflammatory macrolide should be done in symptomatic bronchiectatic patient.

P2169 Can roxithromycin improve quality of life in bronchiectatic patients?

Phumchak Asittam, Santita Kuittirakul, Sirawat Phunthawong, Department of Internal Medicine, Faculty of Medicine, Haritlai, Songkhla, Thailand

Introduction: Azithromycin is an effective prophylactic antibiotic in non-CF bronchiectasis. However, it is known to cause side effects including hearing loss and liver dysfunction, necessitating appropriate patient monitoring. In addition, some experts advocate periods of temporary cessation of treatment, “azithromycin holidays”, to minimise potential toxicity. We have examined our use of azithromycin and how we screen for complications in our specialist non-CF bronchiectasis clinic.

Methods: Data was collected on all patients with non-CF bronchiectasis who attended our specialist clinic over a 3-month period commencing 07/11/2011. In those patients receiving long-term azithromycin, we collected data on patient adherence and any complications, including liver function tests (LFTs), audiometry testing and advice given regarding “azithromycin holidays” over the previous 12-month period.

Results: Seventy patients were studied, of whom 28 (40%) were prescribed long-term azithromycin. Of these, 7 (25%) had been on azithromycin for less than 12 months. Twenty three (82%) patients on long-term azithromycin had had LFTs and 1 (3.5%) had had audiometry testing in the preceding 12 months. Four (17%) of the patients treated for more than 12 months had had an “azithromycin holiday” in the preceding 12-month period.

Conclusion: Monitoring of LFTs was satisfactory in our treatment group but more attention could be paid to audiology testing and the possibility of “azithromycin holidays”. Work to raise awareness of optimal practice in long-term azithromycin prescribing in non-CF bronchiectasis is needed.

P2170 The p38 MAP kinase inhibitor dilmapimod ameliorates airway inflammation induced by ozone challenge in healthy volunteers

P. Kirsten1, Olaf Holz1,2, Ruth Tal-Singer3, Helgo Magnusson1, Henrik Watz3

1. RPI, Pulmonary Research Institute at Hospital Grosshadern, Center for Pneumology and Thoracic Surgery, Grosshadern, Germany; 2ITEM, Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany; 3. GSK, Glaxo Smith Kline, King of Prussia, United States

Introduction: p38 MAP kinase is involved in inflammatory airway diseases. We studied the effects of the selective oral p38 MAP kinase inhibitor SB-681323 (Dilmapimod) on airway inflammation induced by ozone challenge.

Methods: This was a double-blind, randomized, four-period, cross-over study with two doses of Dilmapimod (5 mg, 25 mg), Prednisolone (50 mg), and Placebo...
in healthy ozone responders (increase of neutrophils by >10% in sputum after inhalation of 250 pgbp ozone for 3 hours with intermittent exercise). Study drug was administered 30 minutes prior to each ozone challenge. Induced sputum was collected 3 hours after the ozone challenge for measurement of neutrophils, interleukin-8 (IL-8), and myeloperoxidase (MPO). Treatment periods were separated by 14 days wash-out.

Results: 16 subjects were randomized and 11 subjects completed all treatment periods. There was no evidence of a statistically significant difference for the number of neutrophils in sputum between Placebo and any active treatment. Relative to Placebo, statistically significant reductions of MPO and IL-8 levels in sputum supernatant were observed after treatment with Dilmapimod 25 mg and Prednisolone. Differences based on an exploratory population of 14 subjects with sufficient sputum quality indicated a statistically non-significant reduction of neutrophils by 38%, 31% and 26% in subjects treated with Prednisolone, Dilmapimod 25 mg and Dilmapimod 5 mg, respectively.

Conclusion: Dilmapimod ameliorates ozone-induced airway inflammation. Further studies in appropriate patient populations are needed.

The Study was funded by GSK (GSK number SB-681323/10).

P2171

Effect of lidocaine and its delivery in chronic cough

Rayid Abdulqawi

Effect of lidocaine and its delivery in chronic cough rated by a 14 days wash-out.

Introduction: There are no consistently effective treatments for chronic cough. Patients frequently report an urge to cough sensation in the throat. Nebulised Lidocaine has previously been reported to subjectively improve cough but there are no objective data.

Aims: To compare the effect of lidocaine throat spray, nebulised lidocaine and placebo on subsequent 10-hour ambulatory cough rate (Vitalojak®) and urge to cough visual analogue scores.

Methods: 26 patients with chronic cough completed a randomised double blind, placebo controlled, three-way crossover study. The different treatments were:

- Placebo: nebulised placebo followed by placebo throat spray
- Nebulised lidocaine (600 mg): nebulised lidocaine followed by placebo throat spray
- Throat spray Lidocaine (100 mg): nebulised placebo followed by lidocaine throat spray

Data were analysed using generalised estimating equation models.

Results: 26 patients completed (22 female, mean age 53.5 yrs, median cough duration 10 yrs)

- Median 10 hour cough rate (n=25) (coughs/hr; IQR) was nebulised lidocaine 34.4 (13.5–57) vs placebo 32.7 (19–56). For the natural log transformed cough rate, there was significant difference between placebo and lidocaine throat spray (p=0.02), but not nebulised lidocaine (p=0.8), with most of the effect in the first 3hrs. Compared with placebo, both nebulised (p=0.01) and throat spray lidocaine (p=0.02) substantially reduced the urge to cough, but with no difference between them (p=0.6).

Conclusion: Lidocaine throat spray significantly reduced the 10-hour cough rate compared with placebo. This suggests that local treatment targeting the pharynx may be an effective anti-tussive in chronic cough patients.

P2172

Bidirectional modulation of urge to cough by nasal TRPA1 and TRPM8 agonists in healthy human subjects

Jana Plevková1, Mariana Brozová2, Silvia Gavliaková3, Vladimir Čalkovsky3, Ivan Polack3,1, 1Department of Pathophysiology, Jozef Stefan Institute, Ljubljana, Slovenia; 2Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic); 3Clinic of Ear Nose Throat Diseases, Head and Neck Surgery, Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic); 4Department of Medical Biophysics, Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic).

Cough, the most important airways defensive mechanism is modulated by manyafferent inputs either from respiratory tussigenic areas, but also by afferent drive from other organs. Modulation of cough by nasal afferent inputs could either facilitate cough response or inhibit it in animal models, depending on the type of tussigenic afferents which are stimulated. In recent study we addressed the question of possible bidirectional modulation of cough response in human healthy volunteers by nasal challenges with TRPA1 and TRPM8 agonists respectively. After the challenges with AITC, cinnaamilide, (+) menthol and (+) menthol (all 10-3 M, nasal symptom score, cough threshold (C2), urge to cough (Cu) and cumulative cough response did not reach significance level. Both TRPM8 agonists administered to the nose significantly modulated all parameters including C2 (p<0.05), Cu (p<0.01) and cumulative cough response (p=0.001) documenting strong anti irritating potential of menthol isomers. Except the role of trigeminal afferents expressing TRP channels, also olfactory nerve endings, trigemino – olfactivis relationships, smell perception process and other supramedullar influences have to be taken into consideration as relevant enough to modulate cough in human subjects.

P2173

A new rapid-onset dextromethorphan formulation for cough

Caroline Wright1, Rebecca Gordon2, Rachel Thompson2, David Hall2, Jaymin B. Morjaria1, Alyn Morice1.

supported by VEGAEuroMed 1/0031/11.

Introduction: Dextromethorphan (DEX) is known to be an efficacious anti-tussive agent. A novel DEX gel formulation (Arnold D®; Proctor & Gamble), with supra-oesophageal absorption, has been developed for fast relief from cough.

Aim: To evaluate the time to onset of action of 22mg DEX gel (equivalent to 30mg DEX) compared to standard 50mg oral DEX in a normal volunteer citric acid aerosol (CAA) induced cough model.

Method: Healthy subjects aged 18-65 years with a cough count between 7-20 coughs following five inhalations over 5 min. of 10% citric acid at screening were recruited. Subjects were administered oral DEX 50mg and at a subsequent visit at least 5 days later, DEX 22mg gel. Cough frequency was measured at baseline and at t = 15 min, 1, 2, 4 and 6 hours post dose.

Results: 42 (20 male) subjects were enrolled onto the study. At 15 minutes post dose there was a significant (p=0.001) difference in the mean ± (S.D.E.V) % reduction in cough from baseline of 32.1 (±(4.99) with DEX gel vs 12.8 (±(2.8) with oral DEX. Over the 6 hour time period (AUCt6h) there was a significantly (p=0.02) greater % change in cough/ Lilly following DEX gel AUCt6h= -118.7 compared to oral DEX 50mg. AUCt6h= -114.2. There were no major safety issues.

Conclusion: In the evoked cough model, DEX gel has faster onset of action compared to oral DEX and was more effective over the 6 hour time period despite there being a lower concentration of DEX in the gel preparation. A lack of blinding due to different routes of administration may contribute to this effect. A buccal route of delivery with this formulation holds promise for this and other indications where rapidity of onset is required. This study was supported by unrestricted grant aid from P+G.

P2174

Progressive case of recurrent respiratory papillomatosis successfully treated with gefitinib

Vityazay Kelek1, Marian Hajduch2, Juraj Kultan1, Lucie Fajkosova1. 1Dept. of Respiratory Medicine, University Hospital, Olomouc, Czech Republic; 2Dept. of Experimental Medicine, University Hospital, Olomouc, Czech Republic.

Recurrent respiratory papillomatosis (RRP) or juvenile laryngeal papillomatosis is a rare disease, caused by human papilloma virus (HPV). It is characterized by epitelial neoplastic polyps in larynx, trachea (2 - 5%) and lungs (1%). Typical symptoms are hoarseness, chronic cough and dyspnea. Diagnosis is based on laryngo/bronchoscopy, chest x-ray, biopsy and HPV testing. We describe a case of a woman with progressive laryngeal papillomatosis from the age of 1 year. Disease slowly progressed to trachea, although patient underwent about 80 endoscopic laser procedures. In the age of 37 y, chest X ray showed multiple nodules and cysts filled with fluid. VATS biopsy proved paranchymal papillomatosis. Patient was treated unsuccesfully with interferon, antiviral vaccine and Cidofovir. In the age of 41 y, therapy with gefitinib 250 mg bid was started. Bronchoscopy revealed regression of papillomas after 2 months and normal laryngeal and tracheal mucosa after 6 months. Chest X-ray was normal and CT showed tiny cysts without fluid. Patient felt well without dyspnea and tolerated treatment without problems.

Gefitinib - tyrosine kinase inhibitor of epidermal growth factor receptor (EGFR) was chosen according to knowledge of EGFR overexpression in papillomas and sporadic information about treatment of children with laryngeal papillomatosis. To our knowledge, this is the first report of successful gefitinib treatment of RRP in adult patient. The role of HPV in tumor forming tissue reaction is not known. Frequent HPV detection in gefitinib-responsive lung adenocarcinomas gives another support for gefitinib indication in RPP and a new hope for patients, too.

P2175

Erdosteine – A new drug in the treatment of chronic rhinosinusitis

Ivo Stárek1, Irir Horá1, Petr Schalek2, Renata Kellnerová2. 1ORL Clinic, Faculty Hospital, Olomouc; 2ORL Clinic, Faculty Hospital, Prague.

Introduction: Antiinflammatory macrolide antibiotics proved efficient in chronic rhinosinusitis (CRS). Since this medication is associated with potential side effects such as the danger of development of resistant bacteria, alternative drugs are being sought.

Objectives: Another drug exerting similar, cytokine-mediated antiinflammatory effects is Erdosteine. However, it has not been tested in this diagnosis yet.

In a prospective post-authorisation study we therefore assessed the efficacy of Erdosteine in patients with CRS.
**Conclusions:** The results of our pilot study suggest Erdosteine treatment efficacy in CRS. Additional in vitro and clinical studies are required to determine its precise action.

**P2176**

A cross-sectional study examining inpatients’ metered dose inhaler technique and the impact of assessment and education on its effective use

Judith Jade, Janet Lee, S. Fayyaz Hussain. Respiratory Medicine, Kettering General Hospital, Kettering, United Kingdom

**Introduction:** Metered dose inhalers (MDI) are often prescribed during hospital admission. MDI technique influences clinical effectiveness, yet inpatient assessment and education regarding this skill may not happen routinely.

**Objectives:** We hypothesised that a) inpatients on an acute medical ward often have poor MDI technique and b) simple assessment and education could improve MDI technique.

**Methods:** A cross-sectional study was conducted on inpatients prescribed an MDI on an acute medical ward during the month of October 2011. Technique was assessed using an Aerosol Inhalation Monitor, by a Health Care Assistant (HCA) trained in its use. Patients with poor technique had simple training and assessment was repeated.

**Results:** A total of 38 patients were studied (M:F=1:1.1, Age range=40-91). Initial assessment showed only seven patients (18.4%) were able to use the device effectively. The 31 patients (81.5%) that failed initial assessment had simple education and technique; showed common errors; omitting exhaling before inhalation (10-15%), mouth rinsing or incorrect inhalation (20%) and omission of mouth rinsing. Evaluation of asthma control was performed at baseline and following visits, 22% of asthma patients were under control at baseline, increasing to 43%. Fixed combination inhalers BDP/FP solution spray, F/S discus, B/F Turbuhaler significantly reduced the rate of uncontrolled patients by p=0.004, p=0.001, p=0.003 respectively where no significant decrease was seen with B+F Aerolizer for related asthmatic group (p=0.10).

**Conclusion:** This study collected information on specific use of inhaler devices in persistent asthma patients and a correlation in a balanced perception of use for every device by physicians and patients were shown.

**P2178**

The asthmatic patient and inhaler treatment devices profile in Turkey:

Asthma inhaler treatment study

Fusun Yıldız1, Nese Dursunoglu1, Serap Duru*1, 2, Department of Chest Diseases, Kocaeli University, School of Medicine, Kocaeli, Turkey; 1Department of Chest Diseases, Pamukkale University, School of Medicine, Denizli, Turkey; 2Department of Chest Diseases, Yıldırım Beyazıt Research and Training Hospital, Ankara, Turkey

**Aim:** Factors such as severity, duration of asthma, concomitant diseases, smoking habits, influence asthma control, besides compliance to inhaler devices. In this study, we aimed to profile contributing factors and conditions and inhaler devices in Turkey.

**Methods:** In this non-interventional study asthma patients were surveyed at baseline for asthma history, demographics, concomitant medical conditions and smoking habits, with possible impact on asthma and its prognosis, including exacerbation rates. The profile of treatment agents and devices were also evaluated.

**Results:** A total of 572 patients were enrolled at 31 centers. The majority of asthma patients registered to the study was female (76%) and mean age was 42.7±12.1, the mean asthma age was 7.98±6.28 years. BMI was 28.0 kg/m². During enrolment, asthma symptoms were under control in 22% of patients enrolled, in 38% was not under control and 40% was partially controlled. During enrolment 56% of patients had co-morbid conditions, and 65.5% had rhinosinusitis, 12.8% had GERD, with high percentage of uncontrolled asthma. One in every five patient (18.2%) were current smokers and 49% had uncontrolled asthma during baseline.

**Conclusion:** Patient profile of asthmatics receiving inhaler treatment showed that one out of every five patients enrolled were effectively controlled, despite smokers and presence of complicating concomitant medical conditions. Fixed combinations are the mainstay of therapy in Turkey, with all types of inhaler devices.
P2180
Oxygen use and nasal symptoms
Helen Meredith, Alison Cran, Menelaos Pipis, James Goldring. Respiratory Medicine, Royal Free Hospital, London, United Kingdom

It is recognised that oxygen should be prescribed as a drug, but little has been studied about the comfort or side effects of oxygen.

Aim: We wished to see if oxygen had significant nasal side effects for our in-patients.

Method: A snapshot questionnaire was asked to all patients on oxygen on the medical wards of our large teaching hospital during a one week period. We used the Lund score, using predominantly questions in the nasal domain (rating 1-4; normal to severe), to compare their symptoms pre and during admission.

Results:

24 patients were able to answer the questionnaire; the majority were on nasal oxygen and using it for more than 2 days. 42% reported that oxygen wasn’t comfortable, but there was only a significant difference in the symptom of a dry throat (mean difference 0.71, p= 0.009). 4 patients had worsening epistaxis whilst comfortable, and this further supports the need for care regarding the prescription use of steroids in some. However, nearly half found some aspect of oxygen use uncomfortable, but there was only a significant difference in nasal symptoms; it is possible this was ameliorated by the domiciliary use – 1: Table-top compressors

Discussion: In our patient group using predominantly nasal non-humidified oxygen there was no change in nasal symptoms; it is possible this was ameliorated by the use of steroids in some. However, nearly half found some aspect of oxygen use uncomfortable, and this further supports the need for care regarding the prescription of this drug.

P2181
Comparative in vitro performance of a new re-useable breath-actuated nebulizer (BAN) with other high performance systems intended for domiciliary use – 1; Table-top compressors

Rationale: Treatments by portable compressor/nebulizer systems can offer very different delivery characteristics. We evaluated a new, reusable BAN (AeroEclipse-XL®, Trudell Medical International) optimized with its table-top (Ombra®) compressor.

Methods: Each nebulizer (n=5/group) was filled with 2.5 mL, 1.0 mg/mL albuterol (Ventolin®, GSK Canada Inc.) and, connected to a breathing simulator (ASL5000, IngMar Medical, Pittsburgh, PA) mimicking adult tidal breathing (Vₜ= 600 mL; duty cycle = 33%; rate = 10 cycles/min). Emitted aerosol was captured on a filter at the mouthpiece, replaced every minute until onset of sputterling, defining run time. Recovery/assay of salbutamol was undertaken by HPLC-UV spectrophotometry. Fine droplet fraction (FDF, <4μm) and mass median droplet diameter (MMD) were determined by laser diffraction method. Total fine droplet mass (TDM, <4μm) was the product of total mass and FDF, <4μm. Comparative measurements were made with the Sprint® (PARL, Germany) and reusable SideStream® (Philips-Respiracms, Germany) air entrainment nebulizers using PARI BOY® SX® and Inspiration Elite® table-top compressors respectively.

Results: See Table.

P2183
Pharmaceutical development of a liquid formulation for pulmonary application of a peptide
Hendrik Fischer1, Rudolf Lucas2, Helmut Pietschmann1, Susan Tzotzou1, Bernhard Fischer1. 1APEPTICO, APEPTICO GmbH, Vienna, Austria; 2Vascular Biology Center, Georgia Health Sciences University, Augusta, United States

ALIARDS are acute and severe conditions with mortality up to 50%. Currently, no specific drug-related treatment exists. ALIARDS are characterized by pulmonary oedema due to increased permeability of the endothelial/epithelial barrier. Oedema clearance is linked to Na uptake at the apical side of Type I/II alveolar cells through the amiloride-sensitive epithelial sodium channel "ENaC". AP301, a synthetic peptide derived from the lectin-like domain of TNFα, enhances Na transport through ENaC and thus oedema clearance. As ENaC is located at the inner surface of alveolus, the water soluble AP301 is administered by inhalation of a nebulised aqueous solution. Hence, pharmaceutical development of AP301 as potent new drug for oedema resolution differs from standard orally or parenterally applied medicine and has to follow specific pharmaceutical and medicinal regulations of the Pharmacopoeia and inhalation medicine guidelines. AP301 is nebulised by a mesh-type not a jet or supersonic type nebulizer due to simplicity and effectiveness, but gentle aerosol generation. In order to reach the alveoli the particle size of the aerosol was optimized to <5μm by testing a range of different concentrations of AP301 in combination with various nebulizers. Analyses of biological activity of AP301 in the generated aerosol showed that it was retained during nebulisation. To
Muscarnic and β2-adrenergic receptors of resident lung cells are modulators of airway inflammation and remodeling. Here, we used human primary lung fibro- 

Asmus and A. M. M. Hacker.

Methods and results: The effect of Dex on 39 IL-1β-induced genes was examined in human pulmonary A549 cells by real-time PCR. Dex showed a range of activity in terms of the extent (E_{max}) and potency (EC_{50}) of repression on these genes. These parameters correlated such that the most highly repressed genes were also the most potently repressed. While all 39 genes were NF-κB-dependent, this did not correlate with repression by Dex. Finally, inhibition of protein translation by cycloheximide (CHX) reduced IL-1β-induced expression of 19 genes (secondarily response genes). Of the remaining 21 genes, CHX significantly prevented the Dex-dependent repression of 11 (~50%), suggesting a role for transactivation. These 11 genes were significantly more sensitive (E_{max} and EC_{50}) to repression by dexamethasone when compared to genes showing repression that was insensitive to CHX (and which may represent a classical transrepression mechanism).

Conclusions: Repression of inflammatory gene expression by dexamethasone involves multiple mechanisms. Transactivation appears to play a significant role showing both high potency and high level of repression on target genes.

P2187 Tiotropium provides sustained bronchodilatation in asthmatics with persistent airflow obstruction uncontrolled despite treatment in accordance with guidelines

Huib Kerstjens1, Pierluigi Paggiaro2, Mark Vandekerckhove3, W. Keeshon4, Mater Morsen5, Zengtal6, Eric Hattem7, Department of Pulmonary Medicine and Tuberculosis, University Medical Center, Groningen, Netherlands; 2Dipartimento Cardio-Toracico, U.O. Pneumologia e Fisiopatologia Respiratoria, Ospedale di Cittadella, Pia, Italy; 3Clinical Trials, Clinical Research of the Ozarks, Columbia, MO, United States; 4Medical Department, IFG - Institut für Gesundheitsförderung GmbH, Rüdersdorf Brandenburg, Germany; 5TA Respiratory Diseases, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; 6Biosatistics, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; 7Clinical Research, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; 8TA Respiratory Diseases, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; 9Department of Medicine, Cape Town, South Africa

Introduction: In some asthmatics airflow obstruction persists despite high-dose (HD) inhaled corticosteroids (ICS) and long-acting β2-agonist (LABA) use. In a recent study, adding a long-acting anticholinergic (tiotropium) showed favourable effects over 8 weeks (wk) (Kerstjens HA, et al. ACI. 2011). Methods: In 2 replicate 48-wk, doubleblind, parallel-group trials a total of 912 asthmatics with postbronchodilator (BD) FEV1 <80% predicted and asthma control questionnaire score ≥1.5 while on at least HD ICS+LABA were randomised to additional tiotropium Respimat® 5 mg or placebo. Prespecified co-primary endpoints included peak and trough FEV1; at 24 wks. Secondary endpoints were FEV1 at other time-points, FVC, and daily PEFs.

Results: Baseline characteristics were similar between trials and treatment groups (mean post-BD FEV1: 62% ±11%). Mean change from baseline tiotropium vs placebo after 24 wks in peak pre-BD FEV1 was 86 ±34 mL (P=0.01) or 154 ±32 mL greater (P<0.001), and in trough FEV1, 88 ±34 mL (P=0.01) or 111 ±30 mL greater (P<0.001) in trials 1 and 2, respectively. Improvements in FVC and daily PEFs were also significantly greater with tiotropium. There were no signs of tachyphylaxis. No deaths occurred; adverse events were balanced across both treatments in trials. Conclusion: In asthmatics uncontrolled despite at least HD ICS+LABA, adding tiotropium provided significant lung function improvement at which were sustained over 48 wks. Tiotropium is likely to improve severe uncontrolled asthma on top of treatment in accordance with guidelines.

Study supported by Boehringer Ingelheim and Pﬁzer.

P2186 Transactivation and transrepression in the repression of inflammatory gene expression by dexamethasone

Elizabeth King1, Joanna Chivers1, Mark Giembycz2, Robert Newton1, Cell Biology and Anatomy, University of Calgary, AB, Canada; 2Physiology and Pharmacology, University of Calgary AB, Canada

Background: The anti-inflammatory activities of glucocorticoids are attributed to the repression of inflammatory gene expression. Dogma states that this occurs via direct repression (transrepression) by the glucocorticoid receptor (GR) of transcription factors, such as NF-κB. However, evidence also suggests that gene induction (transactivation) by GR is important for repression.

Aims: To assess the roles of transrepression and transactivation in the repression of inflammatory gene expression by dexamethasone (Dex).

Methods and results: To determine the extent of inflammation polymorphonuclear neutrophils (PMN) from asthmatics with persistent airflow obstruction uncontrolled despite treatment in accordance with guidelines.

Results: A total of 33 patients were studied, 61% male. Baseline spirometry: FEV1(1) 1.13 (SD 0.41), FEV1% 45% (14.7), FVC(1) 2.75 (0.76), FVC(1) 86.3% (17.2), slow VC (l) 2.77 (0.85), slow VC% 84.9 (18.3). Slow VC significantly increased by 303 ml [95% CI 29-297] p=0.01 and 149 ml [95% CI 19-280] p=0.01 at 0.5 and 1 hours respectively. FEV1 significantly increased by 51 ml [95% CI 16-86] p<0.001 and 78 ml [95% CI 40-116] p<0.001 at 0.5 and 1

P2184 Tiotropium enhances the inhibitory effect of the long acting β2 agonist olodaterol on the release of IL-6 and IL-8 by primary human lung fibroblasts of asthma patients

Luigi Costa, Michael Roth, Michael Tamm, Peter Borger. Pulmonary Cell Research, Dept of Biomedicine, University Hospital, Basel, Switzerland

Introduction: Inhaled LPS challenge – Reproducibility of the inflammatory

P2185 Low dose inhaled LPS challenge – Reproducibility of the inflammatory response

Olaf Holz, Frank Schumann, Ole Janssen, Bianca Lavaz-Mokhtari, Heike Biller, Norbert Keog, Jens H. Hohlfeld. Clinical Airway Research, Fraunhofer ITEM, Hannover, Germany

Results: Peak dose LPS caused a reproducible inflammatory response. How-

ever, we found evidence for a more pronounced increase in monocytes in the second challenge. This needs to be considered in proof of concept studies for novel inflammatory compounds.

CCRE was kindly provided by Dr. A. S. Suredini, NIH, Bethesda.

P2187 Tiotropium provides sustained bronchodilatation in asthmatics with persistent airflow obstruction uncontrolled despite treatment in accordance with guidelines

P2188 The effects of sildenafil on lung function in COPD

Andrew Goodie, Pippa Hopkinson, William Anderson, Brian Lipworth, Allan Smithers. Centre for Cardiovascular and Lung Biology Research, University of Dundee, United Kingdom

Background: Sildenafil is a pulmonary vasodilator drug used to treat pulmonary hypertension (PH) via PDE5 inhibition. The precursor to Sildenafil, nitric oxide, has moderate bronchodilator effects in exercise induced asthma. A recent study investigating the haemodynamic effects of sildenafil in COPD associated PH (COPD-PH) noted small but significant improvements in FEV1 and FVC.

Aims: To study the effects of sildenafil on bronchodilation and gas trapping in those with COPD-PH. Methods: COPD patients were invited for echo. RVSP >30mmHg and/or a pul-

monary acceleration time of 120ms defined PH. Subjects with COPD-PH were given 50mg of sildenafil(PO). Spirometry was recorded at 0.5, 1 and 3 hours (t_{1/2}).

Results: A total of 33 patients were studied, 61% male. Baseline spirometry:

FEV1(1) 1.13 (SD 0.41), FEV1% 45% (14.7), FVC(1) 2.75 (0.76), FVC(1) 86.3% (17.2), slow VC (l) 2.77 (0.85), slow VC% 84.9 (18.3). Slow VC significantly increased by 303 ml [95% CI 29-297] p=0.01 and 149 ml [95% CI 19-280] p=0.01 at 0.5 and 1 hours respectively. FEV1 significantly increased by 51 ml [95% CI 16-86] p<0.001 and 78 ml [95% CI 40-116] p<0.001 at 0.5 and 1

Aims: To assess the roles of transrepression and transactivation in the repression of inflammatory gene expression by dexamethasone (Dex).
Conclusion: Acute selenadil use resulted in transient airways dilatation and reduced gas trapping. In the absence of placebo control, spirometric changes due to natural variability cannot be ruled out, although the return to normal at 3 hours suggests a real effect.

P2189 Tolerability and efficacy of budesonide/formoterol via Turbuhaler® vs standard treatment in Japanese patients with moderate to severe COPD: 52-week phase III study results
Masakazu Ichinose1, Hiroyuki Nakamura2, Noriharu Shijubo3, Takafumi Saito4, Hiroyuki Taniuchi5, Toru Tsuda6, Kosho Yoshikawa7, Lars-Goran Carlsson8, 9Third Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan; 10Department of Medicine, Sakaide City Hospital, Kagawa, Japan; 2Department of Medicine, Nakajima Hospital, Fukuoka, Japan; 3Department of Respiratory Medicine, National Hospital Organization Nara Medical University, Nara, Japan; 4Department of Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan; 5Department of Medicine, Respiratory Medicine, National Hospital Organization Tottori General Hospital, Tottori, Japan; 6Department of Medicine, Kirigaoka Tsuda Hospital, Fukuoka, Japan; 7Department of Medicine, Daido Hospital, Aichi, Japan; 8Clinical Sciences, AstraZeneca R&D, Montauban, Sweden

Background: This study evaluated the tolerability and efficacy of budesonide/formoterol (BUD/FORM) vs standard COPD treatment (SCT) in Japanese patients with moderate to severe COPD.

Methods: In this randomised, open-label, parallel-group, phase III study (NCT01070784), patients ≥40 years of age with moderate to severe COPD for ≥2 years received either BUD/FORM 160/4.5 μg 2 inhalations twice daily via Turbuhaler® or SCT (as judged by the investigator) for 52 weeks. Reliever medication: salbutamol via pMDI. Primary outcome: nature, incidence and severity of adverse events (AEs). Secondary outcome variables included: COPD symptoms, lung function and exacerbations.

Results: 260 patients were randomised. BUD/FORM was well tolerated; 404 AEs were reported by 123 patients (94.6%) receiving BUD/FORM vs 367 AEs by 112 patients (86.2%) on SCT. The majority of AEs were of mild or moderate intensity and the AE profile was similar in the two groups. The most commonly reported AEs (BUD/FORM vs SCT) were nasopharyngitis (42.3% vs 39.2%), COPD (10.8% vs 19.2%) and bronchitis (11.5% vs 11.5%). The frequency of pneumonia-related AEs was similar in both groups (13.1% vs 12.3%) while dyspnoea was more frequent with BUD/FORM (5.4% vs 0.8%). Serious AEs were more frequent with SCT (7.6%) vs BUD/FORM (1.5%). No deaths were reported. Efficacy of BUD/FORM was maintained over 52 weeks.

Conclusions: BUD/FORM 160/4.5 μg inhalations twice daily was well tolerated and efficacy was maintained during 52-week treatment in Japanese patients with moderate to severe COPD.

Funding: AstraZeneca.

P2190 Effectiveness of tiotropium in low-risk patients according to new GOLD severity grading
David Haljan1, Marc Decramer2, Bart Celli3, Antonio Martin4, Inge Leimer5, Norbert Metzler6, Donald Tashkin7, 8Respiratory Medicine, Royal Devon and Exeter Hospital, Exeter, United Kingdom; 2Respiratory Division, University of Leuven, Belgium; 3Pulmonary Division, Brigham and Women’s Hospital, Boston, MA, United States; 4Allergy and Respiratory Department, Pfizer Inc, New York, NY, United States; 5Medical Affairs, Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; 6Department of Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States

Background: GOLD recently updated their COPD severity classification to include risk of exacerbations. Increased risk is typically defined by a FEV1 of <50% pred and/or ≥2 exacerbations in the previous year (C/D) and low risk by a FEV1 ≥50% pred or ≤1 exacerbation in the previous year (A/B).

Aims and objectives: To examine the effect of tiotropium 18 μg qd via Handihaler® in GOLD low risk patients (pts) using data from a 4–year, randomised, double-blind, placebo-controlled trial in COPD (UPFLIT®).

Methods: Retrospective analysis of exacerbations, lung function and QoL, (SGRQ) in low-risk pts (pts with a baseline postbronchodilator (BD) FEV1 ≥5%pred ≥50% and ≤1 oral steroid/antibiotic course in the previous year). Pts with high risk (FEV1 <5%pred <50% or more than 1 course of oral steroids/antibiotics) were also analysed.

Results: 2012 pts were analyzed (mean age 64.5±8.6 y, male 74%, mean (±SD) baseline postBD FEV1 1.65 (0.37) L and FEV1 ≥5%pred (±SD) 58.9 (5.8). The HR (tiotropium vs control) for time to first exacerbation was 0.76 (95% CI: 0.68; 0.86; P<0.0001); mean annual exacerbation rates were 0.43 (95% CI: 0.40; 0.48) vs 0.61 (0.56; 0.66), rate ratio 0.72 (0.63; 0.81; P<0.0001). The SGRQ total score after 4 y was significantly improved by tiotropium vs placebo: −3.63 (95% CI: −5.14; −2.12; P<0.0001) and the respective increase for trough FEV1 was 110 mL (95% CI: 84; 136; P<0.0001). SGRQ and trough FEV1, were significantly improved at all time points. The above-mentioned endpoints were also significantly improved in the high-risk population.

Conclusion: Tiotropium qd was effective throughout 4 y in reducing exacerbations and improving lung function and QoL, in low-risk pts with COPD (GOLD A+B).

P2191 Efficacy and safety of fluticasone/formoterol compared to fluticasone alone in patients with asthma
Tatiana Petrovskaya1, Sanjevaa Dissanyake2, Kirsten Kaiser3, 1Chair of Faculty Therapy and Endocrinology of Dnipropetrovsk Medical Academy, Dnipropetrovsk City Clinical Hospital № 6, Dnipropetrovsk, Ukraine; 2European Medical Science, Mundipharma Research Ltd., Cambridge, United Kingdom; 3Medical and Regulatory Development, SkyPharma AG, Muttenz, Switzerland

Background: To demonstrate efficacy and safety of fluticasone propionate/formoterol fumarate MDI (FLUT/FORM) compared with fluticasone (FLUT) alone based on the change in FEV1 from morning pre-dose at baseline over 2 hours post-dose and SCORing in Asthma (SIAQ). From a 2 month, all-cause exacerbation study in asthma.

Methods: Patients included in the study were ≥12 years with symptomatic asthma for ≥1 year; steroid-requiring, had FEV1 ≥50% to 80% [inclusive] of predicted normal values, and documented reversibility within 12 months of the study. Following a 2 week open-label run-in phase with FLUT (100 or 200 μg b.i.d.), 438 patients were randomised to treatment with FLUT/FORM (250/10 μg b.i.d.) or one of two pMDI formulations of FLUT alone (250 μg b.i.d.). The formulations were SkyPharma HEA, pMDI (SKP) and GSK fluticasone pMDI (FLO), with n=146 in all groups. Albuterol/salbutamol was given as rescue medication.

Results: There was a clinically important and statistically significant difference in mean change from pre-dose FEV1, at baseline to 2 h post-dose at week 12 between the FLUT/FORM and both formulations of FLUT (SKP:LS mean difference=0.161 L,P<0.001; FLO:LS mean difference=0.185 L,P<0.001). Results from multiple secondary and tertiary efficacy endpoints assessing lung function, asthma symp- toms, exacerbations and rescue medication use supported a superior efficacy of the FLUT/FORM combination over FLUT. Treatment-emergent adverse events were lowest in the FLUT/FORM group (32.9%) compared to SKP (39.7%) and FLO (40.4%). FLUT/FORM was generally well tolerated.

Conclusion: FLUT/FORM was superior to FLUT alone in the management of moderate to severe asthma in adolescents and adults. The overall safety profile of FLUT/FORM was consistent with that of FLUT.

P2192 Does eosinophil cationic protein (ECP) predict asthma outcome and response to treatment in asthmatic patients? Elena Bacci1, Silvana Cianchetti, Manuela Latore, Lorenza Melosini, Antonella De Franco, Federico D’Amico, Pietro D’Agostino. Cardiothoracic and Vascular Department, University of Pisa, Italy

In order to test whether sputum Eosinophil Cationic Protein (ECP) predicts asthma outcome and response to treatment, we studied 119 mild/moderate, steroid-naive asthmatic patients. All patients underwent spirometry, methacholine test, induced sputum analysis before and after treatment, and recorded symptom score and rescue beta(2)-agonist use on a diary card throughout the study. In patients with high (≥75 mg/mL) sputum ECP baseline FEV1 was lower (high-ECP: 85±17%; low-ECP: 96±14%; p=0.01). Sputum eosinophil percentages were higher in patients with high ECP (high-ECP: 16.3±17.1%; low-ECP: 6.1±8.3%; p=0.01), although the concordance between sputum eosinophils and ECP was poor (κ=0.52, p=0.01). Patients were then treated with either inhaled corticosteroids (ICS, n=76) or long-acting beta2-agonist (LABA, n=43) for 3 to 6 months. In LABA-treated patients, symptom score and beta(2)-agonist rescue use improved regardless of baseline sputum ECP levels; after treatment, however, patients with high baseline ECP levels had greater rescue beta(2)-agonist use (high-ECP: 0.2±0.2; low-ECP: 0.02±0.03, p=0.05). In ICS-treated patients, PEFR symptom score, beta(2)-agonist rescue use and PD20FEV1 methacholine improved regardless of ECP levels; however, FEVI1 significantly improved in ICS-treated patients with high ECP levels only, possibly because they had lower baseline FEV1 values. Thus, high sputum ECP levels may predict less asthma control, as shown by greater rescue beta(2)-agonist use, when treatment does not affect airway inflammation; on the other hand, high sputum ECP levels may predict the response to ICS treatment, possibly because they are associated with poorer baseline lung function.
Methacholine challenge test as an evaluator of response to statins in bronchial hyperresponsiveness

Majid Malekmohammad

1Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran; 2Clinical Research, North Spartanburg, SC, United States; 2Clinical Research, Clinical Research Institute of Southern Oregon, Medford, OR, United States; 2Clinical Research, Clinical Research Institute of Southern Oregon, Medford, OR, United States; 2Clinical Research, North Spartanburg, SC, United States; 2Clinical Research, Clinical Research Institute of Southern Oregon, Medford, OR, United States.

Results: 

Changes in airway responsiveness categories (moderate to severe, mild, border-
line, normal) after the intervention were not significant in atorvastatin group as in placebo group (p=0.04 for atorvastatin in group and p=0.04 for placebo group). Also, changes in methacholine solution number (different concentrations of methacholine) which caused at least 20% decrease in FEV1 were not significant between groups (p=0.03 for atorvastatin group). Although we could not find a significant difference, the patients’ fall in FEV1 in atorvastatin group was observed in higher concentrations of methacholine. Median before treatment versus after treatment in atorvastatin group was 1 versus 4 mg/ml, while those were 2 versus 1 mg/ml in placebo group.

This study showed a better but no significant hyperresponsiveness control in the treatment group. The result may be presented more pronounced, if we could increase the sample size.

P2194 The GOLDEN-1 study: Safety and bronchodilatory effects of nebulized glycopyrrolate (EP-101) using high efficiency nebulizer in patients with COPD

Charles Fogarty1, Edwin Kerwin2, Karen Dunn3, David Singh4, Ahmet Tutuncu5

1, 2, 3, 4, 5 Elevation Pharmaceuticals Inc., San Diego, CA, United States

Elevation Pharmaceuticals Inc., San Diego, CA, United States

Introduction: EP-101 is a long-acting muscarinic antagonist bronchodilator for nebulization using a high efficiency nebulizer for the treatment of COPD. The safety and efficacy of once daily nebulized EP-101 was assessed in this Phase 2b study after 7 days of dosing in patients with COPD.

Methods: This was a multicenter, randomized, double-blind, placebo-controlled, 4-period cross-over, incomplete block design study. A total of 140 patients with moderate-to-severe COPD were randomized to receive 4 of 7 treatments: EP-101 (placebo, 25, 50, 100, and 200 μg) once daily via high efficiency nebulizer, open-label ipratropium 18 μg once daily, and open-label ipratropium 500 μg 3 times daily via jet nebulizer. There was a 7-day washout period before treatment.

Results: All doses of EP-101 were well tolerated with similar AE rates between placebo and EP-101 (31.2%, 29.7%, 26.9%, 35.5% and 30.7% for placebo, 25, 50, 100, and 200 μg, respectively). There was no apparent dose-response relationship for incidence and severity of AEs. Mean changes in vital signs and ECG parameters from baseline on Day 7 were comparable between the treatment groups. All doses of EP-101 demonstrated dose-related and significant improvements in FEV1, AUC (0-24hr) on Day 7 compared with placebo, with estimated differences between EP-101 doses and placebo ranging between 110-169 mL.

Conclusion: Once daily dosing with nebulized EP-101 was well tolerated over a 7-day treatment period and provided rapid onset of bronchodilation with clinically meaningful and sustained improvement in lung function over 24 hours in patients with COPD.

P2195 Spacer cleaning: Nurse and patient survey examines current UK practice

Mark Sanders1, 2, Mark Levy3, Keeley Thompson1, Ron Brun1, 4

1HQ, Clement Clarke International Ltd, Harlow, United Kingdom; 2Senior Clinical Research Fellow, Allergy and Respiratory Research Group, Centre for Population Health Sciences, GP Section, University of Edinburgh, Doorway 3, 3Medical School, Edinburgh, United Kingdom

Introduction: Washing spacers improves drug delivery by reduction of electrostatic charges, and is hygienic. Contamination of spacers and masks has been shown (JAMA 2003;290: 2, 195-196). The ERS/ISAM guideline (ERI 2011;37:1308-1331) identified a lack of standard instructions for good spacer cleaning practice.

Methods: Online structured interview questionnaires by a market research agency, 100 asthma patients (Pts) using pMDI with spacer and 50 respiratory nurses (RN) to establish current practice. Pts: 49 adults, parents of child aged 2-9 yrs (n=30) or 10-15 yrs (n=21).

Results: 74% of RN told Pts to wash spacers weekly, 4% instruct daily and 22% instruct < than weekly. RN reported that Pts describe correct washing: 4% always, 42% mostly, 36% sometimes, 14% rarely and 4% never. RN confidence in patients keeping spacers hygienically was low, with 48% not very not or not at all confident, this figure increased to 56% in respect of masks. 71% of Pts said their RN or doctor explained how to wash the spacer, and 63% received drying instructions. 5% were told how to wash and dry, but 24% were not told either. 13% could not recall being told. 21% of adult Pts don’t wash + dry their spacer (not been told); 6% of children’s spacers were not washed. Of 83 who wash their spacer: 35% do so after each use, 20% every day, 27% once a week and 18% < weekly: 72% report air drying and 27% use a cloth.

Conclusions: RN spacer washing instructions frequently conform tomanufacturer’s instructions. Many Pts wash spacers more frequently than instructed but some do not wash at all; neither may be helpful. Many may disuade the electrostatic benefits of air-drying and encourage contamination.

P2196 Patterns of bronchodilator reversibility of FEV1 in asthma and COPD patients

Ahmet Saharabudhe, Madhuri Joshi, Vikas Oswal

Department of Pulmonary Medicine, Pulmonarytree Dr. D.Y. Patil Medical College, Pimpri, Pune, Maharashtra, India

SAMA (Short Acting Muscarinic Antagonist) has been said to be superior to SABA (Short Acting Beta Agonist) in COPD whereas SABA is preferred bronchodilator in asthma patients. In practice however we observe that the response is variable for individual patient. Therefore we evaluated improvement in FEV1 in 27 asthmatics and 27 COPD patients in response to inhaled SABA (Salbutamol) and SAMA (Ipratropium) on separate days. These patients were in respiratory care with no exacerbation or change of regular treatment in last 4 weeks.

The washout period of their regular treatments was adhered to, before performing their spirometres. SABA produced mean increase of 16.66% and 401 ml in FEV1 of asthmatics vs -1.54% and -150 ml in COPD. SAMA produced 4.07% and 161 ml increase in FEV1 in asthmatics vs. 8.59% and 166 ml in COPD patients. The similar increase in FEV1 in ml in response to SAMA was more significant in FEV1% due to lower baseline FEV1 in COPD patients. An interesting fact observed was that with the increasing duration of Asthma and COPD, the reversibility with SAMA sequentially increased. With a cut off of more than 8 years of duration of disease, the average improvement in FEV1 in response to SAMA was 45 ml (vs. 77 ml in less than 8 year duration) in asthma and 222 ml in COPD, whereas there was no significant change in response to SABA in both groups. There was no correlation with patient’s age or baseline FEV1 value. We conclude that inhaled muscarinic antagonists can be a beneficial adjunct to beta agonists in persistent asthmatics with longer duration of asthma.

P2197 Bronchodilator response and airway cytology as parameters for asthma control: A randomized clinical trial Protocol ID: APITA, NCT00597064, on August 1st, 2008

Ana Lúcia Fernandes, Maria Marta Amorim, Lilian Ballini Caetano, Alexandre Araújo, Bika Lopes Santo. Medicine: Respiratory Division, Federal University of São Paulo, SP, Brazil

Background: Clinical control is hard to define in asthma and there is little experimental data on the optimal timing, sequence and magnitude of treatment. Aim: Measuring the effects of short course of oral corticoid in airway inflammatory and spirometrical values of asthmatic patients to define control.

Methods: A double blind randomized clinical trial to observe the change in spirometry, nasal and sputum cytology in patient under combination therapy, receiving either short course of oral corticoid (OC) or placebo(P). Controlled asthma was defined by ACQ<1.5. They were submitted to clinical evaluation, nasal and sputum cytology, spirometry before and after 15±5 days of randomization. Intervention efficacy was defined by improvement of 200 ml in FEV1.

Results: n=70, 73% female, age 46 ±13.1, 35 received OC and 35 P. Who received OC showed significant improvement in all spirometrical parameters and abolished their positive bronchodilator response related to P. The eosinophils count in the nasal and induced sputum also reduced in OC arm. The logistic regression model identifies for each one year increasing in age there was a 6% decrease in odds of intervention efficacy, associated to 19 times increase in odds related the usage of oral corticoid (related to placebo), and for each increase of 1% in bronchodilator response was associated to 9% increase in odds of efficacy (p=0.02).

Conclusion: The RCT allowed define uncontrolled asthma at baseline and the degree of bronchodilator response, younger age and usage of OC were significant predictors for functional improvement at the end of the trial. Partially funded by FAPESP.
P2198
The effect of smoking on severity of asthma and quality of life in patients treated with inhaled corticosteroids and long-acting β2-agonist (ICS/LABA)
Galina Sergeeva, Alexander Emel'yanov. Lung and Allergy Diseases, Mechnikov North West State Medical University, Saint-Petersburg, Russian Federation
Background: The aim of this study was to assess the effect of smoking on severity of asthma and quality of life in asthmatic patients treated with ICS/LABA in real clinical practice.
Methods: 122 out-patients (aged 20 – 82 yrs, mean age 55 yrs, 28% males) with moderate-to-severe asthma were treated with medium/high doses of ICS/LABA (GINA2010) and LABA in one inhaler for ≥2 years. Quality of life was measured by using Russian version of St. George’s Respiratory Questionnaire (SGRQ).
Results: Never smoked 36% of patients, former smokers were 31% and current smokers were 33%. Among never smoked asthmatics 80% were treated by medium doses of ICS/LABA and 20% received high doses. Patients with history of smoking (current or previous) have administered medium doses of ICS/LABA in 68% and high doses in 32%. FEV1 differed in nonsmokers and current smokers: 70% vs 56%, p < 0.05. History of smoking was associated with FEV1 level (r=0.25, p<0.05) and severity of disease (r=0.3, p<0.05). The difference of Symptom score between smokers (current or former) and nonsmokers was significant (57.6 versus 66.7, p<0.05). We revealed the impact of smoking on all scores of SGRQ in females: Symptom (57 vs 65, p<0.05), Activity (53 vs 51, p<0.05). Impact (39 vs 40, p<0.01), and Total score (46 vs 48, p<0.01) but not in males.
Conclusion: Smoking is common and may decrease effectiveness of ICS and LABA in asthmatic patients in real clinical practice. There were significant correlations between smoking, severity of asthma and SGRQ scores, especially in females.

P2199
The correction of monocyte-derived neohepatocytes from alpha1 antitrypsin deficient patients
Gillian McNab1, Robert Stockley2.1 Centre for Translational Inflammation, University of Birmingham, United Kingdom; 2 Lung Investigation Unit, Queen Elizabeth Hospital Birmingham, United Kingdom
This study explores the culture of monocyte-derived neohepatocytes from PiZ alpha antitrypsin deficient (α1ATD) patients and homologous replacement using small DNA fragments (SDFs) to correct the Z defect.
Monocytes from 6 patients were de-differentiated with MCSF and IL3 and then differentiated into neohepatocytes with FGF-4. Albumin, urea and α1AT secretion. Development of neohepatocytes and cDNA checked for the M or Z message.
SDFs were produced 163±2 g/ml/24h, 298±4 g/mL/24h of protein. Neohepatocytes produced PCR products from Z primers. M SDF treated neohepatocytes and cDNA checked for the M or Z message.
Conclusion: Smoking was associated with FEV1 level (r=0.25, p<0.05) and severity of disease (r=0.3, p<0.05). The difference of Symptom score between smokers (current or former) and nonsmokers was significant (57.6 versus 66.7, p<0.05). We revealed the impact of smoking on all scores of SGRQ in females: Symptom (57 vs 65, p<0.05), Activity (53 vs 51, p<0.05). Impact (39 vs 40, p<0.01), and Total score (46 vs 48, p<0.01) but not in males.

Results: Vno50-200 was strongly correlated with Vno in normal subjects (p=0.94, p<0.001), asthma (r=0.98, p<0.001), COPD (r=0.93, p<0.001), and CF patients (r=0.74, p<0.05). This agreement was confirmed by the Bland and Altman test.

Conclusions: The flow dependent component of exhaled NO is determined by its bronchial production which can be estimated by measuring Vno50-200. This method is simple, does not require sophisticated equipment or mathematical models and is in agreement with Jno calculated mathematically with the conventional linear regression method.

P2201
Endogenous and exogenous metabolites in exhaled breath condensate in asthma
Ananyev1, T.N. Anokhina1, I.A. Revelsky2, A.A. Rodionov2, A.I. Revelsky2, A.G. Chichalin1, 1Clinical Department, Research Institute, Moscow, Russian Federation; 2Chemistry Faculty, M.V. Lomonosov Moscow State University, Moscow, Russian Federation
Profile of metabolites in different biological fluids reflects the physiological and pathophysiological processes in the human organism initiated by internal and external factors. Exhaled breath condensate (EBC) analysis can provide information about the state of metabolic processes in the respiratory tract.

Method: Evaluation of exhaled breath condensate(SVMs) in EBC in asthma patients and healthy subjects. SVMs belong to different classes of chemical compounds: saturated fatty acids (SFAs), hydrocarbons, alcohols, aldehydes, ketones, esters, phenols and aldehydes. The limit of compounds detection was 0.1-10 ppb. 18 SVMs are presented in the Human Metabolome Database (HMDB): 13 endogenous metabolites and 5 exogenous metabolites. SVMs were determined earlier in the blood, urine, but there is still no information in HMDB about these metabolites in EBC. The most representative group consisted of 12 SFAs, 11 of them are endogenous metabolites. The content of steatic and palmitic acids in EBC of patients with asthma was significantly decreased in compared with healthy. We found negative correlations between SFAs in EBC and spirometry parameters (FVC, FEV1 and FEV1/FVC) (p<0.05) in asthma patients.

Conclusion: The pathological process in the respiratory tract changes the expression of SFAs in EBC, indicating the involvement of these metabolites in the pathogenesis of asthma.

Exercise increases the hydrogen peroxide release in exhaled breath condensate
Elke Maximilian Mareck1, Juliane Volke2, Wolfgang Mareck3, Petra Pfaten2.
1Department for Clin. and Exp. Occupational Dermatology, Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr-Universität Bochum (IPA), Bochum, North Rhine-Westphalia, Germany; 2Department of Sports Medicine and Sports Nutrition, Ruhr-Universität Bochum, North Rhine-Westphalia, Germany; 3Institute of Occupational Physiology, Augusta Teaching Hospital, Bochum, North Rhine-Westphalia, Germany
Background: Exhaled breath condensate (EBC) contains numerous mediators of oxidative stress (NO, H2O2). Exercise is characterised by an increase of reactive oxygen species (ROS), which can also be found in EBC. Building of hydrogen peroxide (H2O2) can be induced by ROS. In order to get inside into the correlation of H2O2 release in EBC and exercise, we investigated H2O2 release at rest and at different levels of exercise.

Methods: 20 healthy subjects, (23.3±1.5 years), were investigated, during resting conditions as well as at 60%, 75% and 90% of maximal work capacity(pmax) (each lasting 5 minutes) on a cycle ergometer. 100 L exhaled air along with capillary blood samples were collected under stationary load conditions. EBC was obtained by cooling the exhaled air volume to -20°C. H2O2 was analyzed using the EcoCheck device (EcoCheck, FILT). H2O2 was analyzed using the EcoCheck device (EcoCheck, FILT). In further analysis the release per minute and the release for the total amount of water from 100 L exhaled breath were calculated.

Results: At rest H2O2 concentration in EBC was 216±52 mmol/L. H2O2 release in the collected EBC was 115±45 mmol/min. At 60%, 75% and 90% of pmax, H2O2 concentration in EBC increased to 338±80, 322±71, 334±95 mmol/L (p<0.01). Taking the theoretical water volumes of 4.4 ml EBC derived from 100 L exhaled air into account, H2O2 release increased to 167±75, 250±88 and 357±162 mmol/min (p<0.001). The correlation of H2O2 release and ventilation can be described by a linear relationship.

Conclusions: In healthy subjects, a nearly 3-fold increased of H2O2 release in EBC was observed during moderate and high intensity exercise as well as during high intensity exercise.
EBC was found during exhausting exercise. The elevated levels of H$_2$O$_2$ may be interpreted as an increase of ROS during exhausting exercise.

**Protein markers in the exhaled breath condensate of lung carcinoma patients**

Gabriel Garcia 1, Miguel Burgos 2, Orlando Lopez-Jose 2 1Pneumology, CENASMA, La Plata, Argentina; 2Pneumology, Hospital Antonio Cerradigo, Vicente Lopez, Argentina

Introduction: Chronic obstructive pulmonary disease (COPD) is a common airway inflammatory disorder with structural degradation of the airway tissue. Previous reports showed that patients with COPD had EBT lower than normal subjects. Recently, a new combined COPD assessment was based on the symptoms, spirometric classification and risk of exacerbation (GOLD 2011).

**Objectives:** Evaluate the EBT in COPD patients according to the new combined COPD assessment and compare to healthy subjects.

**Methods:** EBT was measured (using the Xhalo, Delmedica, Singapore) in 80 COPD patients (FEV1: 54±14, age 60±8 years, 46 males) and 80 healthy controls. Lung function, COPD Assessment Test (CAT), exacerbations and previous treatment was performed.

**Results:** There was no differences EBT between COPD patients 34.2±9 vs. healthy subjects 33.9±9. There was no correlation between EBT and FEV1% (r=0.23). EBT and CAT (p=0.01) but patients with previous exacerbations had EBT higher than patients without exacerbations (34.7±8 vs 33.9±9, p=0.001). According to the new combined COPD assessment (20 subjects for each group), the EBT was: Group A 34.1±9, Group B 33.9±9, Group C 34.7±9 and Group D 34.8±9 (p<0.001 between Group B vs Group C and D).

**Conclusion:** Our results showed that COPD patients with frequent exacerbations, 2 or more per year, had increased of Exhaled Breath Temperature, therefore may reflect inflammation in the COPD lung.

**P2004**

**Particle content in exhaled air depending on breathing maneuver**

Per V. Larsson 1, Bergen Baken 1 1, 2, Ekaterina Mirgorodskaya 2

The airway opening generates particles in the distal airways. At high exhalation flows, particles can be formed due to dynamic compression in more central airways. The aim with the present study was to compare particle number and size distributions as well as concentrations of SpA in PEs formed during tidal breathing, airway opening and dynamic compression using forced exhalations.

Ten healthy volunteers performed three different types of breathing maneuvers in randomized order; Reference maneuver (R): no airway closure and no dynamic compression (slow expiration), Dynamic compression (DC): maximal exhalation for surfactant protein A (SpA) content using ELISA. Compared to the R maneuver, the DC maneuver doubled the particle concentration and the AO maneuver gave a ten times increase in the amount of particles per liter exhaled. Flow volume curves indicated that dynamic compression was limited by the back pressure in the instrumentation.

The mass ratio of Sp-A in the PEs were highest in PEs using the R maneuver; 13% ±5%/DC (p<0.001) and 3%/AC (p<0.001), DC to AC difference was not significant (p=0.1). The size distributions were similar in all maneuvers.

**Conclusion:** In conclusion, fast exhalation flows generates more particles than slow exhalation flows, but probably not by the dynamic compression mechanism.

**P2005**

**Exhaled breath temperature in COPD patients**

Gabriel Garcia 1, Miguel Burgos 2, Orlando Lopez-Jose 2 1Pneumology, CENASMA, La Plata, Argentina; 2Pneumology, Hospital Antonio Cerradigo, Vicente Lopez, Argentina

Introduction: Chronic obstructive pulmonary disease (COPD) is a common airway inflammatory disorder with structural degradation of the airway tissue. Previous reports showed that patients with COPD had EBT lower than normal subjects. **P2006**

**Concentrations of nitric oxide metabolites in the exhaled breath condensate in children with different bronchiasthma control**

Svetlana Soudarova 1, Igor Klimanov 1, Tatiana Eliseeva 2, Natalya Rubkheva 1 1Clinical and Experimental Biophysics, Pulmonology Research Institute, Moscow, Russian Federation; 2Department of Internal Medicine, The Medical Institute, Nichny Noegorod, Russian Federation; 1Immunology Laboratory, Municipal Hospital "Aibolit", Nichny Noegorod, Russian Federation

Although bronchial asthma (BA) is an inflammatory disease, the clinical tools that evaluate asthma control today do not include the qualitative measures of inflammations.

**Objective:** Determination of correlations between total concentration of nitrates and nitrites (TNN) in the exhaled breath condensate (EBC) and children asthma control level determined by the Asthma Control Questionnaire (ACQ).

**Material and methods:** 81 patients with atopie BA (from 6 to 17 years old) were clinically evaluated. Patients completed ACQ, underwent spirometry, and measure-ments of their TNN in EBC. In 55 children, the high BA control (ACQ=0.29±0.26) was diagnosis. 13 children had partially controlled BA (ACQ=0.96±0.20), and 13 children had only bad BA control (ACQ=1.95±0.33). Among the children with high BA control, 27 had no steroid (IGKS) treatment, 28 had only basic IGKS therapy, 19 had with partial or bad control had IGKS therapy. In 27 steroid-naive patients with high-controlled asthma, the TNN in EBC was 6.24±2.93 mMk. In 28 patients with controlled BA taking IGKS, TNN was 4.66±2.34 mMk (p=0.03). In patients with partially controlled BA, TNN level was 2.62±2.62 mMk in patients with bad control - 6.52±2.62 mMk. The correlation between TNN and ACQ scores was found in the whole group (p=0.047), however, the significance was varying in groups with different therapy. In the group of steroid-naive patients, p=0.027; in patients treated with IGKS, p=0.024. The interpretation of TNN in patients with BA, if it is performing for the additional characterization of the control level, should include the consideration of therapy taking by patients.

**P2007**

**Saturated fatty acids in exhaled breath condensate in COPD patients**

T.N. Anokhina 1, E.K. Anaev 2, A.I. Revelsky 1, A.A. Revelsky 1, A.G. Chachalin 1 1Clinical Department, Research Institute of Pulmonology, Moscow, Russian Federation; 2Chemistry Faculty, M.V. Lomonosov Moscow State University, Moscow, Russian Federation

In recent years suggest that individual saturated fatty acid (SFA) has specific prop-erties which are associated with important biological functions. The composition of SFAs in exhaled breath condensate (EBC) has not previously been studied.

**Aim:** To identify SFAs in EBC and to assess their relationship with clinical and functional parameters in patients with COPD.

**Methods:** We have studied 20 patients with COPD and 30 healthy non-smok-ers. EBC was collected using E-CScreen. SFAs in EBC have been identified by gas-chromatography - mass-spectrometry method (GC-MS) and NIST-2005 library.

**Results:** 12 SFAs (palmitic acid, stearic acid, myristic acid, etc.) have been identified in EBC in COPD patients. There were no differences in the contents of SFAs in EBC in COPD patients and healthy subjects. We have found the relationship between EBC content of caproic acid (R=0.46), enanthic acid (R=0.61), caprylic acid (R=0.50) and PFC in COPD patients (p<0.05). In addition, the content of myristic acid in EBC significant correlated with oxygen saturation (R=0.798).
on subjective or objective measures. It has been advocated that fractional exhaled nitric oxide (FeNO) can be used to monitor airway inflammation as it correlates with some markers of asthma.

The aim of our study was to assess the clinical usefulness of the assessment of FeNO for monitoring asthma during pregnancy.

Methods: We used the medical data of 72 pregnant asthmatic women: FeNO results, atopic status, spirometry and ACT (asthma control test) (monthly, 257 visits in all; first visit between 8.22-28). We assessed asthma severity on the basis of anamnesis considering mean doses of inhaled glucocorticosteroids taken by the patients and a management approach based on control according to the newest guidelines of Global Initiative for Asthma (GINA) throughout the last three months before pregnancy.

Results: We did not find correlation between FeNO levels at visit one (pregnancy) and asthma severity before pregnancy (p=0.97). In 22 women with worsening asthma during pregnancy, the mean FeNO during visits without asthma symptoms and with asthma worsening did not differ. A comparison of FeNO levels in the groups of women with well controlled asthma during pregnancy and FeNO with visits without asthma symptoms in the group of women with at least one asthma exacerbation did not differ. There was a statistically significant but low correlation between FeNO levels and ACT total scores results, and FeNO levels and FEV1 (r=0.21 and r=0.25 respectively).

Conclusions: FeNO does not seem to be clinically applicable to predict asthma prognosis during pregnancy, especially because of its high coefficient variation.

P2211
Inflammation on the effectiveness of the Mostgraph and fractional exhaled nitric oxide measurement in chronic cough

Chihito Nakano, Nobuyuki Hatanaka, Toru Yamagishi, Hirotsuka Kamenara, Norio Kodaka, Atsuos Miyahara, Yoshiyuki Kuruse, Kayo Segawa, Umiko Kashwka, Yuki Kamata, Haruhi Hayashi, Manabu Toyoda, Kanako Hirayama, Ken Sanno. Respiratory Medicine, Toho University Ohashi Medical Center, Tokyo, Japan

Objectives: Mostgraph, Fractional exhaled nitric oxide (FeNO) measurement, and pulmonary function tests were conducted in patients with chronic cough. The effectiveness of Mostgraph, FeNO measurement, and pulmonary function tests were examined in elucidation of pathology, differential diagnosis, and therapy evaluation of chronic cough.

Method: 1. The subjects were 120 patients who presented with chronic cough. The respiratory resistance measuring device Mostgraph (Chest MI, Inc) was used. For FeNO, NIOX-MINO (Aerocrine) was used. Pulmonary function tests used spirometry. Imaging and blood tests were performed as diagnostic aids. Patients treated with combination of stimulants and inhaled corticosteroid.

Results: Airway resistance at 5 Hz (Rr5) and 20 Hz (Rr20) as well as FeNO tended to increase in patients with chronic cough. Airway resistance and FeNO showed a significant reduction as symptoms improved. Pulmonary function tests showed no significant changes.

Conclusion: 1. In patients with chronic cough, Rr5 and Rr20 increased, and FeNO tended to increase, but decreased with treatment. A combination of Mostgraph and FeNO measurement can be conducted quickly and noninvasively, and this study suggests that this combination may be useful in diagnosis of chronic cough, and in assessing the effectiveness of treatment.

P2212
FeNO (fractional exhaled nitric oxide) measurements in pregnant asthmatic women. The long-term, intra-subject variability of FeNO in controlled asthma

Anna Dor-Wojnarowska1, Marta Nitter-Marszalska1, Robert Pawlowicz1, Hanna Marszalska2, Anna Kazimierczak1, Bernard Panaszek1. 1Department and Clinic of Internal Diseases, Geriatriy and Allergology, Wroclaw Medical University, Wroclaw, Poland; 2Regional Center of Oncology, Wroclaw, Poland

Background: Fractional exhaled nitric oxide (FeNO) is considered a good non-invasive marker to assess airway inflammation in asthma and allergic rhinitis. It has been also been proposed that adjusting anti-inflammatory drugs guided by the monitoring of exhaled NO could improve overall asthma control. However standards, the assessment of long-term repeatability of this parameter as well as the ratio of change which can be considered significant have not been established yet.

The aim of our study was to assess the long-term, intra-subject variability of FeNO in pregnant asthmatic women with controlled asthma.

Methods: Pregnant, non-smoking women with asthma were recruited between 8 and 24 weeks of gestation. Exhaled nitric oxide (FeNO), lung function, and the asthma control test (ACT) were performed at monthly visits up to delivery. The data of 50 subjects with well controlled asthma (20-25 ACT, normal spirometric parameters, no change in treatment) during pregnancy were analyzed. The variability of the FeNO parameter was assessed in asthmatics using the variation coefficient (standard deviation x 100/average).

Results: FeNO showed high coefficient of variation (CV): 35.8% (Me 32;Min 2.45, Max 121.9) in all women with well controlled asthma during pregnancy. There was no significant difference in CV between astatic 36.2% (35.5; 2.45-121.9) and nonatopic 33.9% (25.5; 11-71.9) asthmatic women (p= 0.98).

Conclusions: Long-term variation of FeNO was found to be not satisfactory be
cause the variation coefficient was 35.8%. It means that changes of FeNO should be interpreted with caution.

P2213

No effect of breathing dry gas on exhaled nitric oxide concentration at rest

Ida Solna, Olaf Sampergaret1, Silje Hoel1, Einar Thoresen 1, 2. 1-Institute of Medicine, University of Bergen, Norway; 2-Dept of Occupational Medicine, Haukeland University Hospital, Bergen, Norway

Background: The prevalence of asthma in elite endurance athletes is high, in particular among skiers. Prolonged high ventilatory demands in a cold and dry environment may contribute to the development of, or worsening of the asthma. Training periods often take place at altitudes of 2-3000 meter where ventilatory demand and respiratory heat and water loss are higher. Measurement of exhaled nitric oxide concentration (FeNO) is useful for monitoring eosinophilic asthma, but not neutrophilic asthma.

Aim: To assess the effect of breathing dry air on FeNO.

Methods: Nine healthy subjects aged 21 – 27 yrs (4 men) breathed dry air and humidified air for 90 min at rest in random order on separate days. FeNO was measured with a chemiluminescence analyser (Eco Medics AG, Duernten, Switzerland) at an expiratory flow rate of 50 ml/sec to ~15 min before and ~15 min after the exposures.

Results: There was no difference in the baseline FeNO between the two days. After exposure to dry air, FeNO decreased from 23.3 (SD=17.5) to 20.9 (SD=15.2) ppb, and after humid air it increased from 24.9 (SD=14.6) to 22.9 (SD=13.6) ppb.

Discussion: Breathing dry air at rest did not influence FeNO. Higher ventilatory demands result in larger respiratory water loss, which may be a trigger of a bronchomotor response. The transient reduction in FeNO after exercise must be controlled for when studying the combined effects of exercise and dry air on FeNO.

P2214

Fractional exhaled nitric oxide in bronchiectasis

Young-Jae Cho, Hyo-Jeong Lim, Jong Sun Park, Sei Won Lee, Jae Ho Lee, Cheon Jack Lee. 1-Internet Medicine, Seoul National University Bundang Hospital, Seongnam, Korea

Fractional exhaled nitric oxide (FeNO) can be measured easily, rapidly, and non-invasively for assessment of airway inflammation, especially mediated by eosinophil, such as asthma. In bronchiectasis, the pathogenesis has been known as chronic airway inflammation and infection with abnormal airway dilatation; however, there is little information to evaluate the clinical application of exhaled nitric oxide in bronchiectasis.

From March 2010 to September 2011, 30 patients with bronchiectasis diagnosed by chest high resolution CT performed FeNO, compared with various pulmonary diseases, including asthma (n=24), COPD (n=21) and other infectious diseases (n=25). All patients carried out eosinophil count with chemistry, simple radiograph, sputum examination and spirometry, if indicated. FeNO (mean, ppb) in patients with bronchiectasis was 19.1, compared to 68.4, 31.7 and 18.9 in asthma, COPD and other infectious diseases, respectively. FeNO in bronchiectasis was significantly lower than asthma (P<0.001), however, no statistical differences were seen between bronchiectasis and other pulmonary diseases except asthma. No correlation of FeNO with eosinophil count in bronchiectasis was seen, despite the correlation was true in all of patients enrolled in study. FeNO in bronchiectasis with co-infection of nonmycobacterium tuberculosis was slightly lower than without co-infection (14.8 vs. 20.8). FeNO also tended to decrease along with multi-lobe involvements on CT.

FeNO in bronchiectasis was lower than other respiratory diseases, especially asthma. In bronchiectasis, the pathogenesis has been known as chronic airway inflammation and infection with abnormal airway dilatation; however, there is little information to evaluate the clinical application of exhaled nitric oxide in bronchiectasis.

P2215

The usefulness of the simultaneous measurement of IOS and FeNO in the management of asthma

Sochiro Hozawa, Michikazu Terada, Maki Hozawa. Allergology, Hiroshima Allergy and Respiratory Clinic, Hiroshima, Japan

Background: The evaluation of airway lesions by impulse oscillometry (IOS) and the evaluation of fractional exhaled nitric oxide (FeNO) as the indicator of asthmatic airway inflammation attract attention. [Aim] To evaluate asthmatic airway lesions by simultaneous measurement of IOS and FeNO.

Methods: The subjects were the good controlled 65 patients with asthma (good controlled group), and 42 symptomatic treatment-free initial-visit patients with asthma (initial-visited group). Those subjects were nonsmoker. For the patients in both groups, we measured IOS and FeNO at the same time. IOS measured by MasterScreen and FeNO measured by NIOX MINO.

Results: The mean value of FeNO was 73.1±7.5 ppb in initial-visited group, and was 25.0±2.3 ppb in good controlled group, and the initial-visited group significantly showed high level. In the good controlled group, the positive correlation was accepted between the following IOS parameters, such as the total airway resistance, the small airway component, the peripheral capacitive reactance and the reactance area, the resonant frequency and FeNO (p<0.0001), but the correlation was not found between the large airway component and FeNO. Whereas, in the initial-visited group, the association was not found between these IOS indicators and FeNO.

Conclusions: FeNO mainly shows the inflammation of the small airway in the good controlled patients with asthma. Whereas, in the treatment-free initial-visited patients with asthma, FeNO was reflecting the inflammation of various airway regions.

Discussion: By the simultaneous measurement of IOS and FeNO, the information about asthmatic airway lesions as the target of treatment is obtained in greater detail.

P2216

Asthma control test (ACT), fractionated exhaled nitric oxide (FeNO) and forced expiratory volume in 1 second (FEV1) correlation in asthma control

Ferdous Yamaguchi, Maher Abouda, Marien Triki, Nidhal balloumi, Asma Migaou, Hend Khouami, Mohamed Ridha Chaff. Department of Pneumology, Hospital of FSI, La Marsa, Tunisia

Background: The current goal of asthma treatment is to achieve and maintain control. Numerous markers or measurements of control are available. Among them, functional parameters (spirometry), clinical assessment (symptoms and quality of life) and biomarkers of inflammation are the most widely used.

Objective: This study aimed to clarify the relationship between the Asthma Control Test (ACT), lung function especially forced expiratory volume in 1 second (FEV1) and fractionated exhaled nitric oxide level (FeNO).

Patients and methods: There is a prospective study, for two months, including 37 asthmatic patients followed up outside of an exacerbation. A clinical protocol was followed with an assessment of asthma control by an ACT, spirometry and measurement of exhaled NO.

Results: There were 18 males and 19 females with a mean age of 43 years (12-7 years). The ACT score ranged from 12 to 25 (median=19). Total control of asthma (ACT≥20) was obtained in 18 patients. The average value of FeNO in the total control group (29.1 ppb) was significantly better than those in the less controlled groups with an ACT<20 (48.2 ppb).

There was no correlation between FEV1 and ACT (r=0.05), and between FEV1 and FeNO (r=-0.02). On the contrary, a negative correlation was found between ACT score and FeNO (r = -0.2).

Conclusion: We can postulate that the degree of bronchial inflammation is more sensitively detected by FeNO than by FEV1. The ACT is a good subjective tool for assessing the degree of asthma control which is more correlated with FeNO than FEV1.

P2217

Standardization procedures for in-vitro measurements using differential ion mobility spectrometry (DMS)

Roman Purkhardt1, Rolf Graupner1, Gunther Becher. 1-R&D, Graupner GmbH & CoKG, Gey, Germany; 2-Medicine, BeckerConsult GmbH, Bernau, Germany

Introduction: Air contains a couple of non-gaseous volatile organic substances (VOCs). Differential Ion Mobility Spectrometry (DMS) is an analytical method for detection of VOCs with sensitivity in the ppt-range and the possibility of processing native steam coming samples. A common problem is the pollution of samples by environmental agents, even with similar VOCs as in the samples. The method already was used for detection of bacterial growth.

Methods: For evaluation of ambient air influences on standardized in-vitro samples, bacteria-breeding grounds in closed vials were measured with room air as well as with filtered room air. This method should keep the water-content of the samples unchanged. The spectra were analyzed by a statistical program based on cluster analysis.

Results: The evaluation included up to 120 clusters of peaks. The number of peaks in filtered pure room air was significantly reduced and the total intensity was about halved. The reactive ion peak (RIP) of room air was 1.5-fold increased. Peaks and total intensity of the measured breeding grounds remained virtually unchanged.

Discussion: The filtering of air was capable to reduce environmental pollutants of in-vitro DMS measurements, even if the sample contains ambient air itself. The RIP of the sample tracings remains unchanged or was slightly increased, which can improve the sensitivity of DMS-measurements.

The investigation shows that it is possible to dispense with expensive carrier gases, which allows inexpensive diagnostic measurements in a contaminated environment.

Volatile organic compounds may provide a new and promising tool for diagnosing interstitial lung diseases

Anees Bega1, Roel Schins2, Roger Godschaik1, Catrin Albrecht2, Jan Dallinga1, Aalt Bas1, Florence Schleich3, Marjolein Drent1, Frederik-Jan van Schooten1. 1-Toxicology, Maastricht University, Maastricht, Netherlands; 2-Partikel Forschung, IUF-Leibniz; Institut für Umweltmedizinische Forschung at the Heinrich Heine University, Düsseldorf, Germany; 3-Pulmonary Medicine, Maastricht University Medical Centre, Maastricht, Netherlands

Diagnosing interstitial lung diseases (ILD) requires invasive techniques. A new, non-invasive diagnostic tool includes analyzing volatile organic compounds

3975
These preliminary findings suggest that ventilatory patterns during speech tasks compared to the healthy group found in other parameters, the asthma group had a higher mean RR during all speech in adults with a self-reported history of asthma are characterised by a shorter TI and faster RR compared to ‘healthy’ participants. Research with larger VOCs currently investigated as a new tool for diagnosing ILD in vitro.

**P2219**

**Speech breathing pattern analysis in adults with a self reported history of asthma.**

Rokhsaneh Tehrany 1, Anna Bruton 1, Anna Barney 2.

1Faculty of Health Sciences, University of Southampton, Hampshire, United Kingdom; 2Institute of Sound and Vibration Research, University of Southampton, Hampshire, United Kingdom.

**Background:** While speech and breathing patterns are known to alter in acute episodes of respiratory disorders like asthma, it is not known if they alter in respiratory pathology, during stable periods of the disease.

**Aims and objectives:** To compare speech breathing patterns in healthy adults and those with a self-reported history of asthma.

**Methods:** Eleven adults with a self reported history of asthma (mean age = 29) and 29 ‘healthy’ adults (mean age = 34) with no history of respiratory disease were recruited from the University of Southampton. Breathing patterns were recorded non-invasively using Respiratory Inductive Plethysmography during 4 minutes each of quiet breathing, and 3 speech tasks: reading, describing and conversation.

**Offline analysis** was performed where 6 breathing parameters were extracted; inspiration and expiration time (TI, TE), breath cycle time (Ttot), inspiration and expiration time (TI, TE), breath cycle time (Ttot), inspiration and expiration (Tins, Texp) of the TI, TE, Ttot.

**Results:** Inspiration time was significantly shorter at the 95% level in the asthma group compared to the healthy group.

**Conclusion:** These preliminary findings suggest that ventilatory patterns during speech in adults with a self-reported history of asthma are characterised by a shorter T1 and faster RR compared to ‘healthy’ participants. Research with larger samples is needed to confirm these initial findings, as breathing patterns during structured tasks like speech could be useful for monitoring lung health.

A novel, simple and rapid method to measure soluble mediators in dithiothreitol-treated sputum

Roberta Milone 1, Peter Chalk 2, Ken Grace 1, David Singh 2, Raminder Aul 4, Richard Knowles 1, 2.

1Respiratory TAU, GlaxoSmithKline, Stevenage, Hertfordshire, United Kingdom; 2Aurora Pharma, Steventon, Hertfordshire, United Kingdom; 3Medicines Evaluation Unit, University of Manchester, United Kingdom.

**Sputum** is most often processed by the addition of dithiothreitol (DTT) to liquefy the sputum plug and release cells and soluble mediators for subsequent analysis, but DTT treatment can perturb substantially with these analyses. The aim of this study was to develop a method to reverse this, to allow for the sensitive determination of analytes in DTT treated sputum by the addition of the thiol oxidising agent dithiothreitol. This was applied to the immunoassay of a panel of 21 analytes.

**Methods:** Assays of these analytes were shown to be suppressed to a highly variable degree (0-900-fold, median 25-fold) by the presence of DTT, as a result of a worsening of both background and maximal signal. Treatment of DTT-containing matrix with diastase resulted in a substantial improvement in the signal to background ratio, representing a 1-150 fold improvement (median 5-fold) in the assay. This diastase method was applied to the assay of analytes in the presence of DTT and permitted the sensitive (limit of detection (LOD) <10ng/ml) assay for all analytes except MDC (LOD 136ng/ml), with a high signal to background ratio (median 3700 at 1ng/ml) and acceptable recoveries of spiked sputum supernatants (median 72%).

This protocol was applied to DTT sputum obtained in a study of the dose- and time-dependence of responses to LPS inhalation in healthy smokers as a model of COPD bacterial exacerbations (Aul et al 2012, Brit J Clin Pharmacol in press). We were able to demonstrate significant increases in IL-1β, TNFα, MCP-1 and MIP-1β in sputum, with a maximal effect at 6h.

A simple and rapid dithiothreitol protocol provides a novel way to treat DTT sputum to allow for the sensitive immunoassay of a wide range of analytes.

**P2221**

**C-reactive protein levels in COPD according to clinical parameters, smoking behavior and pulmonary hypertension.**

Funda Akün 1, Nermine Capan 2, Kurtulus Akun 1, Ruhsar Olhoğlu 1, Serma Canbakan 1, Kadır Ökkan Akın 1, Bünyanım Yavuz 1, Chest Diseases, Eskisehir Yunus Emre Hospital, Eskisehir, Turkey; 2Chest Diseases, Atatürk Chest Diseases and Surgery Training and Education Hospital, Ankara, Turkey, 3Division of Immunology and Allergy, Department of Chest Diseases, Eskisehir Osmangazi University, Faculty of Medicine, Eskisehir, Turkey; 4Biochemistry, Kecioren Training and Education Hospital, Ankara, Turkey.

**Aim:** To assess relationship between serum CRP levels and clinical parameters known to predict outcome, smoking history and biomarker exposure in COPD.

**Methods:** Spirometry, echocardiography, SpO2 measurements and serum CRP levels were assessed in 89 stable COPD patients and 60 age- and sex-matched healthy subjects. BODE index scores were assessed in COPD patients. Associations between CRP levels and clinical parameters were evaluated.

**Results:** Of the COPD group (11 stage 1, 48 stage 2, 29 stage 3, 11 stage 4) mean age is 60.6±8.5 years. CRP levels are significantly different between COPD patients treated with inhaled corticosteroids and those not treated (7.90±10.65 mg/L, 6.17±8.46 mg/L, p<0.05). Significant relationship is found between CRP levels and FEV1, FEV1%, FVC, FVC%, SpO2, MRC dyspnea scale, 6 minute walk distance and BODE scores. Using multivariate analysis BODE scores and coexistence of systemic hypertension manifested the strongest association. CRP levels in COPD patients with and without pulmonary hypertension were significantly different (11.86±13.38 mg/L, 5.78±8.05 mg/L, p<0.012). CRP levels did not differ significantly according to smoking status and biomarker exposure in COPD patients though COPD cases due to biomass exposure were never smoked and also had higher CRP levels compared to healthy controls (9.16±10.03 mg/L, 3.14±2.27 mg/L, p=0.028).

**Conclusion:** Systemic inflammation is related to disease severity and to constant systemic hypertension and pulmonary hypertension in COPD patients independent of smoking status or biomass exposure.

**P2223**

**Serological detection of elastin fragments in COPD and IPF patients.**

F. Genovesio, H.B. Skjot-Arkil, E.R. Clausen, F.J. Martinez, C.M. Hogaboam, M. Han, M.A. Karlstad, D.J. Leentjens, Fibrosis Group, Nordic Bioscience, Herlev, Denmark.

**Introduction:** Elastin plays a critical role in the development of respiratory system disorders including COPD and IPF, whose pathogenesis involves an inflammatory response and tissue turnover mediated by proteases, especially matrix metalloproteinase (MMP-12) secreted by activated macrophages.

**Aims and objectives:** Our aim was to evaluate whether a novel biochemical marker of elastin degradation mediated by MMP-12 may provide information in relation to lung tissue destruction during pulmonary disease and aid in the diagnosis of respiratory disease.

**Methods:** Human elastin was in vitro cleaved by different proteases and the resulting peptides were analyzed by LC-MS/MS. Among more than 400 fragments, the MMP-12 generated elastin neopeptipe cleaved at the amino acid position 444 (ELN-441/ELM) was chosen as candidate for antibody generation for its uniqueness for human elastin following assay development. This novel marker was assessed in serum collected in a small cohort of COPD (n=10), IPF (n=29) patients and controls (n=11) using a competitive enzyme linked immunosorbent assay (ELISA).

**Results:** Serum levels of ELM were significantly higher in patients diagnosed with COPD (p<0.0003) and with IPF (p<0.0001) compared to controls. The diagnostic value, measured by means of the area under the curve of receiver operating characteristic (AUROC) was best in COPD patients (AUROC 97%, p=0.00025) and lower but still significant in IPF patients (AUROC 90%, p=0.0001).

**Discussion:** Even though these findings need to be validated in larger clinical settings, the ELM marker described showed potential for the separation of controls from COPD or IPF patients.
P2224 Laryngopharyngeal reflex in chest clinic patients with upper airways symptoms Alexander Spyridoulakis1, Siobhan Lillie3, Jemma Haines1, Aashish Vyas1, Stephen Fowler1,2, Respiratory Medicine, Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 2Respiratory Research Group, University of Manchester, United Kingdom

Introduction: Laryngopharyngeal reflex (LPR) may underlie both chronic cough and laryngitis, and one explanation for a lack of response to standard anti-reflux therapy may be the presence of non-acid reflux. Salivary pepsin is a potential biomarker for LPR. The aim of this study was to evaluate if the detection of pepsin in saliva was associated with signs of laryngopharyngeal reflex in patients having nasendoscopy for investigation of upper airway symptoms.

Methods: We recruited patients from the Airways Clinic requiring nasendoscopy. All patients had the reflex Finding Score (RFS) recorded at nasendoscopy. Salivary pepsin was quantified with a lateral flow device using monoclonal antibody labelling (Peptest, RD Biomed, UK).

Results: Of 20 patients recruited, 12 were confirmed to have VCD and 13 a clinical suspicion of LPR (based on an RFS ≥ 7). Pepsin was detected in the saliva of 11/20 subjects (55%), including 67% of the VCD patients and 61% of those with a high RFS, although 43% of those with a low RFS also had a positive pepsin. Salivary pepsin had a sensitivity of 62% and specificity of 57% for predicting a high RFS. There was no significant correlation between RFS scores and salivary pepsin. Seven of the 10 patients already on treatment for a clinical diagnosis of reflux had a positive pepsin assay.

Conclusions: Salivary pepsin was frequently present in patients with upper airway symptoms, and not strongly related to clinical findings of reflux, suggesting a high prevalence of sub-clinical LPR. Further investigation should determine the clinical relevance of this, and whether LPR treatment results in an improvement in pepsin levels and the associated upper airway symptoms.

P2225 Comparison of serum osteopontin levels in patients with exacerbations and stable chronic obstructive pulmonary disease Yu Che, Kim, Yi Jong, Long Lee, Yome Huang, Internal Medicine, Gyeongsang National University Hospital, Jinju, Gyeongnam, Korea

Background: Osteopontin is recognized as an important adhesive bone matrix and a key cytokine involved in immune cell recruitment, tissue repair and remodeling. Then serum levels of osteopontin have not been evaluated in patients with chronic obstructive pulmonary disease (COPD). The aim of this study is to evaluate and compare the serum levels of osteopontin in patients with exacerbations and stable COPD.

Methods: Serum samples were obtained from 22 healthy control subjects, 18 stable COPD subjects and 13 exacerbation patients. Serum concentrations of osteopontin were measured by the ELISA method.

Results: Serum levels of osteopontin were higher in patients with exacerbation than with stable COPD and in healthy controls (24.5±4.6, 1477±19 mg/ml, 6.3±5.1, p=0.0003). Osteopontin levels were significantly decreased after clinical improvement than during exacerbation (45.2±6.2, 20.0±1.9, 980.1±160.0 p=0.160). Also osteopontin levels showed a significantly negative correlation with forced expiration volume in one second (r=-0.491, p=0.01). No significant correlation was found between absolute macrophage count and osteopontin level. However, osteopontin level was significantly increased after clinical improvement than during exacerbation (45.2±6.2, 20.0±1.9, 980.1±160.0 p=0.0003).

Conclusions: Serum osteopontin level was associated with co-morbidity, and females had higher SAA level than males. Systemic markers were not associated with airway inflammation. The overlap of asthma and COPD is common in older people with obstructive airway disease (OAD). Systemic inflammation is associated with adverse clinical outcomes and co-morbidities in OAD, but its role on asthma-COPD overlap syndrome is unknown. This study aimed to examine systemic inflammation in asthma-COPD overlap, and the potential clinical relevance with OAD.

Method: Serum high sensitivity C-reactive protein (hsCRP), Interleukin 6 (IL-6) and serum amyloid A (SAA) were measured in 108 adults older than 55 years comprising healthy controls (n=27), asthma (n=7), COPD (n=29) and asthma-COPD overlap (n=45). Spirometry, induced sputum, quality of life, co-morbidities and medications were assessed. Levels of systemic inflammatory mediators were compared, and the associations with clinical characteristics were tested in multivariate regression model.

Results: Patients with asthma-COPD overlap had significantly elevated IL-6 levels. SAA level was raised in both the COPD and asthma-COPD overlap groups. CRP was positively associated with BMI, whereas IL-6 was predicted by age, FEV1/predicted, and cardiovascular disease. SAA level was associated with co-morbidity, and females had higher SAA level than males. Systemic markers were not associated with airway inflammation.

Conclusion: Systemic inflammation is an common and important component of the asthma-COPD overlap. The pattern of systemic inflammation in asthma-COPD overlap is differing from COPD characterized as an elevated IL-6 and SAA levels. It is not related to airway inflammation, and may be an independent treatment target.
P2229 Repeatability and inter-relationships of small airway biomarkers in asthma
Sherif Goneim1, SushilaNdevi Natarajan1, Steven Corkill2, Anusha Singapuri1, Dhanamary Dasili,1, Per Gustafsson3, Christopher Brughling1, Saleh Sadaliu1
1Respiratory Medicine, Glenfield Hospital, Leicester, United Kingdom; 2Department of Paediatrics, Central Hospital, Skövde, Sweden

Background: There is evidence that small airway dysfunction may have an important role in asthma. We aimed to determine the within-visit and between-visit repeatability of small airway biomarkers in asthma, and explore the inter-relationships between them and with standard pulmonary function tests.

Methods: We recruited ninety-eight patients with asthma. All participants attended a baseline visit at which they underwent spirometry, body plethysmography, measurement of carbon monoxide diffusion capacity, impulse oscillometry (IXS), multiple breath washout (MBW) and induced sputum cell count. Eighteen patients undertook two-week and three-month follow-up visits, and twenty-six patients undertook six-month follow-up visits, at which all physiological tests were repeated.

Results: Small airway biomarkers displayed excellent within-visit repeatability (intraclass correlation coefficient [ICC] > 0.9), with the exception of S const, which was only moderately repeatable (ICC = 0.629). The biomarkers were all very stable over a three-month time frame, but S cond and Sacin were only moderately stable over six months. Principal components analysis of the variables derived five components, corresponding to the concepts of:
1) Expiratory flow limitation/air trapping
2) Heterogeneous airway constriction/closure
3) Ventilation heterogeneity
4) Airway inflammation
5) Impaired diffusion capacity

Conclusions: Small airway biomarkers are repeatable and stable over three months. Moreover, they appear to provide additional and independent physiological information over and above standard pulmonary function tests.

P2230 Metabolic syndrome and chronic diseases in COPD
Emel Bulcug, Aydanur Ekici, Mehmet Ekici. Department of Pulmonary Medicine, University of Kirkıkkale, Faculty of Medicine, Kirkıkkale, Turkey

Introduction: In this study, we examined accompanying comorbidities and metabolic syndrome (MS) in patients with COPD.

Method: Sixty-six patients with COPD and 40 subjects as control group were included. The index severity of chronic diseases was evaluated by using the MCIRS. MS was defined according to National Cholesterol Education Program.

Results: MS was detected in 18 patients (27.3%) in patients with COPD and in 8 patients (20%) in control group. The rate of MS in patients with stage II COPD was higher than in patients with stage IV COPD (p: 0.04).

Conclusion: Microalbuminuria may be seen in patients with COPD depending on severity of disease and hypoxemia.

P2232 Chronic mucus hypersecretion in asthma: Relation to smoking status and disease severity
Rekha Chaudhuri, Charles McSharry, Mark Spears, Neil C. Thomson. Respiratory Medicine, University of Glasgow, United Kingdom

Background: Chronic mucus hypersecretion occurs in chronic asthma, but the effects of smoking status and disease severity on this symptom are not clearly established. We assessed the prevalence of chronic mucus hypersecretion in patients with asthma recruited to the Glasgow COPD and Asthma Biomarker study.

Methods: One hundred and twenty subjects with asthma, smokers and never smokers of different GINA severity and fifty-four COPD subjects of different GOLD severity were recruited. Assessments included demographics, history of chronic cough and sputum production and spirometry.

Results: Baseline demographic and lung function data in the smokers with asthma and never smokers with asthma were similar. The COPD group were older and had a higher pack year history than the asthmatic group. Chronic mucus hypersecretion was strongly associated with smoking in the whole asthma group (Chi-sq=22.8, p<0.001). The proportion of patients with asthma and COPD of different disease severity and smoking status giving a history of chronic mucus hypersecretion is shown in Table 1.

The role of regional distribution (RD) of body fat mass (BFM) in fat-bone interactions in men with chronic obstructive pulmonary disease (COPD) Sviatlana Lemiashukska1, Alexander Makarevich1, Alla Shelepkovich1, Natalia Vasileva2.

1Department of Internal Medicine No. 1, Belarussian State Medical University, Minsk, Belarus; 2EXA, Republic Centre of Medical Rehabilitation and Balneotreatment, Minsk, Belarus

The aim: Evaluation of the relationships between RD of BFM and TNF-α, some hormones and markers of bone metabolism.

Methods: We used DEXA to analyze RD of BFM. We determined: serum leptin (L), testosterone free (TF), TNF-α, parathyroid hormone (PTH), beta-croscals (beta-CTX) and osteocalcin.

We examined 83 COPD pts (40-70 yrs old) and control group – 15 healthy comparable men. The COPD pts were subdivided into 3 groups (GOLD).

Results: Fat mass (FM) in Android region (A) positively correlated with TNF-α (r=0.33; p<0.01) in all pts groups. Trunk and Arms FM were positively related to L (r=0.36 and r=0.35; respectively) in all pts groups. L level exerted negative influence on bone mineral density (BMD) in lumbar spine (r=-0.43; p<0.01), but not at TNF-α and BMD of the whole body. We found the positive correlations between beta-CTX and total FM (r=0.33) and FM in A (r=0.52) in all pts groups. The total, arms, legs and trunk FM, FM in Android and Gynoid (G) regions were increased in pts with a lower level of TF (p<0.05). Loss of BMD positively correlated (p<0.05) to loss of BMI, AGR ratio, FM in all body regions, PTH, calcium ionized and was inversely related with L in all pts group. Although these pts had decrease of BMD, BMI was increased (29.4 in pts with osteopenia and 24.7 kg/m² – with osteoporosis). Lowering of BMD might result from other factors, such as TNF-α and some hormones which are produced by the adipose tissue.

Conclusion: The study of RD of adipose tissue in the patient’s body is more informative than BMI for assessing the likelihood of developing osteoporosis in men with COPD.

P2234

The indices of body composition (IBC) consideration the changes of serum TNF-α, hormones and oxygen saturation (SO2%) in men with chronic obstructive pulmonary disease (COPD) Sviatlana Lemiashukska1, Alexander Makarevich1, Natalia Vasileva2.

1Internal Medicine No. 1, Belarussian State Medical University, Minsk, Belarus; 2Rep. Center of Medical Rehabilitation and Balneotherapy, Minsk, Belarus

Aim and objectives: to analyze dynamics of changes of IBC and the relationships between IBC and TNF-α, leptin (L), parathyroid hormone (PTH), testosterone free (TF), markers of bone metabolism, SO2%.

Methods: 63 patients (27 male, 36.9±18y) with COPD were recruited and 16 controls (7male, 56.8±18y), perfectly matched. Each patient was evaluated by spirometry, Leicester Cough Questionnaire (LCQ) and Sputum Colour Chart (SCC). Sputum was induced with hypertonic saline inhalation and succeeded in 49 COPD patients and 12 controls. Total/differential cell count in sputum was assessed and total gelatinolytic activity (TGA), neutrophil elastase (N) and MMP-9 were measured.

Results: TGA and NSE were higher in patients vs controls (p=0.05 and p=0.003) and both correlated with neutrophil count (NSE: p=0.009; r=0.38 and TGA: p<0.0001; r=0.60). Subanalysis of high value TGA showed that NSE accounted for 82% of the activity vs 18% MMP-9 (p<0.0001). There was an inverse correlation between neutrophils and FVC% (r=0.02; r=0.35) and NSE and FVC% (r=0.04; r=0.29) in NCFB. No relationship was seen between total LCQ score, LCQ subcores and enzymatic gelatinolytic activity. There was however a significant relationship between the SCC and TGA (p<0.0003) and NSE (p=0.01). SCC also correlated with neutrophils (p=0.001).

Conclusion: TGA is significantly higher in NCFB and correlates with indices of inflammation and infection (neutrophils and SCC). The majority of TGA was exercised by NSE (82%) in NCFB. No correlation was seen with radiologic score or LCQ.

P2233

The role of regional distribution (RD) of body fat mass (BFM) in fat-bone interactions in men with chronic obstructive pulmonary disease (COPD) Sviatlana Lemiashukska1, Alexander Makarevich1, Alla Shelepkovich1, Natalia Vasileva2.

1Department of Internal Medicine No. 1, Belarussian State Medical University, Minsk, Belarus; 2EXA, Republic Centre of Medical Rehabilitation and Balneotreatment, Minsk, Belarus

Conclusion: TGA is significantly higher in NCFB and correlates with indices of inflammation and infection (neutrophils and SCC). The majority of TGA was exercised by NSE (82%) in NCFB. No correlation was seen with radiologic score or LCQ.

P2237

Asthma phenotyping: Correlation between inflammatory phenotype, clinical parameters and associated comorbidities Annemie Van Den Bergh1, Sven Seys1,2, Pieter Goeminne1, Liesven Dupont1, Dominique Ballemans3, Respiratory Disease, University Hospital, Leuven, Belgium; 2Microbiology and immunology, Catholic University of Leuven, Leuven, Belgium

Introduction: Cluster analysis revealed 5 clinically different clusters of asthma: mild atopic (1), mild to moderate atopic (2), late-onset non-atopic (3), severe atopic (4) and severe with fixed airflow obstruction (5) (Moore et al, 2009).

Aim: To link differential cell count and associated comorbidities (BMI, smoking, atopy, reflux, sinussitis and broniectasis) to 5 clusters of asthma based on clinical features (baseline FEV1, maximal FEV1 and age of onset).

Methods: We retrospectively evaluated clinical records from 140 asthma patients (44% male; 43y ± 14) with induced spusa, recruited from outpatient clinic of the University Hospital Leuven between January 1st 2008 and November 1st 2009 and were free of exacerbation for three months prior to sputum induction.

Results: Cluster 1 accounted for 37%, cluster 2 for 26%, cluster 3 for 14% and cluster 4 for 12%. Cluster 5 was too small for further analysis. Cluster 4 as defined by Moore and coworkers is significantly associated with more neuorphils (median: 72%, interquartile: 60-82%); p<0.02) in induced sputum as compared to the other clusters. Relative number of patients with reflux was highest in cluster 3 (55%) compared to cluster 1, 2 and 4 (29%, 34% and 38%). Presence of sinussitis was equally distributed between all clusters (p<0.95).

Conclusion: Severe atopic asthma have a predominant neuorphilic airway inflammation. Patients with late-onset non-atopic asthma have the highest rate of reflux. Previously unrecognized broniectasis were detected in 9% of patients.
As a result of air trapping and hyperinflation. IC decreases further with activity and may correlate more strongly to exercise capacity than measures of airflow (FEV1). 6 minute walk test (6MWT) is an objective measure of functional exercise capacity.

**Objectives**: The objective was to examine the correlation between IC and exercise capacity using 6MWT and FEV1 and exercise capacity in COPD patients and to compare the correlation between IC and exercise capacity with FEV1 and exercise capacity in COPD patients.

**Methods**: This was a retrospective study. All COPD patients undergoing both 6MWT and spirometry and lung volumes in CGH from 1/1/2008 till 9/11/2011 were included.

**Results**: 144 subjects were included. Mean age (years) was 69.12±8.93. 138/144(96.5%) were male. Mean FEV1 (L) was 1.33±0.57. There was statistically significant correlation between FEV1 and 6MWT distance (simple linear regression coefficient, r=29.89, p<0.01, 95% confidence interval 4.42 to 53.57). After adjusting for cardiovascular disease, the correlation was still statistically significant(r=29.00, p<0.01, 95% CI 4.36 to 53.63). There was statistically significant correlation between IC and 6MWT distance(r=38.81, p<0.003, 95% CI 13.08 to 64.53). After adjusting for cardiovascular disease, correlation was still statistically significant(r=39.09, p<0.003, 95% CI 13.22 to 64.96).

**Conclusion**: IC is better correlated with 6MWT distance (functional capacity) (p<0.003) than FEV1(0.021) in COPD patients. Thus, we concluded from this study that IC is a better predictor of exercise capacity than FEV1 in COPD patients.

**P2241**

**Comparison of validity of methacholine and mannitol bronchial challenges in asthma diagnosis**

**Konstantinos Porpodis, Kaliopi Domvri, Theodoros Kontakiotis, Dimitrios Liatsos, Dimitrios Ioannidis, Paschalina Gouleka, Konstantinos Zarogoulidis, Despoina Papakosta, Department of Pneumonology, Aristotle University of Thessaloniki, Hospital “G. Papanicolaou”, Ereschi, Thessaloniki, Greece**

**Background**: Detection of BHR with methacholine or mannitol have been highly sensitive tests to identify asthma diagnosis.

**Purpose**: The purpose of this study was to demonstrate the diagnostic validity of the two bronchial challenges and their correlation with symptoms, atopy and inflammatory markers.

**Methods**: Eighty-eight patients, 47 women and 41 men, aged 14-75 years who presented with asthma related symptoms and were not on any anti-asthma medication, were challenged with mannitol and methacholine. Medical history, physical examination, skin prick tests, Asthma Control Test (ACT) and FeNO levels were also assessed. The clinical diagnosis of asthma was lost on bronchodilator reversibility test.

**Results**: Sixty seven patients were diagnosed with asthma and 21 without asthma. Both methacholine (p<0.014) and mannitol (p<0.000) challenges were significant in diagnosing asthma. The sensitivity/specificity was 62.68%/85.71% for methacholine, 64.17%/95.23% for mannitol and 64.76%/93.75% for both methods together, whereas the positive/negative predictive value was 93.33%/41.86%, 97.72%/45.45% and 97.05%/45.45%, respectively. There was a negative correlation between PD15 of methacholine and the FeNO level p<0.001, and positive with the PD15 of mannitol p<0.001 and the pre-test FEV1 pred p<0.05, whereas PD15 of mannitol was negatively correlated with the FeNO level p<0.001. Furthermore, dyspnoea was the only asthmatic symptom associated with FeNO level p<0.035 and the positivity of mannitol p<0.014 and methacholine p<0.04.

**Conclusions**: Both provocation methods were equivalent in diagnosing asthma, although sensitivity/specificity values appeared to be slightly higher in mannitol challenge.

**P2242**

**Repeatability of peak nasal inspiratory flow rate (PNIF) measurements and its change after administration of 0.05% oxymetazoline**

Anna Doo-Wojnarowska1, Jerzy Laebhart2, Marek Rabk1, Andrzej Fal1, Bernard Panaszek1, Boleslaw Samoliński2, Rafał Dobek1. 1Internal Medicine, Geriatri and Allergology, Wroclaw Medical University, Wroclaw, Poland; 2Department of Prevention of Environmental Hazards and Allergology, Warsaw Medical University, Warsaw, Poland

**Background**: Measurement of PNIF is a cheap and easily performed method to assess nasal patency. However, the assessment of repeatability of this parameter as well as the threshold value of change which can be considered significant have not been established yet.

The aim of this study was to assess the repeatability of PNIF measurements and its change after the administration of 0.05% oxymetazoline.

**Methods**: Repeated measurements of PNIF (In-Check’s Clement-Clark) were performed in 333 (174 women) healthy volunteers. Subjects were divided into three age groups (6-7, 13-14 and 20-45 years). Each subject carried out 5 measurements. PNIF was retaken 30 minutes after inhaling 0.05% oxymetazoline in 294 subjects. The variability of the PNIF measurements appeared to be significantly higher in mannitol challenge.

**Results**: The first four PNIF measurements significantly differed from each other. There was no statistically significant difference only between the fifth and fourth

P2243 Detection of air leaks and their effects on forced oscillometry measurements
Andreas Bikos,1,2, Omar Usman1, Neil Pride1, James Bull1, Ilidiko Horvath1,
Peter Barns2, Paolo Pareli1,1. Airway Disease, National Heart and Lung Institute, Imperial College, London, United Kingdom. 2Department of Pulmonology, Semmelweis University, Budapest, Hungary

Introduction: Forced oscillation technique (FOT) is a method to estimate respiratory resistance (Rrs) and reactance (Xrs). However, some common artefacts may affect the accuracy of FOT readings. In particular, air leaks from lips not sealed around the mouthpiece, or those from the equipment. We studied the significance of this artefact and identified possible markers to detect it.

Methods: 11 healthy subjects (33±6 years) underwent FOT measurements (Jaeger, Wurzburg, Germany) which generated 0.4-kPa peak-to-peak input signals. The Rs and Xrs values at 5 and 20 Hz (R5, R20, X5) were registered in parallel with breathing volumes. To simulate air leaks, we applied artificial holes of increasing sizes (3.5 mm, 6 mm, and 8.5 mm diameters) on the breathing filter at 1 cm from the circumference. FOT data were compared to normal values obtained with no air leaks.

Results: With increasingly bigger filter holes and resulting air leaks, we identified corresponding larger indentations in the descending limb of the breathing volume (ΔV 2.2±0.6 mL, 5 ±2.3 mL, and 7.6±3.1 mL and 14±4.2±9 mL; respectively, p<0.001), indicating that ΔV may be a marker for air leak. This was confirmed by a significant correlation between ΔV and R5 (p<0.001, r=0.74), R20 (p<0.001, r=0.71), X5 (p<0.001, r=0.50). In line with this, a 1 mL increase in ΔV was associated with a 10% decrease in R5 values.

Conclusion: Indentations on the descending limb of the breathing volume may be used to detect the presence and magnitude of air leaks. Visual inspection of the data is required to exclude records where indentations are caused by artefacts.

The first author is receiving an ERS Long Term Fellowship.

P2244 Early diagnosis of small airway disease
Evangelia Danili, Georgios Kaltsakas, Sofia-Antiopi Gennimata, Anastasios Palamidas, John Jordanoglou, Nikolaos G. Koulouris. 1st Respiratory Medicine Dept, Athens University, Sotiria Hospital, Athens, Attica, Greece

Inflammatory changes in the peripheral airways of smokers are detected when “normal” spirometry is still present, indicating that early structural damage in the small airways develop before the diagnosis of overt COPD is established. Therefore, the early diagnosis of COPD is a feasible hypothesis (Thorax 1980; 35: 375-378) and its variations, advocated to early detect small airways disease and discriminate between smokers and non-smokers. However, it is not clear whether of the aforementioned tests is the “best” for early detection of small airways disease.

We studied 30 (15 men) Caucasian subjects (10 never smokers, 10 smokers with normal spirometry, and 10 COPDxers in GOLD I), aged (mean±SD) 52±14 y with FVC%pred=11±12, FEV1%pred=81±14, FEV1/FVC%73±10. All smokers had smoking history more than 10 pack-years. Simple spirometry, the slope of phase III (ANf/AN), and the effective time at the 60-70% part of the forced vital capacity of the lung (TEFFf;3-70) were measured. The ANf±TEFFf;3-70 (64±29) was abnormal in 16/30 subjects. The ANf/ANf;30 (182±150) was abnormal in 14/30 subjects. TEFFf;3-70 was 155±88 and was abnormal in 17/30. Multiple linear regression analysis showed that TEFFf;3-70 was more appropriate, among the tests performed, for discriminating smokers from never smokers (p=0.008). In conclusion, TEFFf;3-70 appears to be a sensitive test for the early detection of small airway disease.

P2245 Prognostic factors in COPD patients controlled in two outpatient clinics
Verónica Hernández, Patricia Sobradillo, Laura Tomás, Lucia Canelo, Francisco Ribas, Mikel Azpiarzu, Vanesa Zorrilla, Begoña Lahladaga, José Luis Lobo. Respiratory, HUA - Taussigutta, Vitoria - Getaria, Araba, Spain

FEV1 and a number of composite indexes (BODE, U-BODE, ADO) predict mortality in the population of patients with chronic obstructive pulmonary disease (COPD) as large. However, patients attending the specialized clinics of tertiary referral hospitals are often old and suffer severe or very severe airflow limitation. We aimed to compare the prognostic value of FEV1, BODE, U-BODE and ADO indexes in patients attending the outpatient clinics of Hospital de Cruces, a tertiary referral hospital in Bilbao (Spain). Patients from two outpatient clinics were included. FEV1, BODE, U-BODE and ADO were values determined at recruitment and patients were followed up for a mean of 4.5 years.

We studied 106 patients (70.5±8.9 yrs; FEV1 44.4±19.9% of ref., 35 of whom (33%) died during follow-up. In this population, FEV1 did not predict mortality, whereas BODE (p=0.001), U-BODE (p=0.000) and ADO indexes (p=0.003) did. BMI did not discriminate survival significantly but dyspnea (p=0.003), distance walked (p=0.000) and age (p=0.002) did.

In patients attending the outpatient clinic of a tertiary referral hospital, FEV1 is not a good prognostic marker, at variance to age, dyspnea, walked distance, ADO, BODE and U-BODE indexes.

P2246 Evaluation of treatment with fixed dose combinations in asthma patients in primary care in Sweden by using mannitol challenge test
Kerstin Romberg,1,2, Anna-Carin Berggren1,3, Health Care Centre, Näsets hälsocentre, Höllviken, Sweden; 1Department of Respiratory Medicine and Allergology, Department of Clinical Science, Lund University, Lund, Sweden; 1Medical Department, Mundipharma AB, Göteborg, Sweden

Background: The mannitol challenge test is an indirect bronchial challenge test suitable for use in a primary-care setting. The test is most often used to diagnose asthma. In this pilot study the test was used to evaluate the effectiveness of ongoing treatment with ICS/LABA combination therapy in patients with asthma.

Objectives: To explore the prevalence of optimal treated asthma patients in primary care in Sweden. The hypothesis was that not all patients are optimal treated.

Methods: Male and female patients, 18-65 years with asthma, who were treated with a fixed dose combination (budesonide/formoterol or fluticasone/salmeterol) were included in the study. The subjects performed a mannitol challenge test (direct FOT), followed by an inhalation of a β2-agonist. A new spirometry (reversibility test) was performed 15 minutes later. The explorative end-point was response or negative response of mannitol challenge test and/or a reversibility of ≥15%.

Results: The preliminary result of this pilot study (100 subjects) shows that an unexpectedly, surprisingly high proportion of the asthma patients had a positive response, either as a direct fall of FEV1 ≥15% in the mannitol challenge test and/or a reversibility of ≥15%.

Conclusion: The result of this study indicates that a large proportion of asthma patients in primary care, who are currently treated with fixed dose combination therapy, may not be optimally treated. Further research is needed to support these findings and to understand the reasons.

P2247 Difference of respiratory reactance between mild and moderate COPD by forced oscillation technique using a MostGraph-01
Yasuhiro Yamanchi, Tadashis Koyama, Tsukasa Jo, Masafumi Horie, Yusuke Mikami, Takahide Nagase. Respiratory Medicine, The University of Tokyo, Japan

Background: COPD is characterized with persistent airflow limitation caused by airway inflammation and parenchymal emphysema. The Forced Oscillation Technique (FOT) can detect the lung impairment by measuring respiratory impedance during tidal breathing without special maneuver of respiration. Respiratory reactance and resistance (Xrs) dynamically change during tidal breathing in COPD patients. We evaluated the difference of the Xrs in respiratory cycle between mild and moderate COPD.

Methods: We recruited 26 outpatients with stable mild (n=13) and moderate (n=13) COPD at the University of Tokyo Hospital. The impedance of respiratory cycle was measured by FOT using MostGraph-01, which was manufactured in Japan CHEST Company. The Xrs during inspiratory and expiratory phase during tidal breathing was evaluated at 4 Hz of oscillatory frequency. Comparisons of Xrs between both groups were performed using the Student’s t-test.

Results: The mean Xrs at 4 Hz (X4) in respiratory cycle were similar in mild and moderate groups. There were also no significant differences between inspiratory X4 (inx4) and expiratory X4 (ex4) in both groups. However, the ratio of inx4 to ex4 in mild COPD was significantly lower than that in moderate COPD (p=0.01).

Conclusion: The ratio of inx4 to ex4 during tidal breathing in mild COPD was lower than moderate COPD. During tidal breathing, the Xrs changes in inspiratory and expiratory phase and might be influenced by airway obstruction and parenchymal emphysematous change. The measurement of Xrs during tidal breathing might be useful property to distinguish the severity of COPD.
**Methods:** We reviewed all tests in our Trust between 2009 and 2011, compared baseline spirometry between positive and negative tests, and looked at immunological evidence of atopy. We reviewed clinic letters for change in diagnosis or management, as well as symptomatic improvement and whether patients were discharged from follow-up (representing clinical stability).

**Results:** Tests were performed on 177 patients between April 2009 and October 2011. The positive and negative groups were compared in terms of spirometry and immunological evidence for atopy (total IgE and IgE to inhaled allergen mix and aspiragel). The test was positive in 40 patients (22.6%). Of these, immunological evidence of atopy was greater than in those with negative tests (mean total IgE 275 vs. 132, IgE to IAP 5.48 and 4.73, IgE to aspiragel 0.6 and 0.25 respectively). Baseline spirometry tended towards more airflow obstruction in the positive group though the means were both within normal range (89% and 97% predicted). Of the 126 patients for whom we had data the manntol challenge resulted in changes in treatment and improved symptoms in 115 (91.2%).

**Conclusion:** Bronchial provocation testing is useful in identifying those with AH, and for guiding treatment leading to symptomatic improvement.

**P2249**

**Best time for evaluating the response to bronchodilators**

**Abouda Maher, El Goul Jamel, Youngui Ferdaous, Triki Miriam, Charfi Med**

**Ridha. Pneumology, FSI, La Marsa, Tunis, Tunisia**

**Introduction:** There is no clear consensus on the time of interpretation of the bronchodilator effect. The interval between administration of bronchodilator type β2-agonist short-acting and the practice of post bronchodilator spirometry remains a controversial issue. Our objective was to define the optimal time of bronchodilator responsiveness in assessing the reversibility or otherwise of an obstructive respiratory disorder (ORD).

**Materials and methods:** Analytical study prospectively over a period of 8 months performed in the pneumology service of FSI Hospital Security. The study included patients with ORD defined by an FEV/FVC <0.7 and who had consulted outside of an exacerbation. Flows and expiratory volumes (FEV, FVC) were measured before and after bronchodilator in the 5th, 10th, 15th, 20th and 30th minute. The response to BD was expressed in absolute and percentage change from baseline.

**Results:** 126 patients were included in the study, mean age 54±15 years with a majority of men. Our study was conducted in patients with asthma and COPD whose airway obstruction was moderate (FEV > 2 liters, or >62% of predicted). (1) The maximum response after bronchodilator occurred at the 20th and 30th minutes respectively for FVC and FEV (2) The number of reversible patients was guideline defining. (3) The maximum number of reversible patients was obtained in the 20th minute with a significant difference compared to that observed at the 5th and 10th minute.

**Conclusion:** The interpretation of the response to bronchodilator in the 20th minute after was the ideal time to assess the reversibility of ORD.

**P2250**

**Small airway dysfunction by impulse oscillometry system (IOS) in asthma.**

**Relationship with spirometry, bronchodilator response and disease control**

**Roberta Pisi, Panagiota Tzani, Marina Aiello, Enrico Martinelli, Emilio Marangio, Dario Olivieri, Alfredo Chetta. Clinical Sciences Dpt, Respiratory Disease Unit, University Hospital, Parma, Italy**

**Rationale:** Small airways are relevant to the pathophysiology of asthma.

**Objective:** We investigated the relationship between small airway function, as assessed by IOS and spirometry, bronchodilator response, disease control and fractional exhaled nitric oxide (FeNO) values, in asthmatic patients.

**Methods:** We studied 38 patients with asthma (24 F, age range 16–70 yr). The fall in resistance from 5 to 20 Hz (R5–R20) and reactance at 5 Hz (X5) in kPa s l–1 by IOS and spirometry at baseline and after 400 mg of salbutamol were measured. Asthma Control Test (ACT) and FeNO (in ppb) were also recorded.

**Results:** R5–R20 and X5 were significantly related to spirometry, with FEF25-75 < 80% predicted (p < 0.01). The maximum response after bronchodilator occurred at the 20th and 30th minutes respectively for FVC and FEV. (2) The number of reversible patients was guideline defining. (3) The maximum number of reversible patients was obtained in the 20th minute with a significant difference compared to that observed at the 5th and 10th minute.

**Conclusion:** The interpretation of the response to bronchodilator in the 20th minute after was the ideal time to assess the reversibility of ORD.

**P2251**

**Comparison of SAPALDIA and ECCS lung function normal values in a Swiss hospital setting**

**Jochen Küttner1, Florent Bary1, Andreas Bloch1, Lukas Kern2, Tino Schneider1, Martin Brutsche1, 1Pneumologie, Kantonsspital St. Gallen, St. Gallen, Switzerland; 2Pneumologie, Zuger Kantonsspital AG, Baar, Switzerland**

The SAPALDIA survey observed better lung function in healthy volunteers than the common ECCS normal values (ECCS) predicted. We thus introduced the SAPALDIA normal values (SAP) for lung function interpretation at the Kantonsspital St. Gallen. We currently analyzed the distribution of FVC and FEV1 in non-pulmonary patients with a normal lung function comparing SAP and ECCS (so far 379 lung functions). Data was analyzed using descriptive statistics, Bland-Altman (BA) analysis and linear regression. Estimated bias and precision were calculated.

For FEV1 we observed a significant difference between ECCS and SAP only in elderly men (>59 y.o.) (7±336 vs. 12±336 ml/s). When comparing FVC using SAP, the Bland Altman analysis revealed a bias, which was significantly lower using ECCS (e.g. in men bias of SAP was 0.33 l (0.27-0.39), bias of ECCS was 0.18 l (0.11-0.24), (fig.1, lower panels).

In summary, SAP tended to overestimate FVC and FEV1 in elderly men compared to ECCS. However, absence of a pulmonary consultation in our population does not exclude a slight impact of the underlying disease on lung function. We consider SAP for FEV1 and FVC appropriate for the measurement of lung function of our population. Cut-off values require special attention especially in elderly.

**P2252**

**Prevalence of hyperinflation and its reversibility in asthma patients with poorly controlled disease or significant dysnea**

**Thierry Pérez1, Pascal Chanzer2, Daniel Dusser3, Daniel Vesque4, Philippe Devillier5, 1Service Clinique des Maladies Respiratoires, CHRU de Lille, Hôpital Albert Calmette, Lille, France; 2Département des Maladies Respiratoires, AP-HP, Laboratoire d’immunologie INSERM CNRS U 600, UMR6212, Université de la Méditerranée, Marseille, France; 3Service Pneumologie, Hôpital Cochin - Groupement Hospitalier Universitaire Ouest - APHP, Paris, France; 4Direction des Affaires Médicales, Laboratoire Chesi SA, Courbevoie, France; 5UPRES EA 220, Hôpital Foch, Suresnes, France**

**Introduction:** Inflammation in asthma involves proximal and distal airways. The latter may induce a significant hyperinflation (HI).

**Aim:** To evaluate the prevalence of HI by body plethysmography in asthmatic patients with poorly controlled disease and/or significant dysnea.

**Methods:** In 324 patients (age 49±17, FEV1 75±18% pred) insufficient asthma control was defined by an ACT score < 20 (n = 302) or a significant dysnea by a MRC score ≥ 1 (n=22).

HI was defined by either a RV > pred + 1.64 RSD (RV-HI) or a FRC > 120% pred (= FRC-HI). HI reversibility after bronchodilator was defined by a decrease of RV > 20% or a reduction of FRC > 10% from baseline. Change in dysnea and chest tightness were evaluated by a VAS. Results: HI was found in 49% (RV-HI) and 47% (FRC-HI) of cases. Prevalence of HI was higher in patients with a FEV1 < 60% pred than in those with a FEV1 > 80% pred: 78% for RV-HI and 70% for FRC-HI, vs 34% and 40%, respectively. ACT score was lower in patients with FRC-HI (13±4±4 vs 14±6±4; p = 0.004). Post-bronchodilator change was -10±13% for FRC, and -12±21% for RV. HI reversibility was obtained in 59% of cases with RV-HI and 47% of cases with FRC-HI. Chest tightness decrease after bronchodilator was greater in patients with...
baseline FRC-HI (-44±25 vs -37±24 mm, p = 0.02). Dyspnea improvement was higher in those with baseline RV-HI (-45±26 mm vs -38±23, p = 0.02).

**Conclusion:** Hypereventilation is frequent in poorly controlled asthma, including patients with normal FEV1, suggesting an involvement of distal airways. It appears reversible in more than half of cases.

### P2253

**Sprirometry and home oxygen in COPD patients with and without a history of illicit drug smoking**

Andrew Singer, Nicola Garner, Janet Bonner, Tracy Monaghan, Hassan Burhan. 
Respiratory, Royal Liverpool University Hospital, Liverpool, United Kingdom

Our 960 bed inner city hospital has 3 full time COPD nurses providing a 7-day a week service reviewing patients admitted with COPD exacerbations. They are employed with a view to reducing length of stay and preventing re-admissions. The team audit their work prospectively. Several patients have recurrent admissions with exacerbations of COPD. We looked at the database from January 2009 to September 2011 and compared spirometric confirmation of COPD and home oxygen prescription amongst four groups of patients: Ex-tobacco smokers and active tobacco smokers with and without a history of illicit drug smoking.

**Results:**

<table>
<thead>
<tr>
<th>No history of drug use</th>
<th>History of Drug Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average Age (yrs)</td>
<td></td>
</tr>
<tr>
<td>70</td>
<td>53.9</td>
</tr>
<tr>
<td>Number of Admissions</td>

</tr>
<tr>
<td>Spirometry (%)</td>
<td></td>
</tr>
<tr>
<td>489 (44)</td>
<td>118 (47)</td>
</tr>
</tbody>
</table>

**Conclusion:** There were no significant differences in the proportion of patients that had documented spirometry or a home oxygen prescription amongst those with and without a history of illicit drug smoking. A greater proportion of ex-smokers with a history of illicit drug smoking had a home oxygen prescription. This may reflect more severe disease which may be caused by the additional damage caused by drug smoking.

### P2254

**Assessment of ventilation heterogeneity by impulse oscillometry in patients with mild asthma**

Gakuya Tamagaki, Hiroshi Katayama, Yukari Kon, Naoko Yoshii, Yukinaka Ichimaru, Kazuhisa Asai, Yoshitohi Tachino, Kazutaro Hira. 
Respiratory Medicine, Osaka City University, Osaka, Japan

Ventilation heterogeneity is an independent determinant of airflow hyperresponsive-ness (AHR) in asthma, and its measurement is complex and technically difficult. Impulse oscillometry (IOS) is increasingly used to obtain information on the state of the respiratory system. In this study, we determined the clinical validity of IOS as a novel and simple method for the assessment of ventilation heterogeneity in asthma.

Serial measurement of resistance at 5 Hz (R5) or 20 Hz (R20) by IOS was performed in 23 mild asthmatic patients and 28 normal control subjects; the measurements were made at baseline, after methacholine (maximal dose) provocation test for asthma and subsequent salbutamol administration. Further, exhaled nitric oxide (eNO) levels were examined and pulmonary function test was also performed. The baseline R5, but not R20, was significantly higher in asthmatic patients than in controls. Both R5 and R20 were not significantly correlated with the degree of airflow obstruction and eNO levels. However, R5 was significantly correlated with the severity of AHR (r = -0.55, P = 0.01), whereas R20 was not.

### P2255

**Heterogeneity of small airways flow and hyperinflation are markers of a persistent obstruction phenotype in severe non-controlled asthmatics**

Regina Maria Carvalho-Pens, Alberto Cukier, Luciene Angelini, Frederico Leon Arrabal Fernandes, João Marcos Salge, Rafael Stelmach. Pulmonary Division, Heart Institute (InCor) - University of São Paulo Medical School, São Paulo, SP, Brazil

Persistent functional impairment in some severe asthmatics, even after maximal treatment, is usually linked to inflammation, which does not explain all asthma limitations and seems to be determined by small airways structural changes too.

**Objective:** Evaluate functional mechanisms related to persistent airflow obstruction (PAO) after an intensive therapeutic regimen in severe asthmatics.

**Methods:** Non-controlled severe asthmatics received high inhaled corticosteroid dose (ICSs) plus LABA for 12 weeks and oral corticosteroid (OC) in the first two weeks, after which they were classified into PAO by an FEV1 after BD< 80% plus FEV1/FVC < 0.70. Complete airway reversibility were labeled as reversible disease.

**Results:** All PAO values, including Slope of Phase III of the single breath nitrogen washout test (dN2), became different after OC and did not return to normal. ACQ in NPAO decreased to near normal values (1.75±0.94).

**Conclusion:** Persistent obstruction phenotype in severe asthmatics showed a high heterogeneity of airflow measured by dN2 and early airway closure due to high resistance (R5), which might be a novel and simple method for the assessment of ventilation heterogeneity in asthma.

**Change in pulmonary function abnormalities in sarcoidosis over time: A review of 75 cases**

Christopher Atkins, Andrew Wilkes, Orion Twentyman, Chris Atkins, Chris Atkins. 
Department of Respiratory Medicine, Norfolk and Norwich University Hospital, Norwich, Norfolk, United Kingdom

Airflow obstruction is common on initial pulmonary function tests (PFTs) in Sarcoidosis. Little has been published about change in PFTs over time, or with treatment. We examined PFT change in patients diagnosed with Sarcoidosis over a 14 year period. 75 patients were included. Median follow-up was 5.1 years. Patients were divided into those treated prior to follow-up (n=39) and those not (n=36). Results are shown in table 1.

Treated patients tended to have greater deterioration of their PFTs. The difference was non-significant, except for a lower decline in FEV1/FVC ratio in those untreated. Previous research (Miller et al. Chest 2011; 139:52-59) suggests fixed ratio values are less accurate than percentile predicted; here, there was no statistical difference in percentile change between groups. Absolute FEV1 and FVC values declined in both groups, though less in those untreated. Both groups showed greater than expected annual decline in FEV1.

---

P2257
Lung clearance index is a reliable and sensitive measure of airways disease in bronchiectasis
Stephen Rowan1, Judy Bradley2, Madeline Ennis3, Alex Horsley2, Nicholas Souch2, Per Gustafson2, Joseph Stuart Elborn1, 1Centre for Infection and Immunity, Queen’s University Belfast, United Kingdom; 2School of Health Sciences, University of Ulster, Belfast, United Kingdom; 3Widneshaave Hospital Adult CF Centre, University Hospitals of South Manchester, Manchester, United Kingdom; 4Bristol Adult CF Centre, University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom; 5Department of Pediatrics, Central Hospital, Skovde, Sweden

Introduction: In bronchiectasis (BE), there is a need for a sensitive outcome measure that is responsive to interventions, particularly in those with mild disease. FEV1 is insensitive to small airways disease and is often within normal range in BE. Lung clearance index (LCI) is a measure of ventilation inhomogeneity derived from multiple breath washout (MBW).

Objective: To assess intra and inter-visit repeatability of LCI and determine the relationship between FEV1 and LCI in stable BE.

Methods: Inclusion criteria: HRCT diagnosis of BE within 5 years; clinically stable (>4 weeks no infective symptoms); no features of CF. Participants attended for 2 visits, 2-4 weeks apart. At each visit they performed MBW in triplicate, using 0.2% SF6 and a modified InnocorTM device. LCI was derived from the mean of at least 2 acceptable washouts. Spirometry was performed at ATS/ERS standards.

Results: 30 patients (14M/16F) attended for 2 visits. The mean (SD) age was 56.6 (14) yrs. Mean (SD) FEV1% predicted was 84.8 (20.7), range (40-117). Mean (SD) LCI was 9.2 (1.7) on visit 1 and 9.3 (1.9) on visit 2 (normal <7.5). The intra- and inter-visit intraclass correlation coefficient was 0.94. LCI negatively correlated with FEV1 (r=-0.73, p<0.001) and FEF25-75 (r=-0.84, p<0.001). Sensitivity of LCI, FEV1 and FEF25-75 for the diagnosis of bronchiectasis by CT was 83%, 40% and 73% respectively.

Conclusions: This is the first report of LCI in BE. LCI has good intra and inter-visit repeatability. Across a range of FEV1 there is a strong relationship between LCI and FEV1. LCI is a more sensitive test of lung function than FEV1 and FEF25-75, and is abnormal in the majority of people with BE who have a normal FEV1.

P2258
Managing asthma in the outpatient clinic - Can the FEV1/FVC indicate when to do a reversibility test
Celeste Porsbjerg, Asger Sverrild, Lise Stensen, Birgitte Nybo Jensen, Backbyn Breathing: Respiratory Research Unit, Bispebjerg Hospital, Copenhagen, Denmark

Background: Testing for reversibility to SABA often constitutes the first step of a diagnostic assessment of asthma. However, patients with a normal or near-normal lung function often do not have significant reversibility, and performing reversibility testing in these patients may not be cost-effective.

Aims: To compare the predictive value of the FEV1/FVC ratio using lower limit of normal (LLN) for predicting significant reversibility to SABA, and to define optimum cut-points that might be applied clinically.

Methods: The MAPoAti study is a retrospective observational study of all patients consecutively referred to a tertiary hospital specialist clinic over a 12-month period, on suspicion of asthma (n=221).

Results: In total, 122 subjects (55%) had a reversibility test performed, among whom 28 (23%) had a significant response to beta-2-agonist, defined as an increase in FEV1 of 12% or more, and at least 200 mL. The area under the curve of the FEV1/FVC % of the LLN for predicting reversibility was 0.76 (p<0.001). The FEV1/FVC ratio was above the LLN in 77% of newly referred asthma patients, including subjects who had a reversibility test performed (94/122 (77%)). Only 14% of subjects with an FEV1/FVC above the LLN had significant reversibility, compared to 54% of subjects with an FEV1/FVC ratio below the LLN.

Conclusion: Absence of significant airflow obstruction at rest was associated with a low likelihood of reversibility to beta-2-agonist. The majority of subjects referred for specialist assessment on the suspicion of asthma did not have airflow obstruction. In these subjects, alternative diagnostic strategies may be more cost-effective.

P2259
The prediction of airway wall thickening by computer aided lung sound analysis
Sumassawadi Mackay1, Anne Bruton1, Anna Barney1, Michael Bennet1, Tom Havelock2, 1Faculty of Health Sciences, University of Southampton, Hampshire, United Kingdom; 2Institute of Sound and Vibration Research, University of Southampton, Hampshire, United Kingdom; 3Southampton Centre for Biomedical Research, University Hospital Southampton NHS Foundation Trust, Southampton, Hampshire, United Kingdom

Computer Aided Lung Sound Analysis (CALSA) has been used to detect and analyse added lung sounds to aid diagnosis of many respiratory diseases. The wall area of the main bronchi, expressed as a percentage of the cross-sectional area of each branch, is a biomarker of chronic airway inflammation which is raised in COPD. The objective of this study was to explore the possible relationship between characteristics of crackles measured by CALSA and percentage of wall area of the main bronchi measured by High Resolution Computed Tomography (HRCT), and hence the possibility of using crackles as a biomarker of COPD. 26 participants (9 healthy non-smokers, 9 healthy smokers and 8 COPD) were recruited. Lung sound data were recorded using a digital stethoscope. HRCT scans were conducted using a Siemens Sensation 64 CT scanner and the resulting data were analysed using the Pulmonary Workstation 2 (Vida Diagnostics, Iowa, USA) software to give measurements of airway geometry. The results showed that the percentage of wall area at the right upper bronchus correlated with the two cycle duration of crackles (r=0.39, p=0.025) recorded at the right upper lobe (RUL), the number of crackles per breathing cycle (NCpB) at RUL (r=0.49, p=0.005) and NCpB at right lower lobe (r=0.49, p=0.006). Additionally, the NCpB at RUL was found to significantly predict the percentage of wall area at the right upper bronchus (adjusted R²=0.20, R²=0.24, p<0.010). These initial results suggest NCpB might be useable to predict changes in percentage of wall area caused by the chronic inflammation of the main bronchi, though a larger sample needs to be examined. This suggests that crackles could possibly be used as a biomarker of COPD.

253. Inflammation in airway diseases: diagnosis and management

P2260
Additive role of exhaled NO and blood eosinophil count to predict wheezing in a random population sample
Andrej Malinovschi1, Joao Fonseca2, Tiago Jacinto2, Kjell Alving3, Christen Janson1, 1Dept. of Medical Sciences: Clinical Physiology, Uppsala University, Uppsala, Sweden; 2Dept. of Health Information and Decision Sciences, University of Porto, Portugal; 3Dept. of Women’s and Children’s Health, Uppsala University, Uppsala, Sweden; 4Dept. of Medical Sciences: Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden

The fraction of nitric oxide in exhaled air (FeNO) and blood eosinophil count (B-Eos), markers of local and systemic eosinophil activation, respectively, are increased in asthma. Little is known about the relation to reported wheezing in a random population sample or the additive value of these two methods. FeNO (NIOX Mino) and B-Eos were measured in 12,408 subjects aged 6-79 years from the National Health and Nutrition Examination Survey 2007-08 and 2009-10. Current wheezing, hay fever and smoking habits were questionnaire-assessed. Subjects with wheezing had higher FeNO and B-Eos than subjects without wheezing (p<0.001). Slightly increased FeNO (25-50 ppb) and high FeNO (>50 ppb) related to a higher wheezing prevalence than normal FeNO (14% and 25% vs 12% for normal FeNO, p=0.001). Slightly increased B-Eos (300-500 Eos/mm3) and high B-Eos (>500 Eos/mm3) related to a higher wheezing prevalence than normal B-Eos (17% and 22% vs 11% for normal B-Eos, p<0.001). The risk of wheezing increased with increased B-Eos for subjects with high FeNO and, similarly, with increased FeNO for subjects with high B-Eos (Table).

Risk of wheezing (odds ratios) with increased FeNO and B-Eos

<table>
<thead>
<tr>
<th>Normal B-Eos</th>
<th>Intermediate B-Eos</th>
<th>High B-Eos</th>
</tr>
</thead>
<tbody>
<tr>
<td>FeNO</td>
<td>1</td>
<td>1.41</td>
</tr>
<tr>
<td>Intermediate FeNO</td>
<td>1.29</td>
<td>1.81</td>
</tr>
<tr>
<td>High FeNO</td>
<td>1.81</td>
<td>3.51</td>
</tr>
</tbody>
</table>

Adjusted for gender, age, BMI, smoking and hay fever.

In conclusion, the prevalence of wheezing increased in this random population sample with increased FeNO and blood eosinophil count and the predictive values of these biomarkers for wheezing is additive. The clinical importance of these findings in asthma with regard to phenotyping and individualized treatment has to be determined.

P2261
The effect of long-term macrolides therapy for acute exacerbation of chronic obstructive pulmonary disease: A meta-analysis
Gianyuan Yao1,2, Meiqin Zhang1, Zhancheng Gao1, Yanliane Ma1, 1Respiratory and Critical Care Medicine, Peking University People’s Hospital, Beijing, China; 2Respiratory Medicine, Beijing健身房 Hospital, Beijing, China

Introduction: Chronic obstructive pulmonary disease (COPD) exacerbations are associated with frequent hospital admission reduction of lung function, and decreased quality of life. Macrolides have airway antiinflammatory actions and may reduce the frequency of COPD exacerbations. Methods: We searched PubMed and Embase databases to identify randomized
Significant differences were observed between the groups in terms of age, desaturator (n=47) and non-desaturator (n=177) groups.

Long-term macrolide therapy in patients with COPD can decrease macrolides (RR=1.35, 95%CI(1.09, 1.67), p=0.007).

Five studies reported adverse events, and adverse events were more frequent with patients with at least one exacerbation( RR=0.50, 95%CI (0.27, 0.90), P=0.02). Five studies reported adverse events, and adverse events were more frequent with macrolides (RR=1.35, 95%CI(1.09, 1.67), p=0.007).

Conclusions: Long-term macrolide therapy in patients with COPD can decrease exacerbations, but the safety is not sure.

The CT emphysema index is a predictor for exertional desaturation in COPD patients without resting hypoxemia.

Results: A total of 224 subjects were selected from the Korean Obstructive Lung Disease cohort. Exertional desaturation was defined as a post-exercise oxygen saturation (SpO2) of >90% and a ≥4% decrease. The cohort was divided into desaturator (n=47) and non-desaturator (n=177) groups.

Conclusions: In patients with COPD, exertional desaturation possibly occurs in parallel with an increase in the CT emphysema index. Exertional desaturation may be a manifestation of emphysema phenotype, and COPD patients with exertional desaturation are associated with a more rapid decline in lung function and poorer health-related quality of life.

Managing asthma in the outpatient clinic: Is the diagnosis of asthma confirmed objectively according to guidelines?

Risk factors associated with persistent airflow limitation in difficult asthma.

Background: GINA guidelines recommend that a diagnosis of asthma is confirmed by an objective measurement of lung function or the presence of airway hyperresponsiveness. However, currently no diagnostic flowchart exists on asthma, and objective tests are used inconsistently.

Methods: The MAPOut I study is a retrospective observational study of all patients consecutively referred to a tertiary hospital specialist clinic over a 12-month period, on suspicion of asthma (n=221).

Data on lung function, peak flow, reversibility to beta2-agonist and airway hyperresponsiveness (AHR) was collected.

The prevalence of bronchiectasis among the asthma patients was 2.2%.

Adherence to asthma treatment: Can it be improved in general practice?

Background: Good treatment adherence is pivotal in maintaining well-controlled asthma, along with the right diagnosis and the right treatment.

Conclusion: The overall treatment adherence improved significantly when a systematic asthma management approach was introduced and applied by dedicated health care staff.

Risk factors associated with persistent airflow limitation in difficult asthma.

Background: Bronchiectasis and asthma are different disease. However, some patients have both diseases. There are insufficient data for the effect of bronchiectasis on asthma exacerbations.

Methods: We investigated 2270 patients having asthma in our hospital. Fifty patients had bronchiectasis and asthma. These patients were compared with fifty age and gender matched patients having asthma only. We evaluated frequency of asthma exacerbations (steroid use, emergency room (ER) visit and hospitalization) in each group.

Results: The prevalence of bronchiectasis among the asthma patients was 2.2%. Follow up duration of each group was 51.9±35.2 months for asthma with bronchiectasis and 53.8±29.8 months for pure asthmatics. The number of asthma exacerbations/year (1.04±1.15 vs 0.35±0.42, p=0.004), steroid use/year (0.4±0.54 vs 0.26±0.36, p=0.006), ER visit/year (0.46±0.84 vs 0.26±0.36, p=0.001) and hospitalization/year (0.7±1.44 vs 0.1±0.17, p=0.04) due to asthma exacerbation was higher in asthma with bronchiectasis vs pure asthma.

Conclusion: The number of asthma exacerbation, steroid use, and ER visit due to asthma exacerbation was higher in asthma with bronchiectasis than pure asthma.

Risk factors associated with persistent airflow limitation in difficult asthma.

Introduction: The clinical manifestations of difficult asthma are heterogeneous. Some patients with difficult asthma develop irreversible airflow obstruction, which is associated with poor outcomes.

Objective: The aim of the study is to determine clinical characteristics associated with persistent airflow limitation in difficult asthma.

Methods: We retrospectively analyzed 48 patients with difficult asthma between 2005 and 2010. Twenty patients (8 female, 12 male) with persistent airflow limitation (post bronchodilator FEV1/FVC ratio < 70%) were compared to 28 patients (13 female, 15 male) with normal post bronchodilator FEV1/FVC ratio. Patients with chronic obstructive pulmonary disease and bronchiectasis were excluded.

Results: There was no significant difference between the two groups in age (51 vs 45 years, p=0.17), sex (p=0.66), age of asthma onset (55 vs 32 years, p=0.07), number of hospitalizations (p=0.39) and frequency of exacerbations (p=0.74).

Conclusion: The most frequent episode of asthma exacerbation was acute asthma exacerbation. Persistent asthma exacerbations were more frequent in patients with normal FEV1/FVC ratio (15% vs 35%). But, the difference was not significant (p=0.41).

Gastroesophageal reflux was found in 25% of patients in both groups.

Risk factors associated with persistent airflow limitation were as follows: longer duration of asthma (22 vs 9.5 years, p < 0.001), current or past smoking (50% vs 21%, p=0.038) and absence of allergy (69% vs 33%, p=0.026). Dust mite sensitization was significantly more frequent in patients with normal FEV1/FVC ratio (26% vs 61%, p=0.33).

Conclusion: Smoking, longer disease duration and absence of sensitization seem to be related to persistent airflow limitation in Tunisian patients with difficult asthma.
P2267
Can we achieve GINA guidelines described asthma control in a developing country?
Kaleem Ullah Toori1, Sumaira Nabi2. 1Department of Medicine, KRL Hospital, Islamabad, Pakistan; 2Department of Medicine, Pakistan Institute of Medical Sciences, Islamabad, Pakistan

Introduction: In Pakistan, 5% of adult population suffer from asthma. Poor disease control accounts for morbidity and recurrent hospitalization. Prospective studies assessing asthma control in Pakistan are lacking.

Aims & Objectives: To assess asthma control and factors predicting good asthma control.

Methods: Consecutive 50 asthmatic patients were studied in this prospective, interventional study from April to December, 2010. Diagnosis was confirmed by a rise in FEV1 of ≥12% after bronchodilator. Patients were assessed during intervention period at weeks 0, 4 and 8 and finally after 6 months. Data was analysed using SPSS version 17.

Results: Mean age was 43 years with predominant females (66%). 50% were in lower social class and 58% had family history of asthma. Majority belonged to mild (42%) or moderate (48%) persistent varieties of asthma. At initial assessment 24% used inhalers correctly and 52% required treatment modification according to GINA guidelines. At completion of intervention period 70% had well controlled asthma, 60% used inhaler correctly and 66% were compliant with treatment. At completion of non-interventional period (after 6 months) only 49% had well controlled asthma, 44% used inhalers correctly and 50% were compliant with treatment. A linear regression analysis recognised correct inhaler technique and treatment compliance as significant predictors of good asthma control while age, gender, social class, educational level, severity and family history of asthma were not of any significance in this regard.

Conclusions: GINA guidelines stated asthma control is achievable in our setting provided repeated patient education, correct inhaler technique and compliance to medical therapy are ensured.

P2268
Long term inhalatory therapy in asthma – Achieving control of the disease
Lavanya Reddy Abigail Audia, Roxandea Umeana. Pneumology, Pneumology Hospital Oradea, Oradea, Romania

Objective: Evaluation of long term inhalatory therapy in asthma and achieving control of the disease using asthma control test.

Methods: This was a prospective study recruiting ambulatory patients aged ≥12 years with asthma at the Pneumology Hospital Oradea between December 2011 and January 2012. We evaluate the effectiveness of long term inhalatory treatment of the disease with ACT as a means of detecting GINA defined uncontrolled, partially controlled and controlled asthma (uncontrolled and partially controlled asthma are together labelled as ‘not controlled’ according to GINA). Patients with the following were included in the study: hospitalized for asthma and ambulatory patients with asthma. The questionnaire used was ACT Romanian and English version for adults from www.asthmacontroltest.com. Eligible patients answered and submitted the questionnaire to the investigator, patients then performed Spirometry tests followed by interviews with a pulmonologist who evaluated their asthma control and provided treatment modifications as required.

Results: A total of 60 patients were included in the study of mean age 55 years. Females comprised of 55% of the participants and 45% male participants. A mean ACT score was 15.05, in which GINA stage 1 and 3 are prominent 35%, but in general patients are unequally distributed among the four stages. Most of the patients were using preventive medication; the majority had uncontrolled asthma according to both GINA and ACT criteria and were stepped up on treatment after their visit.

P2269
Comparing COPD in Malta, to other European hospitals: Results from the ERS COPD audit
Eleanor Gerada, Josephine Bigeni, Cynthia Farrugia Jones. Department of Respiratory Medicine, Mater Dei Hospital, Msida, Malta

Background: Proper management of COPD can reduce exacerbations, which in turn reduces disease-related mortality.

Aim: To find out how management of COPD exacerbations in Malta contrasts with other countries.

Methods: A total of 422 European hospitals took part. Every COPD patient admitted with an exacerbation to our hospital over 8 weeks, was included (n=112). The ERS COPD audit proforma and web tool was used. Data was processed by the Data Analysis Team. The authors take full responsibility for any inferences made in this abstract.

Results: The median length of stay was 5 days, while the European Median (EM) was 8 days; there is no early supported discharge programme locally (31.8% of European hospitals run this). The 90-day readmission rate was 47.6% locally vs. 35.1% EM. In Malta there is no respiratory ward (81.7% EM), no specialist COPD ward (61.8% EM), nor respiratory nurse specialists. There are 4 respiratory teams (EM 80%). On admission, only 48.2% had spirometry results available (59.6% EM). 6.4% needed IV (12.5% EM), but 91.1% of patients improved before IV was needed (40% EM). On discharge 15.5% were given LTOT (30.4% EM), the PaO2 our patients had on admission was 66.9mmHg vs. 59.4mmHg EM. 49.1% of our cases satisfied GOLD criteria to be discharged on LAMA (1.8% vs. 59.8% EM) or ICS + LABA (12% vs. 69.5% EM). 45.5% of our patients were on antibiotics on discharge (11.9% EM). The 90-day mortality was 7.6% (6.1% EM). Still, this was COPD-related in only 37.5%.

Conclusions: In Malta management of COPD needs to be optimised by establishing and adhering to guidelines. Specialised care is recommended as well as re-auditing at a later stage.

P2270
Clinical features of alpha one antitrypsin deficiency in COPD
Mohamed Bahgat, Atef Farouk, Hamdy MohammadAl. Chest Department, South Valley University, Luxor, Egypt Chest Department, Assiut University, Assiut, Egypt Chest Department, Sohag University, Sohag, Egypt

Setting: About 1-3% of patients with diagnosed chronic obstructive pulmonary disease (COPD) are predicted to have alpha1-antitrypsin deficiency (A1ATD).

Objective: To clinically evaluate and increase recognition of AATD in patients with COPD.

Material and methods: Sixty COPD patients were diagnosed on the basis of clinical and pulmonary function tests. They fulfilled the inclusion criteria and divided into group (A) COPD below 40 years (30 cases) and group (B) COPD above 40 years (30 cases). All patients were subjected thorough history taking, radiological examination, blood gas analysis and quantitative measurements of serum alpha-1 antitrypsin by radio-immunoassay.

Results: Mean age of group A&B were (44.17±2.75, 61.87±6.04) respectively with (p value <0.001). The mean serum level alpha 1 antitrypsin in group A&B were (185.03±23.00 with only one case deficient(177.53-94) with only four cases deficient) respectively without statistical significance. There is significant relationship between the age of the patient and A1ATD, where in deficient patients mean age 39.63±13.66, and in normal patients mean age 50.18±12.06) with (P value 0.02). There is also significant relationship between family history and A1ATD, where in deficient patients 50%of cases (4 cases) had positive family history, in contrast to 11.61% of cases(13 case) of normal patients (p value 0.03).

There is a significant difference in ages between deficient and normal group as regards gender distribution, smoking history, symptomatic presentations, physical signs, radiological picture, pulmonary function tests and blood gas parameters.

Conclusion: Emphysema at an early age, non smoker with positive family history are clinical features suggestive for A1ATD.

P2271
Chronic kidney disease (CKD) – A forgotten co-morbidity in COPD
Nawaid Ahamed, Humam Maasood, Raama Haqee. Respiratory Medicine, New Cross Hospital, Bexleyheath, United Kingdom Respiratory Medicine, Russell’s Hall Hospital, Dudley, United Kingdom Respiratory Medicine, City General Hospital, Stoke on Trent, United Kingdom

Background: CKD is a less recognized co-morbidity in COPD and its impact on exacerbations and mortality has been under reported.

Objectives: To look at the prevalence of CKD in patients admitted to hospital with exacerbation of COPD. Secondly, to compare the length of stay (LOS) in hospital and all cause mortality between the CKD and non-CKD cohort.

Methods: We included all patients admitted to hospital with a COPD exacerbation from 1st January 2010 to 31st December 2010. CKD was defined as eGFR<60ml/min/sq.m for at least 3 months. Data was analysed by independent sample t-test, chi-square and Mann Whitney U test using online tool Vassar stats and significance reported at p≤0.05.

Results: 161 patients (56% females) were admitted each with FEV1/FVC ratio<0.7 and median FEV1 36% predicted. Spirometry and BMI data were analysed on 113 patients (CKD n= 90, non-CKD n=23) as records for 48 patients could not be obtained. The prevalence of CKD was 18.6% (n=30). CKD group, was older (mean age 75.8 yrs vs 69.2 yrs; p=0.001), included more males (45% vs 43%), had higher Body Mass Index (30 vs 23.8 kg/m²; p= 0.002), had better FEV1 (46 vs 35.5% predicted; p= 0.02) and longer LOS (8 vs 6 days; p= 0.042). There was no significant difference in mortality between the two groups (n= 7 vs n=30; p=0.84).

Conclusion: CKD is prevalent in COPD and has a significant effect on the LOS during exacerbations; however it does not contribute to increased one year mortality. Hence, more work is required in this field.

Characteristics of αz alpha one antitrypsin deficiency patients on the Irish national registry
Geraldine O’Brien, Catherine O’Connor, Tomas Carroll, N.G. McElvane, Respiratory Research, Department of Medicine, RCSI Education and Research Centre, Beaumont Hospital, Dublin, Ireland

Rationale: Alpha-1 antitrypsin (AAT) is produced by hepatocytes, and is the
most important antiprotease in the lung. AAT deficiency (AATD) is a hereditary disorder resulting from mutations in the AAT gene. Individuals with this deficiency classically present with lung disease in adulthood. WHO guidelines advocate a targeted strategy in screening COPD, non-responsive asthma, cryptogenic liver disease patients and relatives of known AATD patients.

**Methods:** The most common AAT phenotype associated with lung disease is ZZ. A chart review of AATD patients on the National Alpha-1 Registry was performed on ZZ patients (n=100). Our registry collects data on pulmonary function tests, GOLD guidelines, initial reason for screening, complications, and smoking history. The mean age of symptom onset was 37.6 ± 3.9 years; the interval between symptom onset and diagnosis was 6.2 years. The mean number of physicians seen prior to diagnosis was 2.6 ± 0.3. Symptomatically screened ZZ individuals mean age of symptom onset was 36.2 ± 3.0 years; mean age of diagnosis was 44.3 ± 1.9 years (range 6-60). The interval between onset of symptom and diagnosis was 6.2 ± 2.8 years (range 4-60). We evaluated the longitudinal changes in FEV1 in asthmatic outpatients during a 10 year follow-up period (P value 0.01, 0.004, 0.001, 0.001). The mean decrease in FEV1 in symptomatic smokers was 21.4% and in asymptomatic smokers was 10.5%. We recorded the changes in FEV1 variability at 3 months. FEV1 variability at the 1st year was computed. Short term treatments with oral steroids (OS) were used as needed. The best FEV1 measures at 1st, 5th and 10th year were evaluated and normalized for the subject’s height at third power (FEV1/HT3). The slopes FEV1/HT3 vs time during the 1st and 2nd periods were evaluated. We evaluated the effect of body mass index, baseline FEV1, age at enrolment, age of disease onset, disease duration, allergic sensitization, number of OS courses, and FEV1 variability on FEV1 decay slopes. Median FEV1/HT3 slope values were -0.013 and -0.014 (±0.001) for the 1st and 2nd period, respectively (P<0.0001). No correlation was found between the slopes of the two periods. 1st period slopes were correlated to FEV1 variability (P<0.0001), but such correlation was not found for 2nd period slopes. Negative relationship between 1st period slopes and long term reversibility was found (P=0.006). Subjects with disease duration ≤5 years had steeper 1st period slopes (P=0.04). A relationship was found between 1st period slopes and the number of OS courses (P=0.012). In conclusion, FEV1 decay in treated adult asthmatics is not constant. In particular, it drops down over time, and is influenced by some subjects’ clinical and functional characteristics.

**P2276**

**Computer aided lung sound analysis in smokers**

Mohammad Alzahra1, Anne Bruton2, Anna Barney3

1Respiratory Therapy, Prince Sultan Cardiac Centre, Riyadh, Saudi Arabia; 2Health Sciences, University of Southampton, United Kingdom

Computer technology was used to record and analyse lung sounds in two groups of healthy young subjects (smokers and non-smokers).

**Introduction:** Tobacco smoking is known to have adverse effects on human health. It is believed that smoking in early life has a substantial role in the development of chronic lung disease, but it is not yet known when the first measurable effects of smoking can be detected. Computer aided lung sound analysis (CALSA) permits the quantification of lung sounds, which may change in response to smoking. We found that smoking significantly affected lung sound recordings when compared to non-smokers. We compared the lung sound recordings of smokers and non-smokers.

**Method:** Sixty male subjects (30 smokers and 30 non-smokers) aged 26.8 ± 4.7 years were recruited from a staff population. Lung sound recordings were made using a digital stethoscope, following published guidelines. Lung sounds were recorded on a computer with Matlab software. Using signal processing techniques, one characteristic of the crackles was measured (namely the two cycle deflection (2CD)) at each anatomical recording site. Statistical analysis was used to quantify differences in crackles between smokers and non-smokers.

**Findings:** Sixty sets of data have been analysed. The 2CD per site data revealed some statistically significant differences at both anterior sites (anterior left: F(2,57)=7.87, P=0.02, anterior right: F(2,57)=9.51, P=0.00) and both lateral sites (middle left: F(2,57)=4.2, P=0.02, middle right: F(2,57)=9.51, P=0.002).

**Conclusion:** The hypothesis that crackle’s 2CD differ between asymptomatic smokers and non-smokers has been supported.

**P2277**

**Clinical features of alpha one antitrypsin deficiency in non cystic fibrosis bronchiectasis**

Mohamed Badran1, Aref Farouk2, HamdyMohmoudien1

1Chest Department, South Valley University, Qena Faculty of Medicine, Luxor; 2Chest Department, Assiut University, Assiut; Chest Department, Sohag University, Sohag, Egypt

**Setting:** It’s important to identify manifestation of alpha-antitrypsin deficiency (AATD) in bronchiectasis to improve patients care and outcome.

**Objective:** To clinically evaluate AATD in patients with non cystic fibrosis bronchiectasis.

**Material and methods:** Patients with non cystic fibrosis bronchiectasis were diagnosed clinically and confirmed radiologically. They fulfilled the inclusion criteria and divided into group (A) bronchiectasis with hyperinflation (30cases) and group (B) bronchiectasis without hyperinflation (30 cases). All patients were subjected to history taking, pulmonary function tests, and quantitative measurements of serum A1AT by radio-immunoassay. It's important to identify manifestation of alpha1-antitrypsin deficiency (AATD) in bronchiectasis to improve patients care and outcome.

**Results:** Mean age of both groups was (50.5±6.8) and (36.8±7.5) respectively (P=0.001). There were significant difference in gender distribution (P=0.006), and smoking history (P=0.001). Haemoptysis presented in 12 cases (40%), and 20 cases (66.67%) in both groups respectively (P=0.04). Dyspnea presented in 27 cases (90%) and 19 cases (63%) for group A&B with (P=0.02). There were no significant difference in sinusitis, hepatological symptoms, clubbing and family history. There were significant differences compared to normal lung sounds, radiological findings and spirometric tests (P value 0.01, 0.004, 0.001, 0.001).
Conclusion: A LATD is seldom found in patients with bronchiectasis even with concomitant hyperinflation. Inheritance could influence an individual risk of a LATD for developing bronchiectasis.

P2278
Clinimetric properties of outcome measures in bronchiectasis
Stephen Rowan1, Joseph Stuart Elbion1, Madeleine Ennis1, Judy Bradley2,
1Centre for Infection and Immunity, Queen’s University Belfast, United Kingdom; 2School of Health Sciences, University of Ulster, Belfast, United Kingdom

Introduction: In bronchiectasis (BE) there is demand for researchers and regulatory bodies to use robust outcome measures (OM) in clinical trials which have evidence of validity, reliability and responsiveness.

Aim: To explore the evidence for clinimetric properties of commonly used outcome measures in BE.

Methods: A systematic search of key databases (2000-2010) to identify studies in adults with BE which included the following OM; HRCT, FEV1, Quality of life (Qol), exacerbations (PEX), sputum volume/colour and sputum inflammatory markers (IL-8 and elastase). Data relating to clinimetric properties was extracted.

Results: 68 papers met the inclusion criteria. There was good evidence for all components of validity for HRCT, FEV1, Qol, and with exception of predictive validity for sputum volume/colour and sputum inflammatory markers. There was minimal evidence for validity for PEX. The majority of RCTs in BE included FEV1 (n=9/11) as a key OM however none were able to demonstrate a treatment effect with FEV1. Other research designs (e.g. crossover/cohort studies) were also unable to demonstrate a treatment effect with FEV1. A small number of RCTs (n=5) included the other OMs and some of these studies were able to demonstrate a significant treatment effect (Qol, n=2/4, PEX n= 2/4, sputum/colour/n=1/5 and sputum inflammatory marker n=1/5). Other research designs were also able to demonstrate a treatment effect with these outcomes. There are a small number of studies demonstrating test-retest reliability of these OM.

Conclusions: FEV1 is considered to be the primary outcome in clinical trials however current evidence in BE suggests that FEV1 may not be responsive and other outcome measures should be considered.

P2279
PCD – As serious as CF in every day lung clinic?
Annika Halling1, Dept. Women’s and Child Health, Uppsala University, Uppsala CF Centre, Uppsala, Sweden

Background: Cystic fibrosis, CF, and Primary cilia dyskinesia, PCD, have very different genetic background, but present very similar in clinic with vicious mucus, bacteria, bronchiectasis and negatively affected lung function. Our regimen involves mucolytica, inhalations, airway clearance and anti-bacterial treatment regardless of diagnosis, but in all cases individualized.

Aim of study: To see whether PCD patients as a group were as affected as CF patients.

Patients: All patients, CF and PCD, seen regularly at our clinic were compared as a whole group and also in an age and gender matched subgroup of 21 pairs.

Results: When comparing lung function in the two groups, FEV1 (in percentage of expected for age and length) showed, to our surprise, to be worse for the PCD group, both in the main group and in the subgroup. The bronchiectases are evaluated separately and will be presented at the Congress. There were more, but not exclusively, pseudomonas infections in the CF group – an expected finding.

Conclusions: We studied 69 patients (44F, 25M); mean age of 60 (SD 14.2). Mean FEV1 % predicted was 69% (SD 30.2), 24 patients (35%) had chronic P. aeruginosa infection.

P2280
Relation between COPD assessment test (CAT™) and quality of life in COPD patients
Selam Erkun Altun and Metin Alkay1, Aysel Sarac Coskun1, Pinar Celik2, 1Chest Disease, Celal Bayar University Medical Faculty, Manisa, Turkey; 2Chest Disease, Dortyol State Hospital, Hatay, Turkey

The aim was to investigate the relation between COPD assessment test (CAT™) and pulmonary function tests(PFT), BODE index, and St. George Respiratory Questionnaire (SGRQ).

Patients: 100 patients diagnosed by GOLD criteria were included to the study. A Questionnaire that include sociodemographic findings as well as CAT, PFT, SGRQ, and BODE index were assessed for each patient.

Exacerbation number in a year and hospitalization in a year was related with all the parameters above.

Conclusion: There was no relation between CAT and quality of life in COPD patients and also correlation between these parameters and disease stage were observed. CAT can be used as simple, practical test when PFT were unavailable or there was no enough time to apply quality of life questionnaire.

P2281
The impact of airflow obstruction, P. aeruginosa infection and psychological factors on cognitive function in bronchiectasis patients
Tugba Goktalay1, Aysin Sakar Coskun1, Pinar Celik 1, Levent Ozdemir2, Therese Small1, Julia Newton2, Anthony De Soya3, Sir William Leech Centre for Lung Research and Freeman Hospital Bronchiectasis Service, Freeman Hospital, Newcastle upon Tyne, United Kingdom; 2Institute for Ageing and Health, Newcastle University, Newcastle upon Tyne, United Kingdom; 3Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom

Introduction: Bronchiectasis is a chronic lung systemic disease; whilst acute sepsis is associated with cognitive dysfunction, there is little data for chronic lung sepsis. We have compared cognitive function to relevant factors, e.g. airflow obstruction and P. aeruginosa infection.

Methods: Adult Bronchiectasis patients from clinic (3 months) were screened. Cognitive function was determined by the Cognitive Failures Questionnaire (CFQ), a self-reported measure; poor memory has a high score and >40 is abnormal. We recorded airflow limitation (FEV1), MRC dyspnoea (MRCD) and P. aeruginosa infection. The Hospital Anxiety and Depression Scale assessed anxiety (HADS-A) and depression (HADS-D). Fatigue was measured by Fatigue Impact Scale (FIS); abnormal >40.

Results: We studied 69 patients (44F, 25M); mean age of 60 (SD 14.2). Mean FEV1 % predicted was 69% (SD 30.2), 24 patients (35%) had chronic P. aeruginosa infection.

Conclusion: Cognitive dysfunction may be a co-morbidity in Bronchiectasis patients and is associated with anxiety, depression and fatigue. However, it does not appear to be related to objective markers of disease severity.

Conclusions: The difference between the three groups was at the expense of that between PCG and WCG. PCG presented severe course of disease, worse lung function, hyperventilation, some degree of inflammation, increased number of exacerbations and poorer QOL. There was no relationship between worse asthma control and nutrition.

P2283
New GOLD 2011 guidelines: Is there an improvement?
Ana Sofia Santos, Ricardo Coelho, Sofia Granadeiro, Raquel Rosa, Alexandra Borela, João Gonçalves, Paula Cravo, Alexandra Mineiro, Salvador Coelho, Maria Joao Gomes, João Cardoso. Pneumologia, Hospital de Santa Marta, Lisbon, Portugal

Background: The new revision of GOLD report 2011 has established new assessment of COPD based on the patient’s level of symptoms, spirometric classification and exacerbation history.

Aims: To compare and establish the differences between the classification of COPD patients using the guidelines of GOLD report 2010 and 2011.

Methods: A prospective study with a group of consecutive COPD patients from our outpatient clinic was performed. They were assessed according to GOLD 2011 by answering COPD Assessment Test (CAT) and Modified British Medical Research Council (mMRC) Questionnaire; by a spirometric evaluation in the same day and by the history of exacerbations of the previous year. This data was compared with the GOLD 2010 COPD assessment of the same patients.

Results: 45 patients were included (mean age 62.3 (±9); 73% male). The results are as below:

<table>
<thead>
<tr>
<th>2010 GOLD CAT ≥10 mMRC ≥2</th>

In GOLD 2010 classification 92% stage 4 patients had chronic respiratory failure; of those 62% were GOLD grade 3 in the 2011 spirometric assessment.

Conclusions: GOLD 2010 stage 4 patients were the group with greater exacerbation history. With exception for GOLD 2010 stage 1 patients, which were mainly assessed as group A in the 2011 GOLD classification, the remaining patients were mostly placed in the groups with greater symptomatic impact (B and D), which was better assessed by CAT. This shows the burden of disease in patient’s life and the need of a better treatment management, which is one of the goals of the 2011 GOLD assessment.

P2285
Impact of cognitive dysfunction and neuro-psychiatric symptoms over quality of life in stable COPD patients
Pram Parakh Gupta, Hitesh Khurana, Sachin Bansal, Dip Agarwal. 1TBJ & Respiratory Medicine, PGIMS, University of Health Sciences, Rohtak, Haryana, India; 2Psychiatry, PGIMS, University of Health Sciences, Rohtak, Haryana, India; 3Physiology, PGIMS, University of Health Sciences, Rohtak, Haryana, India

Background: Extrapulmonary manifestations in COPD contribute to its morbidity. Aims: To assess quality of life, cognitive functions and neuro-psychiatric symptoms in COPD patients and to analyze if quality of life is influenced by cognitive dysfunctions or neuro-psychiatric symptoms.

Methods: 200 stable COPD patients and 50 healthy volunteers [HV] were included. St George Respiratory Questionnaire (SGRQ) was used to assess quality of life. PGI Memory Scale Questionnaire (PGIQMS) was used to assess cognitive functions under 10 subsets: remote & recent memory, mental balance, attention and concentration, delayed recall, immediate recall, retention for similar & dissimilar pair, visual attention, and recognition. Symptom Check List 80 Questionnaire (SCL-80) was used to assess neuro-psychiatric symptoms under 9 subcales: depression, anxiety, interpersonal sensitivity, somatisation, phobic anxiety, obsessive compulsive neurosis, anger hostility, paranoid ideation, and additional symptoms.

Results: SGRQ scores in COPD patients for symptom, activity, impact subcategories were 28.7±4.8, 33.4±2.8 and 23.4±7.6, respectively. SGRQ scores in HV subjects for these subcategories were 2.9±4.9, 1.1±2.6 and 0.8±1.8, respectively. 105 COPD patients had PGIMSQ scores suggestive of cognitive impairment. 138 COPD patients had one or more neuro-psychiatric symptom. The SGRQ scores were correlated with remote memory, recognition, immediate & delayed recall, depression, verbal retention for dissimilar pair, retention for similar pair, visual retention.

Conclusions: Many COPD patients have cognitive dysfunctions and neuro-psychiatric symptoms that have significant impact over their quality of life.

P2286
The performance of COPD assessment test (CAT) in mustard lung patients
Shahrzad Mohammadzadeh Lari1, Hassan Gholami Maralii2, Davood Attaran1, Mohammad Towhid1, Alasoum Mahmoudpour3. 1Lung Disease & Tuberculosis Research Center, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran; 2Internal Medicine, Ardabil University of Medical Sciences, Ardabil, Islamic Republic of Iran

Introduction: Mustard lung is a form of chronic obstructive pulmonary disease (COPD) due to sulfur mustard exposure. Health-related quality of life (QOL) is an important part of management in mustard lung patients. The properties of COPD assessment test (CAT), in COPD patients have been well documented. The aim of this study was to determine the role of CAT in evaluating the QOL in mustard lung patients.

Methods and materials: Eighty- six consecutively patients with stable COPD with all levels of severity were enrolled into this study. The QOL was evaluated by CAT and ST George Respiratory Questionnaires (SGRQ). Also standard spirometry, 6 minute walk test (6MWT), and pulse oxymetry were performed in patients. Severity of COPD was evaluated by GOLD (Global initiative for chronic Obstructive Lung Disease) and BODE (body mass index, obstruction, dyspnea, exercise) index.

Results: The mean age of the patients was 47.30 (±7.0) SD years. The mean CAT score was26.0±3.8. Thirty-five (43%) patients were in CAT stage 3. There was statistically significant correlation between CAT with SGRQ (p=0.001) and BODE index (p=0.001) respectively. Also statistically significant inverse correlation was found between CAT score with FEV1 (p=0.03) and 6MWT (p=0.001) respectively. There was statistically significant difference in mean CAT score between patients in GOLD stage ≥3 and those with < (p=0.02).

Conclusion: The findings of this study revealed that CAT questionnaire as a simple tool for assessment of QOL in mustard lung patients is valuable and can be used in clinical practice.

P2287
The relationship between COPD assessment test (CAT) scores and severity of airflow obstruction in stable COPD patients
Hassan Gholami Marali, Sadeq Sadehieh-ahari, Shahrzad Mohammadzadeh Lari1, Arad. Internal Medicine, Ardabil University of Medical Sciences, Ardabil, Islamic Republic of Iran

Background: COPD is a major cause of morbidity in smokers. The COPD as-
and community services resulting in a reduction length of hospital stay with low readmission rates.

P2290
Assessment of cognitive functions in stable COPD patients using PGI Memory Scale and to analyze for their correlation with patients' characteristics and BODE index
Prem Parkash Gupta 1, Hitesh Khurana 2, Sachin Bansal 1, Dipi Agarwal 1 1TB & Respiratory Medicine, PGIMS, University of Health Science, Rohtak, Haryana, India; 2Psychiatry, PGIMS, University of Health Science, Rohtak, Haryana, India; 3Physiology, PGIMS, University of Health Science, Rohtak, Haryana, India

Background: COPD is a multisystem disorder with significant extra-pulmonary manifestations.
Aims: To assess cognitive functions in stable COPD patients using PGI Memory Scale Questionnaire [PGIM-SQ] and to seek for any correlation with patients' characteristics and BODE index variables.
Methods: We included 200 stable COPD patients and 50 healthy volunteers (HV).
Their baseline characteristics and BODE index variables were assessed. PGIM-SQ was used to assess cognitive functions under 10 subsets (shown in Table 1).
Results: The age of subjects in COPD Group was 61.3 ± 7.4 year, and of those in HV group was 59.76 ± 7.21 year. 105 COPD patients (52.5%) were having PGIM-SQ scores beyond ± 3 SD of HV scores. PGIM-SQ scores are shown in Table 1.

Conclusion: We observed a global decline of cognitive functions in COPD group and observed their significant correlations with age, duration of illness and BODE index variables.

P2291
An analysis for neuro-psychiatric symptoms in stable COPD patients and to assess for their correlation with patients' characteristics and BODE index
Prem Parkash Gupta 1, Hitesh Khurana 2, Sachin Bansal 1, Dipi Agarwal 1 1TB & Respiratory Medicine, PGIMS, University of Health Science, Rohtak, Haryana, India; 2Psychiatry, PGIMS, University of Health Science, Rohtak, Haryana, India; 3Physiology, PGIMS, University of Health Science, Rohtak, Haryana, India

Background: COPD is known to have significant extra-pulmonary involvement that contributes to COPD morbidity.
Aims: To assess neuro-psychiatric symptoms in stable COPD patients using Symptom Check List 80 Questionnaire [SCL-80] and to seek for any correlation between these symptoms and COPD severity.
Methods: We included 200 stable COPD patients and 50 healthy volunteers (HV).
The COPD subjects had a smoking history > 20 pack years. SCL-80 was used to assess neuro-psychiatric symptoms under 9 subscales (table 1).
Results: The age of subjects in HV group was 59.76 ± 7.21 year, and of those in COPD Group was 61.37 ± 7.4 year. 138 COPD patients (69%) had neuro-psychiatric symptom(s) detected using SCL-80. A total of 78 (39%) patients had a global decline of neuro-psychiatric symptoms in stable COPD patients with significant correlation with patients' characteristics and BODE index variables.

Conclusion: SCL-80 scores (n=120) of COPD patients and 50 healthy subjects (HV) were compared to assess the significant cognitive differences and neuropsychiatric symptoms in stable COPD patients with significant correlation with patients' characteristics and BODE index variables.
scores had positive correlations with SCL-80 scores. FEV1 and distance walked in six minute had inverse correlations with SCL-80 scores.

Conclusions: 60% stable COPD patients had neuro-psychiatric symptoms detected using SCL-80, and the SCL-80 scores had significant correlations with age, smoking pack years, duration of illness and BODE index variables.

P2292
Cross-sectional analysis of the Belgian Severe Asthma Registry
Florannes Schlumberger1, Guy Bourgeois1, Renaud Louis2, Olivier Van der Perre3, Charles Patin1, Rudi Peche1, Guy Joos1, 2. Respiratory Medicine, CHU Sart-Tilman, Liege, Belgium; 2. Dept Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; 3. Respiratory Medicine, Clinique Universitaire Mont Godinne, Yvoir, Namur, Belgium; 4. Respiratory Medicine, Cliniques Universitaires St Luc, Bruxelles, Belgium; 5. Respiratory Medicine, CHU Charleroi, Vésale, Charleroi, Belgium

The Belgian severe asthma registry (BSAR) is a secured web-based registry encompassing demographic, clinical, functional and inflammatory data of severe adult asthmatics as defined by the ATS, raising awareness on severe asthma, studying its natural history, identifying phenotypes, and offering tools to optimize care.

Methods: The cross-sectional analyses of the BSAR included 229 refractory asthmatics from 7 Belgian centers, followed up by respiratory physicians for at least one year prior to inclusion.

Results: Severe asthma was more frequent in women (56%), was associated with atopy (69%) and started early (71%) before age 40; 10% were current smokers and 32% ex-smokers. In addition to high doses of ICS+LABA, 48% of patients received LTRA, 21% anti-IgE and 21% oral corticosteroids. Despite impaired flow rates (mean FEV1<70% pred; PEFV<63%), KCO was well preserved (98% pred).

Eosinophilic asthma (sputum Eos<3%) was the predominant phenotype (60%, n=45) while neutrophilic (sputum Neu≥76%) and paucigranulocytic asthma were 22% and 13% respectively. The median FEV1 was 222pp (4250/25ppb) and the fraction of patients with FEV1<50ppb was 13% (n=155). Comorbidities included chronic rhinosinusitis (35%), nasal polyposis (21%), oesophageal reflux (36%), obesity (34%). Sputum neutrophilic (sputum Neu≥76%) and eosinophilic (sputum Eos≥3%) asthma was impaired (85% had ACT<20 and 87% had AQLQ<0.75) and average AQLQ was 4.39.

Conclusion: In the BSAR, severe asthmatics are characterized by airflow limitation, frequent comorbidities, poor asthma control and quality of life. Paucigranulocytic asthma represents a rare phenotype while a high proportion of severe asthmatics have uncontrolled eosinophilic airway inflammation.

P2293
Impact of short term supervised breathing exercises added to regular medications over nocturnal symptoms, requirement of rescue medication and spirometric variables in asthma patients
Dipti Agarwal1, Sushma Sood 1, Prem Parkash Gupta 2. 1. Dept of Physiology, PGIMS, University of Health Sciences, Rohtak, Haryana, India; 2. Dept of TB & Respiratory Medicine, PGIMS, University of Health Sciences, Rohtak, Haryana, India

Background: Breathing exercises have been described to be useful in asthma management by a few workers.

Objectives: To assess efficacy of breathing exercises (Pranayamas) in asthma patients on optimal medications using spirometric indices, nocturnal symptoms parameters and requirement of rescue medication.

Methods: 60 stable asthma patients (34 females), on optimal regular medications as per GINA guidelines for ≥ 3 months, were enrolled. All subjects continued their respective medications during study period and, in addition, performed seven breathing exercises (BEs) for a period of 3 months initially under full and thereafter, after intermittent supervision at Yoga centre in our Institute. Spirometry, nocturnal symptoms and requirement of rescue medicine (salbutamol, given via an MDI) were assessed before and after study period.

Results: The mean age of asthma patients was 25.45±5.41 years. After study period, mean FEV1 increased from 2.92+0.338 L to 2.74±0.343 L and mean PEF increased from 238.82±51.12 L/min to 336.23±51.47 L/min; all increases were statistically significant. The mean days with nocturnal symptoms/week decreased significantly from 1.417±0.619 to 0.067±0.362. The requirement of rescue medication decreased significantly from 6.23±2.95 to 0.90±1.25 puffs/week.

Conclusions: Breathing exercises, when added to regular medications, observed to be beneficial in stable asthma patients leading to significant improvements in spirometric parameters and significant reduction in nocturnal symptoms as well as requirement of rescue medicine.

P2294
The German severe asthma register
Stephanie Korn1, Marisa Hubner1, Karl-Christian Bergmann2, Antje Jahn3, Peter Kardos4, Andrea Koch5, Marek Lomnitzsch6, Eckhard Hamellmann7, Roland Buhl1, 1. Pulmonary Dept, Mainz; University Hospital, Mainz, Germany; 2. Allergy-Centre-Charité, Charité – Universitätsmedizin Berlin, Berlin, Germany; 3. IMHEL, Mainz; Germany; 4. Lungenpraxis Maimburg, Lungenpraxis Maimburg, Frankfurt, Germany; 5. Pulmonary Department, University Hospital Bergmannsheil, Bochum, Germany; 6. Pulmonary Department, Rostock University Hospital, Rostock, Germany; 7. Children’s Hospital, Ruhr University, Bochum, Germany

Patients with severe persistent asthma represent the highest unmet medical need among the asthmatic population today.

To improve the understanding of more severe disease progresses in pediatric and adult asthma the German Asthma Net (GANE v.) launched a National Severe Asthma Register in December 2011. Enrolled patients undergo detailed clinical and physiologic evaluations, including patients' medical history, allergy, lung function, lung inflammation, blood testing as well as past and concomitant medication and comorbidities. As of February 20, 2012 six participating centers joined the program and recruited 93 subjects (mean age ± SEM 49±1.1 years, 63% female. FEV1 2.0±0.1 L (65 ±5±1.2%), 97% uncontrolled or partly controlled asthma according to GINA, 54% allergic asthma, 46% on oral corticosteroids, 39% on omaluizumab, eNO 51±6 ppb, 3±4±6±4 exacerbations during the last 12 months). Recruitment of a larger number of subjects with severe asthma, including children, is ongoing and will allow further characterization of clinical, physiologic, cellular and biochemical factors related to severe disease in a longitudinal assessment to identify parameters that improve diagnosis, phenotyping, management and treatment of this heterogeneous condition. In addition, the German Severe Asthma Register may help to confirm and extend results obtained in similar databases, including U-BIOPRED and SARPI.

P2295
Factors affecting quality of life in children, adolescents and adults with primary ciliary dyskinesia
Neil Botting1, Andrea PannuGalvin2, Fiona Copeland3, Jane Lucas1. 1. PCD Group, Faculty of Medicine, University of Southampton, United Kingdom; 2. Paediatrics and Child Health, University of Cork, Ireland; 3. PCD Family Support Group, Milton Keynes, United Kingdom

Background and objective: Primary Ciliary Dyskinesia (PCD) is a rare autosomal recessive disorder associated with chronic pulmonary disease, rhinosinusitis, sinusitis, otitis media and often infertility. For example in adolescents, ‘embarrassment from having a runny nose’ had the highest mean score (4.11), whilst ‘physical problems from symptoms of PCD’ was less of an issue (2.56). Lack of understanding about PCD by others was highly relevant for all age groups, but particularly children, whose classmates did not understand (4.43). PCD was reported to have little impact on social life in all ages.

Conclusions: Patients of all age groups reported emotional consequences and embarrassment from PCD. Adults reported physical symptoms to be more relevant than in children or adolescents. The prototype questionnaire with the most relevant items is nearing completion. Cross-sectional and longitudinal validation will be conducted in UK, Ireland and USA.

P2296
Determinants of asthma control and quality of life in stable asthma
Mimma Purokivi1, Heikki Koskela, Kirsi Kontra. 1. Center for Medicine and Clinical Research, Division of Respiratory Medicine, Kuopio University Hospital, Kuopio, Finland; 2. Center for Medicine and Clinical Research, Division of Respiratory Medicine, Kuopio University Hospital, Kuopio, Finland; 3. IMBEI, Mainz University Hospital, Mainz, Germany; 4. Lungenpraxis Maingau, Rastock University Hospital, Rostock, Germany; 5. Children’s Hospital, Ruhr University, Bochum, Germany

Asthma control and quality of life are poorly associated with traditional asthma biomarkers. In the present study we evaluated two new cough provocation tests in this respect.

Asthma Control Questionnaire and Leicester Cough Questionnaire were completed by thirty-six stable asthmatics. Cough provocation tests with hypertonic saline (Koskela HO et al Clin Exp Allergy. 2008 Jul;38(7):1100-7) and isotonic hypopnoea of dry air were performed (Purokivi M, et al. Cough. 2011;7(1):8), as well as spirometry, ambulatory peak expiratory flow (PEF) monitoring, and exhaled nitric oxide measurement (eNO).

Leicester Cough Questionnaire score correlated closely with cough responsiveness to hypertonic saline and isotonic hypopnoea of dry air (Rs = 0.66, p<0.001
and Rs = 0.49, p<0.002, respectively). Asthma Control Questionnaire also correlated with the cough responsiveness to these challenges (Rs = 0.52, p<0.001 and Rs 0.43, p<0.08, respectively). FEV1 (%predicted), diurnal PEF variation and ACQ did not correlate with cough-related quality of life but showed some association with asthma control. There was a significant correlation between Leicester Cough Questionnaire and Asthma Control Questionnaire (Rs = 0.54, p<0.001.

Asthma control and cough-related quality of life are more closely associated with cough sensitivity to the investigated cough provocation tests than to eNO and traditional indices of bronchial obstruction. Cough is a major contributor to poor asthma control.

P2297
The inhaled corticosteroids questionnaire shortened version (ICQ-S): A brief patient-rated scale for monitoring inhaled corticosteroid side effects in clinical practice
Juliet Foster1, Siebrit Schokker2, Robbert Sanderman3, Dirkje Postma4,5

Methods: At days 0 and 14, adults with doctor-diagnosed asthma and prescribed an ICS inhaler, completed the ICQ, ICQ-S, 6-minute ACQ and AQOL(y). The intraclass correlation coefficient (ICC) between day 0 and 14 ICQ-S assessed test-re-test reliability. Cronbach’s alpha (coefficient) and item-total correlations tested the internal consistency of ICQ-S. Associations (Spearman’s rho) between the ICQ-S total score and relative associations of the ICQ and ICQ-S with the AQOL(y) assessed criterion validity. Patients reported duration and perceived difficulty (1=very difficult, 5=very easy) of ICQ-S completion.

Results: 62 patients (female 63%, mean age 54 (SD 13) yrs., mean ACQ 0.79 (SD 0.83), median ICS dose 1000 μg (IQR 500,1000)) were eligible. The ICC between day 0 and 14 ICQ-S scores was 0.90, u coefficient was 0.90 and all item-total correlations were rho>0.2. ICQ and ICQ-S were strongly associated (rho=0.80) and 81% patients completed the ICQ-S within 5 minutes and 97% reported that it was not difficult to fill in.

Conclusion: The ICQ-S is a patient-friendly tool which retains the reliability and validity of the original ICQ scale but is brief enough for monitoring/managing inhaled steroid side effects in clinical practice.

A study of neuromuscular dysfunction in patients with chronic obstructive pulmonary disease
Mohamed El-Senoufy1, Ehab S. Mohamed1, Azza A. Ghal1, Ahmed S. Mohamed1,2 Department of Neurology, Tanta University Hospital, Faculty of Medicine, Tanta, Gharbia, Egypt; 1Department of Neurology, Tanta University Hospital, Faculty of Medicine, Tanta, Gharbia, Egypt

Methods: This was a prospective study, which included 20 inpatients with severe chronic obstructive pulmonary disease (COPD) and 15 healthy subjects as a control group. All patients subjected to clinical assessment. All subjects were subjected to respiratory functions tests, blood gases, X-ray chest and computed tomography. The levels of CD4 + CD25high peripheral blood was measured using fluorescence-activated cell sorting.

Results: 20 patients (female 70%, mean age 70 (SD 13) yrs., mean FEV1=80,7 (SD 11)%) and 15 healthy (30,0 (28,0:35,0) yrs.) were eligible. The ICC between post-bronchodilator FEV1 and post-bronchodilator FEV1/FVC was 0.90, Rs 0.43, p=0.008, respectively. FEV1 (%predicted), diurnal PEF variation and ACQ did not correlate with cough-related quality of life but showed some association with asthma control. There was a significant correlation between Leicester Cough Questionnaire and Asthma Control Questionnaire (Rs = 0.54, p<0.001).

Asthma control and cough-related quality of life are more closely associated with cough sensitivity to the investigated cough provocation tests than to eNO and traditional indices of bronchial obstruction. Cough is a major contributor to poor asthma control.

P2299
The relationship between radiologic findings and lung function impairment in chronic obstructive pulmonary disease
Virginija Šileikienė1,2, Ingrida Zeleckiene1,3, Mindaugas Matacsiuma1, Jolita Norkuniene4,5, Edvardas Danila6,7, 1Clinic of Infectious, Chest Diseases, DzūEmmaurotologija and Allergy, Vilius University Hospital; 2Centre of Pulmonology and Allergy, Vilius University Hospital; 3Centre of Radiology and Nuclear Medicine, Vilius University Hospital Santariskiu Klinikos, Vilius, Lithuania; 4Department of Mathematical Statistics, Vilius Gediminas Technical University, Vilius, Lithuania; 5Applied Sciences, Vilniaus Koledžia University, Vilius, Lithuania

Objectives: To evaluate the presence of peripheral neuropathy and myopathy in chronic obstructive pulmonary disease (COPD) patients. Replicated emerging pulmonary symptoms: cough, breathlessness, and fatigue, may be associated with bronchiectasis and emphysema. The patients with more severe airflow obstruction (group II) during remission had more severe respiratory function status during exacerbation comparing to group I patients.

Conclusions: Our study showed that relationship between radiologic findings and lung function impairment in COPD is variegated. Determination in DLCO values could be supported emerging pulmonary symptoms: cough, breathlessness, and fatigue, may be associated with bronchiectasis and emphysema. The patients with more severe airflow obstruction (group II) during remission had more severe respiratory function status during exacerbation comparing to group I patients.

T-reg cells levels in smoking and non-smoking patients with asthma
Evgeniy Kulikov, Natalya Kirilova, Elena Kremer, Ivan Deev, Ludmila Ogorodnova, Polina Selivanova, Olga Fedorova. Hospital Therapy/Faculty Pediatrics, Siberian State Medical University, Tomsk, Russian Federation

Backgroumd: Tobacco smoking is associated with severity of asthma, response to basis therapy and control achievement. Cigarette smoke reduces the pool of T- regulatory cells in healthy smokers but the role of T-regs in the development of allergic diseases still unclear.

Objective: To assess the level of CD4 + CD25high T-reg in healthy and asthmatic with different status of smoking.

Materials and methods: Were enrolled 55 patients with asthma: mild asthma (n=14, (35.2 (32.0:40.0) years), mean FEV1=100,9 (94,3:111,5%), moderate asthma (n=20), (35,4 (30,6:50,6) years), FEV1=80,24 (72,4:89,5%), severe asthma (n=21), (45,0 (41,0:49,0) years), FEV1=66,6 (48,9:70,7%), and 17 healthy (30,0 (28,0:35,0) years), FEV1=104,0 (98,0:111,0%). Peripheral blood mononuclear cells were isolated in Ficoll density. To study the phenotypic characteristics of regulatory T cells was assessed variation of CD markers (CD4 + , CD25 + ) by flow cytometry (FACAFCalibur Becton Dickinson, USA) using appropriate monoclonal antibodies. Results and discussion: The levels of CD4 + CD25high peripheral blood was lower in smokers (0.84 (0.59:2.09%) compared with non-smokers (2.07 (1.20:2.92%) (p<0.05). In current smokers patients and patients with history of smoking the levels of CD4 + CD25high peripheral blood were lower (0.62 (0.22:0.94)) compared with non-smokers (2.20 (0.73:3.47) (p<0.05). A negative correlation between pack-years and the level of CD4 + CD25high (r = -0.51; p<0.05) in healthy volunteers was shown.

*Significant at p<0.01
Conclusion: Cigarette smoke may have an independent influence on asthma course not only as trigger (irritant) but also as factor that leads to reducing the population of CD4+ CD25high Treg and inadequate suppression of Th2-response.

P2301
Peripheral Thelper1/Thelper2/Thelper17/regulatory T cell imbalance in asthmatic pregnancy
Lili Tamsi1, Gergely Toldi2, Attila Molnarcz2, Balázs Stenzczer2, Veronika Tél2, Levian Ivanov3, Nómi Elnor4, Andor Banosz5, Anikó Boldai1, János Rigo Jr.1, György Loosyocz1.
1 Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Semmelweis University, 1st Department of Pediatrics, Budapest, Hungary; 3Semmelweis University, 1st Department of Obstetrics and Gynecology, Budapest, Hungary

Asthma and pregnancy show bilateral clinical interactions with mostly unknown mechanisms. Healthy pregnancy is characterized by a sensitive balance of Th1/Th2/Th17/regulatory T cell and compromised immune tolerance characterizing asthmatic pregnancy. The aim of this study was to describe the prevalence of these cell subtypes in asthmatic pregnancy.

The prevalence of Th1, Th2, Th17 and Treg lymphocytes was identified by cell surface and intracellular marker staining in 24 healthy non-pregnant (HNP), 23 healthy pregnant (HP), 15 asthmatic non-pregnant (ANP) and 15 asthmatic pregnant (AP) women using flow cytometry. HP and ANP were characterized by increased Th2/Th1 ratio compared to HNP, but no further increase was observed in AP. Healthy pregnancy increased Treg cell level by 1.03% compared with HNP data (4.64% vs. 2.98%; p<0.05), and this pregnancy-induced elevation was absent in AP women (2.52% vs. HP; p<0.05). Th17 cell prevalence was similar in the HP and HNP groups (2.78% vs. 3.17%; p>0.05). Asthma increased Th17 prevalence in non-pregnant patients (3.81% vs. HNP; p<0.05), and this asthma specific increase of Th17 cell prevalence was also observed in AP patients (AP vs. HP: 3.44% vs. 2.78%; p<0.05). As a result, Th1/Th7/Treg ratio was decreased in HP, but not in AP women, compared with HNP data.

Peripheral Thelper1/Thelper2/Thelper17/regulatory T cell imbalance may play a role in the interrelationship and compromised immune tolerance characterizing asthmatic pregnancy.

Activin-A induces human regulatory T cells that control allergic asthma
Sofia Tousa, 1 Gergely Toldi, 2 Attila Molnarcz, 2 Balázs Stenzczer, 2 Veronika Tél, 2 Levian Ivanov, 3 Nómi Elnor, 4 Anikó Boldai, 1 János Rigo Jr., 1 György Loosyocz.
1 Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Semmelweis University, 1st Department of Pediatrics, Budapest, Hungary; 3Semmelweis University, 1st Department of Obstetrics and Gynecology, Budapest, Hungary; 4Actoviva Hungary Ltd.

Activin-A is a cytokine involved in essential biological processes. Our previous studies have uncovered activin-A as a controller of experimental asthma through the induction of mouse regulatory T cells (Tregs). Here we studied the role of activin-A in the induction of human Tregs in patients with allergic asthma.

Our data reveal that activin-A greatly inhibits human T cell proliferation and Th2 cytokine release. Activin-A treated T cells remain hyporesponsive after allergen restimulation and do not express effector cytokines. Still, they express significantly increased amounts of immunosuppressive IL-10. Notably, activin-A-treated T cells restimulation and do not express effector cytokines. Activin-A-treated T cells remain hyporesponsive after allergen restimulation and do not express effector cytokines. Activin-A-treated T cells also restrain Th2 responses in the bronchoalveolar lavage (BAL) of severe asthmatics. Using a humanized model of asthma, we show that, co-transfer of act-A+Tregs with human T effectors confers protection against asthma in vivo, as shown by greatly decreased airway hyperresponsiveness, BAL, lung inflammation and Th2 responses in the lungs and draining lymph nodes. Our data reveal that activin-A generates IL-10-producing Tregs that suppress human allergen-driven responses and protect against asthma. Our findings may facilitate the use of act-A+Tregs in adoptive-transfer therapies as re-establishing tolerance in asthma.

P2303
4-1BBL mediated balance of Th17/Treg in patients with allergic asthma
Xiaoyan Ai, Yi-Xin Xu, Shuguo Chao, Xiaoxia Hou.
1Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Semmelweis University, Department of Medical Biotechnology, Budapest, Hungary; 3Department of Medical Biotechnology, Budapest, Hungary

Peripheral blood CD4+ T cells were stimulated with a clinically-appropriate allergen extract. Neutrophil functions were measured with flow cytometry. The s4-1BBL concentrations of patients with asthma (202.47±60.68 μg/L) were decreased than controls (298.29±46.32 μg/L; p<0.01). The m4-1BBL on monocytes of patients with asthma (2.99±1.55%) was decreased than the controls (9.06±6.79%; p<0.01). The supernatant concentrations of TGF-β (655.81±476.26 ng/mL) and IL-17 (5201±4143.74 pg/mL) in PBMCs stimulated with allergen extract (410.50±363.03 ng/L, IL-17: 8377±3839.98 ng/mL, both p<0.05). There was a lower proportion of Th17 cells (1.298±0.53% vs 1.536±1.01%) and a higher proportion of Treg cells (3.45±1.03% vs 2.76±0.97%) in the 4-1BBL mAb group than isotype control, but no difference between the two groups (p>0.05).

Conclusions: Both s4-1BBL and m4-1BBL decreased in peripheral blood of patients with allergic asthma. In vitro agonistic 4-1BB antibody stimulation enhanced TGF-β but inhibited IL-17, which might be due to the ability of s4-1BBL to decrease TGF-β. The balance between Th17/Treg may restore Th17/Treg balance in allergic asthma more likely by changing the function of Th17 and Treg cells.

P2304
Efficacy of basis therapy and level of immunoregulatory T-cells (T-regs) in COPD
Natalya Kiriashova1, Elena Kremer1, Ivan Deev2, Ludmila Ogorodova2, Georgy Chernogorok2, Evgeniy Kuklin2, Sergey Fedosenko1, 1Department of Pulmonology and Rehabilitation, Lithuanian University of Health Sciences, Kaunas, Lithuania; 2Department of Pediatrics, Semmelweis University, Budapest, Hungary

Conclusions: COPD is heterogeneous disease with variable clinical and radiographic signs, different response to therapy and rate of decline in lung function and survival of patients. The levels of T-cells could influence on the efficiency of the basis therapy of COPD.

Aim and objectives: Compare the data of COPD clinical course dynamics during basic therapy and levels of inducible (CD4+FOXP3+) T-regs.

Methods: We included 60 patients with COPD stages II-IV, mean age was 57.8±10.9 years, m/f=50/10, mean duration of disease was 10.6±3.5 years. The observation period was 24 weeks after administration of appropriate basis therapy (GOLD recommendations). At visits were performed spirometry, index BODE, SGRQ. Peripheral blood mononuclear cells were isolated from heparinized blood by Ficoll density gradient (1.077 g/ml). The circulating percentage of CD4+FOXP3+ T-regs in peripheral blood was estimated by the flow cytometry analysis (FACSCalibur Becton Dickinson, USA) using appropriate monoclonal antibodies.

Results: Persons with the levels of CD4+FOXP3+ T-regs cells less than 7% in peripheral blood, were characterized by significant reductions in SGRQ-scores from 53,29±36.3 points at visit 1 to 48,24±4,13 points at visit 2 (p<0.05); stable increase in FEV1 from 37.7±3.08% (visit 1) to 46.63±3.39% (visit 2) (p<0.05); decreased BODE index from 410.1±37 points (visit 1) to 346.0±43 points (visit 2) (p<0.05). COPD patients with the level of CD4+FoxP3+ more then 7% didn’t have the positive dynamics of clinical and functional parameters as a result of a 24-week treatment of patients. The levels of T-regs could influence on the efficiency of the basis therapy of COPD.

P2305
Peripheral blood neutrophil activity during D. pteronyssinus induced late-phase airway inflammation in asthma and rhinitis patients
Simona Ivanivskaja1, Jolanta Jeroch2, Ieva Bajoriene3, 1Department of Pulmonology and Immunology, Lithuanian University of Health Sciences, Kaunas, Lithuania; 2Department of Pulmonology and Immunology, Lithuanian University of Health Sciences, Kaunas, Lithuania; 3Department of Pulmonology and Immunology, Lithuanian University of Health Sciences, Kaunas, Lithuania

Conclusions: High level of CD4+FoxP3+ Tregs (>7%) is associated with impaired response to basis therapy COPD.

Background: Recent investigations suggest that neutrophils may play an important role in the late-phase allergen-induced inflammation in allergic airway diseases.

Aim: To evaluate neutrophil chemotaxis, phagocytosis, and reactive oxygen species (ROS) production in patients with allergic asthma and rhinitis challenged with inhalated D. pteronyssinus.

Methods: Twenty eight patients with allergic asthma and 27 with rhinitis, all sensitized to D. pteronyssinus, as well as 10 healthy subjects underwent challenge with D. pteronyssinus. Neutrophils from peripheral blood were isolated 24 h before as well as 7 h and 24 h after challenge. For chemotaxis analysis neutrophils were stimulated with interleukin-8, and for ROS analysis as well as for phagocytosis were stained with S. aureus bacteria. Neutrophil functions were analyzed flow cytometrically.

Upregulation of myeloid derived suppressor cells (MDSCs) in chronic obstructive pulmonary disease and its relationship with disease severity
Simonetta Baraldo1, Laura Pinton1, Andrea Ballarin1, Susanna Mandruzat2, Enrica Bazzan1, Erika Falisi1, Graziella Turato1, Kim Lokar Oliani1, Mamed Costo1, Paola Zanovello1, Marina Saetta1, 1Cardiological, Thoracic and Vascular Sciences, University of Padova and Padova City Hospital, Pneumology Section, Padova, Italy; 2Department of Surgery, Oncology and Gastroenterology, Immunology and Oncology Section, University of Padova, Italy; 3Meunks Christie Laboratories, McGill University, Montreal, Canada

MDSCs have received growing interest as suppressors of immune responses in cancer, induced in the attempt to escape immune surveillance. MDSCs have been recently implicated in immune modulation in chronic inflammatory diseases, particularly autoimmune. Since we proposed an autoimmune component in COPD, we examined the induction of MDSCs in peripheral blood of smokers with COPD with or without lung cancer. In particular, we evaluated the α chain of the IL-4 receptor (IL-4Rα, which has been proposed as a marker for MDSCs) in patients with COPD (n=102, 8 with concomitant cancer) compared to subjects with a similar smoking history who did not develop COPD (n=8) and non-smokers (n=10). The expression of IL-4Rα was increased in monocytes from smokers with COPD (P<0.01) and was higher in patients with COPD and concomitant cancer (10±1.6%) compared to non-smokers (9.4±1%; P<0.05 for both). This increase was particularly evident in COPD patients with concomitant cancer (23±3%) but was also present in those without cancer (16±1%). A similar IL-4Rα pattern was observed in the granulocytic fraction of blood leukocytes (8±1 vs 3±2 vs 4±2.2%). Of note, IL-4Rα expression was not linked to smoking status or cumulative history, but was correlated with the degree of airflow limitation (P<0.01 and P<0.03, respectively). MMP2 and 9 mRNA were upregulated in BAL cells (P<0.001 and P<0.03, respectively). MMP9 protein was elevated in BALF (P<0.001). Serum concentrations of TIMP4 paralleled increased expression of MMP2 and 9 mRNA in BAL cells (P<0.005 and P<0.007, respectively). The number of TIMP1 transcripts correlated with the number of months free of exacerbation(s) during 2-years follow-up after the BAL sampling (p=0.03).

In conclusion, distinct expression profiles of MMPs/TIMPs were observed at systemic and local level in our COPD patients. These pilot data will be subject to further extension and verification, including subanalyses according to the GOLD stage.

Grant support: IGAUPU LF_2012_07, CZ.1.05/2.1.00/01.0030.
tively) and 20 man from control group. Lymphocytes were isolated by two-color labeled monoclonal antibodies flow cytometry to examine the quantities and percentage of CD4+CD25+ T cell, CD4+CD25++ (CD4(+)Treg), CD3+CD19- T cell, CD3+CD4+ T cell, CD3+CD8+ T cell, respectively. Enzyme immunoassay was used to detect the expression of interleukin-10 (IL-10), tumor necrosis factor alpha (TNF-α), procollagen (PCT) and C-reactive protein (CRP). Mann-Whitney test was used for comparison between data before and after treatment and control group.

Results: In patients with mild and moderate AECOPD take place significant decreasing of Treg cells (CD4+CD25++) from 3.3+0.8% in control to 1.1+0.17% and 1.3+0.12%, respectively (p < 0.01). Interestingly that percentage of Treg didn’t change in dynamics of conventional therapy. Reliable increase of TNF-α and decrease of PCT take place in both groups (p < 0.01). Nevertheless CRP and IL-10 levels of patients with COPD don’t differ from the same values of control group.

Conclusion: The decrease of Treg response and the lost balance between inflammatory/antiinflammatory cytokines, suggest a lack of regulation of the systemic inflammatory response that may contribute to pathogenesis in AECOPD of mild and moderate stage.

P2311

The declined CD4+ CD25+ Treg cells in patients with moderate to severe asthma associated with over-expressed Th2 response

Yuheng Shi, Guochao Shi.
Department of Pulmonary Medicine, Shanghai Third People’s Hospital, Shanghai, China; Department of Pulmonary Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Recent studies have showed that Th2 cells can induce the apoptosis of CD4+CD25+ Treg cells or resist the immunosuppressive effect of Treg cells. We hypothesize that an imbalance of Th2/Treg is presented in patients with allergic asthma.

Methods: Twenty-two patients with mild asthma, 17 patients with moderate to severe asthma and 20 healthy donors were enrolled. All patients were allergic to house dust mites. The proportions of peripheral blood CD4+CD25+ Treg cells and Th2 cells were determined by flow cytometry. The concentration of IL-10, TGF-β and IL-4 in plasma was determined by ELISA. The expression of Foxp3 and GATA-3 mRNA in PBMCs from asthmatic patients and healthy donors was detected by RT-PCR.

Results: Compared with healthy donors and patients with mild asthma, the frequency of CD4+CD25+ Treg cells and plasma IL-10 levels were decreased in patients with moderate to severe asthma. There was no difference of Foxp3 mRNA expression among three groups. However, the frequency of Th2 cells, IL-4 levels and expression of GATA-3 mRNA in patients with moderate to severe asthma was significantly lower than in the control group. The ratio of Th2/Treg and their cytokines was increased in allergic asthma, especially for moderate to severe asthma. The ratio of GATA-3/Foxp3 mRNA was increased in allergic asthma. Patients with moderate to severe asthma, the frequency of peripheral blood Treg cells was negatively correlated to the percentage of Th2 cells and IL-4 levels.

Conclusions: The decline of Treg cells in patients with moderate to severe asthma may play an important role in progress of the disease.

P2312

Peripheral blood Th17 cells and serum IL-17 levels in patients with D. pteronyssinus-induced late-phase asthmatic response

Ieva Bajoriuniene1, Konstantinos Samitas1, Jolanta Jeroch1, Edita Gasiuniene1, Astra Vitkauskiene1, Konstantas Malakauskas1, Kestutis Malakauskas1, Simona Lavinskiene1, Jolanta Jeroch1, Edita Gasiuniene1, Astra Vitkauskiene1, Raimundas Sakalauskas1.
1Department of Pulmonary Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania; 2Department of Clinical Medicine, Saga Medical School, Saga, Japan; 3Department of Laboratory Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: Biphasic cellular immune reaction which follows inhalation of allergen is the specific feature of allergic inflammation. Therefore, Th17 cells and IL-17 may have a role in the development of the late-phase asthmatic response in patients with allergic asthma.

Objectives: To evaluate the percentage of Th17 cells in peripheral blood (PB) and serum IL-17 levels in patients with D. pteronyssinus-induced late-phase asthmatic response.

Methods: We studied 28 patients with allergic asthma who developed early-phase asthmatic response (EAR) (n=16) and late-phase asthmatic response (LAR) (n=12) after bronchial challenge with D. pteronyssinus. The control group included 10 healthy subjects (HS). PB collection was performed 24 h before as well as 7 and 24 h after challenge. The percentage of Th17 cells was analyzed by FACS. Serum IL-17 levels were determined by ELISA.

Results: See Table 1.

Conclusions: D. pteronyssinus-induced late-phase asthmatic response in patients with allergic asthma is associated with increased percentage of Th17 cells in PB and elevated serum IL-17 levels.

P2313

ActiVin-A expression is increased in severe asthma and is involved in tissue angiogenesis

Konstantinos Samitas1,2, Eleftherios Zervas1, Nikolaos Poulos1, Maria Semitekolou2, Stelios Vittorakis1, Harsha Kariyawasam3, Vili Panoutsakopoulou2, Georgia Xanthou2, Mina Gaga1, 17th Respiratory Dept and Asthma Centre, Athens Chest Hospital, Athens, Greece; 2Cellular Immunology Laboratory, Division of Cell Biology, Center for basic Research, Biomedical Research Foundation of the Academy of Athens, Greece; 3Dept of Allergy and Medical Rheinology, Royal National Thorax Nose Ear Hospital, London, United Kingdom

Background: Our recent studies showed that ActiVin-A (Act-A), a cytokine belonging to the TGF-β superfamily, suppresses mouse allergic responses; however its effects on human asthma remain unknown.

Objectives: To determine ActiVin-A expression in healthy controls (CTRL) and asthmatics, identify its cellular sources and signaling mediators, and examine correlations with disease severity and airway remodeling.

Methods: Serum samples were obtained from 46 mild-to-moderate asthmatics (MMA), 27 severe asthmatics (SA) and 41 CTRL subjects (18 CTRL, 18 MMA, 19 SA) underwent bronchial challenge with endobronchial biopsy and BALF collection. Act-A levels in the serum were examined. Expression of Act-A and its principal signaling mediator ALK4 in the bronchial tissue were assessed by conventional microscopy, basement membrane thickness, goblet cell hyperplasia and angiogenesis (vessels/mm2) were also determined.

Results: Act-A levels were significantly increased in MMA and in MMA and SA in BALF. Serum Act-A was further increased during asthma exacerbation. Bronchial tissue Act-A expression was significantly increased in asthmatics, especially in the subepithelium in SA, while ALK4 expression decreased with disease severity. Act-A was mainly expressed by mast cells, neutrophils, macrophages and smooth muscle cells. Act-A and ALK4 were also localized in endobronchial cells, particularly in SA. Subepithelial Act-A expression correlated with angiogenesis and disease severity.

Conclusions: Our data suggest that Act-A plays a crucial role in asthma inflammation and participates in the regulation of angiogenesis in SA. Ongoing in vitro studies will further elucidate its specific role.

P2314

Relevance of measurement of serum periostin for diagnosing bronchial asthma and estimating its lung function abnormalities

Kenji Kohyama1, Kenji Ishihara2, Akemi Kohyama1, Kentaro Nakano1, Ryojiro Kubo1, Hiroyoshi Yamashita1, Takeo Okada3, Naoto Fuel3, Shinichiro Ohba1, Juno Ono1, Yoshinori Azuma3, Hiroshi Sagara4, Department of Respiratory Medicine, Dokkyo Medical University, Koshigaya Hospital, Koshigaya, Saitama, Japan; 2Division of Medical Biochemistry, Department of Biomolecular Sciences, Saga Medical School, Saga, Japan; 3Department of Clinical Medicine, Saga Medical School, Saga, Japan; 4Research and Development Section, Shino-test Corporation, Sagamihara, Kanagawa, Japan

Bronchial asthma is diagnosed by combination of presence of characteristic symptoms and measurement of reversibility of lung function abnormalities. Non-invasive markers such as levels of exhaled nitric oxide (FeNO) and sputum eosinophilia have potential usefulness for diagnosis of bronchial asthma and determination of optimal treatment; however, these biomarkers contain several problems in specificity in diseases. Periostin, an extracellular matrix protein downstream of IL-4/IL-13 signals, has emerged as a novel biomarker for bronchial asthma. Particularly, it has been recently shown that efficacy of anti-IL-13 antibody can be predicted using serum periostin levels in steroid-resistant asthma patients. However, it still remains undetermined how measurement of serum periostin level is relevant for diagnosing bronchial asthma. The study group comprised 37 patients with asthma and 30 healthy subjects. In both groups, serum concentrations of SCCA1, SCCA2, periostin (SS18A SS17B) were measured. In asthmatic patients, serum IgE concentrations, eosinophil counts, and exhaled NO levels were also measured. Serum concentrations of periostin (SS18A SS17B) was significantly higher in the asthmatic patients than in the control subjects. Serum concentrations of both types of periostin strongly correlated with eosinophil counts and exhaled NO levels. In contrast, serum SCCA concentrations did not differ between the control subjects and asthmatic patients or significantly correlate with any variable studied. Our results suggested that serum periostin concentrations may be a significant diagnostic marker of bronchial asthma that correlates with eosinophil counts.
Methods: BALB/c mice were randomly assigned to three groups (asthma group, 4-1BB group and control group). Mice in the asthma group were sensitized and challenged with OVA. Agonistic 4-1BB mAb was administered in the 4-1BB group. Mice in control group were treated with PBS.

Results: (1) The serum IgE concentration [23.350 (65.945-42.635) ng/mL, vs. 99.292 (182.185-293.931) ng/mL, P<0.01], total number of cells [17.35±3.23×10^6 vs. 6.44±1.90×10^6, P<0.05] and eosinophils [9.79±3.38×10^3 vs. 9.91±0.37×10^3, P<0.05] in bronchoalveolar lavage fluid (BALF) and airway inflammation in the 4-1BB group were decreased compared with the asthma group. (2) Agonistic 4-1BB mAb treatment decreased IL-17 [225.747±15.000] ng/mL vs. (6.44×10^3) ng/mL, P<0.05] in bronchial airway in mice. Agonistic 4-1BB mAb inhibited the expression of Th17 cells (3.18±0.23)% vs. (20.32±2.62)% (P<0.01) and RORγt mRNA [10.76±3.28×10^-5] vs. (30.83±5.68×10^-5), (P<0.01) in lung.

Conclusions: Agonistic 4-1BB mAb treatment partially alleviated airway inflammation by restoring the function of Treg cells and inhibiting the proliferation and function of Th17 cells.

P2316
IL-25 secreted from epithelial cells has the potential to promote airway remodeling in asthma

Fen Liu1, Jinxing Wu1, Jinqing Zhao1, Wen Liu1, Liang Dong1, Wenxiang Bi1.

1. Department of Pulmonary Medicine, Qilu Hospital of Shandong University, Jinan, Shandong, China; 2. Institute of Medical Science, Medical School of Shandong University, Jinan, Shandong, China.

Introduction: Interleukin (IL)-25 plays a pivotal role in the pathogenesis of asthma, not only in airway inflammation, but also in airway remodeling.

Objective: To explore the function and significance of IL-25 in the pathogenesis of eosinophilic asthma (EA) and non-eosinophilic asthma (NEA).

Methods: Patients were diagnosed as asthma patients: 26 with EA, 24 with NEA. Serum and induced sputum from all the participants were collected and the level of IL-25 in the samples was determined by enzyme-linked immunosorbent assay (ELISA). Expression of IL-25 in bronchial epithelium and basement membrane thickness were quantified by immunohistochemistry.

Results: Compared with healthy control subjects, the lung function was impaired in patients with EA and NEA. ELISA results showed that the levels of IL-25 in the serum and induced sputum of asthmatic patients were significantly higher than healthy subjects (p<0.05). But there were no statistic differences between EA and NEA patients (p>0.05). The immunohistochemistry results indicated that high expression of IL-25 and thickened basement membrane were observed in asthmatic bronchial epithelium. Correlation analysis showed that the level of IL-25 in serum and induced sputum was positively correlated with the average thickness of basement membrane in asthmatic patients.

Conclusion: IL-25 secreted from epithelial cells has the potential to promote airway remodeling in asthma.

P2317
Inhibition of collagen receptors: α1β1 and α1β2 integrins decreases eosinophil transmigration, but has no impact on peripheral blood mononuclear cell movement through human microvascular endothelial cell monolayer

Stanislawa Bazan-Socha1, Joanna Zwik1, Cezary Macinkiewicz2, Lech Zareba1, Hanna Płucinska1, Ewa Młeka-Kowalczyk1, Jacek Musial1. 1. Dept. of Internal Medicine, Unit of Allergy and Clinical Immunology, Jagiellonian University Medical College, Kraków, Poland; 2. Department of Biology, College of Science and Technology, Temple University, Philadelphia, PA, United States; 3. Institute of Mathematics, University of Rzeszów, Poland.

Introduction: Recruitment of the inflammatory cells to the airways is mediated by adhesive molecules. Among integrins, the most important in cell trafficking are those containing α1 and β1 subunits. We hypothesized that also collagen integrin receptors: α1β1 and α1β2, are involved in asthma pathogenesis. We recently described increased expression of both: α1 and β1 subunits on blood eosinophils and α2 on CD4 T lymphocytes in asthma.

Aim: The aim of the study was to analyse effect of α1β1 and α1β2 integrin inhibition on transmigration of eosinophils and peripheral blood mononuclear cells (PBMC) through human microvascular endothelial cell lung monolayer in 12 healthy controls. We analysed also CD4/CD8 ratio in PBMC population before and after transmigration assay.

Methods: PBMC were separated by gradient centrifugation; eosinophils by gradient centrifugation and negative magnetic separation. For inhibition purposes we used snake venom derived anti-adhesive proteins: vepistatin, VP12, VL05 and VL04 (potential and selective inhibitors of α1β1, α1β2, α1β3 and α5β1 integrins, respectively).

Results: In both groups of subjects all anti-adhesive proteins inhibited eosinophil transmigration, but only VL05 and VL04 PBMC transmigration; CD4 T cells migrated better than CD4 in control samples, but their transmigration was decreased after incubation with anti-adhesive proteins.

Conclusion: These findings suggest that expression of α1β1 and α1β2 integrins are involved in eosinophil transmigration. The role of α5β1 on lymphocyte is probably different.

P2318
The prognostic value of CD8+ and CD25+ lymphocytes blood content for asthma exacerbation

Zhanna Artabovich, Vladimir Tsarev, Natalia Goncharova.

Methods: 48 patients with asthma exacerbation and 48 with asthma remission were randomly selected and 30 matched control subjects were included. All were submitted to detailed clinical history and examination, pulmonary function testing. Investigation of CD8+ and CD25+ lymphocytes in blood was carried out by flow cytometry.

Results: Patients with asthma exacerbation had significantly lower values of CD8+ lymphocytes than patients with asthma remission (20.4±1.52 % vs. 23.2±5.08 % (P<0.01)) and controls (20.4±1.52 % vs. 23.2±3.37 % (P=0.005), they also had significantly higher values of CD25+ cells than patients with asthma remission (10.2±2.43±6.09 % vs. 5.49±3.59±6.01 %; P<0.001) and controls (10.2±2.43±6.09 % vs. 5.49±3.59±6.01 %; P<0.001). The regression equation for the prediction of asthma exacerbation was: Z =exp(2.059±0.498)×0.28831X-0.20392Y+(0.289094×0.20392)+0.289094×0.20392Y, where X – % of CD25+ cells and Y – % of CD8+ lymphocytes. If Z≥0.5, the patient has remission; if Z<0.5, the patient has exacerbation; the above Z, the above asthma exacerbation probability.

Conclusion: Decrease of CD8+ lymphocytes blood content and increase of CD25+ lymphocytes blood content can predict for asthma exacerbation and allows to predict asthma exacerbation with the probability of 81%.

P2319
Lentikoterin (LTC4), aggravate blooomycin-induced pulmonary fibrosis in mice

Yoshiki Murayama, Hirokumi Hirata, Takeshi Fukuda, Masakazu Arima.

Methods: PBMC were separated by gradient centrifugation; eosinophils by gradient centrifugation and negative magnetic separation. For inhibition purposes we used snake venom derived anti-adhesive proteins: vepistatin, VP12, VL05 and VL04 (potential and selective inhibitors of α1β1, α1β2, α1β3 and α5β1 integrins, respectively).

Results: In both groups of subjects all anti-adhesive proteins inhibited eosinophil transmigration, but only VL05 and VL04 PBMC transmigration; CD4 T cells migrated better than CD4 in control samples, but their transmigration was decreased after incubation with anti-adhesive proteins.

Conclusion: These findings suggest that overexpression of LTC4 using trans-

P2320 Continuous airway inflammation is related to the development of airway remodeling

Kyoju Suoma1, Kazuomi Fukuda2, Kentaro Nakano1, Mayuko Tanaka1, Mari Mizuguchi1, Kiyokazu Kikuchi1, Kenya Koyama1, Naoto Fueki1, Hironori Sugara1,2. Dept. of Respiratory Medicine, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan; 2Koshigaya Hospital Joint Research Center, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan

In bronchial asthma, airway remodeling leads to refractoriness to treatment. Recent studies have demonstrated that mechanical stress induces inflammation. For this hypothesis, we examined the effects of continuous mechanical stress and airway inflammation in the mouse. Mice were divided into three groups: an airway inflammation group (group A), a methacholine-inhalation-induced mechanical stress group (group B), and a control group (group C). On days 14 to 29 after sensitization by intraperitoneal injection of ovalbumin, the mice in each group inhalined physiological saline, ovalbumin or methacholine. Counts of eosinophils and other inflammatory cells, smooth-muscle/basement-membrane thickening, and goblet-cell hyperplasia were compared among the groups. Eosinophil counts increased with time in group A, but not in group B or C. Smooth-muscle thickening was slightly greater in group A and group B than in the control group up to day 10 after sensitization. Group A showed a continuous trend toward increased smooth-muscle thickness up to day 15. In contrast, group B showed a slight decrease in smooth-muscle thickness. The difference was more marked in the peripheral than in the central airway. Basement-membrane thickening progressed with time in group A, but was not evident in group B or group C. Goblet-cell hyperplasia calculated on the basis of mucus scores significantly increased in group A, but was unchanged in group B and group C. Conclusion: Mechanical stress was transiently associated with thickening and proliferation of airway smooth muscle, but this effect decreased with time, suggesting that chronic, continuous airway inflammation plays an important role in remodeling.

P2321 Blocking costimulatory signal for treating steroid-resistant asthma model

Mika Enoki1, Yo Ejima1, Chihiro Mitui1, Chiyako Oshikata1, Hidenori Tanimoto1, Yuma Fukutomi2, Kyoshi Sekiya1, Masami Taniguchi1, Yuji Maeda1, Mamoru Ohtomo1, Maki Hasegawa1, Kazuo Akiyama1, Takayuki Ohtomo1, Osamu Kaminuma1. Clinical Research Center, National Hospital Organization, Sagamihara National Hospital, Sagamihara, Kanagawa, Japan; 1Department of Pharmacotherapeutics, Tokyo University of Pharmacy and Life Science, Tokyo, Japan; 2Department of Allergy and Immunology, The National Hospital Organization, Sagamihara National Hospital, Sagamihara, Kanagawa, Japan

Background: We have constructed steroid sensitive (SS) and resistant (SR) murine asthma models by transferring SS and SR helper T (Th) clones into unprimed mice, respectively. Effect of CTLA4-Ig was analyzed both in vitro and in vivo. Method: For in vitro experiments, ovalbumin (OVA) reactive Th clones were cultured with antigen presenting cells, OVA, and various concentrations of dexamethasone (DEX). The proliferative response of each Th clone was measured by 3H-thymidine uptake. For in vivo experiments, unprimed BALB/c mice were transferred with Th clones, challenged with OVA, and administered with DEX subcutaneously. CTLA4-Ig was administered through nasal inhalation or venous injection. The number of infiltrating cells in bronchoalveolar lavage fluid (BALF) was measured. Results: SS and SR clones were selected in terms of the proliferation of antigen-stimulated clones. Airway inflammation of eosinophils and lymphocytes of mice transferred with SS clones were effectively inhibited by the administration of DEX. In contrast, those of mice transferred with SR clones were not significantly inhibited by DEX. Administration of CTLA4-Ig significantly suppressed in vitro proliferation of DEX-treated SR clones, and in vivo eosinophil infiltration of SR asthma model transferred with SR clones. Conclusion: Steroid sensitivity of Th clones measured in vitro were consistent with that of adaptively transferred asthma model measured in vivo. Steroid resistant asthma models can be treated by blocking costimulatory signal mediated through CD28-CD80 and 86.

P2322 The effects of inspiratory muscle training on interleukin-6 concentration during cycling-exercise and volitional hyperpnea

Dean Mills1, Michael Johnson2, Martin McPhillimy1, Neil Williams3, Javier Gonzalez1, Yvonne Barnett1, Sharpe Graham1,2. Sport, Health and Performance Enhancement (SHAPE) Research Group, School of Science and Technology, Nottingham Trent University, Nottingham, Nottinghamshire, United Kingdom; 3School of Life Sciences, Northumbria University, Newcastle upon Tyne, Newcastle, United Kingdom

The plasma concentration of interleukin-6 (IL-6) increases during cycling exercise (EX) (Starke et al. J. Physiol 2001; 533:385-591) and inspiratory resistive breathing (IRB) (Vassilakopoulos et al. Am. J. Physiol 1999; 277:R1013-R1019). Whether inspiratory muscle training (IMT) can attenuate the magnitude of the IL-6 response to EX and volitional hyperpnea (VH) rather than IRB is unknown. Therefore, we tested the hypothesis that IMT would reduce the IL-6 response to EX and/or VH. Twelve male participants performed either 6 weeks of pressure-threshold IMT (n=6) or placebo (PLA) training (n=6). Before and after training, participants undertook three, 1 hour experimental trials: (i) passive rest; (ii) EX; and (iii) VH. EX was performed at maximum lactate steady state power. In VH, participants voluntarily mimicked at rest the breathing and respiratory muscle recruitment pattern attained during EX. IL-6 peaked immediately after EX for both the IMT and PLA groups (6.75±1.6 and 5.64±1.76 pg·ml⁻¹). Following training, this response was reduced (P<0.03) for the IMT but not the PLA group. Blood lactate concentration ([Lac⁻]₀) during EX was also reduced (P<0.05; P=0.09) for the IMT group only. IL-6 and [Lac⁻]₀ increased (P<0.05) during VH in both groups, but there was no effect of training on these responses. There were no increases in IL-6 or [Lac⁻]₀ over time in either group during passive rest. In conclusion, 6 weeks of IMT reduces IL-6 during EX but not VH. The reduction in IL-6 concentration following IMT may be related to a decreased carbohydrate utilisation as indicated by the post-IMT reduction in [Lac⁻]₀ during EX but not VH.

P2323 Assessment of the time course of chronic inflammation in the murine house dust mite model

Stephen Jordan1, Robert Carrington1, David Lanham1, James Cartwright1, Rachel Armstrong1, Kenneth Meecham1. 1Pharmacology, Huntington and Life Sciences, Cambridge, United Kingdom; 2Biologics and Biomarker Analysis, Huntington Life Sciences, Cambridge, United Kingdom; 3Pathology, Huntington Life Sciences, Cambridge, United Kingdom

House dust mite (HDM) allergens are associated with allergic disorders and the use of this clinically relevant allergen is increasing in animal models. We assessed the chronic inflammatory time course and the anti-inflammatory efficacy of a phos- phodiesterase 4 inhibitor and a corticosteroid. BALB/c mice were challenged intransanally with HDM for 5 days/week for 5 weeks. Animals were sacrificed weekly 24 hours after final challenge and recruitment of inflammatory cells assessed in bronchoalveolar lavage fluid (BALF). Lung tissue was stained for the evaluation of a histopathological response. Roflumilast (10 mg/kg) and prednisolone (10 mg/kg) were administered orally twice daily from week 3. Chronic HDM extract exposure resulted in significant recruitment of eosinophils, neutrophils, lymphocytes and macrophages as early as week 1, peaking (1.13±0.32, 0.31±0.05, 0.66±0.10 and 0.33±0.4 x 10⁶ cells/animal respectively) between Weeks 3 and 5. Within the lymphocyte population the proportion of B cells increased from 4 to 46% over the 5 week exposure period. Mice developed perivascular, peribronchiolar and alveolar inflammation which increased in severity during the five week exposure period. The inflammation was accompanied by epithelial and mucus cell hypertrophy/hyperplasia in the bronchi and bronchioles which reached maximum severity during weeks 3 to 5. Perivascular/peribronchiolar fibrosis peaked in week 5. Therapeutic treatment with prednisolone and roflumilast significantly (P<0.001) inhibited BALF cell recruitment and reduced the severity of the airway remodelling suggesting this model, in our laboratory, has the potential to test novel compounds for the treatment of allergic disorders.

P2324 Effects of exercise on lung inflammation in ovalbumin-sensitized and single challenged mice

Mauri Calzada da Silva, Adenir Perini, Adair Roberto Soares Santos, Deborah de Camargo Hizume. Department of Physical Therapy, State University of Santa Catarina, Florianopolis, SC, Brazil Department of Physiology, Federal University of Santa Catarina, Florianopolis, SC, Brazil Department of Medicine, School of Medicine, University of Sao Paulo, SP, Brazil

Background: Studies suggest that physical exercise reduces lung function decline and risk of exacerbations in asthmatic patients. However, the inflammatory lung response involved in exercise during sensitization remains unclear. Aim: To evaluate the effects of aerobic exercise in an experimental model of sensitization and single ovalbumin (OVA) challenge. 419s
Methods: Male Swiss mice were divided into 4 groups: mice non-sensitized, non-exposed to OVA or exercise (Control, n=7); animals submitted to moderate treadmill exercise (Exercise, n=6), animals sensitized (OVA 10 μg) and single exposed to aerosolized OVA 1% (30 min) (OVA, n=6) and animals sensitized to exercise and single exposed to OVA (OVA+Ex, n=6). 24 hours after a single OVA/saline exposure, anesthetized mice were euthanized and we performed measures of inflammatory cells from bronchoalveolar fluid (BALF); IL-4, IL-5, IL-10, IL-1ra from lung tissue by enzyme-linked immunosorbent assay and qualitative assay and measures of IgG1 and IgE OVA-specific by IgE. The median of titles of IgE and IgG1 OVA-specific in OVA+Ex group was significantly lower than OVA group, and IL-4 and IL-5 were also decreased in OVA+Ex when compared with OVA group (p<0.05). Levels of IL-10 and IL-1ra did not reach significance difference.  

Conclusion: Our results showed that aerobic physical exercise attenuated the acute lung inflammation induced by a single OVA-challenge in sensitized mice, suggesting immunomodulatory properties of exercise on sensitization process in asthma.

P2325

Effects of swimming on lung inflammation in ovalbumin-sensitized and challenged mice

Thaysie Regina Brugemann, Leonardo César Melo Ávila, Bárbara Fortkamp, Morgana Duarte da Silva, Francisca Bobinski, Leidiane Mazzardo-Martins, Daniel Fernandez-Martins, Aida Roberto Soares Santos, Deborah de Camargo Huzme. Department of Physical Therapy, State University of Santa Catarina, Florianópolis, SC, Brazil Department of Physiology Science, Center of Biological Research, Federal University of São Paulo, São Paulo, SP, Brazil

Background: Epidemiologic studies have suggested that aerobic exercise decreases asthma prevalence and severity, improving aerobics capacity. However, the effects of high intensity exercise during sensitization on lung inflammation in asthma still unclear.

Objective: To evaluate the effects of high intensity exercise during sensitization process on lung inflammation in an experimental model of allergic pulmonary inflammation.

Methods: Male Swiss mice were divided into 4 groups: mice non-sensitized, non-exposed to ovalbumin (OVA) or submitted to exercise (Control, n=12); animals submitted to swimming 30 min/day for 21 days (Exercise, n=7); animals OVA sensitized (OVA 10 μg) and exposed to OVA (OVA+Ex, n=12); (30 min/day, 48 hours during four days) (OVA, n= 9) and animals sensitized, submitted to swimming and exposed to OVA (OVA+Ex, n=11). 48 hours after last exposure to OVA/saline, anesthetized mice were euthanized and we performed measures of total inflammatory cells from bronchoalveolar fluid (BALF), IL-4, IL-5, IL-10, IL-1ra and immunoglobulin IgE by enzyme-linked immunosorbent assay (ELISA).

Results: Swimming sessions decreased total number of cells from BALF as well as IgE, IL-4 and IL-5 levels in OVA sensitized and challenged mice (p<0.05). On the other hand, levels of IL-10 and IL-1ra showed a decrease in OVA+Ex group when compared with OVA group (p<0.05).  

Conclusion: In this experimental model exercise decreased pro-inflammatory cytokines, but also decreased regulatory/anti-inflammatory cytokines, maybe suggesting that during high intensity exercise, anti-inflammatory effects are not mediated by regulatory cytokines in sensitization process in allergic pulmonary inflammation.

P2326

Poly IC causes exacerbation in a murine allergic inflammation model driven by house dust mite in Freund's complete adjuvant

Joscey De Alba1, Raquel Otal1, Elena Calama1, Félix Gil1, Neil Gozzard2, Elif Melis Bicer1, Ian Mudway1, Ben Forbes1, Graham Somers1, Anders Blomberg1, Nirna Larsson1, Annelie Behndig1, Nasra J. et al. Am J Respir Crit Care Med 181;2010:A2842.

Background: Recent epidemiological and experimental reports have suggested that helminth infection could also play a role limiting the availability of Fe, which would otherwise support bacterial growth. In the present study we hypothesized that these innate defenses would be impaired in asthma, associated with an increased bacterial burden in the airways.

Antimicrobial protein concentrations were determined in bronchial wash (BW) samples obtained from mild asthmatic and healthy volunteers. To examine the relationship between these proteins and bacterial load, measurements of lipopolysaccharide (LPS) and adjuvant associated factor (LTA) were made.

Results: BW samples were obtained from mild asthmatics (n=16, 26.76.2) and healthy controls (n=16, 25.06). Lactoperoxidase, lactoferrin, transferrin, and lysozyme concentrations were determined using ELISAs. LTP concentrations were established using the urea method. LPS measurements were made using the Limulus Amebocyte Lysate assay and LTA concentrations determined using ELISA.

Significantly lower BW transferrin (p<0.01 Mann Whitney U-Test) and lysozyme (p<0.03) concentrations were observed in asthmatics. A similar trend was apparent for lactoperoxidase (p=0.08), though for this and the remaining proteins considered intra-individual variation was apparent. Correspondingly BW LPS was significantly greater (p=0.04) in asthmatics, concentrations were not simply related to transferrin or lysozyme levels.

These results reveal impaired microbicide defense at the air-lung interface of mild asthmatics. Such a deficiency could render the asthmatic airway more susceptible to infection.

P2328

Helminth extract from opisthorchis felineus suppresses allergic inflammation through modulation of dendritic cells phenotype

Elena Kremer1, Natalya Kuryllova1, Ludmila Ogorodova1, Sergey Logovnyov2, Tatiana Perevozchikova1, Elena Fajt3, 1Central Research Laboratory, Siberian State Medical University, Tomsk, Russian Federation; 2Department of Hospital Therapy with a Course of Physical Rehabilitation and Sports Medicine, Siberian State Medical University, Tomsk, Russian Federation; 3Department of Pediatrics Faculty, Siberian State Medical University, Tomsk, Russian Federation; 4Department of Histology, Cytology and Embryology, Siberian State Medical University, Tomsk, Russian Federation.

Background: The objective of this study was to use poly IC, a synthetic analogue dsRNA, to elicit exacerbation in a murine model of allergic pulmonary inflammation driven by house dust mite (HDM) in Freund's Complete Adjuvant (FCA). This model, developed in partnership with UCB as part of UIBOPRED WP6, is characterized by airway hyperresponsiveness (AHR) and a mixed T-helper phenotype [1].

Methods: Mature DCs were cultured from peripheral blood monocytes of healthy control (n=17) and asthmatic patients (mild BA, n=19; severe BA, n=24) using IL-4 and GM-CSF during 6 days. DCs were stimulated with O.f. extract and LPS on day 4 of incubation. After culturing DCs were harvested and labeled for CD86, CD11c, CD200 and analyzed using flow cytometry.

Results: O. f. inhibited the expression of co-stimulatory molecules as CD80 in mature DCs. Number of CD86+CD200+ DC was significantly decreased in different severity of BA compared to healthy donors. Patients with mild and severe BA had increased levels of CD200+ DCs compared to controls.

Conclusions: Our findings suggest that levels of co-stimulatory molecules expression on DC are important in immune response balancing and polarization. Increased levels of co-stimulatory molecules as CD86 on DC after helminth stimulation with O.f. might suppress airway inflammation in BA.

Conclusions: Poly IC exacerbates the inflammation and AHR in a murine model that mimics certain aspects of persistent asthma. This model could be used to investigate new mechanisms of action underlying viral exacerbation in persistent asthma and for the assessment and evaluation of novel therapies for such condition.

TSLP pathway blockade is a potential strategy for asthma treatment, as TSLP modulates cytokine production by mast cells and regulates the activation of dendritic cells (DCs), which prime the differentiation of naive T cells into inflammatory Th2 cells. We thus tested the effects of TSLP blockade on the development of allergenic inflammation and bronchocostriction in cynomolgus monkeys after Ascaris suum allergen challenge. Antibodies against human TSLP were generated and competitively neutralized. Animals were dosed once, either with nontreated MD-DCs, and siRNA against IL-27 and anti-IL-12 mAb suppressed the effect of GSH-OEt on IFN-α production by CD4(+) T cells compared to control subjects. Interleukin-27 α-p28 siRNAs and α-phosphorylated STAT3 and upregulation of α-SMA,collagen I expression were detected in intranasal OVA on days 14 and 21 (OVA/adjuvanted group). The animals received a-DEC-205-OVA treatment after OVA sensitization (OVA/DEC group). The treatment consisted of two injections of a-DEC-205 a week apart. We found that treatment with a-DEC-205 decreased significantly allergic inflammation as revealed by total cell numbers and eosinophils counts in bronchoalveolar lavage (BAL) fluid. We treated the group treated with a DEC-205 but not with the isotype control, we observed a reduction of total and OVA-specific IgE antibodies as well as IL-4 and IL-5 levels in BAL. Furthermore, treatment with a DEC-205 decreased the methacholine-induced respiratory trachea pattern associated with allergy. Our results indicate that treatment with anti-DEC-205 monoclonal antibody conjugated to OVA is effective in reducing allergic responses in animals previously sensitized to OVA. These results suggest a potential therapeutic use of a DEC-205 in allergic disorders.
P2334 Which children have the strongest longitudinal associations between early exposure to environmental tobacco smoke and age of asthma development? Elinor Simons 1,2, Teresa To 1, Rahim Moineddin 1, David Stieb 1, Sharon Dell 1,2, 1Child Health Evaluative Sciences, Hospital for Sick Children, Toronto, ON, Canada; 2Respiratory Medicine, Hospital for Sick Children, Toronto, ON, Canada; 3Family and Community Medicine, University of Toronto, ON, Canada; 4Air Quality Health Effects, Health Canada, Ottawa, ON, Canada

Objective: We sought to understand the effects of risk factors such as atopy on the longitudinal association between early-life exposure to environmental tobacco smoke (ETS) and age of physician-diagnosed asthma (PDA) development in childhood.

Methods: In the Toronto Child Health Evaluation Questionnaire, parents of 5619 grades 1-2 students reported age of PDA development, exposure to ETS during pregnancy and the first year of life and age of PDA development. We used Cox proportional hazard models, we conducted stratified analyses by potential effect modifiers.

Results: Household ETS exposure prevalence was 8.3% during pregnancy and 10.6% in the first year of life; 15.5% of children developed PDA, 31.2% had a history of atopy and 9.8% had a history of maternal asthma. Children exposed to ETS during pregnancy developed asthma sooner (adjusted hazard ratio (aHR) 1.27, 95% confidence interval (CI) 1.00-1.61). Stronger associations were seen among children without a history of atopy (aHR 1.92, 95% CI: 1.42-2.61) and without maternal asthma (aHR 1.74, 95% CI: 1.34-2.25); these relationships persisted for ETS exposure in the first year of life (aHR 1.52, 95% CI: 1.12-2.07 and 1.39, 95% CI: 1.08-1.79, respectively).

Conclusions: Longitudinal associations between ETS exposure during pregnancy or the first year of life and age of PDA development are stronger in children without a history of atopy and without maternal asthma. Greater understanding of these associations may guide hypotheses regarding possible mechanisms of association and suggest strategies for exposure reduction in higher-risk children.

P2336 Prognosis of allergic and non-allergic asthma

Anna Rask-Andersen 1, Monica Uddenfeldt 1, Erik Lampa 1, Christer Janson 2, 1Department of Medical Sciences; Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden; 2Department of Medical Sciences, Respiratory Medicine and Allergology, Uppsala University, Uppsala, Sweden

Some studies indicate that atopy is less important as a predictor of severe asthma. Remission is more uncommon in allergic asthma than in non-allergic asthma. The purpose of this study was to investigate the prognosis of asthma and risk factors for asthma onset, especially sensitization of specific allergens. A cohort of three age groups responded to a respiratory questionnaire in 1990 and 2003. At baseline, 2060 subjects who reported respiratory symptoms and 482 controls responded to interviews, spirometry and skin prick test. A total of 721 asthmatics and 976 subjects without respiratory disease were clinically verified. At follow-up in 2003, 340 subjects with persistent asthma and 186 subjects with asthma remission were identified while 76 subjects reported new asthma onset. Sensitisation to pets and a high symptom score were significant determinants of persistent asthma (ORs 3.23 [95% CI 1.95-5.67], and 5.76 [2.35-13.34] respectively), and of asthma onset, (ORs 2.65 [1.13-4.86] and 1.7 [1.21-2.35].
respectively). A high self-reported responsiveness to airway irritants (OR 1.6 [1.12-2.2]), and more asthma medications (OR 2.0 [1.32-2.9]) were additional risk factors for persistent asthma at the follow-up. By the older age group decreased the risk of having persistent asthma or asthma onset. In conclusion, the findings of this study show that asthmatics sensitized to pets have a more severe prognosis than asthmatics not sensitized to pets. Sensitization to pets was also a strong predictor for onset of asthma. Our study indicates that special care should be given to asthmatics who report having problems with a high number of airway irritants as such patients are more likely to suffer from persistent problems.

P2337
Standardization, sensitivity and specificity of an ash (Fraxinus excelsior) pollen allergen extract
Frédéric de Biasi1, Ashok Purohit 1, Olivier Broutin2, Agnès Viarte2.
1AllergoImmunologie, Service des Maladies Respiratoires, CHU Saint Denis, Saint Denis, Reunion, France; 2Global Clinical Development, Stallergenes S.A., Antony, France;

Background: Ash (Fraxinus excelsior), a wind-pollinated tree species causing spring time pollinosis, is the main representative of the Oleaceae family in temperate zones.

Aims and objectives: There is a need to standardize allergen extracts. Here we calibrated the biological activity of an ash pollen in-house reference preparation (BHRP) in allergic subjects and assessed the sensitivity and specificity of a prick test solution prepared from this BHRP.

Methods: 27 ash pollen allergic subjects, with ash pollen and nOe l 1-specific serum IgEs (sIgE) >0.2 kUA/L and >0.7 kUA/L, respectively and positive ash pollen nasal challenge tests (NCT) participated. Skin prick test (SPT) with BHRP was performed and the concentration inducing a mean wheal diameter of 7 mm was defined as 100 IR/mL. Subsequently, a 100 IR/mL solution of BHRP was assessed in 30 ash allergic subjects (history of ash allergy and ash-specific sIgE >0.7 kUA/L) and 30 non-allergic subjects (no history of allergy and ash-specific sIgE <0.35 kUA/L).

Results: The 100 IR/mL concentration corresponded to 1/148 weight/volume. All ash allergic subjects had a positive SPT (>3mm) and 29/30 non-allergic subjects had a negative SPT. Therefore, the sensitivity of the 100 IR/mL solution was 100% [88.6-100] and its specificity was 96.7% [83.3-99.4].

Conclusions: A 100 IR/mL prick test solution for in vivo diagnosis of ash pollen allergy was shown to be highly sensitive and specific.

P3239
Effectiveness of omalizumab in improving quality of life in patients with 'steroid-resistant' asthma and severe allergic rhinitis
Bakir Omarovic, Bernard Tangy. Consultation d’Allergologie, Service des Maladies Respiratoires, CHU Saint Denis, Saint Denis, Reunion.

Asthma is a heterogeneous disease, not only in its clinical expression and course but also in its response to treatment with deleterious effects on Quality of life (QoL). Anti-IgE can spare these patients with unnecessary exacerbations and have a better QoL. The objective of this study was to evaluate the effectiveness of omalizumab treatment in improving QoL in patients with severe allergic rhinitis and asthma.

Methods: 41 patients aged ≥ 18 years with steroid-resistant asthma were enrolled in this open label study. Patients were examined at baseline and were treated with omalizumab administered subcutaneously every 2 or 4 weeks (at least 0.016 mg/kg/IgE/μL), in addition to existing treatment. At both visits, investigators assessed QoL on a 4-point scale in the following domains: nasal, ocular and asthmatic symptoms. Scores were calculated for individual symptoms, total scores for each domain. Patients were also assessed on impairment of sleep and daily activities.

Results: Omalizumab significantly reduced scores from baseline in both nasal and ocular symptoms. Reductions were also seen in the asthmatic symptom scores: significance was noted in wheezing (P=0.0002) and breathlessness scores (P<0.0002). At baseline, 62% of patients had some degree of daily activity impairment, increased to 81% in the final visit only 31% had daily activity impairment. Similarly, while 55% of patients had some sleep impairment at baseline, this was reduced to 28% at the final visit.

Conclusions: This open label study demonstrated that omalizumab was an effective treatment for the symptoms and sleep/day life impairments associated with severe allergic rhinitis and asthma.

P2340
Population pharmacokinetics of tralokinumab, an investigational anti-IL-13 monoclonal antibody, in asthmatic and healthy adults
Paul Baever1, Raffaela Faggioni2, Balaji Agoram 1. 1Clinical Pharmacology DMPK, MedImmune, Cambridge, United Kingdom; 2Clinical Pharmacology DMPK, MedImmune, Hayward, CA, United States.

Interleukin-13 (IL-13) is considered a critical mediator in the development and maintenance of asthma. Tralokinumab (CAT-354), a human IgG4 monoclonal antibody that specifically neutralizes IL-13, is currently trials in subjects with uncontrolled, severe asthma.

The aim of this study was to develop and evaluate a population pharmacokinetic (PK) model of tralokinumab.

Four phase I studies and one phase 2a study constitute the data to be analysed comprising a population of 247 healthy and asthmatic adults. Nonlinear mixed-effects modeling of pooled data was conducted using the software NONMEM®. The influence of demographic features on tralokinumab PK was evaluated by covariate analysis. Predictive performance of the model was assessed through simulations. The PK parameters for a 2-compartment model after IV and SC dosing were all well established. We retrospectively reviewed medical records 12 months pre- and post-omalizumab initiation in patients (≥12 years) with severe persistent asthma who were (n=81) or were not (n=55) hospitalised for asthma in the year before omalizumab initiation. Baseline characteristics in hospitalised and non-hospitalised patients were similar: mean age 39.7 and 43.6 years; 27.2% vs 22.7% females, respectively. A high self-reported responsiveness to airway irritants (OR 1.6 [1.12-2.2]), and more asthma medications (OR 2.0 [1.32-2.9]) were additional risk factors for persistent asthma at the follow-up. By the older age group decreased the risk of having persistent asthma or asthma onset. In conclusion, the findings of this study show that asthmatics sensitized to pets have a more severe prognosis than asthmatics not sensitized to pets. Sensitization to pets was also a strong predictor for onset of asthma. Our study indicates that special care should be given to asthmatics who report having problems with a high number of airway irritants as such patients are more likely to suffer from persistent problems.

P2338
The APEX study: A retrospective review of outcomes in patients with severe allergic asthma who were not or were hospitalised in the year prior to omalizumab initiation in UK clinical practice
Neil Barnes1, Adel Mansur2, Andrew Menzies-Gow3, Amr Radwan4, on behalf of the APEX Study Investigators. 1Respiratory Medicine, London Chest Hospital, London, United Kingdom; 2Respiratory Medicine, Birmingham Heartlands NHS Trust, Birmingham, United Kingdom; 3Asthma and Allergy, Royal Brompton Hospital, London, United Kingdom; 4Respiratory Medicine, Novartis Pharmaceuticals UK Limited, Frimley/Camberley, Surrey, United Kingdom.

The link between increasingly severe asthma and increased hospitalisation risk is well established. We retrospectively reviewed medical records 12 months pre- and post-omalizumab initiation in patients (≥12 years) with severe persistent asthma who were (n=81) or were not (n=55) hospitalised for asthma in the year before omalizumab initiation. Baseline characteristics in hospitalised and non-hospitalised patients were similar: mean age 39.7 and 43.6 years; 27.2% vs 22.7% females, respectively. A high self-reported responsiveness to airway irritants (OR 1.6 [1.12-2.2]), and more asthma medications (OR 2.0 [1.32-2.9]) were additional risk factors for persistent asthma at the follow-up. By the older age group decreased the risk of having persistent asthma or asthma onset. In conclusion, the findings of this study show that asthmatics sensitized to pets have a more severe prognosis than asthmatics not sensitized to pets. Sensitization to pets was also a strong predictor for onset of asthma. Our study indicates that special care should be given to asthmatics who report having problems with a high number of airway irritants as such patients are more likely to suffer from persistent problems.

P3241
Cough variant asthma may be a incipience of bronchial asthma
Yasushi Obase1, Terufumi Shimoda2, Mikio Oka2, Reiko Kishikawa2. 1Department of Respiratory Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan; 2Clinical Research Center, Fukushima National Hospital, Fukushima, Japan.

Cough variant asthma (CVA) is characterized by chronic cough that persists for more than two months and suggested to be a precursor of bronchial asthma (BA). To analyze if the position of cough variant asthma is early or mild stage of the classical bronchial asthma analyzed according to the airway inflammation,
bronchial hyperresponsiveness, airway obstructive damage, newly diagnosed 46 cough variant asthma patients and 57 bronchial asthma patients naive to oral or inhaled corticosteroids and free of asthma exacerbation were subjected to spirometry, impulse oscillometry (IOS), bronchial hyperresponsiveness test, induction of sputum, and measurement of fractional exhaled nitric oxide (FeNO).

P2342 Effects of budesonide/formoterol combination therapy versus budesonide on airway dimensions in asthma
Makoto Hoshino, Department of Respiratory Medicine, Atami Hospital, International University of Health and Welfare, Atami, Shizuoka, Japan

Background: The combination of inhaled corticosteroids and long-acting β2-agonists results in improved asthma symptom control compared with inhaled corticosteroids alone, but the effects of combination therapy on airway structural changes are still unknown.

Aims and objectives: The aim of the study was to compare the effects of budesonide/formoterol versus budesonide on airways dimensions and inflammation in asthma.

Methods: Fifty asthmatic patients were randomized to treatment with budesonide/formoterol (200/μg, two inhalations bd) or budesonide (200 μg, two inhalations bd) for 24 weeks. Airway dimensions were assessed by CT, and wall area correlated with body surface area (WA) and with body mass index (BMI) was assessed by IOS, wall thickness (Tc/BSA) and luminal area (As/BSA) at the right apical segmental bronchus were measured. The percentage of eosinophils in induced sputum, pulmonary function, and Asthma Quality of Life Questionnaire (AQLQ) were also evaluated.

Results: Significantly decreases in WA/BSA (p < 0.05), WA/BMI (p  < 0.001) and Tc/BSA (p < 0.05), and increases in As/BSA (p < 0.05), and improvements in the AQLQ and the frequency of exacerbations were observed in patients treated with budesonide/formoterol compared with budesonide. The reduction in sputum eosinophils and increase in FEV1 % were greater for budesonide/formoterol compared with budesonide. The changes in WA were significantly correlated with changes in sputum eosinophils and FEV1 % (r = 0.84 and r = 0.64).

Conclusions: Budesonide/formoterol combination is more effective than budesonide for reducing airway wall thickness and inflammation in asthma.

P2343 Effects of breast feeding on the prevalence rates of asthma, rhinitis and eczema in Chinese school children
Ning Song, Mohammed Shamssain, Jin Zhang, Shutang Hao, Jianliang Wu, Chuchun Wu, Xian Yan, Respiratory Medicine, The Second Hospital of Hebei Medical University, Shijiazhuang, Hebei, China School of Health Sciences, University of Sanderland, United Kingdom Respiratory Medicine, The Second Hospital of Shijiazhuang, Shijiazhuaing, Hebei, China

Background: Exclusive breastfeeding for at least 4 months is recommended by many governments and allergy organizations to prevent allergic disease. There is conflicting evidence concerning the relationship between breast feeding and asthma, wheezing illness and allergic disorders. The objective of this study was to investigate whether there is any association between breast feeding and asthma and allergic disorders in Chinese schoolchildren.

Methods: Study subjects comprised 10824 randomly selected 6 to 18 year old schoolchildren from Shijiazhuang in Hebei Province in China. Information on breast feeding, asthma, rhinitis and eczema was gathered by parental questionnaire using the Chinese version of ISAAC questionnaire.

Results: Children who have been breastfed had significantly lower prevalence rates of exercise-induced wheezing, asthma ever, and rhinitis ever than those who have not (3.1% vs 4.2%, p < 0.05; 1.6% vs 2.7%, p < 0.05; 2.7% vs 3.9%, P <0.05; 10.2% vs 12.4%, P <0.05; 12.5% vs 16.2%, P<0.001 and 11.4% vs 13.2%, P<0.05, respectively). There was a similar trend with chronic cough. Children who have been breastfed more than or equal to 12 months had lower prevalence rates of ever wheezed, wheeze in the past year, exercise-induced wheezing, persistent cough past year, ever had rhinitis, and ever had eczema than those who have been breastfed less than 12 months (3.1% vs 6.8%, P<0.05; 1.6% vs 2.7%, P<0.05; 2.7% vs 3.9%, P<0.05; 10.2% vs 12.4%, P<0.05; 12.5% vs 16.2%, P<0.001 and 11.4% vs 13.2%, P<0.05, respectively). The present study confirms the protective effect of breastfeeding on symptoms of asthma, rhinitis and eczema.

P2344 Effects of water aerosol on pediatric allergic asthma
Martin Gaisberger, 1 Renata Sanowicz, 1 Hedemarie Doblas, 1 Predrag Kolar, 1 Angelika Meder, 1 Josef Thulhammer, 1 Anna Selinom 1, Isidor Huttegger 1, Markus Ritter 1, Arnulf Hartl 1, 1 Institute of Physiology and Pathophysiology, Paracelsus Medical University, Salzburg, Austria; 2 Institute of Physics, University of Belgrade, Serbia; 3 Department of Molecular Biology, University of Salzburg, Austria; 4 Clinical Centre, University of Sarajevo, Bosnia and Herzegovina; 5 Department of Pediatrics, University Hospital Salzburg. Paracelsus Medical University, Salzburg, Austria

Objective: Ionized water aerosols have been suggested to exert beneficial health effects on pediatric allergic asthma. Their effects was evaluated in a controlled randomized clinical trial as part of a summer asthma camp.

Methods: Asthmatic allergic children (n=54) spent three weeks in an alpine asthma camp; half of the group was exposed to water aerosol for one hour per day, whereas the other half spent the same time at a “control site”. Immunological analysis, lung function and FeNO testing was performed during the stay, and sustaining effects were evaluated after 2 months. Symptom score testing was done over a period of 1 days.

Results: The water aerosol group showed a significant improvement in all lung function parameters whereas the control group only in peak expiratory flow. All patients showed significant improvement in symptom score and significant decrease of FeNO after the camp. Only the water aerosol group exhibited a long lasting effect on asthma symptoms, lung function and inflammation in the follow-up examination. Induction of IL-10 and regulatory (Treg) cells was measured in both groups, with a pronounced increase in the water aerosol group. IL-13 was significantly decreased in both groups, whereas IL-5 and eosinophil cationic protein were decreased only in the water aerosol group.

Conclusion: Our findings confirm the induction of Treg cells and reduction of inflammation by climate therapy. They indicate a synergistic effect of water aerosols resulting in a long lasting beneficial effect on asthma symptoms, lung function and airway inflammation.

P2345 Simultaneous analysis of clinical markers for predicting increased lung function fluctubility in stable asthma
Kazuto Matsumura, Atsushi Hayata, Tatsuhiko Hirano, Masakazu Ichinose, Third Department of Internal Medicine, Wakayama Medical University, School of Medicine, Wakayama, Japan

Background: Airway hyperresponsiveness (AHR) has been shown to be associated with the loss of asthma control. Predicting the increased fluctuation of lung function might be useful to regulate the future risk of poor asthma control because peak expiratory flow (PEF) variability well correlates with AHR.

Objective: We simultaneously analyzed the clinical markers for predicting increased PEF variability in stable asthma.

Methods: We studied non-smoking asthmatic patients who were receiving conventional therapy and clinically stable for 8 weeks. Patient medical records were obtained and asthma control questionnaire (ACQ), spirometry, and exhaled nitric oxide fraction (FENO) were measured. Associations between these variables and PEF variability over a week (Min/Max) were prospectively assessed.

Results: 52 of 287 asthmatics (17.5%) showed the increased PEF variability (Min/Max > 80%). These subjects were receiving more intensive therapy, but had more severe asthma symptoms, more airflow obstruction, and more evidence of airway inflammation. Especially, ACQ, forced expiratory volume in one second (FEV1) and BO were significantly correlated with changes in sputum eosinophils and FEV1 % (r = 0.84 and r = 0.64).

Conclusions: These results suggested that ACQ, %FEV1 and FENO can stratify risk for increased fluctuation of lung function among the clinically stable asthmatics.

P2346 Impact of allergy diagnosis on patients’ perceptions and experience of HDH allergy: A European survey
Christine Rolland, Michèle Lhermitte-Barrand, Lisa Tauleigne, Marie David, Lise Lemennier, Erika Valovarta. Asthma & Allergy, Association, Boulogne, France Stallergesens, SA, Antony, France LT, Insight, Paris, France Stallergesens, SA, Antony, France Stallergesens, SA, Antony, France Allergy Clinic, Trivesteto Turkis, Tarka, Finland

Background: We assessed allergy awareness and diagnosis in a survey in four European countries. A post-hoc analysis determined the impact of diagnostic status on the perception of house dust mite (HDM) allergy and its management.

Methods: 4016 adults (France: n=1001; Germany: n=1002; Italy: n=1004; Spain: n=1009) answered an anonymous, online, questionnaire on their perception and personal experience of HDM allergy. The results were analyzed according to whether the subjects had been diagnosed with HDM allergy by a physician (n=611) or not. Survey procedures complied with the ESOMAR International Code of Marketing and Social Research Practice.

Results: 56% of the overall survey population stated that they experienced symp-
tom's (repetitive sneezing, nasal discharge, stuffy nose, eye irritation and breathing difficulties). 15% had been diagnosed with HDM allergy and another 23% thought that they were allergic to HDMs but had not been diagnosed. Of the diagnosed patients, 47% presented year-round symptoms, 35% had seasonal symptoms and 14% rarely had symptoms. A high proportion of diagnosed patients considered that their symptoms were due to dust (66%) or indoor air pollution (27%), versus 66% for HDMs. 87% of diagnosed patients felt well informed, whereas 37% of the latter had not identified HDMs as the cause of their symptoms. Diagnosed patients appeared to be more aware that untreated HDM allergy can progress to asthma when that allergy is difficult to treat.

**Conclusion:** Physician-diagnosed HDM allergy patients had greater levels of awareness of HDM allergy and its management than non-diagnosed patients. However, some topics need to be reinforced through health education measures.

**P2347**

Helminths for asthma: Findings of a Cochrane systematic review

Ashley Czok1, Peter Bagter2, Sushil Kumar3, Pat Manning4. 1Headquarters Surgeon General, Whittington Barracks, Lichfield, Staffordshire, United Kingdom; 2Department of Epidemiology Research, St George’s University Artillerivej, Copenhagen, Denmark; 3Division of Basic and Translation Research – Department of Surgery, University of Minnesota, Minneapolis, MN, United States; 4Consultants’ Clinic, Bon Secours Hospital, Galway, Dublin, Ireland

**Background:** Helminths modulate the natural immune response of their human hosts, and may prevent or cure immune-mediated or allergic diseases, such as asthma. Recent randomised clinical studies support this hypothesis.

**Objectives:** To assess the safety and effectiveness of helminth therapy in people with asthma.

**Methods:** We searched the Cochrane Airways Group Specialised Trials Register and additional sources for published and unpublished trials. We included all randomised controlled trials where the intervention was any helminth species administered to people with asthma. We combined dichotomous data using risk ratio (RR) and continuous data using mean difference (MD).

**Results:** We found 5 published reports, describing 2 studies (64 adult participants). Both studies used a single percutaneous application of 10 third stage Necator americanus larvae. Pooled efficacy data showed no difference in airway hyperresponsiveness between the helminth and placebo groups (MD 0.51, 95% CI –0.54 to 1.56) and no difference in study dropouts (OR 2.15, 95% CI 0.36 to 12.76). Other outcomes (asthma symptoms, use of reliever inhalers, quality of life) did not differ between the groups. Adverse events were few.

**Conclusions:** There was no clinical benefit from helminth therapy. The trials however were small and not powered to show effectiveness. Administered to humans in carefully measured doses, helminths appear to be safe. More preclinical studies should be performed, before larger and extended duration trials of helminths for asthma are carried out. "Trickle colonisation" with helminths may be more effective. A better understanding of the host-helminth bolus, but this therapeutic approach has not yet been tested for asthma.

**P2348**

Changes in total and specific IgE following treatment with mebendazole in patients with persistent asthma and HDM allergy to Ascaris lumbricoides

Rosanna, Non-randomised study.

**Background:** Recent studies have reported that patients with ascaridiasis and high levels of total and specific IgE were included in the study. Though they had been treated as chronic bronchitis patients with bronchial asthma, and these cases of bronchial asthma and sinus complications are reported to correlate with worsening of symptoms of asthma. Diagnosis of rhinitis and sinusitis are commonly diagnosed by clinical symptoms, X-ray, laryngoscope and sinus CT, but there are only a few reports of CT findings of sinus in patients with bronchial asthma.

**Patients and methods:** From April 2010 to December 2011, 115 patients with bronchial asthma were enrolled in this study. Duration of disease, treatment steps (i.e. hormonal treatment, smoking cessation, using bronchodilator, etc) and comparison of sinus CT finding were evaluated.

**Results:** Eighty-four patients (73%) showed sinusitis by sinus CT in these 115 patients. Nasal polyps were detected in 15 (13%) patients, and higher treatment steps were observed in patients with bronchial asthma complication sinusitis (p<0.05). Nasal symptoms were detected in 76 (66%), and nasal voice (61, 53%) is significantly highly detected in patients with bronchial asthma complication sinusitis. ACQ and parameters of pulmonary function were not significantly different in asthmatic patients with or without sinusitis.

**Conclusion:** Incidence of sinusitis in our study was relatively higher than the incidence of 66.3% previously reported by Matsuo et al. (2008). Patients with sinusitis detected by sinus CT tend to receive higher treatment steps, and it is speculated that sinus CT is useful for detecting and evaluating sinusitis as a complication of bronchial asthma.

**P2350**

Chronic parasanal sinusitis exacerbates allergic inflammation in patients with asthma and contributes to refractoriness to treatment

Necator americanus (i.e. hookworm) larvae. Pooling of data showed no difference in airway hyperresponsiveness between the helminth and placebo groups (MD 0.51, 95% CI –0.54 to 1.56) and no difference in study dropouts (OR 2.15, 95% CI 0.36 to 12.76). Other outcomes (asthma symptoms, use of reliever inhalers, quality of life) did not differ between the groups. Adverse events were few.

**Conclusions:** There was no clinical benefit from helminth therapy. The trials however were small and not powered to show effectiveness. Administered to humans in carefully measured doses, helminths appear to be safe. Efficacy and safety of 300IR 5-grass pollen sublingual tablet in allergic patients with and without asthma

Robert K. Zeldin, Armeille Monastigu, Joasine Cognet-Sicé, Kathy Abiteboul.

**Global Clinical Development, Stadlerges SA, Antony, France**

**Background:** Efficacy and safety of 300IR tablet has been demonstrated. Here we report the impact of asthma status on efficacy and safety.

**Methods:** Grass pollen allergic adults were randomised to placebo or 300IR pre-and co-seasonally for 3 seasons, starting 4 months (4M) or 2 months (2M) prior to each season and continuing for its duration. Asthmatic patients requiring no more than GINA Step 1 therapy could be included. The primary efficacy endpoint, Average Adjusted Symptom Score (AAdSS), adjusting rhinoconjunctivitis symptoms for rescue medication use, scale 0-18) during the pollen period in Year 3, was analysed by ANCOVA. Asthma presence at baseline was a pre-specified covariate. Treatment by asthma status interaction was tested.

**Results:** Among 581 patients included in the Year 1 full analysis set, 14.1% were asthmatic, with a balance between groups. vs. each of the other two groups). Asthmatic subjects sensitized to both aero- and food allergens had higher levels of FeNO and sECP than non-sensitised or non-atopic (p<0.001). Food allergy is common among children with allergic asthma and has been linked with respiratory allergies (RAs; allergic rhinitis and asthma) in order to identify national gaps and patients’ needs. The survey was part of the 4-year Allergy Awareness Project of the European Federation of Allergy and Airways Disease Patients Associations, Brussels, Belgium

**Aim:** To evaluate, from the patients’ perspective, how European cares for patients with respiratory allergies (RAs; allergic rhinitis and asthma) in order to identify national gaps and patients’ needs. The survey was part of the 4-year Allergy Awareness Project of the European Federation of Allergy and Airways Disease Patients Associations (EFA).

**Methods:** Data were collected via an online 3-part questionnaire: 1) Basic facts: epidemiology, disease definitions, prevalence and costs; 2) Access to care: diagnosis, management, role of healthcare professionals in patient management and follow-up; 3) Quality of care: national policies and best practices. EFA member associations (n. 38) received the questionnaire. The survey was a part of the 4-year Allergy Awareness Project of the European Federation of Allergy and Airways Disease Patients Associations (EFA).

**Results:** Associations from 18 countries returned the questionnaire. RA affect 20%-30% of the European population. But RAs, and particularly allergic rhinitis, are not considered serious diseases, and thus often remain underdiagnosed and undertreated despite the heavy burden they place on patients and society. In all 18 countries, direct RA costs reach millions of euros. In most countries, patients have difficulty in seeing specialists, and coordination among physicians is lacking.

**Conclusions:** We have seen reduced costs and better quality of care.

**References:**

1. European countries

3. Professor of Allergology, University of Turku & EFA Medical Advisor, Turku, Finland.

5. Communication and Research, Scientific Communication Srl, Naples, Italy.

6. Patients Support, Asthma Fonds, Amsterdam, Netherlands.

7. Project and Fundraising Office, European Federation of Allergy and Airways Disease Patients Associations, Brussels, Belgium.
Conclusions: Awareness of RAs and their social burden is low. There is a need for better prevention and coordination among healthcare professionals. Patients’ associations can help increase public awareness, and must be actively involved in devising and implementing RA management and education programs.

The effects of inspiratory muscle training on the interleukin-6 response to intense volitional hyperpnoea
Dean Mills1, Michael Johnson1, Martin McPhilimy1, Neil Williams1, Javer Gonzalez2, Barnett Yvarne1, Sharpe Graham1, 1Sport, Health and Performance Enhancement (SHAPE) Research Group, School of Science and Technology, Nottingham Trent University, Nottingham, Nottinghamshire, United Kingdom; 2School of Life Sciences, Northumbria University, Newcastle upon Tyne, Newcastle, United Kingdom

Vassilakopoulos et al. (Am. J. Physiol. 1999; 277:R1013–R1019) demonstrated a breathing-induced interleukin-6 (IL-6) response. Whether inspiratory muscle training (IMT) can attenuate this response is unknown. Therefore, we tested the hypothesis that IMT can reduce IL-6 response to volitional hyperpnoea (VH) in young healthy men. Twelve male participants performed either 6 weeks of pressure-threshold IMT (n=6) or placebo (PLA) training (n=6). Prior to training, a maximal incremental cycling test (max) was performed. Before and after training, participants undertook two 1 h experimental trials on separate days: passive rest and VH. In VH, they voluntarily mimicked at rest the breathing and respiratory muscle recruitment pattern equal to 70-80% of the maximum minute ventilation achieved during max. IL-6 increased (P<0.01) following the pre-training VH and was (mean±SD) 5.02±0.63 and 4.87±0.86 pg·mL-1 at 2 h post for IMT and PLA groups, respectively. [Lac-]B remained (P>0.01) elevated above baseline values for the duration of VH at 1.36±0.24 and 1.29±0.18 mmol·L-1. The IL-6 (-29%) and [Lac-]B (-11%) responses were reduced (P<0.05) for the IMT, but not for the PLA group. There were no increases in IL-6 or [Lac-]B over time for either group during passive rest and no evidence of diaphragm fatigue during any trial. In conclusion, 6 weeks of IMT reduces the magnitude of the IL-6 response to VH with no evidence of diaphragm fatigue. The reduction in IL-6 may be related to the post-IMT reduction in [Lac-]B.

Estrogen protects against airway inflammation via upregulation of SLPI and downregulation of IL-33
Christina Draijer1,5, Machteld N. Hylkema2,5, Catherine M. Greene3, Pieter A. Klokh, Wim Timens2,3, Dirk S. Postmans4,5, Barbara N. Maelicke1,5, 1Pharmacokinetics, Toxicology and Targeting, University of Groningen, Netherlands; 2Pathology, University of Groningen, University Medical Center Groningen, Netherlands; 3Respiratory Research Division, Department of Medicine, Royal College of Surgeons in Ireland, Education and Research Centre, Beaumont Hospital, Dublin, Ireland; 4Pathology, University of Groningen, University Medical Center Groningen, Netherlands; 5GRIAC Research Institute, University of Groningen, University Medical Center Groningen, Netherlands

Airway epithelium (AE) can modify airway responses through production of anti-inflammatory mediators like secretory leukoprotease inhibitor (SLPI) and pro-inflammatory mediators like interleukin-33 (IL-33). Estrogen can modulate AE responses and we therefore investigated how estrogen affects severity of airway inflammation and SLPI and IL-33 production in mice. Female balb/c mice were ovariectomized (OVX) or sham-treated and received a 0.1 mg estrogen (E2) pellet at OVX or not (all groups n=8). Four weeks after OVX, mice were sensitized i.p. with OVA and alum on days 1 and 7 and challenged with 1% OVA on days 14-20. On day 21, allergic inflammation (OVA-specific IgE, eosinophils) and production of IL-33 and SLPI were assessed.

Ablating estrogen significantly increased airway inflammation as compared to sham-treated mice. Treating OVX mice with E2 significantly reduced the higher airway inflammation induced by OVA as judged from lower eosinophil numbers in lung and lower OVA-specific IgE levels in serum. In the parenchyma of E2-treated OVX mice we found more type II alveolar epithelial cells (AECII) expressing IL-33. IL-33 production in mice. This study shows that estrogen protects female mice against the development of airway inflammation and this is associated with higher SLPI and lower IL-33 production by AECII. We therefore postulate that estrogen has a protective effect on asthma development through induction of anti-inflammatory SLPI production and inhibition of pro-inflammatory IL-33 production by AECII.

IL-4 induces Th2 cells to resist the IL-27 counterregulation by downregulating STAT1 and STAT2 phosphorylation
Zhongchi Chen, Shanze Wang, Chunchui Bai, Rafeul Alam, Hua Huang. Division of Respiratory, Zhongshan Hospital, Shanghai, China

Rationale: Asthma is a chronic airway inflammation caused by overproduction of Th2 cytokines. IL-27 has been shown to inhibit differentiation of naive CD4+ cells into Th2 cells in mice. However, it is not clear whether IL-27 can inhibit Th2 cell differentiation in asthmatic patients.

Methods: Purify CD4+ T cells from human PBMC and mice spleen were cultured under Th2 or Th2 + IL-27 conditions. IL-4 and IFN-gamma were detected by ELISA. IL-27r and p-STAT1 were determined by qRT-PCR and Western blot respectively.

Results: Human IL-27 suppressed Th2 differentiation in healthy subjects (p=0.006), but failed to do so in asthmatics (p=0.064). The suppressive effect of IL-27 on Th2 development was independent of IFN-g, IL-10 and T-bet. However, studies with STAT1-knockout mice showed that this inhibitory effect of IL-27 was STAT1-dependent. IL-27 resistance to Th2 differentiation in asthmatics was not dependent on impaired IL-27r. In further found that Th2-inducing conditions could induce resistance to IL-27 in a dose-dependent manner and IL-4 is the most critical factor. Although IL-2 is imperative in Th2 cell priming, it does not contribute to induction of the IL-27 resistance. We demonstrated that high dose of IL-4 treatment resulted in impairment of STAT1 phosphorylation, but not STAT3 or STAT4 phosphorylation.

Conclusions: IL-27 suppresses the development of Th2 immune response in both mice and human, which is STAT1-dependent, but independent of IFN-g, IL-10 and T-bet. CD4+ T cells from asthmatics developed resistance to IL-27-mediated inhibition. IL-4 induced resistance to IL-27-mediated inhibition by impairing STAT1 signaling.

Regulatory role of antigen-induced IL-10, produced by Tr1 cells, in airway neutrophilia in a murine model for asthma
Takeshi Nabe1,2, Kashiya Yada1,2, Anke Siechert1,2

Asthma is a chronic airway inflammation caused by overproduction of Th2 cytokines. IL-27 has been shown to inhibit differentiation of naive CD4+ cells into Th2 cells in mice. However, it is not clear whether IL-27 can inhibit Th2 cell differentiation in asthmatic patients.

Methods: Purify CD4+ T cells from human PBMC and mice spleen were cultured under Th2 or Th2 + IL-27 conditions. IL-4 and IFN-gamma were detected by ELISA. IL-27r and p-STAT1 were determined by qRT-PCR and Western blot respectively.

Results: Human IL-27 suppressed Th2 differentiation in healthy subjects (p=0.006), but failed to do so in asthmatics (p=0.064). The suppressive effect of IL-27 on Th2 development was independent of IFN-g, IL-10 and T-bet. However, studies with STAT1-knockout mice showed that this inhibitory effect of IL-27 was STAT1-dependent. IL-27 resistance to Th2 differentiation in asthmatics was not dependent on impaired IL-27r. In further found that Th2-inducing conditions could induce resistance to IL-27 in a dose-dependent manner and IL-4 is the most critical factor. Although IL-2 is imperative in Th2 cell priming, it does not contribute to induction of the IL-27 resistance. Probiotics and symbiotics: Effects on chronic asthma in mice
Seri Sagar1,2, Aletta D. Kranefeld1, Niki A. Georgiou1,2, Johan Garssen1,2, Gert Folkerts1,2, Aletta D. Kranefeld1, Niki A. Georgiou1,2, Johan Garssen1,2

Asthma is a chronic inflammatory disorder of the airways characterized by structural changes of the airways which may contribute to airway obstruction and airway hyperresponsiveness. Modulation of the intestinal microbiota by probiotics and related products as a potential therapy for allergic diseases has been subject to investigation. Several murine models of asthma and clinical studies demonstrated beneficial effects of probiotics and symbiotics in asthma management. However, the effects on chronic symptoms of asthma have never been investigated in murine models.

Methods: Mice were sensitized twice (day 1 and 12) with ovalbumin (OVA)-injected alum and challenged from day 17 till 23 daily with OVA. From day 24 till day 56, animals were challenged with OVA 3 times a week and on the same days the animals were treated with either control solution or glucocorticoids (GCS)

Results: Treatment with probiotics or GCS significantly inhibited the OVA-induced increase in basal airway resistance and hyperresponsiveness. Probiotics, but also symbiotics and GCS significantly reduced pulmonary leukocyte infiltration by 50% especially eosinophilia. Neutrophilia in the airways was reduced by GCS and probiotics. Effects on airway remodelling are in process.

Conclusion: The probiotics and symbiotic used in this study seem to be as potent as GCS in reducing cell infiltration in mice with chronic asthma.
In summary, our data provided the first evidence of YKL-40-induced IL-8 expression and increased proliferation and migration of BSMCs. By comparison, IL-8-depleted conditioned culture media (YKL-40-BEAS-2B-CM) to BSMCs, which led to YKL-40 treatment. In addition, we treated BEAS-2B with YKL-40 and added YKL-40 showed YKL-40 induced IL-8 at the transcriptional level. Furthermore, BEAS-2B hypoxia significantly elevated and were associated with asthma severity. Although these studies raise the possibility that YKL-40 may influence asthma, the mechanisms remain unknown. In this study, we investigated the mechanisms involved in YKL-40-mediated IL-8 production from human bronchial epithelial cells (BEAS-2B) and analyzed the soluble factors (including IL-8) secreted by BEAS-2B-exposed to YKL-40 that were responsible for increasing proliferation and migration of primary normal human bronchial smooth muscle cells (BSCMs). We found BEAS-2B treated with YKL-40 resulted in a significant increase of IL-8 expression and release. Moreover, YKL-40 mediates phosphorylation of JNK, ERK, but not p38 in BEAS-2B. Transfection using a NF-κB-luciferase reporter also showed YKL-40 induced IL-8 at the transcriptional level. Furthermore, BEAS-2B pretreated with inhibitors of JNK, ERK or NF-κB decreased IL-8 release upon YKL-40 treatment. In addition, we treated BEAS-2B with YKL-40 and added the conditioned culture media (YKL-40-BEAS-2B-CM) to BSCMs, which led to increased proliferation and migration of BSCMs. By comparison, IL-8-depleted YKL-40-BEAS-2B-CM failed to induce the proliferation and migration of BSCMs. In summary, our data provided the first evidence of YKL-40-induced IL-8 expression in BEAS-2B via MAPK (JNK, ERK) and NF-κB pathways, and the induced IL-8 was found to further stimulate the proliferation and migration of BSCMs. Our results raise the possibility that YKL-40 may play a role in asthma by inducing IL-8 production.
did not change in both ROG-pDNA3.1- and ROG-sRNA-transfected Th1 and Th2 cells (P = 0.05).

**Conclusions:** ROG can inhibit the expression of Th1 and Th2 cytokines by down-regulating the expression of ICOS, which could be a potential regulating target for asthma treatment.

Long-term bortezomib treatment decreases allergen-specific IgE but fails to amend chronic asthma in mice

Michael Wegmann1, Lars Lunding1, Zane Orinkska2, David M Wong1, Rudolf A. Manz3, Heinz Fehrenbach1, 1Bereich Experimentelle Pneumologie, Forschungszentrum Borstel (FZB), Borstel, Germany; 2Abteilung für Immunologie, Forschungszentrum Borstel (FZB), Borstel, Germany; 3Institut für Systemische Entzündungsforschung (ISEF), Universität Lübeck, Germany

Since allergen-specific immuno-global E (IgE) enables mast cells and eosinophils to react on allergen-contact it plays a critical role in the formation of allergic inflammation and has been identified as a target for asthma therapy. By inhibiting the proteasome, bortezomib efficiently depletes Ig-secreting plasma cells and, thus, reduces Ig-serum titers. The present study evaluates the therapeutic potential of Bortezomib in a mouse model of chronic experimental asthma. Therefore, BALB/c mice were sensitized to ovalbumin (OVA) and challenged with OVA-aerosol for twelve weeks. Bortezomib treatment was started after six weeks of challenge, and continued for one week (short-term) or six weeks (long-term), respectively, with a dosage of 0.75 mg/kg body weight with two intra-venous injections weekly. Airway responsiveness to metacholine, lung histology, Ig serum titers, and plasma cell numbers were assessed. In mice with chronic experimental asthma short-term treatment resulted in decreased eosinophil numbers in BAL fluids, while long-term treatment significantly lowered serum titers of anti-OVA IgE. Nevertheless, neither short-term nor long-term treatment significantly diminished ed plasma cell numbers, anti-OVA IgG1 serum titers, allergic airway inflammation or improved lung function. These results demonstrate that Bortezomib has no therapeutic effect on chronic experimental asthma in mice. Therefore, Bortezomib treatment could have only limited value as plasma cell depleting therapy against allergic bronchial asthma.

**P2371**

A low total sputum cell count is a marker for asthma remission during adolescence

Khalid Basak1, Zamir Al-Shammari1, Laurie Lau2, Wilfred Karmous3, Susan Ewart4, Ramesh Kurukulaaratchy1, 1Clinical and Experimental Academic Unit, Respiratory Biomedical Research Unit, and David Hide Asthma and Allergy Research Unit, University JSC, Astana, Kazakhstan; 2Respiratory Medicine, Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom; 3Asthma, Childrens Disease No. 1, Astana Medical University JSC, Astana, Kazakhstan; 4Veterinary University JSC, Astana, Kazakhstan

One of less studied is the test of histamine serial dilutions sensitivity and exactly this test may be very important for antihistamine preparations effectiveness study.

**Materials and methods:** We studied 96 patients; from them 48 were patients of ENT department, who suffered from drug hypersensitivity reactions of various severity, from mild urticaria to anaphylaxis (study group). The control group consisted of 48 ENT patients with same diseases, but without drug hypersensitiv- ity. Patients were determined into “study” and “control” group according to “case-control” principle. Seven day before histamine sensitivity tests cell anhi-sensitization preparation were stopped. Histamine serial dilutions test was performed with standardized prick-needle. We used test 1:0.1 histamine preparation. The end point was histamine dilution that caused papule ≥ 2mm in diameter.

**Results and discussion:** In the control group in 54.2% the end point was ≥ 0.1 histamine dilution, in 29.2% - ≥ 1.0, in 7.3% - ≥ 1.0, in 5.1% - > 1.0. There were few cases, when our patients debit react by papule formation to 0.1% histamine dilution and reacted only to 0.1% of histamine. In patients with drug allergy we found an elevated skin sensitivity. Thus, the end-point 1:2 was found in 39.5% of patients, 10-3 - in 21.6%, 10-4 - in 9.9%. The difference in 10-2 dilutions and 10-3 dilutions between the control and studied group was statistically significant. We concluded that in patients with drug allergy the increased skin sensitivity to histamine was found, and the level of this hypersensitivity should be considered in individual antihistamine preparations prescription.

New enzyme linked immunosorbent assay using recombinant antigens from Saccharopolyspora rectivirgula for Farmer’s lung disease serodiagnosis

Corale Barron1, Laurence Millon1, Gabriel Reboux1, Bénédicte Regn2, Sandrine Roussel1, Manfredo Quadrini1, Jean-Charles Dalphin1, Michel Monod1. 1Mycological Department, UMR/CNRS 6249 Chrono-Environment, University Hospital, Besançon, France; 2Mycological Department, UMR/CNRS 6249 Chrono-Environment, University Hospital, Besançon, France

Since allergen-specific immuno-globulin E (IgE) enables mast cells and eosinophils to react on allergen-contact it plays a critical role in the formation of allergic inflammation and has been identified as a target for asthma therapy. By inhibiting the proteasome, bortezomib efficiently depletes Ig-secreting plasma cells and, thus, reduces Ig-serum titers. The present study evaluates the therapeutic potential of Bortezomib in a mouse model of chronic experimental asthma. Therefore, BALB/c mice were sensitized to ovalbumin (OVA) and challenged with OVA-aerosol for twelve weeks. Bortezomib treatment was started after six weeks of challenge, and continued for one week (short-term) or six weeks (long-term), respectively, with a dosage of 0.75 mg/kg body weight with two intra-venous injections weekly. Airway responsiveness to metacholine, lung histology, Ig serum titers, and plasma cell numbers were assessed. In mice with chronic experimental asthma short-term treatment resulted in decreased eosinophil numbers in BAL fluids, while long-term treatment significantly lowered serum titers of anti-OVA IgE. Nevertheless, neither short-term nor long-term treatment significantly diminished ed plasma cell numbers, anti-OVA IgG1 serum titers, allergic airway inflammation or improved lung function. These results demonstrate that Bortezomib has no therapeutic effect on chronic experimental asthma in mice. Therefore, Bortezomib treatment could have only limited value as plasma cell depleting therapy against allergic bronchial asthma.
antigens in pigeon serum regardless of possessing PFL, and there was no difference in magnitude of response between the groups. No pigeon-specific IL-4, IL-5 or IL-17 ELISPOT response could be detected in any individual.

**Conclusion:** These findings show that an unconventional T cell response is generated in conjunction with pulmonary exposure to pigeon antigens that may be necessary but not sufficient to cause PFL disease, and so further analysis of these cells is warranted.

P2375

**Roles of periostin in vascular remodeling of allergic granulomatous angiitis in murine model**

Naomi Suzuki1, Nobuhito Sasaki1, Miyuki Nisato1, Yu Utsumi1, Yoshio Nakajima1, Masahito Yamashita1, Yukata Nakamura1, Hiroshi Kobayashi1, Takashi Sawa1, Kohei Yamauchi1, 2Division of Pulmonary Medicine, Allergy and Rheumatology, Department of International Medicine, Iwate Medical University School of Medicine, Morioka, Japan; 3Department of Pathology, Iwate Medical University School of Medicine, Morioka, Japan

**Background:** We reported an allergic granulomatous angiitis (AGA) model of C57BL/6 mice (Exp Lung Res 2010). We also reported the suppressive effects of imatinib mesylate (IM) on vascular remodeling (ERS 2010). Periostin is a matricellular protein involved in airway remodeling in asthma and pulmonary fibrosis.

**Objectives:** To elucidate the role of periostin (PO) in vascular remodeling in AGA, we measured the concentrations of PO in bronchoalveolar lavage fluids (BALF) and serum in an AGA model of C57BL/6, in BALB/c as control and in C57BL/6 treated with IM.

**Methods:** C57BL/6 and BALB/c were sensitized with ovalbumin (OVA). They were exposed to aerosolized OVA daily for 7 days. C57BL/6 mice (im treated) were also administered with IM (4.5 mg/kg, p.o.) in parallel with daily exposure to aerosolized OVA for 7 days (n=12). On the 7th day, BALF was performed and the lungs were excised for pathological analysis. The concentrations of PO in BALF and serum were measured and the values were expressed as mean ± SE.

**Results:** The PO concentration in BALF of sensitized C57BL/6 mice exposed to OVA was significantly higher than that of BALB/c (C57BL/6 vs BALB/c; 39.3±6.58 vs 13.56±2.42%, p<0.003). PO in BALF of the IM treated C57BL/6 was significantly reduced compared to positive control mice (control vs IM treated; 40.3±1.85 vs 39.3±1.95%, p=0.019). The pathological scores were reduced significantly in the IM treated group compared to the control group (control vs IM treated; 3.67±0.2 vs 2.20±0.2, p=0.004).

**Conclusion:** The PO concentration in BALF was associated with vascular remodeling in a murine AGA model, suggesting its pivotal role in myofibroblast proliferation in pulmonary arteries.

**Challenges in the management of patients with ANCA-associated vasculitides**

Ionela Nicoleta Belaconi1, Wanda de la Beluac1, Claudia Lucia Toma1, Stefan Dumitrascu-Rajmansi2, Cornelia Tudose1, Diana Leonte1, Miron Alexandru Bogdan1, 3Division of Pulmonary Medicine, Allergy and Rheumatology, Department of International Medicine, Iwate Medical University School of Medicine, Morioka, Japan; 4“Marius Nasta” Institute of Pneumology, Bucharest, Romania

**Background:** Granulomatosis with polyangiitis (Wegener’s) and microscopic polyangiitis are antineutrophil cytoplasm antibodies (ANCA)–associated vasculitides with significant morbidity and mortality.

**Objective:** We evaluated the evolution of 12 patients diagnosed in our clinic between 2000 and 2011, treated with conventional treatment (prednisolone and pulse cyclophosphamide initially, and in remission with prednisolone and azathioprine).

**Results:** We evaluated 12 patients (10 females), median age of 46 years (range 20-74), with a median duration of follow up of 5.2 years (range 1-12 years).

**Conclusions:** Six patients had relapses (50%), 1 developed subglottic stenosis, 1 retro-orbital pseudo tumor and 2 patients developed lung abscesses inside a cavity which imposed lobectomy after unsuccessful antibiotic treatment. Two patients developed lung tuberculosis (one multi-drug-resistant) and 1 pulmonary nocardiosis linked to resected lobectomy after unsuccessful antibiotic treatment. Two patients developed careful dialysis for renal failure. Two patients died of stroke (1) and severe active vasculitis (1). Older age and renal failure were predictors of death.

P2377

**Omalizumab decreases IgE production in patients with severe allergic asthma**

Marisa Huebner1, Stephanie Kern2, Matthias Jung1, Roland Buhl3, 1Pulmonary Department, Mainz University Hospital, Mainz, Germany; 2Division of Clinical Immunology and Allergy, General Hospital, ASL Salerno, Agropoli, Salerno, Italy; 3Division of Transfusion Medicine, General Hospital, ASL Salerno, Agropoli, Salerno, Italy; 4Public Health Hygiene, ASL Salerno, Vallo della Lucania, Salerno, Italy

**A pharmacokinetic-pharmacodynamic model predicts that omalizumab reduces production of IgE.** 2. To test this hypothesis serum total-IgE concentrations were quantified in 64 patients with severe allergic asthma (mean±SEM; 46.2±13 yrs, 41 female, 81±6±15 kg, total IgE; 397±189 IU/ml, FEV1±1 L±1.1 L or 67±2±2.4%, pred, CNO0 51.2±7.4 phb treated with omalizumab (median 450 mg/month). Total serum IgE, asthma control (ACQ), lung function (FEV1) and exhaled nitric oxide (eNO) were evaluated at baseline (w0, n=64), after 16 weeks (w16, n=64) and after 52 weeks (w52, n= 24) of treatment.

50 patients responded to omalizumab treatment. Overall (n=64), after 16 weeks ACQ (w16 vs w0, 0.34±0.18, p<0.001), FEV1 (w16 2.3±0.12; p=0.01) and eNO (w16 40.1±5.4; p=0.027) improved significantly. Total IgE increased by 536±141 IU/ml (w16 984±215 IU/ml; p<0.01). Changes in total-IgE did not differ between responders and non-responders. After 52 weeks total IgE was 634±197 IU/ml, a decrease by 99±53 IU/ml vs. week 16 IgE levels, whereas ACQ, FEV1, and eNO remained stable. In this period total IgE serum concentrations decreased in 19 of 24 patients.

These results support the conclusion that long-term omalizumab treatment reduces IgE production. Further, total serum IgE should provide a means to monitor IgE production and guide individual treatment decisions.

**Impact of omalizumab treatment persistence on asthma control**

Marie-Hélène Lafeuille1, Jonathan Gravel1, Jie Zhang2, Boris Gors1, Maria Figliomeni2, Patrick Lefebvre3, 1Health Economics and Outcomes Research, Groupe d’analyse, Ltée, Montréal, QC, Canada; 2US Health Economics & Outcomes Research, Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

Omalizumab is indicated for moderate to severe allergic asthma patients with inadequately controlled symptoms. The purpose of the current study was to evaluate the impact of omalizumab treatment persistence on asthma control. Health insurance claims from the MarketScan database (2002Q1-2011Q2) were analyzed. Asthma patients with >12 months of continuous omalizumab use after the first omalizumab claim (index date) following 6 months of continuous omalizumab use were included. A 12-month landmark period following the index date was used to assess treatment persistence, defined as uninterrupted treatment without a gap of ≥ 28 days in omalizumab use. The impact of persistence with omalizumab treatment on asthma-related emergency-department (ED) visits and hospitalizations occurring between months 13 and 24 was evaluated. Multivariate time-varying Cox regressions were also conducted to assess the adjusted impact of treatment interruption (lack of persistence) on asthma control from month 1 to month 24.

In total, 3044 patients (mean age: 48.5; female: 62.4%) formed the study population. Persistence with omalizumab treatment at 12 months (39% of patients) was associated with a 51% reduction in the mean (SD) number of ED visits per patient (persistence vs. non-persistence: 0.064 [0.3] vs. 0.129 [0.5], P<0.001) and a 28% reduction in hospitalizations (0.131 [0.4] vs. 0.182 [0.6], respectively, P=0.034). Multivariate analyses corroborated these findings (HR [95% CI] for persistence vs. non-persistence: 0.064 [0.3] vs. 0.129 [0.5], P<0.001). Changes in total-IgE did not differ between responders and non-responders. After 52 weeks total IgE was significantly reduced compared to positive control mice (control vs. IM treated: 2.42%, p=0.003). PO in BALF of the IM treated C57BL/6 was significantly reduced compared to positive control mice (control vs. IM treated: 40.1±5.4; p=0.027). The pathological scores were reduced significantly in the IM treated group compared to the control group (control vs. IM treated: 3.67±0.2 vs. 2.20±0.2, p=0.004).

**Conclusion:** The management of patients with ANCA-associated vasculitides is difficult, and marked by significant adverse effects of the therapy.

**Gender medicine and different prevalence in asthma by reports on anti-IgE (omalizumab) treatments**

Vincenzo Patella1, Carmine Orticchio2, Giovanni Florio1, Ada Giuliano3, 1Division of Clinical Immunology and Allergy, General Hospital, ASL Salerno, Agropoli, Salerno, Italy; 2Division of Transfusion Medicine, General Hospital, ASL Salerno, Agropoli, Salerno, Italy; 3Public Health Hygiene, ASL Salerno, Vallo della Lucania, Salerno, Italy

**Background:** Generally, pathogenesis and prevalence of bronchial asthma indi-
cates that age and sex are the major risk factors. Detailed physiological mechanisms of the changing sex ratio are not fully known. We investigated the influence of gender on anti-IgE treated asthmatics.

**Methods:** We pooled data from ten published studies from 1999 with more of our data of severe persistent asthma treated with omalizumab (anti-IgE) monoclonal antibody. Static analysis was used to find gender risk factors as the ratio of treatment effect difference on standardized exacerbation rate and frequency of asthma exacerbations.

**Results:** The studies included 3270 omalizumab treated patients, whose had severe persistent asthma according to Global Initiative for Asthma (GINA) classification. Analysis of two groups male vs female showed that the efficacy of omalizumab on asthma exacerbations was unaffected by patient age, gender, baseline serum IgE (split by median) or by 2- or 4-weekly dosing schedule, although a more large number of women were treated (92115349, 59% women vs 41% men; p < 0.001) and benefit in absolute terms appeared to be greatest in women patients which had a more severe asthma, defined by a lower value of percentage predicted forced expiratory volume in 1 s (FEV1) at baseline, this subgroup showed odds of being a responder (composite definition) 1.25 times higher (95% confidence interval, 1.18 to 3.01) than men.

**Conclusions:** These results suggest that in population of asthmatics treated with anti-IgE the number of women is higher than men, it confirms that asthma should be considered with different approach by the gender for being adequately controlled on current therapy.

**P2380**

Factory predicting airflow obstruction in severe asthmatics

Baierzy Zeng, Li Long Tan, Than Huy Hong, Leong Long Tan,
Mariko Koh. Respiratory Critical Care Medicine, Singapore General Hospital,
Singapore, Singapore

Severe asthma was defined as “treatment-resistant severe asthma” and includes asthmatics on highest level of recommended treatment (high-dose Inhaled Corticosteroids (ICS) or high-dose ICS plus Long-Acting Beta2 Agonists combination) 1.

Airway remodeling was defined as FEV1 ≤60% FVC. Factors predicting remodeling were studied which include demographic profile, duration of asthma, allergen sensitization, presence of bronchial hyper-reactiveness, asthma-related comorbidities and frequency of acute exacerbations. 270 fulfilled severe asthma definition. Amongst these patients, 59 had airway remodeling. Airway remodeling was associated with increasing number of allergic sensitization (p=0.032). Amongst those with 5-8 allergic sensitization, 37.5% (n=12) had FEV1 ≤60%. In comparison, 15.9% (n=7) had FEV1 ≤60% amongst those with 1-4 allergic sensitization. The presence of bronchial hyper-reactiveness on methacholine challenge test, significant bronchodilator response and smoking were also significantly associated with FEV1 ≤60% (p < 0.001, p=0.011 respectively).

Frequency of asthma exacerbations (steroid burst, admissions and unscheduled emergency department visits), duration of asthma and presence of bronchial hyper-reactiveness on methacholine challenge test, significant bronchodilator response and smoking were also significantly associated with FEV1 ≤60% (p < 0.001, p=0.011 respectively).

We have found that patients with broader spectrum of allergic sensitization were more likely to have airway remodeling. Early detection of allergic sensitization may be important and aggressive treatment of allergies may be able to arrest or reverse the remodeling process. Our findings concur with previous reports of presence of bronchial hyper-reactiveness, bronchodilator response and smoking being risk factors for remodeling.

**P2381**

Severe asthma in old patients is characterized by signs of immunosuppression and by lymphocyte resistance to glucocorticoids

Alexander Pukhalsky1, Galina Shmarina1, Tamara Vyleghzhanina2,
Tamar Chervinskaya2, Olga Kozyrenya2, Vladimir Alshoshkin3. Department of Cystic Fibrosis, Research Centre for Medical Genetics, Moscow, Russian Federation, 1Department of Asthma, NRC Institute of Immunology, Moscow, Russian Federation, 2Laboratory of Cell Systems, G.N. Gubarevichsky Institute of Epidemiology and Microbiology, Moscow, Russian Federation

The aim of this study was to investigate the adaptation system in asthmatic patients. Twenty one patients were enrolled into the study. In 15 patients the clinical course was evaluated as severe and 6 patients demonstrated the middle asthma (mean age, 60.3±2.5 and 30.8±3.0 years, respectively). Individual susceptibility of peripheral blood lymphocytes (PBL) to glucocorticoids (GCs) was evaluated by Δh value calculation: an integrative parameter, including the level of mitogen-induced lymphocyte proliferation and inhibition degree of the cell proliferation by dexamethasone. In healthy subjects the mean h value calculation: an integrative parameter, including the level of mitogen-induced lymphocyte proliferation and inhibition degree of the cell proliferation by dexamethasone. In healthy subjects the mean Δh value was −0.24±0.30 (negative values of Δh correspond to high cell sensitivity to GCs). Results of the study are presented in the Table 1.

Aim: To correlate asthma phenotypes with hospitalisation, in acute exacerbations of asthma.

Compliance and persistence among users of subcutaneous and sublingual allergen immunotherapy

Menna Kiel1, Esther Reeder2, Wim Hop1, Maaiwenn A1, Roy Gerth van Wijk2, Maureen Rutten-van Molen1. 1Dept. of Health Economics, Institute for Medical Technology Assessment, Erasmus University, Rotterdam, Netherlands, 2Section of Allergology, ErasmusMC-University Medical Centre, Rotterdam, Netherlands, 3Department of Epidemiology & Biostatistics, ErasmusMC-University Medical Centre, Rotterdam, Netherlands

Background: Subcutaneous(SCIT) and sublingual (SLIT) allergen immunotherapy is a safe and effective treatment of allergic rhinitis, but high levels of compliance and persistence are crucial to achieving the desired clinical effects. The objective was therefore to assess levels and predictors of compliance and persistence among grass & tree pollen, and house dust mite immunotherapy users in real-life, and estimate costs of premature discontinuation.

**Methods:** A retrospective analysis of a community-pharmacy database from The Netherlands containing data from 6486 patients starting immunotherapy for one or more of the allergens of interest between 1994 and 2009. 2796 patients received SCIT and 3690 received SLIT. Time-to-treatment discontinuation was analyzed and included Cox proportional Hazard models with time-dependent covariates, where appropriate.

**Results:** 82% of patients did not reach the minimally required duration of treatment of three years (SCIT: 77%, SLIT: 93%). Median durations for SCIT and SLIT users were 1.7 and 0.6 years, respectively. Of the persistent patients, 58 per cent were never late in picking up their medication from the pharmacy. Other independent predictors of premature discontinuation were prescription, with general practitioners prescribing longer persistence than those of allergologists and other medical specialists, multiple-allergen therapy, higher socioeconomic status, and younger age. Direct medication costs per nonpersistent patient were €3,800.

**Conclusion:** Persistence is better in SCIT users than in SLIT users. Further studies are needed to determine whether persistence can be improved by administering the therapy close to the patient’s home.

Changes in the prevalence of asthma, rhinitis and eczema in different age groups in Chinese schoolchildren

Ng Seng, Mohammed Shamssain, Jin Zhang, Shuting Hao, Jiao Guan, Xiaoming Wu, Chunling Fu, Xiuming Xu. 1Department of Respiratory Medicine, Hebei Medical University, Shijiazhuang, Hebei, China School of Health Sciences, University of Sunderland, United Kingdom Respiratory Medicine, The Second Hospital of Shijiazhuang, Shijiazhuang, Hebei, China

Introduction: Little is known about the prevalence of allergic diseases in children of different ages. This study aimed to investigate the prevalence of allergic diseases in children over a wide age range in Chinese schoolchildren in Shijiazhuang city in Hebei Province in China. In a cross-sectional study, we studied 10824 Chinese schoolchildren, aged 6-18 years, using ISAAC questionnaire. We classified children into three age groups: 6-8 years, 9-12 years, and 13-18 years. Asthma symptoms had significantly decreased with age from 6-8 year age group to 13-18 year age group (ever wheeze from 7.9% to 2.8%, P < 0.001, current wheeze from 2.2% to 1.4%, cough from 11.6% to 10.6%, and ever asthma from 1.3% to 0.5%, P<0.001, respectively). Rhinitis symptoms had significantly increased with age from 6-8 year age group to 13-18 year age group (ever rhinitis from 11.2% to 16.4%, P<0.001, current rhinitis from 8.2% to 11.6%, rhinconjunctivitis from 3% to 3.5%, P<0.05, and hay fever from 3.3% to 4.8%, P<0.05, respectively). Rash and eczema symptoms had significantly decreased with age from 6-8 year age group to 13-18 year age group (rash ever from 2.7% to 2.0%, current rash from 1.8% to 1.0%, P<0.001 and eczema from 15.4% to 7.2%, P<0.001, respectively). The study shows that symptoms of asthma and eczema had significantly decreased with age in these children while rhinitis symptoms had significantly increased indicating that rhinitis symptoms are major public health problem in Chinese children. The study will help to implement intervention strategies to control symptoms of rhinitis in this population.

**P2384**

Phenotypic predictors for hospital admission in adults with asthma: A case-controlled study

Josef Miccile, Eleanor Gerada, Richard Pullicino, Marianna Gauci, Steven Montefort. Department of Respiratory Medicine, Mater Dei Hospital, Msida, Malta

Background: RTIs are a known risk factor for admission with asthma exacerbation. Few studies give further insight to other possible risk factors.

**Aim:** To correlate asthma phenotypes with hospitalisation, in acute exacerbations of asthma.
Conclusions: Pulmonary function test changes after cessation of inhaled corticosteroid
asthma control. Cost and easily applicable questionnaires that are validated in the assessment of
CARATa and ACT test scores. This study highlights the importance of using low
significant association between subjective control of the disease and CARATt, score (CARATa) and ACT test (r=0.8, p
It may be possible that patient s with a FEV1 above 95% predicted
asthma Control of allergic rhinitis and asthma test, asthma control test and FeNO in
Asthma exacerbation is more likely in those who are atopic and
atopy and FeNO (p
Se Ig E levels and eosinophils were found to be positively correlated (p=0.027), however, no correlation was established between acute or convalescent Se IgE and duration of asthma, personal or family history of atopy (p<0.05). There is no significant difference between Se IgE levels in different BMI classes or in different age
groups (p<0.05). This study demonstrated a statistically significant association between subjective control of the disease and CARATt, CARATa and ACT test (p<0.05). It was demonstrated a statistically significant association between atopy/positive bronchodilatation test and FeNO values were higher (p<0.05).This study demonstrated a statistically significant correlation between the total CARAT (CARATa) and ACT test (r=0.7, p<0.05), as well as between asthma CARAT sub-score (CARATa) and ACT test (r=0.6, p<0.05). It was demonstrated a statistically significant association between subjective control of the disease and CARATt, CARATa and ACT test (p<0.05).

Methods: Control of allergic rhinitis and asthma test, asthma control test and FeNO in

Objective: Assessment of asthma and/or rhinitis control through the application of two questionnaires and the measurement of Fractional Nitric Oxide concentration in exhaled breath (FeNO).

Results: Ninety patients, 65.7% women, mean age 32.6±17.9 years. Of these, 63.3% had asthma and rhinitis, 24.8% had asthma and 11.9% had rhinitis. The mean FeNO was 36.4±24.4 ppb (min/max=4/115). 58.7% patients were atopic and a statistically significant association was established between atopy and FeNO (p<0.05). In patients with acute bronchodilatation test, FeNO values were higher (p<0.05). A positive correlation between age of asthma onset and a

P2388

Control of allergic rhinitis and asthma test, asthma control test and FeNO in

rhinitis that, in a two months period, visited a respiratory function laboratory to

to perform lung functional tests with measurement of FeNO and to whom were applied 2 questionnaires: Control of Allergic Rhinitis and Asthma Test (CARAT) and Asthma Control Test (ACT).

Results: 109 patients, 65.7% women, mean age 32.6±17.9 years. Of these, 63.3% had asthma and rhinitis, 24.8% had asthma and 11.9% had rhinitis. The mean FeNO was 36.4±24.4 ppb (min/max=4/115). 58.7% patients were atopic and a statistically significant association was established between atopy and FeNO (p<0.05). In patients with acute bronchodilatation test, FeNO values were higher (p<0.05).

Conclusions: Asthma exacerbation is more likely in those who are atopic and have a longer duration of asthma. This was not evident for smoking asthmatics and BMI. Convalescent Se IgE levels are higher in males post exacerbation.

Methods: We included 109 asthmatics admitted with an acute exacerbation over 14 months; matched for age and sex with a 100 well-controlled asthmatics from asthma clinic. Information on sociodemographic variables, clinical and laboratory data was collected. Acute and convalescent (at 6 weeks) titter of serum immunoglobulin E (Se IgE) and serum eosinophil count were taken. SPSS was used for statistical analysis.

Results: We detected a positive correlation between age of asthma onset and a

family history of atopy (p<0.0001) and a family history of atopy (p<0.023); but no correlation with Se IgE levels was found (p<0.05). There was no significant difference in the number of hospitalisations over the previous year between smokers and non-smokers (p=0.308). The difference between convalescent Se IgE levels in males (mean 324) and females (mean 159) was statistically significant (p<0.029). Acute Se IgE levels and eosinophils were found to be positively correlated (p<0.027), however, no correlation was established between acute or convalescent Se IgE and duration of asthma, personal or family history of atopy (p<0.05). There is no significant difference between Se IgE levels in different BMI classes or in different age groups (p>0.05). This study demonstrated a statistically significant association between subjective control of the disease and CARATt, CARATa and ACT test (r<0.05). It was demonstrated a statistically significant association between atopy/positive bronchodilatation test and FeNO values were higher (p<0.05).

Conclusions: Asthma exacerbation is more likely in those who are atopic and have a longer duration of asthma. This was not evident for smoking asthmatics and BMI. Convalescent Se IgE levels are higher in males post exacerbation.

Introduction: Parental passive smoking has been associated with adverse respira-
tory outcomes in children. Evidence remains inconclusive as to whether smoking is a risk factor for allergic disorders in children. The aim of the study was to evaluate the association between paternal smoking and symptoms of asthma and allergies in Chinese schoolchildren.

Body: We studied 10824 Chinese schoolchildren from Shijiazhuang city in Hebei province in China. We used an ISAAC questionnaire and we added questions related to paternal smoking. The prevalence of paternal and maternal smoking in China is 56.52% and 1.34%, respectively. The prevalence rates of all symptoms of asthma, rhinitis and eczema were significantly higher in children exposed to paternal passive smoking compared with children not exposed to paternal smoking (wheeze ever 6.5% vs 4.6%, P<0.001; current wheeze 2.3% vs 1.5%; exercise-induced wheezing 3.9% vs 2.4%, P<0.001; cough 13.2% vs 8.7%, P<0.001; ever rhinitis 15.3% vs 11.6%, P<0.001; current rhinitis, 10.8% vs 8.1%; hay fever 4.7% vs 3.7%, P<0.05; ever chronic rash 2.9% vs 1.8%, P<0.01; current rash 1.8% vs 0.9%; and eczema 12.9% vs 9.7%, P<0.001, respectively). The study which is part of a major longitudinal study on Chinese children shows an association between parental smoking and symptoms of asthma, rhinitis and eczema and that Paternal passive smoking is an important risk for asthma and allergic children in China.

P2389

Contribution of lung function tests in asthma screening: About a

respiratory panel

Introduction: The major difficulty in epidemiological studies of asthma is due to
the methods used to formulate the diagnosis. Studies conducted through ques-

Conclusions: In the absence of gold standard, it is difficult to define asthma in
epidemiological studies. If the measure of bronchial hyperresponsiveness has a specificity similar to questionnaires on asthma symptoms, it is also less sensitive.

P2389

Does allergens influence resistin levels in children with allergic rhinitis?

Conclusion: The purpose of this study was to confirm the relationship between resistin levels and atopy and to assess whether these levels were influenced by Skin Prick Test (SPT) patterns in children with nasal obstruction.

Methods: 35 children (15 males; mean age 9 yr) were selected for nasal obstruc-
tion: 12 monosensitized to house dust mites (HDM), 10 to grass pollens (GP) and
35 children (15 males; mean age 9 yr) were selected for nasal obstruction in 11 individuals, 7 of which were reversible. Fifty subjects gain more than 12% in forced expiratory volume (FEV1). Of these, 20 did not report symptoms of asthma but had symptoms of atopy. We deduce that 19.6% of asthmatics had a reversibility and 6.8% were asymptomatic.

Conclusions: In the absence of gold standard, it is difficult to define asthma in
epidemiological studies. If the measure of bronchial hyperresponsiveness has a specificity similar to questionnaires on asthma symptoms, it is also less sensitive.
were 5.5 ng/ml in children sensitized to HDM and 3.6 ng/ml in those sensitized to GP. This difference was statistically significant (0.001 < p < 0.01).

**Conclusions:** Our results confirm that serum resistin levels are associated with the allergic inflammatory process in children. Among patients with AR, higher resistin serum levels also showed a stronger association with HDM monosensitization. Thus, resistin, as a proinflammatory protein, may be influenced also by persistent allergen exposure.

**Results:** Resistin serum levels associated with HDM monosensitization. Our results confirm that serum resistin levels are associated with the allergic inflammatory process in children. Among patients with AR, higher resistin serum levels also showed a stronger association with HDM monosensitization. Thus, resistin, as a proinflammatory protein, may be influenced also by persistent allergen exposure.

**Methods:** Serum resistin levels were measured by ELISA in 100 children (50 with AR and 50 healthy children) with a mean age of 12 years.

**Results:** Resistin serum levels associated with HDM monosensitization. Our results confirm that serum resistin levels are associated with the allergic inflammatory process in children. Among patients with AR, higher resistin serum levels also showed a stronger association with HDM monosensitization. Thus, resistin, as a proinflammatory protein, may be influenced also by persistent allergen exposure.

**Background:** Asthma is a problem worldwide, with an estimated 300 million affected individuals. Obese and asthma are both chronic conditions affecting millions worldwide.

**Aim:** To assess serum leptin levels in obese and non-obese patients with bronchial asthma.

**Methods:** This study was performed on 120 asthmatic patients, 60 patients (50%) were obese and 60 patients (50%) were non-obese according to BMI. According to the GINA guidelines, they were classified into mild, moderate, severe and very severe asthma. Serum leptin level measurement for all patients was done after 8 hours fasting, by ELISA technique.

**Results:** Serum leptin level showed a significant increase in serum of obese asthmatics (23.2 ± 3.8) than non-obese asthmatics (7.9 ± 3.1). There was a highly significant increase in serum leptin level in obese asthmatic females than in non-obese asthmatic females with the same degree of asthma (p < 0.001). In obese asthmatic males, there was a significantly higher increase in serum leptin level in obese asthmatic females than in non-obese asthmatic males with the same degree of asthma (p < 0.001). Also, there was a highly significant increase in serum leptin level in obese asthmatic females than obese asthmatic males with the same degree of asthma (p < 0.001). In non-obese asthmatic females and non-obese asthmatic males with the same degree of asthma (p < 0.001). The results of this study showed a significant positive correlation between serum leptin level and grades of asthma as well as a significant negative correlation between serum leptin level and FEV1, FVC and FEV1/FVC (p < 0.001).

**Conclusions:** The high serum leptin level in asthmatic patients is related to and affected by; the high BMI, female gender and degree of asthma severity.

**Effectiveness of therapy:** The peak effectiveness of therapy was achieved after 6 months of treatment. In the group of patients who continued treatment, a significant improvement in pulmonary function was observed. The decrease in FEV1 and FVC was less pronounced in the group of patients who continued treatment for 6 months compared to those who discontinued treatment after the first 3 months.

**Conclusion:** The peak effectiveness of therapy was achieved after 6 months of treatment. In the group of patients who continued treatment, a significant improvement in pulmonary function was observed.

Epidemiological study of bronchial asthma among preparatory school pupils in Assuit district
Alameldin Abdallah, Khalid Samy, Wafaa Shaaban, Dalia Mahran, Alaa Hussein. Pediatrics, Faculty of Medicine, Assuit, Egypt Pediatrics, Faculty of Medicine, Assuit, Egypt Community Medicine, Faculty of Medicine, Assuit, Egypt Chest Diseases, Faculty of Medicine, Assuit, Egypt

**Background:** The prevalence of asthma and allergies is increasing in both western and developing countries. Few studies evaluated asthma prevalence in Egypt.

**Aims:** Determination of the prevalence and risk factors of asthma among preparatory school children in Assuit district, in upper Egypt.

**Subjects and methods:** A cross sectional study was conducted among preparatory school students in Assuit city and two rural areas in Assuit governorate in upper Egypt. Twelve schools were selected randomly from different regions in Assuit city and two rural areas. The total coverage of the students included was 1048 (482 boys and 566 girls).

**Data were collected by self administered questionnaire (in Arabic Language) which was fulfilled by the participants.**

**Results:** Of the 1048 positively responding subjects, 65 fitted the diagnosis of asthma with over all prevalence of 6.2%. No significant difference was found between urban and rural areas (P: 0.075). A positive family history of allergy and the presence of other allergic disease were significantly associated risk factors for asthma.

**Conclusion:** Bronchial asthma is a significant health problem among children and adolescents in Assuit governorate and needs special care services. Wider scale multi-center studies in upper Egypt and other localities of Egypt are needed to outline the profile of bronchial asthma among children and adolescents in the whole country.

**P2396**

The in vitro effect of vitamin D on peripheral blood mononuclear cell cytokine expression in COPD
Niall Steward, Richard Wood-Baker. Centre for Clinical Research Excellence (Respiratory), University of Tasmania, Hobart, TAS, Australia

**Background:** Vitamin D is recognised as a powerful modulator of immune responses. It promotes T helper 2 (Th2) immunity and the anti-inflammatory cytokine Interleukin-10 (IL-10). However, little is known about the effects of vitamin D on the immune response in COPD, a Th1 mediated disease.

**Aims and objectives:** We hypothesised that in COPD vitamin D would push a Th2 response, with increased levels of the Th2 cytokine Interleukin-4 (IL-4) and the suppressive cytokine IL-10. Such a shift could be beneficial in COPD.

**Methods:** We recruited 10 COPD subjects from whom we isolated peripheral blood mononuclear cells (PBMC) and measured serum 25(OH)D. PBMC were stimulated with antibodies to the T cell receptor either with or without added blood mononuclear cells (PBMC) and measured serum 25(OH)D. PBMC were stimulated with antibodies to the T cell receptor either with or without added

**Results:** For both IL-4 and IL-10, we observed a biphasic effect of vitamin D supplementation. For those with low (<30nmol/L) and high (>80nmol/L) serum 25(OH)D, added vitamin D suppressed IL-4 and IL-10 (Figure 1,2). Between these two levels, vitamin D increased expression.

**Conclusions:** Serum 25(OH)D levels may be an important determinant of the usefulness of vitamin D in beneficially modifying the immune response in COPD.

**P2397**

Experience of surgical treatment of massive purulent-destructive processes of the lungs and pleura
Stanislav Skryabin. Murmansk Regional Hospital by P.A. Bayandin, Murmansk, Russian Federation

Given the conditions of the Far North and the specificity of the social status of some patients, we have extensive experience in the surgical treatment of massive, widespread purulent-destructive processes. Despite the possibility of treating this disease patients conservatively, performing minimally invasive procedures, we concluded that it remains relevant surgical radical intervention - lung resection, removal of empyema cavity, to prevent chronicity and recurrence of the process. We have experience treatment 679 patients: 340 conservatively, 369 surgically.

The main indications for radical surgery have been ineffective conservative therapy and the progression of the process, the recurrence of a chronic process, initially massive processes, life-saving operation: bleeding, a large pulmonary pleural fistula, the threat of sepsis (big abscess, gangrene and empyema).

We are get almost patiens fit for the operation (conservative therapy). We performed 380 operations: 151 lobectomy, 15 lobectomy, 64 atrial resections, 18 - segm-

mentectomy, 67 - pneumonectomy, 40 - decortications and elimination of empyema cavity without resections, 16 - VATS decortications, 9 - reimplantations stump of bronchus. We have good results after operations: only 5 patiens died (1.3%), 48 - complications (13%) (13 of them - inconsistence of stump of bronchus),360 patiens (97.6%) - after radical interventions recovered.

Effectiveness of partial lung resection at multi-drug resistance of tuberculosis mycobacteria
Shavkat Sabirov, Tulkun Kariev, Akram Irgashev. Thoracic Surgery, National Centre of Phthisioloogy and Pulmonology, Tashkent, Uzbekistan

Partial resection of lung at multiple drug resistance of mycobacteria was performed in 59 patients (males 36, females 23) in ages 17 – 54 years. All the patients had fibrous-cavernous tuberculosis with long clinical course (over 3 years) and resistance of mycobacteria to isoniazid + rifampicin in 4 patients, to isoniazid + rifampicin + streptomycin – in 24, to isoniazid + rifampicin + streptomycin + ethambutol – in 31. The characteristic peculiarities of illness were dissemination (61.0%) and progress (45.8%) of the tubercular process, pulmonary hemorrhage (27.1%), various somonitant pathology (32.2%), and ineffective ofpreced-

ing long treatment. After pre-operative chemotherapy (pirazinamid + amicacin + ofloxacin + prothionamide + paraaminosalicylic acid + cycloceryl) with pneu-

moperitoneum, UV irradiation of blood, transfusion of protein, saline and synthetic solutions, a segmental lung resection was performed in 9 patients, lobectomy – in 38, combined resection – in 12. After operations, bronchial fistula and pleural empyema developed in 4 patients, early re-activation of tuberculosis – in 3. These complications were eliminated in 6 patients.

Good effectiveness of partial lung resection was reached in 58 patients (98.3%).

One patient (1.7%) died from the progress of post-operative pleural empyema and cardio-pulmonary insufficiency.

Lung resection in hematologic patients with pulmonary invasive fungal disease: Changing pattern in recent years
Christian Nebiker1, Didier Lardinois 1, Lilian Junker 2, Franco Gambazzi 1, Joerg Halterman1, Dianna Stolz1, Nils Kopecky1, Boris Gasser1, Lukas Hoesli1, Beat Luscher-Liem1, Christian Schibli1, Christiane Hauser1, Lilian Junker 2, Franco Gambazzi 1, Didier Lardinois 1, and Gürhan Öz 2.

Division of Hematology, University Hospital, Basel, Switzerland; 2 Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital, Basel Switzerland; 3 Division of Hematology, University Hospital, Basel, Switzerland; 4 Division of Infectious Diseases & Hospital Epidemiology, University Hospital, Basel, Switzerland; 5 Department of Pathology, University Hospital, Basel Switzerland.

Pulmonary invasive fungal disease (IFD) is a frequent complication in patients with hematologic malignancies. We analysed the outcome of 71 hematologic patients undergoing lung resection for suspected pulmonary IFD at a single centre and we compared patients operated before 2002 (group A n=41) with those undergoing surgery after 2002 (group B n=30). Forty-four patients were neutropenic and 41 had a platelet count below 50 x 10^9/L. 45 non-anatomical resections and 26 lobectomies were performed. Fungal infection was histologically proven in 53 patients. Reseption was needed in 4 cases: bronchial stump dehiscence, persistent air leak, chylolithorax and seoma. Minor complications at the site of surgery occurred in 14 cases. In only two cases there was an uncontrolled disseminated fungal infection. Overall mortality at 30 days was 7% (5/71). The age was significantly higher (group B 40y versus group A 49y, p=0.0239) in the recently operated patients and also the number of reoperations was significantly higher (group B versus group A 17% in group A vs 90% in group B, p<0.0001) was found between the two groups. Recently operated patients underwent VATS in 47% of cases as compared to 5% in group A. In contrast to group A there were 6 cases of rare fungal infections in group B (Case of histoplasmosis, 2 Rhizopus, Micor, Zygomycetes).

Conclusion: Lung resection is a therapeutic option for hematological patients suffering from pulmonary fungal infection with an acceptable morbidity and mortality. In recent years patients were older, sicker, VATS was performed more often and in a considerable number of cases rare fungi could be detected.

P2400
Argonplasma coagulation in surgery of pulmonary tuberculosis

Department of Thoracic Surgery, Ataturk University, Erzurum, Turkey; 2 Department of Anesthesia and Reanimation, Ataturk University, Erzurum, Turkey.

Background: Argonplasma coagulation (APC) proved itself to be a hæmostatic tool in various fields of surgery (Farin G., Grund K.E. 1994). Coagulation occurs without contact the active electrode with the tissue, while the flow argon displaces the zone of coagulation of oxygen, which reduces burning of tissue. The problem of bleeding in surgery of severe forms of pulmonary tuberculosis (PTB) is difficult and unsolved.

Aim: To study APC in this field and assess initial (first) results.

Method: APC was applied in 66 cavitary PTB patients with the help of High-frequency electrosurgical APC generator. Namely, in 13 pneumonectomies, in 20 lobectomies, and in 24 cases for debridement of empyema cavity including 12 videothoracoscopic procedures. In cases of firm adhesions pnumonectomy was performed using regimen BLEND cutting with coagulation. For haemostasis during lobectomies, and in 24 cases for debridement of empyema cavity including 12 videothoracoscopic surgeries BLEND cutting with coagulation was used.

Results: None of the patients were approached with thoracotomy and decortication is recommend. This may identify underlying causes.

Conclusion: Simultaneously transdiaphragmatic approach to liver and lung cysts
Yener Aydin1, Mine Celik 2, Ali Bilal Ulus 3, Atilla Ergul 4, and Nurlay Karacagol 5.

Department of Thoracic Surgery, Afyon Kocatepe University Medicine Faculty Hospital, Afyon, Turkey.

Results: None of the patients were approached with thoracotomy and decortication is recommend. This may identify underlying causes.

Conclusion: Simultaneously transdiaphragmatic approach to liver and lung dome cysts is a safe and effective treatment method

P2403
The management of postoperative complications in childhood pulmonary hydatid cysts
Gokturk Finik1, Seray Hazer 1, Koray Aydrogdu1, Gürhan Öz 2, Nurettin Karaoglanoglu1, Safi Kaya1, 2 Thoracic Surgery, Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, Ankara, Turkey; 5 Thoracic Surgery, Ayfın Kocatepe University Medicine Faculty Hospital, Afyon, Turkey.

Background: Hydatid disease in children has previously been discussed many times in the literature. However, management of postoperative complications has been rarely discussed. In this study, the complications of our cases are evaluated and discussed.

Material and methods: Ninety-seven patients under 16 years of age with hydatid cysts who were operated on between January 2001 and January 2007 were analyzed retrospectively. All the patients were followed up with examination and chest X-ray after surgery. The complications occurred in the first 48 hours after surgery are considered as early complications, and the complications between 48 hours and 30 days are considered as late complications.

Results: 61 male and 36 female pediatric hydatid disease patients with a mean age of 10.31 were operated on. Postoperative first 48 hours, atelectasis was observed in 17 cases (17.5%) and bronchoscopy was performed for these patients. After 48 hours, pneumonia occurred in one patient and he was treated with antibiotics. Prolonged air leak was observed in 4 patients (4.1%) and they were treated with continued tube thoracostomy. 2 patients with prolonged air leak were hyperventilated with positive pressure under general anesthesia. Wound infection was seen in 2 patients. Regular wound dressing and antibiotic treatment were performed for these cases. Empyema was occurred in 2 patients. In these cases antibiotics were given and tube thoracostomy was continued.

Conclusion: Atelectasis, which is most common postoperative complication, should immediately be treated. It should be kept in mind that early treatment of atelectasis prevents the development of greater complications in children.

P2402
Simultaneously transdiaphragmatic approach to liver and lung cysts
Yener Aydin1, Mine Celik 2, Ali Bilal Ulus 3, Atilla Ergul 4, and Nurlay Karacagol 5.

Department of Thoracic Surgery, Ataturk University, Erzurum, Turkey; 2 Department of Anesthesia and Reanimation, Ataturk University, Erzurum, Turkey.

Background: Hydatid cysts are clinical problem at developing and non developed countries. Liver and lung are the two organs which they often settle. In this study we aimed to present lung and liver hydatid cysts which we underwent transdiaphragmatic surgery.

Methods: Consecutive 50 patients with lung and liver hydatid cyst whom underwent surgical treatment by transdiaphragmatical way at our clinic between January 1998 and December 2011 were evaluated retrospectively.

Results: Twenty-four (48%) patients were male and 26 (52%) patients were female. The average age of the patients was 34±21 (3-72 years old). All cases have liver cyst and 37 of them also have lung cyst. In 9 of the 37 patients with lung cyst, bile cysts were bilateral (17 patients). In patients whom have multiple cysts the largest cyst diameter has been 9±3.5 cm (4-18.40). Forty-eight cases of the patients were approached with thoracotomy, one of them is approached with laparotomy and one of them is approached with median sternotomy. In 49 cases it was interwoven to lung and in 1 case it was interwoven to lung by phrenotomy. Excessive biliary drainage was observed in postoperative 2 case. In one case fistulate was observed from drain path which is placed in liver cyst. Plevral effusion was observed in one patient. None of the patients was no hospital mortality. Average hospital stay was 9±4.38 (3-21 days).

Conclusion: Simultaneously transdiaphragmatic approach at lung and liver dome cysts is a safe and effective treatment method

P2401
TB empyema
Abdulrahman Nazzal1, Hassan Adel1, Ebrahim Razai 1, 2 Surgery Department, Kashan Medical University, Kashan; 2 Pulmonology Department, Qum Medical University, Qum; 3 Pulmonology Department, Kashan Medical University, Kashan, Islamic Republic of Iran

Background: Parapneumonic effusion mostly is resolved with medical management but sometimes became complicated. We studied the etiology and possible underlying causes of it.

Materials and method: Study on 81 patients with postneumonic empyema which required decortication carried out in Kashan, Shahid Beheshti General Hospital, from Oct 2006 to Dec 2011, Management of patients such as appropriate antibiotic, and thoracotomy and tube drainage was done in internal medicine ward. Complicated cases were referred to us for thoracotomy and decortication.

Conclusion: Partial resections at fibrous-cavernous tuberculosis with multiple drug resistance of mycobacteria is a highly effective method of treatment and it heals 98.3% of patients with chronic pulmonary pathology.
How severe pulmonary hemorrhage influence on surgical tactics at patients with lung abscess and gangrene

Evgeny I. Kovalenko1, Sergey Pushkin2, Alexander Reshetov2, Yaroslav Voloshyn2

Objective: How severe pulmonary hemorrhage influence on surgical tactics at patients with lung abscesses and gangrene. We retrospectively investigated 42 consecutive pre-school patients who underwent surgical treatment.

Methods: We retrospectively investigated 42 consecutive pre-school patients who were diagnosed and surgical treated for hydatid cysts in our clinic between January 1998 and December 2011. The authors present a group of 12 patients with destroyed lung secondary to tuberculosis and gangrene. The study assessed the efficiency of surgical intervention in the form of intrapleural cut of cavity (cut of abscess) with excision of externally walls of bronchial arterios.

Results: At 1797 patients with lung abscess without severe pulmonary hemorrhage operation of various chronic destructive lung disease. Of these, the tuberculosis was observed in 23 people, a chronic abscess - with 16 people, bullous disease - in 23 people, aspergilloma - with 3 people.

Conclusions: At 28 cases' cyst was in only one lung, in 5 cases' cyst was in single lung, in 35 cases cyst was in bilateral lungs. Average cyst diameter was 6.2 cm. It was interventioned to right lung and liver cysts by transdiaphragmatic approach. Conlusion:

Intrapleural cut of cavity (cut of abscess) with excision of externally walls of bronchial arterios. We have performed 8 pneumonectomies, 69 lobectomies, 16 wedge resections. Mortality = 6 patients (3.9%). From 68 patients with severe pulmonary hemorrhage 10 dead before operation. To another 58 patients at first we perform rengionenovascular embolization of bronchial arterios, then 16 pneumonectomies, 42 lobectomies. General mortality = 26 patients (38.2%).

Background: Hydatid cyst is a major health problem in developing countries and it usually settled in lungs in children. In this study we aimed to present our pre-school children cases with lung hydatid cysts that we underwent surgical treatment.

Methods: We retrospectively investigated 42 consecutive pre-school patients who were diagnosed and surgical treated for hydatid cysts in our clinic between January 1998 and December 2011.

Results: Seventeen (40.5%) patients were female and 25 (59.5%) patients were male. The average age of the patients was 5.2±1.3 (between 2-7 ages). The most common symptoms were cough (%74), chest pain (%26.2) and fever (%26.2). Twenty eight cases' cyst was in only one lung, in five cases cyst was in single lung and in six cases cyst was in bilateral lungs and liver, in three cases cyst was in bilateral lungs. Average cyst diameter was 6.2±2.4 (2.1-12 cm). It was interventioned to right lung and liver cysts by transdisphragmatic approach together in five cases. In different stance operation was performed to nine patients with bilateral cyst hydatid.

Conclusion: Surgery is the definite treatment of lung hydatid cyst. The most important way to protect against adverse effects of thoracotomy is to eliminate routes of transmission. The postoperative complications were very good, the mortality and morbidity rates being comparable with other pathologies.
evaluated until delivery at tertiary care centres. This approach guaranteed an easy admission and immediate surgical treatment in our Institute. CT and angi/CT were performed in all pts prior to operation to confirm diagnosis.

Results: All pts underwent open lateral thoracotomy (18 pts/lobectomy, 4pts/segmentectomy respectively). Age at intervention ranged 1-51 days (mean 10.6±7.2). CCAM localisation was: right lung lower lobe (7), left lung upper (6) and lower (1). Of those children. Following shows that early surgical intervention does not disturb development very well tolerated.

Conclusions: 1 Most CCAMs are diagnosed prenatally by means of routine USG analysis. 2 Early surgical treatment of CCAMs is safe and elective lobectomy appears to be very well tolerated. 3 Follow-up shows that early surgical intervention does not disturb development of those children.

P2411
Computed tomography-detected apical bullae in young men with Marfanoid phenotype
Maria Vereshchina1, Dmitry Skripkin2, Natalia Orlova3, Yuri Ignatiev3, Sviatoslav Akesson2, 1Department of Therapy and Family Medicine, Omsk State Medical Academy, Omsk, Russian Federation; 2Department of Computed Tomography, Omsk Clinical Diagnostic Center, Omsk, Russian Federation; 3Department of Radiology, Omsk State Medical Academy, Omsk, Russian Federation
Subpleural bullae in young men are often the cause of primary spontaneous pneumothorax (SP), which is one of the common thoracic surgical conditions requiring hospital admission. Screening and prevention SP have not been developed so far, because the lung bullae pathogenesis in young people is not known.

One hypothesis suggests a hereditary weakness of the connective tissue, the most developed so far, because the lung bullae pathogenesis in young people is not known.

Computed tomography (CT) performed 50 clinically healthy men with no episodes of primary SP in history. Marfanoid phenotype was diagnosed in identifying specific major and minor criterion (skeletal, skin, eye, vascular, and others), which together made it impossible to diagnose the full Marfan syndrome. Deficiency of alpha 1-antitripsin was rejected after a genetic test. The average age of the surveyed was 24 years. The men were smokers with a mean age of 24 years. The frequent maximal size of bullae was 0.5-1cm and the average number of bullae was 1-6. In almost all of the cases bullae were located in the apex. In 5 cases bullae were spread more extensively and were found up to the level of the carina and in 2 patients also bellow the carina. Correlation analysis confirmed the association between bullae and smoking history, as well as the severity of skeletal changes. These data confirm the importance of hereditary diseases of connective tissue in the genesis of bullous emphysema. CT scan may be useful for determining the risk and prevention of primary SP.

P2412
An extraordinary triplet and a single surgery: Lung cancer, retained bronchial foreign body and actinomycosis
Hasan Türür1, Halit Canırmızı2, Ayşel Kurt3, Ariz Gimusu1, Hasan Gücer3, 1Thoracic Surgery, Rize University Faculty of Medicine-Education and Research Hospital, Rize, Turkey; 2Chest Diseases, Rize University Faculty of Medicine-Education and Research Hospital, Rize, Turkey; 3Pathology, Rize University Faculty of Medicine-Education and Research Hospital, Rize, Turkey
This unique and previously undocumented report illustrates an extremely rare co-occurrence of early staged-primary bronchial carcinoma, retained organic bronchial foreign body and actinomycosis on the right lower lobe of a patient in whom resection surgery was curative. A 67-year-old man was hospitalized to evaluate the etiology of recurrent pneumonia. Thoracic computed tomography revealed an ill-defined mass with heterogeneous density, invading nearly total of the right lower lobe. Fibroptic bronchoscopy showed a rigid, mobile, gray endobronchial lesion on the orific of right lower subsegments associated with dense granulation tissue. Histopathological examination of the biopsy from the upper segment was reported as bronchogenic carcinoma. Right lower lobectomy was performed. During the removal of the lower lobe, a hard, brownish foreign body was detected on the orifice of lower lobe subsegments. The foreign body was retained seed of "Cherry laure". Also in the parenchyma, focal fields of actinomycosis was detected. In cases with retained bronchial foreign body in whom chronic respiratory problems (actinomycosis as well) lead investigative approaches, a simple bronchoscopy may offer the chance of the diagnosis of an early-stage bronchogenic carcinoma. It is a debate to conclude that chronic retained foreign body is the cause of the neoplastic course.

P2413
Diaphragmatic plication for diaphragmatic eventration: An evaluation of mid-term results
Rauf Gongoz, Akın Yıldızhan, Nuretin Yiyit, Fahit Candas, Haluk Sasmaz, Vurgut İsmailağ, Thoracic Surgery, GATA İHE, Uluslu, Istanbul, Turkey

Diaphragmatic eventration is a rare congenital anomaly in the musculary portion of the diaphragm. Eventration of the diaphragm is occur due to congenital or acquired etiology, is thought to be caused by an acquired complete or in complete paralysis of the diaphragmatic leaf. Operative repair is indicated for adult patient who has symptoms. Classically thoracostomy approach and diaphragmatic plication have been the approaches of choice forsymptomatic diaphragmatic eventration. The aim of our study was to objectively assess our mid-term results of diaphragmatic plication for hemidiaphragmatic eventration with the use of PFT.

We performed 28 diaphragma plication and analysed pre and postoperative pulmonary function tests (PFT) at our instution between 2006-2012. All operation performed under lateral decubitus position and one lung ventilation. The classical approach was a posterolateral thoracotomy through 7th intercostal space. The thinned diaphragmatic leaf was repaired with plication. We compared pre and postoperative PFT, we found significant improvements in PFT results at 3 months after operation. We had no postoperative mortality or any other major complication. Diaphragmatic plication for hemidiaphragmatic eventration demonstrated significant midterm improvements in symptom and pulmonary function test results.

P2414
Complex surgical solution for thoracic wall necrotizing fasciitis
Cornel Petrescu1, Leonard Mihai2, Roxs Constantin Coman3, Elisabeta Balans1, Nicolae Galie1, 1Thoracic Surgery, National Institute of Pneumology "Marius Nasta", Bucharest; 2Anesthesiology and Intensive Care, National Institute of Pneumology "Marius Nasta", Bucharest, Romania

Necrotizing fasciitis of thoracic wall is a severe disease which is associated with a high rate of mortality, especially for immunosuppressed patients. Multiple drainage incisions, excision of necrotic tissues and appropriate antibiotics represent the best therapeutic solution.

The authors present the case of a 43 years old male, diagnosed with left empyema secondary to pulmonary tuberculosis. A left tube thoracotomy was performed for drainage, followed by surgical empysema (secondary to increase air leaks) and necrotizing fasciitis surrounding the tube thoracotomy, which has extended to left hypochondrium. First, multiple drainage incisions were performed, with excision of necrotic tissues and antibiotics. Azonin's procedure was performed after, closing the left bronchus and the air leaks were stopped.

After 18 days, the thoracic wall wounds were healed, allowing left pneumonectomy to be performed. Sputum exam became negative soon after closing the left main bronchus.

Closing the left main bronchus using the Azonin's procedure stopped the air leaks, which led to decreased of microbial contamination of the thoracic wall wounds and good out-come.
P2415
Thoracoscopic video-assisted partial resection of rib for pain control in patient with atypical pulmonary and bone Langerhans histiocytosis
Tsvetan Minchev1, Emanuel Manolov1, Vladimir Marinchev1, Anton Angelov1, Galina Kirova2, Ivan Stotemov1, 1Thoracic Surgery, Tokuda Hospital, Sofia, Bulgaria; 2Medical Imaging, Tokuda Hospital, Sofia, Bulgaria; 3ICU, Tokuda Hospital, Sofia, Bulgaria

Introduction: Langerhans histiocytosis (LH) is a rare disease that occurs in 1-2.2 millions of people, which affects mainly children and adults between twenty and forty years old. Bones affection is an rarely occurs.

Clinical case: A 19 year old female with severe pain and discomfort of left subskapular area. After CT procedure, it was found that there are bilaterally a great number of small diffusely scattered nodular lesions in the lung parenchyma and formations, destructed cortex on the 5-th rib with the suspected for histiocytosis X.

Treatment: A video-assisted thoracoscopic (VATS) partial resection of the fifth rib has been made, under three port. Lung biopsy has been made over several suspected lesions. The postoperative period has been uneventful. The pain and the discomfort were reduced.

Conclusion: VATS resection of the rib could be a good modern approach to eradicate or interference of pain in the rib LH. VATS remains the ultimate cross-cutting unique therapeutic approach for the treatment of the bone Langerhans-cellular histiocytosis and change the quality of life in these patients.

P2417
The role of video-assisted thoracic surgery on the diagnostic evaluation and the therapeutic management of thoracic injuries
Athanasia Stamatelopoulou, Petros Michos, Ioannis Gakidis, Cristos Gakidis.
Thoracic Surgery, KAF General Hospital of Athens, Attica, Greece

Aim: The aim of this study was to evaluate the experience of our institution with the use of video-assisted thoracic surgery (VATS) in chest trauma. 

Materials and methods: Between January 1999 and December 2011, 75,126 patients presented with chest trauma to the emergency room, and 6865 were admitted to our service. Fifty five (55) hemodynamically stable patients (0.8%) underwent VATS. They were 44 men and 11 women with an average age of 42 years (range, 19–67 years).

Results: Indications included post-traumatic hemothorax in 26 patients, and post-traumatic empyema in 7, treated after 24 h of trauma. Indications for exploratory VATS in the acute phase included suspected diaphragmatic injury in 6 patients, persistent pneumothorax in 5, continued hemorrhage in 8 and removal of intrathoracic foreign body in 3. There was no mortality and complications occurred in 8 patients (14.5%).

Conclusions: Management of hemodynamically stable thoracic injuries by using VATS provides diagnostic accuracy and therapeutic efficacy. It can be successfully applied in the trauma setting and surgeons should gain experience with its use.

P2418
Over 2000 cases of thoracic trauma – 10 years experience of a single clinical centre
Alexandru Nicodin1, Ovidiu Burlacu2, Voicu Voiculescu, Gabriel Coxma, Calin Tutea. Thoracic Surgery, Timisoara Municipal Hospital, Timisoara, Timis, Romania

Objectives: We present the experience of our clinic in the diagnosis and treatment of thoracic trauma, there being some controversial issues in this field in medical literature.

Material and methods: This study encompasses 2156 cases admitted over a period of 10 years (2002 – 2011). Patients were analyzed in terms of sex, age, causative mechanism, as well as thoracic and extrathoracic lesions. Methods of diagnosis and surgical treatment, complications that occur, duration of hospital stay, and evolution under treatment are presented.

Results: Hospitalization due to thoracic trauma represents on average 21% of all admissions. Cases of polytrauma (35%) were managed by a multidisciplinary team. Regarding diagnostic tools, computerized tomography was used in 35% of the cases and bronchoscopy in 6%. Fine needle aspiration biopsy was used for the differential diagnosis of pulmonary contusions in 1.4% of the cases. The most frequent thoracic lesions were rib fractures, pleural effusions, and pulmonary contusions. Pleurotomy was most frequently used (47%) while thoracotomy was used in 8% of the cases operated upon. Complications affected 18% of the cases. 76% of patients that required over 3 weeks of hospitalization presented with extensive pulmonary contusion. Unfavorable results were seen in 4% of the patients while 2.6% of the patients died.

Conclusions: Thoracic trauma represents a difficult challenge, often with a surprising evolution. The diagnosis and application of the best surgical management, often with the help of a multidisciplinary team, is paramount. Associated pulmonary contusion prolongs hospital stay.

P2419
Spontaneous rib fractures
Yucel Akkas1, Ozgul Katarcioglu1, Sulhatten Arslan2, Eker Sahin3. 1Chest Surgery, State Hospital, Sivas, Turkey; 2Chest Diseases, Medical Faculty, Cumhuriyet University, Sivas, Turkey; 3Chest Surgery, Medical Faculty, Cumhuriyet University, Sivas, Turkey

Introduction: Other than trauma, rib fracture can occur in patients spontaneously due to a severe cough or sneeze. In this study, patients with spontaneous rib fracture were analyzed according to age, sex, underlying pathology, treatment and complications.

Materials and methods: 12 patients who presented between February 2009 and February 2011 with spontaneous rib fracture were analyzed retrospectively. The patients were evaluated according to anamnesis, physical examination and chest X-rays.

Results: 7 patients (58.4%) were male. The age of the patients ranged from 34 to 77 years (mean ± SD. 55.9±12.20). All patients had severe cough and chest
pain. Multiple rib fractures were detected in five patients (41.7%). The fracture were detected most frequently between 4th and 9th ribs. 8 (66.66%) patients had COPD; 2 (16.66%) patients had bronchial asthma and 2 (16.66%) patients had osteoporosis as well. The patients with COPD and bronchial asthma were treated with high dose steroids for over a year. Bone densitometry revealed high risk of bone fracture in all patients.

Conclusion: Spontaneous rib fracture due to severe cough may occur in patients with osteoporosis or with COPD and bronchial asthma receiving long-term steroid therapy. If these patients have severe chest pain, chest radiography should be evaluated for bone lesions particularly.

P2420
Analysis of 430 chest trauma patients in Kashan trauma center: 2003-2011
Abdolhossein Davoodabadi, Surgery, Kashan Medical University, Kashan, Islamic Republic of Iran

Background: Chest trauma as a potentially life threatening injury is increasing with increased number of high-speed accidents in Iran.

Methods: 430 patients were treated for chest trauma (Mar 2003 and Dec 2011) patients’ age and gender, blood pressure, respiratory rate on admission, Glasgow Coma Scale (GCS) scores, types of trauma, the extent of intra thoracic injury, types of associated injuries, length of hospital and ICU stay, morbid conditions, and deaths were analyzed.

Results: 343 pt were male (80%).Mean age was 37.67±19.14. 305 patients (70.9%) had blunt and the rest (29.1%) penetrating chest trauma. (83patients (19%) had hemorhorax 53 patients (12%) pneumothorax and the rest were cardiac, (10%), great vessel (12%) and tracheal injuries (8%). Rib fracture was the most common thoracic injury with 270pt (63%), were treated with closed thoracotomy drainage 65 patients (15%) had hemorhorax and lung contusion, whoever 42patients (11%) of penetrating injury and lung contusion leads to empyema, who need thoracotomy with decortications and diaphragmatic repair Motorcycles and car accidents were the most common etiologic causes in 331 (76%).

The most frequent extra-thoracic injury with (33%) was pelvic and limb injuries, while (25%) needed surgical intervention during the first 24 hours. The most common operation was laparotomy. Mean duration of hospital stay was 7.49±4.75 days (range: 1-70) and ICU stay 19.71 days. Overall mortality was (1.7%) Conclusion: Chest trauma is a major preventable cause of mortality and morbidity in our country. Systolic blood pressure ≤90, pulse rate ≥120, respiratory rate ≥29, GCS ≤8 at the time of admission, and blunt type of trauma were found as the predictors of mortality and morbidity.

P2421
Our first steps in osteosynthesis of fractured ribs using Matrix Rib technologies
Sergey Pushkin, Armen Benyan. Thoracic Surgery, Samara Regional Clinical Hospital, Samara, Russian Federation

Objective: Surgical management of multiple fractured ribs is the one of the undecided questions of thoracic trauma.

Aim: Illustration of our experience of osteosynthesis of fractured ribs using Matrix Rib technologies.

Materials and methods: Since December 2011 we have operated 5 patients. All they had blunt thoracic trauma with multiple fractured ribs and other injuries. Number of fractured ribs was from 4 to 9. Three patients had bilateral rib fractures. Also, 2 patients had hemorhorax, 1 patient had fracture of sternum, and 1 patient had rupture of left cupula of diaphragm. The middle terms from moment of trauma to operation were 1.5 days. To all of patients we have applied Matrix Rib technologies for rib osteosynthesis. The number of synthesized ribs was from 2 to 5.

Also we have performed 3 thoracoscopy (1 including suturing of diaphragm) and 1 osteosynthesis of sternum. Results: We have observed all 5 patients during postoperative period. The average of ventilation days was 2.4. There were no respiratory or wound complications. All patients had early activation. The respiratory function improved rapidly, increase of FVC before discharge was 25%. Long-term results didn’t show any significant respiratory function.

Conclusion: The osteosynthesis is the indicated operation at multiple and bilateral rib fractures. It helps to early activation, prevents complications and improves respiratory function.

P2422
Predictive factors for succeeded thoracoscopic treatment in patients with retained hemothorax-experience from two centers
Aleksimir Voronkov,1, Georgiy Yankov,2, Angel Chukov1, Krassimir Mourdjev1, Atanas Batsabala,2, Danail Petrov1,2.1, Thoracic Surgery, UMBRAB “St. George”, Plovdiv, Bulgaria; 2Thoracic Surgery, SKALBB “St. George”, Sofia, Bulgaria

Introduction: In 5–55% of retained hemothorax cases the chest tube doesn’t allow adequate evacuation of hemothorax. Video-assisted thoracis Surgery (VATS) decreases the need of thoracotomy in these cases.

Aim of study: A retrospective analysis of patients, operated on for retained hemothorax, was performed in two thoracic surgery centers in order to investigate the predictive factors for succeeded VATS treatment.

Materials and methods: For five years period a total of 50 patients were operated on for retained hemothorax (35 by VATS and 15 by thoracotomy). The demographics and clinical parameters (age, sex, type of trauma, side of hemothorax, days after chest tube insertion, diameter of chest tube, antibiotic use, quantity of hemothorax, additional diaphragmatic injury, ribs trauma, days after trauma, injury severity score and abbreviated injury severity score) of all cases were investigated with univariate analysis by logistic regression analysis (statistical significance when p<0.05).

Results: The perioperative antibiotic prophylaxis (OR, 2.4[1.9-4.9]; p=0.03), the volume of hemothorax >900 cc. (OR, 4.2[1.6-8.9]; p=0.01), the diaphragmatic injury (OR, 3.4[2.0-8.6]; p=0.04) and the period between the trauma and surgery (OR, 4.8[3.4-12.1]; p<0.001) were found to be the leading factors predicting conversion to thoracotomy.

Conclusion: VATS is effective in patients with performed perioperative antibiotic prophylactic, with no diaphragmatic injury, early performed chest tube drainage and hemothorax with volume less then 900 cc.

P2423
Bronchoscopic approach in the treatment of postoperative bronchopleural fistula
Levent Dalar1, Ahmet Levent Karasulu1, Sinem Nedime Sokcu1, Cengiz Özdenir1, Seda Öner1, Umut Mutlu2, Ahmet Ali Bedirhan1, Aliya Gunes1, Sedat Altun1.1, Interventional Pulmonology Unit, Yedikule Teaching and Research Hospital, Istanbul, Turkey; 2Thoracic Surgery, Yedikule Teaching and Research Hospital, Istanbul, Turkey

Aim: Bronchopleural fistula (BPF) is one of the worst complications of thoracic surgery. Its incidence is between 0.8-15%. Its mortality can reach up to 70%. Most important reason of death is accompanying aspiration pneumonia or ARDS.

Method: Consecutive 13 cases that were treated bronchoscopically due to postoperative bronchopleural fistula were evaluated.

Results: Twelve of the patients were male. Mean age was 55.6 (35-71). Fistula was located at the right in 9 cases while located on the left in 4 of them. Reoperation was applied to seven of the cases for squamous cell carcinoma, one of the cases for adenoacarcinoma, one of the cases for aspergilloma and one of the cases for tuberculosis sequel. Silicon Y stent was placed in two and straight silicon stent was placed in one of the cases. In one of the cases in which empyema surgery was applied, lingula segments were closed by suture. Small size fistula was closed by coagulation. Three of the cases were died 6, 35 and 94 days after the stent insertion. Procedures were successful in eight, partly successful in one and not successful in four of the cases.

Conclusion: If surgical reconstructive repair could not be done in postoperative bronchopleural fistula, mortality is high. In these cases, bronchoscopic treatment is the only treatment option. Cure can be obtained in some of the cases in which infection control is maintained. Survival is significantly increased in cases with wide fistulas after stent insertion.

P2424
Stratification of risk factors of developing of bronchopleural fistula after pneumonectomy
Shukrat Khudaybergenov1, Georgiy Pahomov2, Ozbek Edemkhozhiev1, Dmitrii Ivrieva2, Rustem Hayaliyev2.1, Lang and Medico-legal Medicine, Republican Specialized Centre of Surgery named after Academician VVladimirov, Tashkent, Chilanzar, Uzbekistan; 2Hospital and Faculty Surgery, Tashkent Medical Academy, Tashkent, Sobir Bahimov, Uzbekistan

Background: It is known that bronchial stump fistula (BSF) is general causes of efficacy decrease of surgical treatment of pulmonary cancer. Stratification of patients with local distributed and disseminated cancer forms of any localization is scientifically proved and it allows to determine heterogeneity of patients’ group
in relation to the nearest and remote prognosis as well as to work out volumes of surgical treatment into practice.

Methods: Stratification data of risk factors of bronchial stump failure (BSF) development in 575 patients, who underwent primary pneumonectomy in this article were presented. Control group (CG) consisted of 477 patients, 390 patients of them had different tumors of the lungs and 87 patients had parulent diseases of the lungs. The main group (MG) consisted from 98 patients. Formation of risk groups depending on localization of disease showed that in the planning of left sided PE minimum risk was determined in 258 (67.9%) patients, mean risk - in 83 (21.8%) patients and maximum risk - in 39 (10.3%) patients.

Results: An incidence of BSF after PE in patients of CG accounted for minimal risk 1.3%, at an average – 16.0%, and maximal – 32.3%, in its turn, an implementation of factor estimation of risk degree of development of BSF after PE in MG allowed to reduce an incidence of this complication until 0.0%, 2.6% and 9.1% respectively.

Conclusion: Peculiarities of a tactics of surgical intervention in PE must be determined strong in accordance with risk degree of development of BSF and, depending on the latter, include various in their efficacy of hermetization as well as work volume of accomplishment methods of suturing bronchus stump and consolidation of suture line.

P2425
Extremely rare complication of pulmonary resection: Systemic tumor embolization (A case report)
Hasan Cavliak, Kuthan Kavakli, Erzin Sarpnaz, Sezai Cubuk, Hakan Isik, Okan Karatas, Sedat Guler, Alper Gorubuyuk, Orhan Yucel, Onur Genc. Thoracic Surgery, Gulhane Military Medical Academy, Ankara, Turkey

Introduction: Determining of systemic tumor embolization during pulmonary resection is a rarely seen situation. Tumor emboli of metastatic tumors of the lungs are extremely rare unlike to primary lung cancers. Herein, we presented a case of systemic tumor embolism during metastasectomy of Ewing’s sarcoma.

Case report: A 41-year-old man underwent right lower lobectomy for Ewing’s sarcoma of the anterior chest wall. Then he was followed-up for three months period. The patient underwent metastasectomy for nodular lesion of right lower lobe after four years from initial resection. He was hospitalized again for the symptoms of dyspnea and pleuritic chest pain six months after the first metastasectomy. Computed thorax tomography was revealed metastatic recurrence involving the entire right lobe. Then the patient underwent a right lower lobectomy. In the operation, when we divided the right lower pulmonary vena after dissection, we did not see any bleeding. In second postoperative day, he had a severe left leg pain. There was no pulsation of dorsalis pedis artery and the lower extremity ulcer was seen. In fourth postoperative day, the patient had left leg pain, dyspnea with intercostal retractions. Breathing sounds were diminished at the right hemithorax. Distal part of the NGFT was seen at the pleural space via thoracostomy system in chest X-ray. Pleural effusion and pneumothorax were also determined. NGFT was removed immediately and chest tube thoracostomy was applied. Medical therapy was rearranged due to the patients clinical situation. NGFT must be applied with care also chest X-ray controls may be helpful for prevention morbidity and mortality of malposition.

P2427
Delayed traumatic diaphragmatic hernia: Case series
Aktelhossein Dezovodzadhi. Thoracic Surgery, Kashan Medical University, Kashan, Islamic Republic of Iran

background: Traumatic diaphragmatic rupture after blunt trauma is an uncommon condition, and often is initially missed diagnosis. We report 5 cases of traumatic diaphragmatic rupture after blunt injury 20±6 years prior to admission.

Case 1: 37-year-old man with chronic vomiting abdominopelvic pain and recently thoracic empyema, he had car accident 2 years ago. Left thoracotomy revealed small perforation of stomach which repaired and reduced in abdominal cavity, then diaphragm repaired (fig. 1).

Case 2: 25-year-old man with multipli injury 2 years ago admitted for acute abdomen. Thoracotomy revealed oniomoc and transverse colon left hemi thorax (fig. 2).

Case 3: 43-year-old female with chest trauma in car accident at right posterolateral thoracotomy revealed herniation of right liver lobe (fig. 3).

Case 4: 29-year-old female with chest trauma and rib fractures in 3 year ago left thoracotomy revealed herniation of omontome left liver lobe some part of left coloc and stomach after reduction of this organs diaphragm repaired (fig. 1).

Case 5: 47-year-old man with history of vomiting abdominopelvic pain abd dyspnea in barium study stomach. Spleen transverse, colon small bowel lie in left hemi thorax with left l thoracotomy this organs reduced diaphragm also repaired (figs. 4-7).

Case 6: 67-year-old man with history of vomiting abdominopelvic pain, respiratory insufficiency, sepsis he had car accident 16 years ago left posterolateral thoracotomy was done due to stomach torsion gangrene was happened. after operation the patient die.

Conclusion: In patients with gastro intestinal complaints and history of chest and abdominal trauma, must have high index suspicion to diaphragmatic injury.

P2428
The pleura and rheumatoid arthritis: A case series
Rahul Makkerjea, Mehreen Ahmad, Shiva Bikhmaia, Vikas Panamya, Sandu Agarwal. 1Department of Respiratory Medicine & Physiology, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; 2Department of Medicine, Milton Keynes Hospital, Milton Keynes, United Kingdom; 3Department of Thoracic Surgery, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom

Background: Pleurisy is observed in almost 30% and effusions can be recurrent, occasionally leading to fibrothorax in chronic seropositive rheumatoid arthritis [Chest 1991; 100:235-238]. Pulmonary nodules occur in up to 5%, 50% cavitating to cause pneumothorax, haemoptysis or bronchopleural fistula.

Recurrent pneumothoraces and effusions are difficult to manage by surgical decortication [1 Thor Cardiovasc Surg 1975; 6:347-354].

Case series: We report four cases of chronic seropositive rheumatoid arthritis on longterm immunomodulator therapy, presenting with pleural effusions which were prone to recurrence & complicated by development of pneumothorax. The common theme was all had chest drains inserted initially, then surgical pleurodesis, re-presented with recurrent pleural effusions draining purulent material after failed pleurodesis and had indwelling pleural catheters inserted. One isolated Aspergillus species and died of multiorgan failure; the rest were left with indwelling chest drains.

Discussion: Our case series highlights the paucity of evidence in management of complicated rheumatoid pleural disease and calls for registries of interventions for
such patients. It is important to initiate early conservative approach in management of rheumatoide pleural effusions as surgical management is problematic due to trapped lung and pleural rind. Opportunistic infections in the context of an ever of rheumatoid pleural effusions as surgical management is problematic due to such patients. It is important to initiate early conservative approach in management of pleural effusion pH, Karnofsky score and the degree of pleural involvement were investigated. The last one was defined from 0 (minimum) to 3 (maximum) for each parietal, visceral and diaphragmatic pleuras at the time of thoracoscopic.

Background: Postoperative pulmonary complications (PPCs) following cardiothoracic surgery remained to be alarmingly high. This study was done to determine the risk factors associated with PPCs following cardiothoracic surgery in children 6 years old and below who underwent cardiothoracic surgery from November 1, 2010-October 31, 2011 at the Philippine Heart Center.

Methods: A prospective cohort study was done among 120 patients. Thirty five risk factors were included. Outcome measures included postoperative pulmonary complications. Comparisons of categories between with and without postoperative complications were done using Chi-square and independent T-test for all continuous variables. All independent variables were entered into a binary logistic regression model.

Results: The incidence of PPCs in this study is 73%. The history of respiratory tract infection (RTI), preoperative mechanical ventilation, high pulmonary artery pressure (PAP), hypertension, hypercoagulability, lymphocytopenia, prolonged protime, hypoalbuminemia, high ASA and RACHS-1 scores, prolonged postoperative mechanical ventilation, recovery room (RR) stay, pediatric intensive care unit (PICU) stay and length of postoperative hospital stay were associated with PPCs. Tidal breathing analysis was not found to be significantly associated with PPCs.

Conclusion: Fourteen out of the 35 risk factors were associated with PPCs in children 6 years old and below. With the incidence of PPCs remaining to be high especially in the lower pediatric age group, knowing the risk factors of its occurrence is of paramount importance.

P2430 The retrospective analysis of reasons of prolonged air leakage after pulmonary resection
Armen Benyan1, Evgeny Korymasov1, Sergey Pushkin1
Chair of Surgery, Samara State Medical University, Samara, Russian Federation; Department of Thoracic Surgery, Samara Regional Clinical Hospital, Samara, Russian Federation

Objective: Prolonged air leak is one of the most frequent complications after pulmonary resections. The aim of our study is to identify the reasons of prolonged air leak by carrying out a retrospective analysis of cases with such complication.

Materials and methods: We have studied 878 case reports of patients, who underwent pulmonary resection, for last 10-year period (2002-2011). The patients had chronic non-specific lung diseases – 266 (30,3%), interstitial lung diseases – 192 (21,9%), tumors – 182 (20,7%), purulent diseases of lung – 112 (12,7%), parasitic diseases – 71 (8,1%), tuberculosis – 55 (6,3%). We have performed: 218 lobectomies, 25 segmentectomies, 271 open and 364 VATS wedge resections.

Results: Prolonged air leak we have observed at 85 patients (9,7%). The reasons of prolonged air leak were integrated into 3 groups: a) reasons due to inadequate drainage functioning – 21 patient (2,4%); b) reasons due to thoracic wall – 2 patients (0,2%); c) reasons due to operated lung – 62 patients (7,1%). At 68 patients the problem was eliminated by use of different therapeutic and auxiliary methods. Re-operation was needed at 18 patients (2,0%). During re-operation we have also revealed: migration of drainage – at 3 patients, pulmonary fistula on resection line – at 9, unnoticed bulla on previous operation – at 1, lung destruction with bronchopleural fistula – at 2, lung laceration because of pleural adhesions – at 2, perforation of lung tissue with drainage – at 1 patient. The pathologic reason of prolonged air leak was eliminated in every case.

Conclusion: Identification of reasons of prolonged air leak assists to timely application of different curative methods for its elimination.

P2431 Karnofsky score, pH and degree of pleural involvement as prognostic factors for survival in patients with malignant pleural effusions
Alekseandr Yanuklin1,2, Anastas Chapkanov1, Krassimir Mourdjev3, Angel Chekanov1, Dainis Pētrovs4

Objective: The patients with malignant pleural effusions (MPE) have a short survival which is influenced by different factors. We investigate the prognostic value of pleural effusion pH, Karnofsky score and pleural involvement in these patients.

Methods: A prospective study was carried out for the period of 2.5 years. A total of 100 MPE patients were treated by video-assisted thoracoscopic surgery with or without pleurectomy in case of trapped lung. Their preoperative fluid pH, Karnofsky score and the degree of pleural involvement were investigated. The last one was defined from 0 (minimum) to 3 (maximum) for each parietal, visceral and diaphragmatic pleuras at the time of thoracoscopic.

Results: The overall survival of 21 months in patients with pH>7,40 was statistically longer compared to the 15 months in patients with pH<7,40 (p<0,001). Patients with Karnofsky score 10-30 had overall survival up to 6 months, instead of these with Karnofsky score 70-80, who were alive for 21 months. The patients with scores 40-50 and 60 have a survival between 10 to 17 months. A coherence were also found between fluid pH and Karnofsky score and index of correlation equal to 0,5636, also between Karnofsky score and degree of pleural involvement with index correlation 0,766 and pH and pleural involvement with index equal to 0,6749.

Conclusion: We can conclude that some preoperative factors (pH and Karnofsky score) and intraoperative one (degree of pleural involvement) can be useful as prognostic factors for survival in MPE patients.

P2432 Late radiation injury in preoperative chemoradiotherapy
Yunika Takahashi, Ei Miyamoto, Takeya Terashii, Hiroshi Hamakawa
Thoracic Surgery, Kobe City Medical Center General Hospital, Kobe, Japan

Background: Preoperative chemoradiotherapy (CRT) seems to increase survival rates in advanced non-small cell lung cancer. In the evaluation of this study, overall survival (OS) and early complications are generally referred. However, the influence of induction CRT remains controversial. Therefore, the aim of this study is to identify the reasons of prolonged air leak after thoracic surgery. The incidence of this complication is 16.3% in all patients.

Methods: From 1996 to 2010, 167 patients treated with major lung resections after CRT (139 lobectomy, 24 pneumonectomy, 3 wedge resection, and 1 segmentectomy) were enrolled. They were treated with platinum-based regiments and had 40 Gy delivered to the primary tumors, hilum and mediastinum. The postoperative condition of residual lungs was assessed in 142 cases.

Results: 72 patients died. Of 72, 49 died of lung cancer, 17 died of other disease, and 6 died of postoperative complications (operative mortality was 3.0%). Of other disease death, 3 aspergilllosis and 2 idiopathic pulmonary fibrosis were related to induction therapies. The 5-year OS rates of p-stage 0, 1a, 1b, 2a, 3a and 3b were 72%, 62%, 52%, and 42% respectively. The 5-year OS rates of p-N0, N1, and N2 were 69.5%, 50.7% and 22.0% respectively. In 142 cases assessed postoperative condition of residual lungs, 27(19.0%) mild fibrosis, 36(3.5%) severe fibrosis, 37(26.1%) shrinkage, and 96(3.5%) cavitated dead score formation occurred. Radiation injury appeared when residual normal lung was irradiated.

Conclusions: Preoperative CRT increased survival rate in patients who achieved p-N0, but was associated with higher rates of pneumonectomy and operative mortality. Radiation might affect postoperative devastation in residual lungs. This therapy should be performed cautiously.

P2433 Enlarging the lung donor pool by using extended criteria donors: a single-center study
Jana Somers1, Caroline Meers1, Shana Wouters1, Stijn Verleden2, Annemie Vaneylen2, Bart Vanaudenaerde2, Geert Verleden3, Dirk Van Raemdonck4,4
Laboratory for Experimental Thoracic Surgery, KULeuven, Vlaams-Brabant, Belgium; Laboratory for Pulmonary, KULeuven, Vlaams-Brabant, Belgium; Division of Pneumology, UZ Leuven, Vlaams-Brabant, Belgium; Divison of Thoracic Surgery, UZ Leuven, Vlaams-Brabant, Belgium

Previous studies have reported comparable medium-term outcome after lung transplantation (LTx) from extended-criteria donors (ECD) when compared to standard-criteria donors (SCD). However, long-term outcome after LTx from ECDs is not well studied. All effective heart-beating lung donors within our hospital network between 2006 and 2007 (n=50) were classified (SCD, n=23; ECD, n=27) according to the criteria listed in Table 1. Lung recipients were followed up to 5 years. Survival, rates of acute and chronic rejection, pulmonary function (VC, FEV1), total and differential cell count and IL5 levels in BAL were compared between groups. IL8 concentration was measured in BAL using standard ELISA. Differences in donor groups were assessed using Fisher’s exact test, unpaired t-test, Mann-Whitney test or repeated measurements ANOVA. Survival curves were calculated with the Kaplan-Meier method and compared using the log-rank test.

No significant differences were seen in 5-year survival (87% vs. 70%; p=0.14).
freedom from BOS (70% vs. 63%; p=0.44), rate of acute rejection, pulmonary function, total and differential cell count of lymphocytes and neutrophils between lung recipients from both donor groups. A significant difference in the course of IL8 concentration over time after LTx was observed (p=0.002) between SCDS and ECDs. The acceptance of ECDs doubled the number of transplants performed annually.

This policy did not negatively influence long-term results after LTx.

P2434
Extracorporeal membrane oxygenation in awake patients as bridge to lung transplantation
Thomas Fuehner1, Christian Kuehn2, Tobias Welte3, Gregor Warnecke2, Jens Gottlieb1, Christian Kuehn2, Karen Olsson1, Igor Tudorache2, Tobias Welte3, Gregor Warnecke2, Jens Gottlieb1.

Endotracheal intubation in patients with end-stage lung disease before lung transplantation (LuTx) is associated with a poor outcome. New bridging strategies of critical patients are of major interest.

We performed a retrospective, single-center, intention-to-treat analysis of consecutive LuTx candidates with terminal respiratory or cardiopulmonary failure receiving "awake ECMO" support. The outcomes were compared with a historical control group with conventional mechanical ventilation (MV group).

Twenty-six patients (58% female, median age 44 years, range 23-62) were included in the awake ECMO group and thirty-four patients (59% female, median age 36 years, range 18-59) in the MV group. The duration of ECMO support or mechanical ventilation, respectively, was comparable in both groups (awake ECMO: median 9 days; MV: median 15 days; p=0.02). Six of 26 (23%) patients in the awake ECMO group and 10/34 (29%) patients in the MV group died before a donor organ was available (p=0.20). Survival at 6 months after Tx was 80% in the awake ECMO group versus 50% in the MV group (p=0.02).

P2435
Rehabilitation after lung transplantation with extracorporeal membrane oxygenation
Martin Daesch1, Thomas Fuehner1, Tobias Welte1, Gregor Warnecke2, Jens Gottlieb1, Christian Kuehn2, Karen Olsson1, Igor Tudorache2.

Extracorporeal membrane oxygenation (ECMO) is applied in respiratory failure before lung transplantation (LTX). The success of pulmonary rehabilitation (PR) following LTx with ECMO is unknown. Hypothesis: a 3-week inpatient PR in ECMO-treated patients is as efficient as in conventional transplanted.

Following LTx, 26 patients (12 female, median age 58 years, range 30-69) were included in the awake ECMO group and thirty-four patients (59% female, median age 51 years, range 27-74) in the MV group. ECMO: median 9 days; MV: median 15 days; p=0.02. Six of 26 (23%) patients in the awake ECMO group and 10/34 (29%) patients in the MV group died before a donor organ was available (p=0.20). Survival at 6 months after Tx was 80% in the awake ECMO group versus 50% in the MV group (p=0.02).

Figure 1. Kaplan-Meier curve.

Patients in the awake ECMO group required shorter postoperative mechanical ventilation (p=0.04) and showed a trend towards a shorter postoperative hospital stay (p=0.06). Extracorporeal membrane oxygenation (ECMO) support in awake and non-ventilated patients is a new and promising strategy for bridging patients to LTx.

P2436
Prevalence of sleep apnea – Hypopnea syndrome among lung transplantation candidates
Ana Hernández Vieh1, Pedro Benavides Matas2, Maria Dolores Hisado Diaz3, Soreya Jorda Sanchez1, Alicia De Pablo Gafas4, Jesus Muñoz Méndez5, María Josefa Diaz De Atauri Rodríguez6.

Sleep and Lung Transplantation Units.

Aim: To analyze the prevalence and possible associated factors with the Sleep Apnea – Hypopnea Syndrome (SAHS) among patients evaluated for Lung Transplantation (LT).

Methods: Transversal descriptive study of a cohort of patients evaluated for LT, with a standard polysomnography (PSG), from September 2008 to February 2012. SAHS was defined as the presence of Apnea Hypopnea Index (AHI) ≥ 10 and excessive daytime sleepiness symptoms. Severity of these symptoms was evaluated by Epworth sleepiness scale. Anthropometric, clinical and blood test measurements were also analyzed in all patients.

Results: During this period a number of 52 patients were studied. 50% of them were male, average age was 54.8 years (SD ± 9.96). Principal LT indication pathologies were due to COPD (46.2%), Pulmonary Idiopathic Fibrosis (15.4%) and Usual Interstitial Pneumonitis (11.5%). PSG were performed with supplementary oxygen in 96.2% of the cases. AHI average was 8.26 (SD ± 9.96). SAHS was diagnosed in 13 patients (25%). Among these, 8 (61.5%) had COPD. Next table shows relationships between groups and principal analyzed variables.

Conclusions: In this series of LT candidate patients, prevalence of SAHS is high. We have not found anthropometric, clinical nor blood test data significantly associated with the diagnoses of SAHS which can contribute to make a clinical pretest suspect. Performance of a standard polysomnography in LT candidates is probably recommendable.

P2437
Coping strategies in patients awaiting lung transplantation
Torunn Stavnes Soyseth1, May Britt Lund1, Oystein Bjortuft1, Vidar Soyseth1, Aasta Heldal1, Geo Kulli1, Hauagst. Division of Cancer Medicine, Surgery and Transplantation, Oslo University Hospital, Oslo, Norway Medical Decision, Akershus University Hospital, Lørenskog, Norway Faculty of Health Science, Oslo and Akershus University College, Oslo, Norway

Introduction: Living with severe lung disease is a stressful situation. Constraint coping strategies may constitute an additional burden. We aimed to describe coping strategies in patients awaiting lung transplantation

Material and method: A national cohort of 121 consecutive patients was screened by psychometric questionnaires as part of the work-up for lung transplantation during the period 2006-2010. 86 of the patients scored the Ways of Coping Questionnaire (WCQ) (Lazarus and Folkman 1988). WCQ measures 8 different coping strategies (N=86).

Conclusions: In this series of LT candidate patients, prevalence of SAHS is high. We have not found anthropometric, clinical nor blood test data significantly associated with the diagnoses of SAHS which can contribute to make a clinical pretest suspect. Performance of a standard polysomnography in LT candidates is probably recommendable.

We have not found anthropometric, clinical nor blood test data significantly associated with the diagnoses of SAHS which can contribute to make a clinical pretest suspect. Performance of a standard polysomnography in LT candidates is probably recommendable.
The patients had higher scores in emotionally-focused coping strategies than healthy references. This may be of clinical importance when it comes to understanding how patients deal with postoperative challenges.

The impact of smoking relapse on the outcome after lung transplantation

David Rutten, Stijn Verleden, Robin Bos, Anemie Vaneylenck, Elly Vandermeulen, Michael Thomeer, Dirk Vantardendoch, Bart Vanaudenaerde, Geert Verleden. Leuven Lung Transplant Unit, UU Leuven and UZ Gasthuisberg, Leuven, Belgium

Lung transplantation (LTx) is a treatment for end-stage lung diseases. Smoking free period of 6 months is required to be listed for LTx. We however reported that 17% of former smokers resume smoking after LTx. The current aim is to re-evaluate the prevalence of post transplant smoking resumption and the impact on outcome after LTx with as main parameters chronic rejection, solid tissue cancer.

All 335 LTx recipients currently in follow-up in our center were included and evaluated for past and current smoking habits by a questionnaire and an eCO measurement with an electrochemical (Bedfont ECSO, pieCO-V Smokekeyer) sensor (eCO > 10 ppm was considered positive). The association between smoking and solid tissue cancer was tested using a contingency table (GraphPad prism 4.0). 213 patients (65%) smoked before LTx of which 144 had COPD (43%). 35 patients (11%) reported smoking post-LTx of which 32 were transplanted for COPD (91%), 14 (4.2%) were current smokers. eCO was elevated in 23 patients of whom only 10 patients admit that they smoke.

Second-hand smoking was reported in 33% of the total population and 86% of the active smokers (78% had a smoking family member).

In the 35 patients admitting smoking post-LTx, 10 patients suffered from chronic rejection (28% compared with 25% of the total population) and solid tissue cancer was reported in 6 patients (17% compared with 7% of the total population) (p=0.03), median follow–up time in both groups is comparable. 11% of patients smoked after LTx, especially the COPD patients. There increased risk for de development of a solid tissue cancer. There is a discrepancy between the eCO and there questionnaire therefore combining with urinary cotinine seems to be necessary.

Use of immune cell function assay in immune surveillance of lung transplant recipients: Correlations with clinical outcome and other immune assays

Francesco Bini, Annmari Mäkinen, Riina Di Donato, Monica Mostromi, Tiberio Oggionni, Manuela Cova, Luisetti Maurizio, Federica Meloni. Haematological Pneumological & Cardiovascular Science - Section of Pneumology, University of Pavia & Foundation IRCSS Polliclinico San Matteo Pavia, University of Pavia, Italy

Introduction: Infection still remains a significant cause of morbidity after lung transplantation. The Cylex ImmunoKnow assay (IKA), provides a global assessment of CD4 T cell immune function to help monitor the immune reactive capacity of graft recipients. We use IKA in the immunological follow-up of lung recipients. We assess clinical utility of IKA and correlate its results with other immunological parameters.

Methods: IKA was always performed on clinical demand. From October 2008 to February 2012 we performed IKA on 110 samples. The values of CD4+ T cell activation were classified as strong (> 520 kc/s cell) and low (< 225). Than we correlated a subgroup of 74 IKA samples with CD4+ cells, CD8+ cells, ratio CD4+/CD8+, NK cells, CD4+CD25hiCD127low cells in blood and BAL.

Results: High correlation between lower values and the occurrence of infectious episodes was observed (p<0.05).

Number of infections and IKA levels

<table>
<thead>
<tr>

</tbody>
</table>

Instead, no correlation was found with the biopsy confirmed diagnosis of acute rejection.

Values of IKA did not correlate with levels of tacrolimus (P=0.8).

Similarly, only a trend toward an inverse relationship was present with CD4+ cell counts.

As for Treg cells counts, again no significant correlation was present.

Of note in 81% of low IKA results, the test was the basis of a change in the immunosuppressive regimen.

Conclusion: IKA values are helpful in identifying patients at high infectious risk and can be used to adapt IS regimen to patient need.

**P2442**

Effect of the type of end-stage lung disease on postoperative evolution of lung transplantation patients

Marc Brosseau, Thomas Vandemoorte, Charles Poirier. Department of Medicine (Respirology Division), Centre Hospitalier de l’Université de Montréal (CHUM), Montreal, QC, Canada

Introduction: The postoperative period is a critical time in lung transplantation. It has already been established that the type of end-stage lung disease has an impact on the survival benefit after lung transplantation. However, the specific aspects of postoperative evolution such as mechanical ventilation duration (MVD), intensive care unit length of stay (ICU LOS), and hospital LOS have not been extensively studied.

Methods: We reviewed the experience in our center through a retrospective chart analysis of 201 patients who underwent lung transplantation from 2004 to 2010. We investigated if the MVD, ICU LOS, hospital LOS and the need for a tracheotomy LTx has been shown to be associated with bronchial anastomosis healing complications. We hypothesized that, in select LTx recipients, sirolimus due to its antiproliferative properties and minimal side effect profile when begun within the first post-operative month is safe and associated with a favourable short and long term outcome.

Materials and methods: Between December 2004 and October 2011, 62 LTx were performed in a single institution. Ten patients (16.1%) mean age 46.9±11.9 years old were selected to received early sirolimus based immunosuppression regime along with cyclosporine and prednisone with all receiving induction immunosuppression. Patients were selected to receive early sirolimus based on an uncomplicated post-operative course and decisively after bronchoscopic assessment.

Results: Sirolimus was begun on mean POD 20.5±5.4 (14-32). In hospital/30-day mortality was 0%. On-long term follow up 3 patients died, 2 due to bacterial infection and in one patient PCT infection. Mean survival was 3.6±1.9 years (1.1 – 6.9), 1-year survival was 90% and 5-year survival was 75%. In 4 patients (40%) sirolimus was stepped, in 3 due to infection and in one because of re-transplant. None of the patients displayed BOS based on FEVI. In the patients still taking sirolimus renal function was within normal range. The study patients did not suffer increased rate of bacterial, PCT or CMV infection when compared to standard immunosuppression patients.

Conclusion: Contradictive to previously published studies, our results show that early sirolimus based immunosuppression is safe and is associated with a beneficial side-effect profile.
are related to the underlying end-stage lung disease. We analyzed the data with
descriptive statistics to identify differences between subgroups. Access to medical
cards was granted by the Research Ethics Committee.

**Results:** Our results show that Idiopathic Pulmonary Fibrosis (IPF) patients have
much longer MVD, ICU LOS and hospital LOS; require more tracheotomies and
have higher mortality in the postoperative period when compared to other
end-stage lung diseases (Table 1).

**Conclusion:** Patients with IPF have longer ICU LOS and this seems to be related
to longer MVD. Further research could address methods of improving weaning
from mechanical ventilation in these patients.

**Background:** Non-cystic fibrosis bronchiectasis (nCFBr) is an infrequent indication for lung transplantation and poorly described compared to CF and COPD. We describe our experience in the largest series to date.

**Methods:** Retrospective review of case-notes and transplant databases from 1990 to 1999 (22 years). Two time cohorts were set (1990-2000 and 2001-present date).

**Results:** 43 patients with nCFBr underwent lung transplantation at our centre. 42 patients had bilateral lung and one had heart-lung transplantation. Median age at transplant was 48 years. Mean pre-transplant FEV1 was 22% predicted (range, 10%-49%; n= 38). At assessment 84% (32 of 38 complete datasets; p=0.02) were surviving 1 year post-transplant. More patients were transplanted in the first cohort (n=26 vs. n=17). Mean pre-transplant FEV1 (% of predicted) was similar in both time cohorts (21% vs. 23%; p=NS) though patients transplanted in 1990-2000 were younger (mean: 45 vs. 51 years, p=0.026). Our survival rates were 74% at 1 year, 64% at 3 years, 61% at 5 years and 48% at 10 years. Infection and multi-organ failure were common causes of death within 1 year pre-transplant.

**Conclusions:** P aeruginosa infection is not universally seen in our cohort. Our sur-

**Neurocognition in airway pathogens during the first year after lung transplantation: A single center experience**

**Zuzanna Kowalska,** Zoltan Suto, Gabriella Murakozy, Aniko Bohacs, Csaba Vajai, Kornzina Creebe, Gyorgy Losonczy, Veronika Muller. Department of Pulmonology, Semmelweis University, Budapest, Hungary

After lung transplantation (LuTx) high level of immunosuppression is needed to prevent rejection, which makes recipients more susceptible to infections. Pul-

**Results:** 13 patients (6 LuTx, 7 new LTx) were included in the univariate and multivariate analysis. Pneumonia infections are a major clinical problem during the first postoperative year and regular surveillance examinations and immediate adequate treatment is mandatory. As seasonality of respiratory tract infections is well known in chronic pulmonary diseases, we assessed pathogen spectrum and number of infections in the first postoperative year in LuTx recipients.

**Airway pathogens registered during the first posttransplant year in 16 Hungarian LuTx patients (underlying disease: cystic fibrosis: 8, interstitial lung disease: 4, obstructive lung disease: 3, primary pulmonary hypertension: 1) were analyzed. Microbiological samples were taken from upper and/or lower respiratory tract and serum as part of the routine care. Number of positive samples was analyzed according summer (S=March to August) and winter (W=September to February) period.

A total of 107 infections were registered during the first posttransplant year. The

**Conclusions:** More frequent pathogens were Gram negative bacteria (n=43) and fungi (n=39). Total number of respiratory infections in S were significantly less frequent as compared to W (S=49, W=61), including Gram positive: S=25, W=41; Gram neg-

### P2446

**Microbiological impact of regular colistin use in a population of lung transplant recipients**

**Mohamed Al-Aloul,** Bashar Al-Shelhky,® Jamal Salal,® Barbara Isalska.®

**1Transplant Unit, Wythenshawe Hospital, Manchester, United Kingdom; 2Department of Microbiology, Wythenshawe Hospital, Manchester, United Kingdom**

**Aim:** To describe the results of regular colistin use in our LT recipients and we now present its impact on microbiological surveillance.

**Population:** 3 groups between June 2005 and December 2011. Gp1: IV colistin for new and past LTxs with confirmed or suspected gram negative infection not responding to treatment with tazorin (n=171). Gp 2: Prophylaxis in CF recipients with previous Pa to prevent/delay graft colonisation (n=32): colistin/TobI nebs alternate months for 1 year then withdraw.

Long term outcomes of lung transplantation (LTxs) are partly limited by infection. Due to increasing prevalence of multiresistant Pseudomonas aeruginosa (Pa) iso-

**Methods:** Use of noninvasive ventilation in the early postoperative period of lung transplantation (LT) for new and past LTxs with confirmed or suspected gram negative infection not responding to treatment with tazorin (n=171). Gp 2: Prophylaxis in CF recipients with previous Pa to prevent/delay graft colonisation (n=32): colistin/TobI nebs alternate months for 1 year then withdraw. Gp 3: Eradication of new Pa isolates in Pa naive recipients (n=29): 2 weeks of IV B-lactam+colistin followed by 3 months of nebulised colistin. Gp 2 and 3 had sputum/bronchial lavage tested 3 monthly for 1 year after treatment.

**Results:** Gp1 – 443 courses of IV colistin, median dose 3 mg/day for a median 16 days; pathogens were confirmed in 69%. Gp2 – continued growth, no growth and
Prevalence and outcome of donor transmitted Acinetobacter baumannii in acute rejection or initiation of acute rejection therapy within 3 months.

Eid Almutairy, Naseer Alshekaily, Basha Khan

Lung transplant recipients (LTR) are at risk of respiratory viral infection (VI). Our goal was to characterize clinical factors associated with upper or lower respiratory tract VI, as well as the relation between VI and acute graft rejection (AR) in a cohort of LTR patients.

Methods: LTR patients (n=112) from Lausanne & Geneva University hospitals had systematic nasopharyngeal swabs (NPS) and when indicated bronchoalveolar lavage (BAL) with transbronchial biopsy (N visits=903). We screened 18 distinct respiratory viruses with rt-PCR during: a) seven 6-week investigator-driven screening period (n=570), b) regular (n=124) and c) emergency visits (n=209).

Results: During follow-up, 172/903 VI (19%) were identified in 68/112 (61%) LTRs with 34/276 infected BAL and VI rate was highest during emergency visits (p<0.01).

P2447 Incidence of viral infections in patients with lung transplantation Pierre-Olivier Bridevaux1, John-David Aubert1, Paola Soccal1, Thierry Rochat1, Laurent Kaiser1, 2Pulmonary Division, University Hospitals, Geneva, Switzerland; 2Pulmonary Division, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Background: LTRs are at risk of respiratory VI. Our preliminary study shows basiliximab induction reduces incidence of acute rejection without significantly increasing the risk of CMV and invasive fungal infections.

Methods and patients: In an ongoing prospective study 28 clinically stable lung transplant recipients (16 male, age 54±8.4 years, BMI 25.5±4.1 kg/m², range 6 months to 9 years after transplantation) were screened for SDB by the Berlin Questionnaire and the Stop Bang Questionnaire. These results were compared to in-lab polysomnography (PSG). Diagnostic accuracy of both questionnaires was compared to gold standard PSG using a cut-off AHI of 10/h as definition for SDB.

Results: The prevalence of SDB was 57%. Sensitivity and specificity for the Berlin Questionnaire and the Stop Bang Questionnaire were 85% and 30%, respectively. The corresponding values for the Stop Bang Questionnaire were 8% and 80%, respectively. The corresponding values for the Berlin Questionnaire were 85% and 30%.

Conclusion: The diagnostic accuracy of the Berlin Questionnaire and the Stop Bang Questionnaire is high in order to identify patients with SDB in a lung transplantation population.

P2451 Kf determination after ischemia-reperfusion in lungs treated with sildenafil and tadalafil

Raúl Guerra, Carlos Bravo, Nadezdha Aguilar, Diana Aguilar, Patricio Santillán

Background: Donor transmission of organism to the lung transplant recipient is a known entity. The shortage of ideal donors and the increasing pool of lung transplant candidates is increasing the pressure to utilize extended donors. Large number of our donors have been on ventilator for extended period of time, hence bringing the risk of nosocomial infections. We describe our experience with acinetobacter baumannii pneumonia in the lung transplant patients.

Methods: Retrospective chart review of all the patients transplanted between March 2010 and August 2011. The patients with acinetobacter baumannii pneumonia transmitted from donors were compared to those not affected by such infections. The primary graft dysfunction, duration of mechanical ventilation, ICU length of stay, acute kidney injury and mortality were measured.

Results: A total of 18 patients underwent lung transplant during this period. There were 8 male and 10 female recipients. A total of 6 patients developed acinetobacter baumannii multdrug resistant pneumonia. The primary graft dysfunction was severe in all patients. median duration of mechanical ventilation was 14 vs. 2; median ICU length of stay was 19.5 vs. 6.5; acute kidney injury was 33% vs. 41% and mortality was 33% vs. 8% in the acinetobacter vs. non-acinetobacter group.

Conclusion: Infection of acinetobacter baumannii in respiratory culture from donor lungs was associated with worse outcomes in transplanted patients as compared to donor lungs without acinetobacter. Antibiotic coverage should be tailored to include this organism when suspected as soon as possible. Also a method for rapid identification of acinetobacter baumannii is needed.
263. Management of severe respiratory infections

P2453
Comparison of treatment outcomes in community-acquired pneumonia patients treated with beta lactam-macroide combination versus fluoroquinolone monotherapy

Oguz Kilinc1, Ozan Soyay2, Aykut Cilir2, Ayisn Sakar3, Sezai Tasbakan4, Hulya Ellidokuz5, Burcu Celek6, Cemil Cemikaya7, Canan Gunduz4, Abdullah Seyin1.

Chest Diseases, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey; 2Chest Diseases, Akdeniz University Faculty of Medicine, Antalya, Turkey; 3Chest Diseases, Celal Bayar University Faculty of Medicine, Manisa, Turkey; 4Bone Diseases, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey; 5Biostatistics, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey.

The clinical outcomes of patients with community-acquired pneumonia treated in accordance with the recommendations of Turkish Thoracic Society (TTS) guidelines and who had received beta-lactam-macrolide combination or fluoroquinolone (FQ) monotherapy were evaluated using the data from four contributing sites to the TURCAP database of TTS Assembly of Respiratory Infections. A total of 343 patients was included. Of these patients, 63.6% had received combination treatment and 36.4% had received FQ monotherapy. There was no difference between the two groups regarding age, gender and comorbidities. However, the mean Pneumonia Severity Index (PSI) scores were 101.8±35.8 and 91.0±28.9 (p=0.006) and CURB-65 scores were 2.3±1.0 and 2.0±0.8 (p=0.002), respectively. The length of hospital stay was 9.5±6.1 days in the combination and 8.3±4.4 days in the FQ group (p=0.24). The rates for cure, partial improvement and mortality were 59.1%, 28.2% and 12.8% for the combination group versus 72.6%, 24.2%, 3.2% for the FQ group, respectively. There was no significant difference between the two groups in terms of improvement rates; on the other hand, the mortality was higher in the combination group (p=0.03).

Conclusion: Regression analysis showed that mortality was associated with PSI score and not with the choice of antibiotic treatment. In this retrospective analysis of TURCAP database, the clinical success rates were similar in patients who received a combination of beta lactam and macrolide and fluoroquinolone monotherapy. The lower mortality observed in the latter group was found to be associated with less severe disease at presentation.

P2454
Pharmacokinetics and pharmacodynamics of newer fluoroquinolones in patients with lower respiratory tract infections

Paschalina Kontou1, Kalliopi Chatzika2, Katerina Mamika3, Georgia Pisis1, Maria Stionoudo1, Ioannis Kiosiou1,2,3,4, ICU, G. Papandreou Hospital, Thessaloniki, Greece; 2Pharmacokinetics Laboratory, Pulmonary Department, Aristotle University, Thessaloniki, Greece; 3Pulmonary Department, Aristotle University, Thessaloniki, Greece

Introduction: Levofloxacin (LVF) and moxifloxacin (MXF), have been recommended as first line therapy for patients with acute exacerbations of chronic bronchitis and community-acquired pneumonia. Aim: The aim of this study is to evaluate the pharmacokinetic (PK) and pharmacodynamic (PD) parameters of LVF and MXF for lower respiratory tract infections (LRTI).

Methods: Eighteen patients (2 groups of 9, aged 69.6±8.7 and 74.8±8.8) with LRTI received 500 mg LVF IV q12h or 400 mg MXF IV q24h. Serial blood samples were obtained at steady state condition (3rd day of therapy). Plasma concentrations were determined by a validated HPLC method. The PD target was evaluated for both antibiotics based on our hospital’s MIC90 of the most common respiratory pathogens.

Results: The PK data are presented in Table 1.

Table 1: PK data

Conclusions: LVF and MXF exhibit a favorable PK profile in patients with LRTI. There is adequate PD exposure against most strains of S. pneumoniae, H. influenzae and M. catarrhalis with low MICs.

P2455
Combination therapy (beta-lactam-macroide) vs fluoroquinolone monotherapy for the treatment of CAP

Charalampos Triantafylidis1, Vasiliis Kapardelis1, Elissavet-Christina Philippidou1, George Papaefis1, Maria Apostolidou1, Ioannis Nikolopoulos2, Dora Orlandou1, Angelos Pefanis1, 3rd Department of Internal Medicine, Medical School, National and Kapodistrian University of Athens, Attica, Greece; 2Centre for Respiratory Failure and Intensive Care Unit, “Sotiria” General Hospital for Thoracic Diseases, Athens, Attica, Greece; 31st Department of Respiratory Medicine, Kavala General Hospital, Kavala, Greece

Background: According to the 2007 IDSA/ATS guidelines for the treatment of CAP monotherapy with fluoroquinolones is the first choice and combination therapy remains an alternative treatment option. Combination therapy was the first recommended treatment option by the 2003 IDSA update of practice guidelines for the treatment of CAP.

Aim of study: The aim of this study was to assess whether any of the two proposed alternative treatment options for CAP is statistically superior and related with advanced clinical course.

Material and methods: A prospective observational study which incorporated 300 immunocompetent adults, who referred to the ER of “Sotiria” General Hospital for Thoracic Diseases and after diagnosed with CAP, were all hospitalized.

Results: 250 patients (83.3%) received combination therapy and 50 patients...
(16.67%) received monotherapy with fluoroquinolone. 235 (94%) out of the 250 patients who received combination therapy had a favourable clinical course (survived) and 15 (6%) had an unfavourable clinical course (died). 42 (85%) of the 50 pts who received monotherapy with fluoroquinolone survived and 8 (15%) of them died. The mortality rate of the second group was significantly higher than the mortality rate of the first group (15% vs 6% respectively, p=0.033).

**Conclusion:** The mortality rate of hospitalized patients with CAP receiving monotherapy with fluoroquinolones was significantly higher compared to patients receiving combination therapy. There are a few other studies supporting these results and one possible explanation could be the immunomodulating activity of macrolides, which is verified but still a field of detailed, extended and persistent investigation.

**P2456**

Tolerance of nebulised gentamicin in adult bronchiectasis – A single centre study

Jonathan Miller, Hilary Tedd, Sunny Syba, Helen Groves, Anthony De Soyza.

Adult Bronchiectasis Service, Freeman Road Hospital, Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

**Background:** British Thoracic Society non CF bronchiectasis (nCFBr) guidelines suggest that long-term nebulised antibiotics should be considered in patients with more than 3 exacerbations per year. Nebulised gentamicin reduces bacterial load and exacerbations in nCFBr. Adverse effects can occur with aerosolised delivery of antimicrobials and so limit their use. We studied the tolerability of nebulised gentamicin in a real world population

**Methods:** We measured spirometry in nCFBr patients challenged with 80mg of nebulised gentamicin, at baseline, 1min, 5min, and 10min post nebulised gentamicin, assessing short term tolerability and benefits were assessed

**Results:** Forty-two patients (19male:23female) were enrolled Feb 10-Dec 2011. Mean age was 60yrs (range 17-77). Colonisation with *Pseudomonas aeruginosa* and *Staphylococcus aureus* was seen in 17(40%), 11(26%) and 4(9%) patients respectively. Mean baseline FEV1 was 1.48L(min 0.56 pred), range 0.3-3.7L/min (16-108% pred). Mean FEV1 was preserved at 1min (1.45L/min), 5min (1.52L/min) and 10min (1.53L/min) post nebulised gentamicin. There was no difference between pre-dose and 10min post-dose FEV1 (p>0.05). One patient was unable to tolerate the nebulised challenge due to fall in FEV1 and symptoms. Long-term, 8 patients (19%) were unable to tolerate nebulised gentamicin due to side effects. It was stopped in 5 patients (12%) as they did not report benefits

**Conclusions:** These data show nebulised gentamicin is well tolerated in acute challenges even in patients with severe airflow obstruction but long-term adherence declines. We aim to present microbiological data. The utility of acute challenge studies remain unclear in predicting longer term tolerability.

**P2457**

An audit of microbiological investigations performed on patients admitted with community acquired pneumonia

Lois Wilson, JM Sloan, C.L. Griffin, M.E.M. Wilkie, J.D. Chalmers, S. Schembri. Respiratory Department, Ninewells Hospital, Dundee, United Kingdom

**Introduction:** The British Thoracic Society (BTS) guidelines suggest that blood and sputum culture be performed in patients with moderately severe community-acquired pneumonia (CAP). Atypical testing and viral PCR are recommended in severe CAP. The aim was to identify whether the appropriate microbiological investigations are being performed on patients with CAP.

**Method:** This was a retrospective audit. CAP was defined as a clinical diagnosis of pneumonia in a patient with a new radiographic infiltrate. Microbiology investigations performed in CAP patients were compared against the same data collected in 94 CAP patients in 2008. The 2009 BTS guidelines served as the audit standard.

**Results:** 210 patients were included. 55% had blood cultures taken, with bacteremia confirmed in 15 patients. This compared with 70% having blood cultures in 2008, p=0.02. 16% (34) had sputum culture compared with 25% (24) in 2008, p=0.06.

11% had legionella antigen analysis compared with 16% in 2008. 10% had atypical serology carried out in 2011 and 22% in 2008. 12% had viral PCR compared to 5% in 2008.

In total, only 2.4% of patients had all of the recommended microbiology investigations (2.1% in 2008). 35.2% had no microbiology testing (21% in 2008, p=0.02).

**Conclusions:** Recommended microbiology investigations are underutilised in CAP patients at our centre. There has been a reduction in microbiological testing in comparison with 2008 figures.

**P2458**

Management of community acquired pneumonia (CAP) in a UK district general hospital (DGH)

Usman Maqsood1, Nawaid Ahmad2. 1Acute Medical Unit, Solihull Hospital, Birmingham, United Kingdom; 2Respiratory Medicine, New Cross Hospital, Wolverhampton, United Kingdom

**Background:** Although there are published BTS guidelines [Thorax 2009;64(Suppl III)] for the management of CAP, its practice across UK hospitals is variable and at times lacking; in achieving satisfactory outcomes.

**Objectives:** To audit the management of patients admitted with CAP in a UK DGH.

**Method:** A retrospective audit was undertaken between the periods covering 01/10/2010-31/08/2011. We included all patients admitted through the emergency or community referral system with a radiological diagnosis of pneumonia. We excluded patients who were immunocompromised or under 16 years of age.

**Results:** A total of 56 patients (59% female; n=33) were included. CURB-65 score was documented in 20% (n=11). With regards to anti-microbial treatment, 12.7% (n=7) patients were given B-lactam alone, 76.3% (n=42) were given B-lactam + Macrolide, 10.9% (n=6) were given Levofloxacin and one patient each received either Meropenidazole or gentamycin. Time between diagnosis and first dose of antibiotic was greater than 4 hours in 57.3% (n=32) patients. 27% (n=15) patients received antibiotics against the published local guidelines (local guidelines followed BTS guidelines). Total length of stay varied from 0-101 days with a median of 7.5 days. There were 6 deaths within 30 days of discharge, of which 2 died on admission.

**Conclusions:** Despite guidelines, there was poor documentation and recognition of the severity of CAP. There was deviation from recommended prescribing, hence risking emergence of resistant strains. Many patients received antibiotics beyond the recommended time window. Therefore, hospitals need to make sure that guidelines are being followed, in order to achieve further reduction in morbidity and mortality.

**P2459**

Resistance of problematic Gram(-) respiratory pathogens selected from in-patients (Yaroslavl, Russia, 2011)

Shamil Fulvatin, Ilya Zibler, Svetlana Monakhova, Svetlana Angelova, Marina Ershova, Galina Abrosimova, Elena Poletoeva, Alexander Petrochenko. Clinical Pharmacology, Yaroslavl State Medical Academy, Yaroslavl, Russian Federation

**Pulmonology, Clinical Hospital #2, Yaroslavl, Russian Federation
Clinical Microbiological Laboratory, Infectious Clinical Hospital #1, Yaroslavl, Russian Federation

**Background:** The problem of the spread of resistant Gram(-) agents becomes more urgent. These changes in the respiratory pathogens in hospitals create difficulties in antibiotic therapy and lead to increase of patients’ lethality and the burden for general healthcare.

The aim of our study was to assess the prevalence of resistance of the problematic Gram(-) pathogens in hospitalized patients.

**Methods:** Pathogens were isolated from hospitalized patients in Yaroslavl. The selection of pathogens and the determination of resistance was performed centrally in the microbiological laboratory (NCCLS standards, disc-diffusion method).

**Results:** In 2011 in the city’s hospitals 98 strains of *Pseudomonas aeruginosa*, 71 - *Acinetobacter* spp were allocated from respiratory tract in hospitalized patients. Resistance of *P. aeruginosa* was extremely high practically to all drugs, including carbapenems. The only exception was polymyxin (all strains were sensitive). The average rate of resistance was 39.2%. Resistance *P. aeruginosa* to piperacillin/tazobactam, cefoperazone/sulbactam, imipenem, meropenem, ciprofloxacin, gentamycin, amikacin was 51, 48, 48, 49, 54, 47 and 48% respectively. At a time, 99% of strains were sensitive, meropenem - 94%.

**Conclusions:** Most of the strains of *P. aeruginosa* and *Acinetobacter* spp show high resistance to antimicrobial agents. The greatest concern is the resistance to carbapenems in *Pseudomonas aeruginosa*. 448s
Evaluating flutter device and the active cycle of breathing technique in non-cystic bronchiectasis: The prospective randomised study

Gandemir Aliyaz1, Bilge Uzmenezoglu1, Necdet Sun1, Hakan Tuna2, Osman Nur Hatipoglu3, 1Respiratory Medicine, Trakya University Hospital, Edirne, Turkey; 2Respiratory Medicine, Social Security Hospital, Edirne, Turkey; 3Department of Biostatistics, Trakya University Hospital, Edirne, Turkey; 4Departments of Physical Medicine and Rehabilitation, Trakya University Hospital, Edirne, Turkey

Background: Chest physiotherapy is an important part of the routine treatment of patients with bronchiectasis. The aim of present study was investigate the efficacy of two frequently used physiotherapies in bronchiectasis: active cycle of breathing (ACBT) techniques and the Flutter device.

Methods: A prospective randomized study was performed in 36 stable patients with non-cystic bronchiectasis at home, in which 4 weeks of daily ACTB (n=17) were compared with the Flutter device (n=19). We compared symptoms, pulmonary function tests, dyspnea scores and Health-Related Quality of Life with two different physiotherapy techniques.

Results: Expiratory cough and Weakness was reduced (respectively p=0.000, p=0.004), sputum expectoration was increased (p=0.002), dyspnea score was reduced (for Medical Research Council p=0.001, for Borg Dyspnea Scale p=0.002) and Short Form-36 ‘Physical Health’ component summaries score was produced (for Medical Research Council p=0.001, for Borg Dyspnea Scale p=0.002)

Conclusions: Chest physiotherapy is a effective method increasing sputum expectoration, reducing symptoms and dyspnea score and party improvement Health-Related Quality of Life. ACTB and Flutter techniques are suitable usage a home-based treatment.

P2461

RCT of chest physiotherapy versus chest physiotherapy and pulmonary rehabilitation in non cystic fibrosis bronchiectasis

Pallavi Mandal1, Manjit Suhur2, Lian Kope3, Wendy Pollock3, Lorna Stevenson1, Shelley MacQuarrie1, Joanna Pentland3, 1Department of Respiratory Medicine, Royal Infirmary of Edinburgh, United Kingdom; 2Respiratory Medicine, Royal Infirmary of Edinburgh, United Kingdom; 3Department of Physiotherapy, Royal Infirmary of Edinburgh, United Kingdom

Aim: To assess the efficacy of pulmonary rehabilitation(PR) in addition to regular chest physiotherapy in non-cystic fibrosis bronchiectasis.

Methods: Patients with bronchiectasis were invited to participate if their exercise tolerance was limited, due to bronchiectasis, from Edinburgh Bronchiectasis clinic, in a prospective study 15 received chest physiotherapy and 15 received PR-chest physiotherapy. Review was at baseline/4 weeks/8weeks/end of intervention and 20 weeks(completion of study). Outcome measures were improvement in incremental shuttle walking test(ISWT), endurance walk test(EWT), health related quality of life(HRQoL),St-Georges Questionnaire(SGRQ) and Leicester Cough Questionnaire(LCQ).

Results: Results are presented as mean(standard error). The minimum clinically important difference(MCID) for SGRQ and LCQ was 4 and 1.3 units respectively. Comparison of changes between the 2 groups was calculated using unpaired t-tests.

Conclusions: PR in addition to regular chest physiotherapy, improves exercise tolerance and HRQoL in bronchiectasis and the benefit was sustained at 3months post end of PR.

P2462

Unexpectedly high incidence of pneumothorax in patients with pulmonary Mycobacterium avium complex infection

Eri Hagiwara, Atsuhito Nakazawa, Tsuneyuki Oda, Takahiro Enomoto, Wendy Pollock3, Lorna Stevenson1, Shelley MacQuarrie1, Joanna Pentland3, 1Centre for Inflammation Research, QMRI, Edinburgh, United Kingdom; 2Respiratory Medicine, Royal Infirmary of Edinburgh, United Kingdom; 3Department of Physiotherapy, Royal Infirmary of Edinburgh, United Kingdom

Aims: To assess the effectiveness of inhaled colistin in elderly patients with non cystic fibrosis bronchiectasis (CF) bronchiectasis in chronic bronchial infection with pseudomonas aeruginosa, where there is limited evidence for elderly patients

Methods: Prospective, controlled, randomized and open. We included patients with HRCT diagnosed bronchiectasis, after an acute exacerbation admission and appropriate antimicrobial therapy. We collected data on demographics, clinical and functional characteristics, admissions and sputum microbiology. We followed the patients for one year, evaluating microbiological results, functional tests, readmissions and exuhs.

P2463

Effects of nebulizer therapy by hypertonic saline, gender and breastfeeding on evolution of acute bronchiolitis

Ekaterina Kutsia, Tina Ghonghade, Tamaz Zhorzhialian. PICU, M.Ashvili Children’s Central Clinic, Tbilisi, Georgia Infant’s Department, G. Zhvania Pediatric Clinic, Tbilisi, Georgia

Acute bronchiolitis is most common viral infection of lower respiratory tract in infants. In 90% it is caused by respiratory syncytial virus. The incidence of pneumothorax in patients with pulmonary MAC infection was as high as 2.4% (18 out of 746 all MAC patients), 2.1% in female and 3.0% in male patients.

Conclusions: The incidence of pneumothorax in patients with pulmonary MAC infection is unexpectedly high, especially in elderly, male, and progressed MAC disease. It is often difficult to treat and to easy to recur.

P2464

Inhaled colistin in elderly patients with bronchiectasis and chronic bronchial infection with pseudomonas aeruginosa

Eva Tabernero1, Ramon Alizka1, Pilar Gil1, Javier Garros1, David Cantero, Juan L. Artola1, Luciano Ramos. 1Pneumology, Hospital Santa Marina, Bilbao, Spain; 2Dermatology, Hospital Galdakao, Galdakao, Spain

Bronchiectasis is the end result of several different illnesses and a frequent cause of admission in hospitals for elderly people and chronic diseases. Although many guidelines recommend treatment with inhaled antibiotics in non cysitic fibrosis (CF) bronchiectasis in chronic bronchial infection with pseudomonas aeruginosa, there is limited evidence for elderly patients

Aims: To assess the effectiveness of inhaled colistin in elderly patients with non CF bronchiectasis and chronic bronchial pseudomonas infection

Methods: Prospective, controlled, randomized and open. We included patients with HRCT diagnosed bronchiectasis, after an acute exacerbation admission and appropriate antimicrobial therapy. We collected data on demographics, clinical and functional characteristics, admissions and sputum microbiology. We followed the patients for one year, evaluating microbiological results, functional tests, readmissions and exuhs.
Results: We included 25 patients, 13 treated with inhaled colistin and 12 in control group. Four patients stopped the treatment because of adverse effects. Main results are shown in the table.

*Statistically significant.

Conclusions: Significant more patients in the treatment group achieved Pseudomonas eradication; but we could not demonstrate clinical or functional benefits in our elderly patients. These results may be due to small sample size. Side effects were frequent.

P2465

Changes in the lower airway bacterial community of from adult non-CF bronchiectasis population are significantly associated with exacerbations and the presence of *Haemophilus influenzae*

Paul Purcell1, Stephen Cummings1, Hannah Jary1, Anthony De Soyza1

Tyne, Tyne & Wear, United Kingdom;1Department of Respiratory Medicine, Freeman Hospital, Newcastle upon Tyne, Tyne & Wear, United Kingdom;2Department of Microbiology, Freeman Hospital, Newcastle upon Tyne, Tyne & Wear, United Kingdom;3Department of Respiratory Medicine, Telemark University College, Buskerud, Norway.

Background: The aim was to investigate the polymicrobial communities in sputum samples derived from an adult non cystic fibrosis bronchiectasis (nCFB) population using culture independent methods. The cohort consisted of 70 individuals with HRCT proven nCFB. Twenty patients presented at the clinic for sputum collection with symptoms consistent with exacerbations, the remainder were clinically stable.

Methods: DNA was extracted from sputum samples of all patients (n=70). Universal primers for 16S and 28S rDNA, the resulting fragments were analysed by denaturing gradient gel electrophoresis. Demographic and culture data were used in constrained ordination analyses to identify any significant association between these data and changes in the sputum microbiota.

Results: The microbiota was significantly correlated with a reduced lung function. Bacterial profiles indicated a significantly different community was present in exacerbating patients compared to those that were clinically stable (P = 0.0002). *H. influenzae* carriage also produced significant changes (P = 0.004) in community structure. Moreover, *H. influenzae* was never found in samples that harboured *P. aeruginosa*. Bacterial communities appeared to be randomly assembled. Fungal taxa were scarce.

Conclusions: Bacterial communities from adult non-CF bronchiectasis patients have distinct differences between exacerbating and clinically stable episodes. Persistent colonisation by *Haemophilus influenzae* is significantly associated with reduced lung function, and is negatively correlated with *H. influenzae* carriage.

P2466

Rapid detection of *Mycoplasma pneumoniae* IgM antibodies using ImmunoCard Mycoplasma kit compared with complement fixation (CF) tests and clinical application

Ryuta Ueda, Juti Okamura, Yasushi Inoue, Taichi Mochizuki, Tetsuo Sato.

Respiratory Medicine, JUHM Mita Hospital, Tokyo, Japan.

Purpose: *Mycoplasma pneumoniae* is a leading cause of community-acquired pneumonia. For a rapid diagnosis of *M. pneumoniae* infection, we often use ImmunoCard Mycoplasma kit (IC), a 10-min-card-based enzyme-linked immunosorbent assay (ELISA) for IgM antibodies to *M. pneumoniae*. However, widespread clinical application of this test is hampered by an inability to identify pathogen directly with adequate sensitivity and specificity. Therefore, we examined the clinical usefulness of IC test retrospectively.

Method: We evaluated 316 samples which were measured by IC from October,2008 to March,2009. We also compared IC with the complement fixation (CF) test, and estimated false positive and negative rate based on the clinical course and other laboratory findings.

Results: Among 316 samples, 69 (21.8%) were positive of IC and 247 (78.2%) were negative. Sixteen cases were also measured by CF test with the paired serum, and in 5 (31.3%) cases of these, there was a discrepancy between the result of IC and that of CF test. On the basis of a clinical diagnosis, IC gave the false positive rate of 80.0%, false negative rate of 31.3%.

Conclusions: IC has so far been attributed to the rapid diagnosis of *M. pneumoniae* infection because it is unnecessary to use paired serum and possible to judge the infection rapidly. But a positive result of IC does not always indicate acute infection because the result of IC were not always concordant with that of CF test. According to our results, it seems that the interpretation of the result of IC is very difficult in order to use it clinically.

P2467

Legionella pneumonia in patients hospitalized with community-acquired pneumonia (CAP) in Norway

Wenche Royault1, Øystein Simonsen2, Andrew Jenkins3, Marit Sarjoma4, Yngvar Iverton5, Eivind Ragnhildsdottir5, Martin Veil Svensden5, Anita Kanestrøm5, Halfred Waage5, Jetmund Ringstad2,1Department of Occupational and Environmental Medicine, Telemark Hospital, Skien, Norway; 2Department of Medical Microbiology, Unlabs Telelæsb, Ask, Skien, Norway; 3Faculty of Art and Sciences, Telemark University College, Buskerud, Norway; 4Clinic of Internal Medicine, Telemark Hospital, Skien, Norway; 5Department of Medical Biochemistry, Telemark Hospital, Skien, Norway.

Background: The aim was to investigate the frequency of *Legionella pneumonia* among hospitalized CAP-patients in Norway.

Methods: Adult patients with radiologically confirmed CAP were prospectively included at the main acute care hospitals of two counties in Norway (Telemark and Østfold) during a 20-month study period in 2007-2008. Microbiological analyses included culture of blood and sputum, urinary antigen testing for *Streptococcus pneumoniae* and *Legionella pneumophila* serogroup 1, real time polymerase chain reaction (PCR) of a throat swab for atypical agents, and serology for *L. pneumophila* serogroup 1-6.

Results: A total of 374 patients were included in the study. *Legionella pneumonia* was identified in 21 cases (6%). Eight cases were identified by a non-ICU department stay by urinary antigen testing, and 13 cases were identified later by serology, of whom four were classified as probable cases (single high convalescent titre). Three of the patients were part of a small outbreak of *Legionella* and another two patients probably were infected from the same source. Two of the patients may have been travel-associated. Otherwise, *S. pneumoniae* was the most common etiological agent detected (20%), followed by *Haemophilus influenzae* (6%).

Conclusions: *Legionella pneumonia* seems to be more prevalent than previously recognized in Norway, and testing for *Legionella* should be considered more frequently than currently practice.

P2468

Bronchiectasis in Auckland, New Zealand: Ethnic differences in severity

Anita Kanestrøm1,2, Halfrid Waage3, Jetmund Ringstad2.

Sciences, Telemark University College, Bø in Telemark, Norway; 3Department of Clinical Biochemistry, Telemark Hospital, Skien, Norway.

Introduction: Bronchiectasis is more prevalent in Maori and Pacific Islanders (PI) than Europeans. The aim of this study was to evaluate differences in severity and microbiology between ethnicities.

Methods: Records of 250 patients (66% female, mean age 62yrs, FEV1% predicted 64.6%) attending the bronchiectasis clinic at Auckland District Health Board were retrospectively reviewed. Demographic and clinical variables were recorded. Ethnicity was compared to NZ Department Statistics 2006 census data for central Auckland.

Results: PI (23%) and Maori (12%) are over-represented in this cohort; European (44%) and Asian (16%) under-represented. Mean FEV1%predicted was higher in Europeans (70.7%) than Maori (63%) and PI (54%), p < 0.001 and remained so when corrected for smoking status p<0.001. Similar statistically significant differences were seen in FVC%predicted. Maori patients were younger (mean age 56yrs) than PI (66yrs) and Europeans (66yrs), p=0.02. There was a trend to later diagnosis in Maori and PI compared to Europeans. 124 patients had at least one sputum sampled that year with Haemophilus 29%, Pseudomonas 13.7%, Aspergillus 4.8%, Pneumococcus 2.4% and non tuberculous mycobacteria 2.4%.

There was no significant difference in sputum microbiology by ethnicity. Conclusions: Maori and PI are over-represented in the bronchiectasis clinic and tend to be younger with more severe disease than other ethnicities. Disease severity is independent of smoking status, microbiology and gender suggesting other factors such as genetic susceptibility or socioeconomic status influence outcome.

P2469

Pneumonia and Clostridium difficile infection: Hospital acquired infection in a non-ICU department

María Carrabba1, Marina Zarrantonello1, Simone Formica1, Luca Mellace1, Silvana Castaldi2, Maria Domenica Cappellini1, Giovanna Fabio1.

1Internal Medicine, Università degli Studi & Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.

Introduction: European studies have reported that *Legionella pneumonia* accounts for 0-10% of the cases of CAP in hospitalized patients. In Norway, data on the etiology of CAP in hospitalized patients is limited, and *Legionella pneumonia* has been considered a rare disease.

Aim: To investigate the frequency of *Legionella pneumonia* among hospitalized CAP-patients in Norway.

Methods: Adult patients with radiologically confirmed CAP were prospectively included at the main acute care hospitals of two counties in Norway (Telemark and Østfold) during a 20-month study period in 2007-2008. Microbiological analyses included culture of blood and sputum, urinary antigen testing for *Streptococcus pneumoniae* and *Legionella pneumophila* serogroup 1, real time polymerase chain reaction (PCR) of a throat swab for atypical agents, and serology for *L. pneumophila* serogroup 1-6.

Results: A total of 374 patients were included in the study. *Legionella pneumonia* was identified in 21 cases (6%). Eight cases were identified by a non-ICU department stay by urinary antigen testing, and 13 cases were identified later by serology, of whom four were classified as probable cases (single high convalescent titre). Three of the patients were part of a small outbreak of *Legionella* and another two patients probably were infected from the same source. Two of the patients may have been travel-associated. Otherwise, *S. pneumoniae* was the most common etiological agent detected (20%), followed by *Haemophilus influenzae* (6%).

Conclusions: *Legionella pneumonia* seems to be more prevalent than previously recognized in Norway, and testing for *Legionella* should be considered more frequently than currently practice.

The antibiotic use for pneumonia treatment contributes to the worldwide spreading of Clostridium difficile infection (CDI). Among all hospital acquired infections, CDI is an emerging cause of hospital morbidity, mortality and costs. We investigated the prevalence of CDI acquisition rates in patients hospitalized with pneumonia and compared all causes of inhospital mortality among patients.
Aims and objectives:
To determine whether there are clonal strains within the non-CF bronchiectasis.

In total 50 non-CF bronchiectasis population in Northern Ireland.

(CibeRes, CB06/06/0028), Barcelona, Spain; 4Servicio de Enfermedades Elena Prina¹,², Miquel Ferrer¹,³, Eva Polverino¹,³, Catia Cilloniz ¹,³,

It is well-known that antibiotic therapy for pneumonia, mainly based on newer fluoroquinolones, b-lactams and macrolides, combined with high-dose or long-term use of proton pump inhibitors drugs increase the risk of CDI. Our data suggest that CDI could be a very common etiology of hospital acquired infection also in non-ICU and non-outbreak setting with low endemic rate.

P2470 Clonal typing of Pseudomonas aeruginosa strains in non-CF bronchiectasis
Maire Drane¹, Lan Wei², Deirdre Gilpin², Michael Tunney², Deirda Kennè³, Stuart Elborn1. 1Centre for Infection and Immunology, Queen’s University of Belfast, Ireland; 2School of Pharmacy, Queen’s University of Belfast, Ireland; 3Department of Microbiology, Health Protection Agency, London, United Kingdom

Introduction: Pseudomonas aeruginosa is the most clinically significant infecting organism in non-CF bronchiectasis.

Aims and objectives: To determine whether there are clonal strains within the non-CF bronchiectasis population in Northern Ireland.

Method: In total 50 Pseudomonas aeruginosa isolates from 26 patients were analyzed by pulse field gel electrophoresis (PFGE).

Results: There were 10 individual strains identified by PFGE band pattern after DNA macrorestriction. 350 isolates were unique novel strains from 5 separate individuals. There were two dominant strains in this cohort. BELFCITPA-1 in 14/50 isolates in 5 patients. 12/50 isolates in 7 patients were identified as BELFCITPA-5. Stable patients were found to have one strain per sample whereas there was greater diversity within the samples collected from patients with an exacerbation. 12 strains on average.

Conclusion: There are a number of common strains of Pseudomonas aeruginosa found in the sputum of non-CF bronchiectasis patients. Although there are at least 2 clonal strains identified in this small cohort, it is unclear whether this is because they are common environmental strains in the region or because of cross-infection between individuals.

P2471 C-reactive protein in community acquired pneumonia – Correlation with main clinical indices
Pavlina Nikolova¹, Yavor Ivanov¹, Nikolay Yanes², Iliana Pavlova³. 1Radiology, Plovdiv University Medicine and Pharmacy, Plovdiv, Bulgaria; 2Internal Medicine, Medicus Medical Centre, Plovdiv, Bulgaria

Background: C-reactive protein (CRP) has a significant role as a factor, correlating with main clinical indices of the community acquired pneumonia (CAP).

Aim: To evaluate the relationship between CRP-levels and main clinical signs of CAP – severity, length of stay, complications, outcome.

Results: At admission the levels of CRP were increased up to 434 mg/dl, mean value 83.41 mg/dl (normal range 0-5mg/dl). Most of the patients (54%) had score 3 concerning CURB65. Followed by 2 – 24% and 4 – 20%. 62% of them have had concomitant diseases, mainly cardiovascular – in 44% of the cases. The most frequent used antibiotic was ceftriaxone – in 92% of cases. 72% of the patients were treated with two antibiotics, 12% - with three. The duration of antibiotic treatment was average 7.2±1.69 d (from 5 to 12 days). The length of stay was 8.4 d (from 7 to 12 days). Significant relationship was established between CRP and: severity of CAP (CURB65 p<0,05, r=0,38, the duration of intravenous antibiotic treatment p<0,05, r=0,32; antibiotic prescription at leaving hospital day p<0,05; r=0,39; complications; length of stay p<0,05; r=0,30; outcome p<0,05; r=0,50.

Conclusion: CRP is a sensitive and reliable factor, correlating with the severity of CAP, length of stay and outcome.

264. Respiratory infections: prognosis and outcome

P2473 Prediction of prognosis in healthcare-associated pneumonia
Isao Inoue¹, Tadashi Ishida¹, Hirotsa A Tsubakawa³, Hiromi Tomita³, Seizo Kadowaki¹, Naoya Tanabe¹, Michiaki Mishima¹. 1Respiratory Medicine, Kobe University Hospital, Kobe, Japan; 2Respiratory Medicine, Kurashiki Central Hospital, Kurashiki, Japan; 3Respiratory Medicine, Kobe City Medical Center West Hospital, Kobe, Japan; 4Internal Medicine, Ono Municipal Hospital, Ono, Japan

Rationale: Healthcare-associated pneumonia (HCAP) is a new category of pneumonia. Since patients with HCAP are at risk for infection with drug-resistant pathogens and increased mortality compared to patients with community-acquired pneumonia (CAP), predicting their prognosis is an important issue in HCAP.

Purpose: To apply prognostic scoring systems of CAP (PSI, CURB-65 and Japanese A-DROP systems) in prospectively collected patients with CAP and HCAP.

Methods: Patients admitted in three educational hospitals in Japan were analyzed. Receiver operator characteristic curve (ROC) analyses were performed for the three scoring systems in CAP and HCAP. Further, better system was sought in HCAP.

Results: 927 cases with CAP (mean age 73.2 years) and 469 cases with HCAP (81.8 years) were enrolled. Compared to HCAP, CAP showed larger values of area under the curve (AUC) in all scoring systems (CAP vs HCAP: PSI 0.77 vs 0.64, CURB-65 0.76 vs 0.65, A-DROP 0.80 vs 0.65). To develop a better scoring system for HCAP, candidate factors for predicting prognosis were extracted by univariate analysis followed by stepwise method. By logistic regression analysis, serum value of albumin (Alb) was related to the prognosis. Each of AUC in prognostic ROC
Thrombocytosis is a marker of poor outcome in community-acquired pneumonia.

Elena Prina 1,2, Miquel Ferre 1,3, Ovatio Tavares Ranzani 1,4, Eva Polverino 1,5, Catia Cilfone 1,6, Encarnación Moreno 1,7, Josep Menesà 8, Beatriz Montull9, Rosario Menéndez 10, Roberto Cosenìni 11, Anton Ferre 11,12, Servies de Pneumologia, Institut del Tonus, Hospital Clinic, IDIIBAPS, Universitat de Barcelona, Spain; 2Emergency Medicine Department, IECCS Fondacion Ca Grupo, Ospedale Maggiore Policlinico, Milan, Italy; 3Centro de Investigación Biomédica en Red-Enfermedades Respiratorias, (CibeRes, CB06/06/0028), Barcelona, Spain; 4Respiratory Intensive Care Unit, Hospital das Clínicas, Faculdade de Medicina da Universidade de São Paulo, SP, Brazil; 5Servicio de Enfermedades Infecciosas, Hospital Clinic, IDIIBAPS, Barcelona, Spain; 6Servicio de Neumología, Hospital Universitario La Fe, Valencia, Spain

Background: Thrombocytosis, often considered a marker of normal inflammatory reaction of infections, has recently been associated with increased mortality in community-acquired pneumonia (CAP).

Methods: We evaluated 2,423 hospitalized patients with CAP. We excluded patients with immunosuppression, neoplasm, tuberculosis or haematological disease. The aim was to assess characteristics and outcomes of patients with CAP and thrombocytosis (platelet count $>400,000$ mm$^{-3}$) compared with thrombocytopenia (platelet count $<100,000$ mm$^{-3}$) and normal platelet count.

Results: Fifty-three patients (2%) presented thrombocytopenia, 204 (8%) thrombocytosis and 2,166 (90%) a normal platelet count. Patients with thrombocytosis were younger ($p<0.001$), while those with thrombocytopenia more frequently had chronic heart and liver disease ($p<0.001$ both). Patients with thrombocytosis more frequently presented respiratory complications such as complicated pleural effusion/empyema ($p<0.001$). Patients with thrombocytosis were more likely to be admitted due to chronic diseases ($p<0.001$), had a longer duration of mechanical ventilation ($p=0.001$) and ICU admission ($p=0.011$). Patients with thrombocytosis had longer hospital stay ($p=0.004$), higher 30-day mortality ($p=0.001$) and readmission rate ($p=0.001$) than those with a normal platelet count.

Conclusions: Thrombocytosis in CAP is associated with poor outcome, complicated pleural effusion/empyema. Therefore thrombocytosis in CAP should encourage us to rule out respiratory complications and could be considered for severity evaluation.

P2474

Thrombocytosis is a marker of poor outcome in community-acquired pneumonia

Elena Prina 1,2, Miquel Ferre 1,3, Ovatio Tavares Ranzani 1,4, Eva Polverino 1,5, Catia Cilfone 1,6, Encarnación Moreno 1,7, Josep Menesà 8, Beatriz Montull9, Rosario Menéndez 10, Roberto Cosenìni 11, Anton Ferre 11,12, Servies de Pneumologia, Institut del Tonus, Hospital Clinic, IDIIBAPS, Universitat de Barcelona, Spain; 2Emergency Medicine Department, IECCS Fondacion Ca Grupo, Ospedale Maggiore Policlinico, Milan, Italy; 3Centro de Investigación Biomédica en Red-Enfermedades Respiratorias, (CibeRes, CB06/06/0028), Barcelona, Spain; 4Respiratory Intensive Care Unit, Hospital das Clínicas, Faculdade de Medicina da Universidade de São Paulo, SP, Brazil; 5Servicio de Enfermedades Infecciosas, Hospital Clinic, IDIIBAPS, Barcelona, Spain; 6Servicio de Neumología, Hospital Universitario La Fe, Valencia, Spain

Background: Thrombocytosis, often considered a marker of normal inflammatory reaction of infections, has recently been associated with increased mortality in community-acquired pneumonia (CAP). Methods: We evaluated 2,423 hospitalized patients with CAP. We excluded patients with immunosuppression, neoplasm, tuberculosis or haematological disease. The aim was to assess characteristics and outcomes of patients with CAP and thrombocytosis (platelet count $>400,000$ mm$^{-3}$) compared with thrombocytopenia (platelet count $<100,000$ mm$^{-3}$) and normal platelet count.

Results: Fifty-three patients (2%) presented thrombocytopenia, 204 (8%) thrombocytosis and 2,166 (90%) a normal platelet count. Patients with thrombocytosis were younger ($p<0.001$), while those with thrombocytopenia more frequently had chronic heart and liver disease ($p<0.001$ both). Patients with thrombocytosis more frequently presented respiratory complications such as complicated pleural effusion/empyema ($p<0.001$). Patients with thrombocytosis were more likely to be admitted due to chronic diseases ($p<0.001$), had a longer duration of mechanical ventilation ($p=0.001$) and ICU admission ($p=0.011$). Patients with thrombocytosis had longer hospital stay ($p=0.004$), higher 30-day mortality ($p=0.001$) and readmission rate ($p=0.001$) than those with a normal platelet count. Multivariate analysis confirmed a significant association between thrombocytosis and 30-day mortality (OR 2.588 95% CI 1.502-4.460 $p=0.001$).

Conclusions: Thrombocytosis in CAP is associated with poor outcome, complicated pleural effusion/empyema. Therefore thrombocytosis in CAP should encourage us to rule out respiratory complications and could be considered for severity evaluation.

P2475

eCURB outperforms CURB-65 and A-DROP for predicting 30-day mortality in pneumonia

Barbara Jones 1,2, Jason Jones 1,2, Al Jephson 3, Naresh Kumar 4, Ben Briggs 5, Caroline Vines 6,7, Todd Allen 8,9, Nathan Dean 10, 11, Palmonary and Critical Care Medicine, University of Utah, Salt Lake City, UT, United States; 2Palmonary and Critical Care Medicine, Intermountain Medical Center, Murray, UT, United States; 5Medical Informatics, Kaiser Permanente, Pasadena, CA, United States; 9Emergency Medicine, University of Utah, Salt Lake City, UT, United States; 10Emergency Medicine, Intermountain Medical Center, Murray, UT, United States

Rationale: Severity assessment tools that use objective data available in the electronic medical record include CURB-65, eCURB, and A-DROP, an electronic version of CURB-65 using continuous variables (Jones et al. Chest. 2011;140:156-163). Our aim was to compare eCURB, CURB-65, and A-DROP versus 30-day mortality in a contemporary, emergency department pneumonia cohort.

Methods: We identified pneumonia patients by ICD-9 code plus code compatible radiograph in 7 emergency departments Dec 1, 2009-Dec 1, 2010. Patients with community-acquired pneumonia (CAP) and health-care acquired pneumonia (HCAP) were included. We extracted initial clinical features and triage information from the electronic medical record. We determined mortality from the Utah Population Database. Receiver operator characteristic (ROC) analysis of mortality was conducted.

Results: We studied 2394 patients. 30-day mortality was 3.5% for 2061 patients with CAP and 16.2% for 333 patients with HCAP. The table shows areas under the curve (AUC) versus 30-day mortality.

<table>

<td>0.83</td>
<td>0.75</td>
</tr>
</tbody>
</table>

Conclusion: eCURB outperformed CURB-65 and A-DROP for mortality prediction in patients with CAP. For HCAP patients, all mortality predictors performed poorly.
Background: The CURB-65 score predicted hospital mortality better than IDSA/ATS minor criteria in low-mortality-rate settings is not clear. The purpose of this study was to determine the speculation.

Methods: 1230 adult patients admitted to our hospital from 2005 to 2009 for CAP were reviewed retrospectively.

Results: The hospital mortality was 1.3%. Percentage mortality increased significantly with CURB-65 score and the increasing number of IDSA/ATS minor criteria present. The number of CURB-65 criteria or IDSA/ATS minor criteria patient had significant increased odds ratios for mortality of 7.547 and 2.711, respectively. The sensitivities of a CURB-65 score of ≥ 3 and the presence of at least 3 minor criteria in predicting mortality from CAP was only 25% and 37.5%, with specificities of 92.2% and 96%, respectively. However, the sensitivities and specificities of a CURB-65 score of ≥ 5 and the presence of ≥ 2 minor criteria were 75% and 62.5%, and 91.8% and 86.5%, respectively. The area under the receiver operating characteristic curve for CURB-65 was 0.915 for predicting mortality, and the corresponding area for IDSA/ATS minor criteria was 0.805.

Conclusions: CURB-65 score predicted hospital mortality better than IDSA/ATS minor criteria, and a CURB-65 score of ≥ 2 or the presence of 2 or more minor criteria might be more valuable cut-off values for severe CAP in a low-mortality-rate setting.

P2482

Thrombin generation test – As a potential marker of severity and outcome of severe pneumonia with pulmonary sepsis

Tatiana Martynenko1,2, Irina Balatskaya1, Shtoychet Yakov1, Momot Alexei1, Olga Rusakova1, Anastasia Grebenyuk2. 1Dept of Postdiploma Education, The Altai State Medical University, Barnaul, Russian Federation; 2Dept of Pneumology, The Altai Regional Pulmonology Centre, Municipal Hospital #5, Barnaul, Russian Federation.

Background: There is an important interaction between inflammatory mechanisms and coagulopathy in severe pneumonia (SP) with pulmonary sepsis. The aim. Determine the prognostic role of thrombin generation test (TGT) as a marker of severity in patients with SP with sepsis.

Materials and methods: 35 adults (18 years old or above) with SP and pulmonary sepsis were enrolled in the study. All patients were divided into two groups: survivors – 30 patients (85.7%, group 1) and died – 5 (14.3%, group 2) and stratified according to APACHE II score.

Results: According to TGT, the greater number of patients (84.6%) showed reduction in intensity of thrombin generation. We observed lengthening of Lat time.
of thrombin, reduction of Peak thrombin, and increase in tPpeak, and in general - reducing endogenous thrombin potential (ETP) (table 1). Analysis of the average of the absolute values of thrombin generation curve showed that mean values of ETP and Peak thrombin remain below the reference in both groups, and Lag time and tPpeak - higher than in control. In group 2, in comparison with the first one, peak thrombin was lower at 82.9%, tPpeak was shorter by 15.1%, and ETP was reduced by 3.9-fold.

When comparing patients according to severity, in group with APACHE II > 20 (compared with APACHE II <10), reduced Peak thrombin by 71.8% and ETP by 58.2% were defined, while lengthening lag time at 70.7% and increasing tPpeak by 234.4%.

Conclusion: According to our preliminary data, reducing the intensity of TGT in SP with pulmonary sepsis is associated with more severe course of the disease and can be regarded as a predictor of poor outcome.

P2483

Developing hospital admission criteria for electronic pneumonia decision support
Barbara Jones1, Jason Jones2, Al Jepshen3, Naresh Kumar7, Ben Brigg3
Caroline Vines1, Todd Allen2, Nathan Dean1,2, 1Pulmonary and Critical Care Medicine, Intermountain Medical Center, Murray, UT, United States; 2Pulmonary and Critical Care Medicine, University of Utah, Salt Lake City, UT, United States; 3Emergency Medicine, University of Utah, Salt Lake City, UT, United States

Rationale: Severity assessment tools that use objective data available in the electronic medical record to predict mortality include CURB-65, <CURB (an electronic version of CURB-65 using continuous variables), and A-DROP. We developed an electronic decision support tool for the emergency department that recommends admission for patients with 1) CURB 30-day mortality estimate ≥5% 2) ≥3 severe community acquired pneumonia criteria (2007 IDSA/ATS), or 3) PaO2/FiO2 ratio ≥280. Our aim was to compare the tool’s admission rule to the mortality predictors.

Methods: We identified pneumonia patients by ICD-9 code plus radiograph in 7 emergency departments Dec 1, 2009-Dec 1, 2010. We extracted initial clinical features, triage information and mortality from the electronic medical record; physician review identified multilobar infiltrates from radiograph reports. Simple agreement with hospital triage (outpatient versus inpatient) and mortality were compared.

Results: 57% of all patients were admitted (54% CAP and 76% HCAP) with a 30-day mortality of 5.5% (3.5% CAP, 17% HCAP). Table shows simple agreement with triage and mortality. While the actual admission rate was 57% with 13 outpatient deaths, the admission rule would have resulted in a 48% admission rate with 9 outpatient deaths.

% Agreement

Conclusion: The tool’s admission rule agreed accurately with observed triage and might lower admission rate with improved patient safety.

P2484

Risk factors predicting mortality in patients with lung abscesses
Shaista Ghazal, Nazrat Idrees, Ahsok Kumar, Nadeem Razvi, Chest Medicine, Jinnah Post Graduate Medical Centre, Karachi, Sindh, Pakistan

Introduction: Lung abscesses continue to express high mortality in patients hospitalised with the disease.

Objectives: To identify the factors associated with increased mortality in patients diagnosed with lung abscesses.

Methods: Retrospective study performed via hospital records on patients admitted with lung abscesses between January 2009 and January 2011 at the largest state-owned tertiary care centre in Karachi, Pakistan. Of 41 patients hospitalised, 17 could not survive and were evaluated for factors to determine association with heightened mortality.

Results: Mortality due to lung abscess stood at 41.46% (17/41). Adult male patients were found to have a higher mortality with 13/17 (76.5%) expired patients being male. Majority (21/41, 51.2%) of the cases belonged to the 41-60 year old age group with highest mortality (9/17, 52.9%). Number of patients with blood sugar levels of >200 mg/dl who succumb to disease was 9/17, 52.9%. Patients with history of smoking, diabetes mellitus, and alcohol intake expressed mortality rates of 70.6%, 58.8%, and 17% respectively; while 29.4% of the mortalities were positive for Pseudomonas aeruginosa on sputum culture. A significant association was found between elevated mortality and low haemoglobin levels at time of admission; mortality was 76.5% (13/17, p < 0.013) in patients with Hb between 7-10 mg/dl.

Conclusions: The risk factors involved with heightened mortality included male gender; older age; history of smoking, and diabetes. High blood sugar levels and detection of Pseudomonas aeruginosa on sputum cultures were also implicated. Hb level of <10 mg/dl was a statistically significant predictive factor for increased mortality.
P2488

Weight of CURB-65 criteria for community-acquired pneumonia in a very low-mortality-rate setting

Qi Guo1, Hai-yan Li2, Yi-ping Zhou1, Ming Li1, Xiao-ke Chen1, Hui Liu1, Hong-lin Peng1, Hai-qiong Yu1, Xin Chen1, Nian Liu1, Li-hua Liang3, Qing-zhou Zhou1, Mei Jiang1. 1Department of Respiratory Medicine, Affiliated Futian Hospital, Guangdong Medical College, Shenzhen, China; 2Department of Primary Care, Affiliated Futian Hospital, Guangdong Medical College, Shenzhen, China; 3Department of Radiology, Affiliated Futian Hospital, Guangdong Medical College, Shenzhen, China; 4Guangzhou Institute of Respiratory Diseases (State Key Laboratory of Respiratory Diseases), First Affiliated Hospital, Guangzhou Medical University, Guangzhou, China

Background: The CURB-65 score is a simple well validated tool for the assessment of severity in community-acquired pneumonia (CAP). Weight of each criterion in very low-mortality-rate settings is not clear.

Objective: To determine the weight.

Methods: 1230 adult patients admitted to our hospital from 2005 to 2009 for CAP were reviewed retrospectively.

Results: 30-day mortality rose sharply from 0%, 1%, 8.2% and 16.7%, respectively, for patients with CURB-65 scores of 0, 1, 2 and 3 to 100.0% for patients with the scores of 4 (p < 0.001). Confusion had the strongest association with mortality.

<td>19.391 (4.383–85.789)</td>
</tr>
</tbody>
</table>

Low blood pressure was not associated with mortality. Confusion, urea > 7 mmol/L and age ≥ 65yrs showed independent relationships with mortality (Odds ratio, 11.537, 5.988 and 10.462; respectively). Urea > 7 mmol/L was most strongly associated with sequential organ failure assessment (SOFA) scores. Confusion was in closest relation to hospital length of stay. Age ≥ 65yrs had the strongest association with costs.

Conclusions: The individual CURB-65 criteria were of unequal weight in predicting 30-day mortality, SOFA scores, hospital length of stay and costs in a very low-mortality-rate setting, and low blood pressure was not associated with mortality.

P2489

Pulmonary CT findings of visceral larva migrans due to Ascaris suum

Koschi Honda1, Fumito Okada1, Yuiko Ando2, Asami Ono1, Hiroki Mori1. 1Radiology, Oita University Faculty of Medicine, Oita, Japan; 2Radiology, Nishihennn National Hospital, Oita, Japan

Objective: To retrospectively evaluate the CT findings of pulmonary involvement in patients with visceral larva migrans due to Ascaris suum.

Methods: Institutional review board approval was obtained, and informed consent was waived. Chest CT scans obtained between January 1994 and December 2007 in 35 patients with Ascaris suum were retrospectively evaluated by three chest radiologists. In 4 patients who underwent surgical or transcortical biopsy, comparisons of the CT images with the actual specimens were performed.

Results: On CT scans, abnormal findings were seen in 30 patients. The most common abnormality consisted of nodules (n=20) in which the majority had a halo of ground-glass attenuation (n=18), followed by ground-glass attenuation (n=19), and interlobular septal thickening (n=15). These abnormalities were predominantly seen in the peripheral lung (n=25). Of the 7 patients who underwent follow-up CT scans, nodules (n=6) and ground-glass attenuation (n=5) had migrated in 4 patients. Pathologically, these findings corresponded to marked eosinophilic infiltration into the interstitium.

Conclusions: These CT findings are considered to be suggestive of thoracic involvement in patients with visceral larva migrans due to Ascaris suum.

P2490

Community acquired pneumonia in the emergency department: Comparison of clinical indication to in-hospital treatment and severity scales predicting mortality

Rodolfo Ferrari1, Fabio Tumietto2, Fabrizio Giostri1, Sara Tedeschi1, Mauro Bernardi1, Pierluigi Viale1, Mario Cavazz1. 1Dipartimento Emergenza/Emergency, Chirurgia Generale e dei Trapianti. U.O. di Medicina d'Urgenza e Pronto Soccorso, Policlinico Sant'Orolo – Malpighi, Azienda Ospedaliero Universitaria di Bologna, Università degli Studi di Bologna; 2Dipartimento Malattie Apparato Digerente e Medicina Interna, U.O. di Malattie Infenerative, Policlinico Sant'Orolo – Malpighi, Azienda Ospedaliero Universitaria di Bologna, Università degli Studi di Bologna, Italy

Introduction: Severity scoring systems (SSS) are used to predict risk, to help decisions about management strategies. The most notable scales in clinical use for Community acquired pneumonia (CAP) in the Emergency Department (ED) are CURB65 and CRB65.

Objective: To analyze cases in which the clinical judgement to admit and treat in-hospital a Patient with CAP disagreed with the low risk profile established by SSS.

Materials and methods: Observational clinical study in the ED of a university teaching hospital, enrolling every adult Patient with CAP related hospitalization in 4 months period.

Results: 73 Patients were emergently admitted: 172 resulted in high-intermediate risk class according to SSS. We compared high-intermediate versus low risk groups. The first were higher in mortality. Dimler, urca, creatin, CK, CKMB, LDH, NTproBNP, dyspnoea, neurologic dysfunction, need for mechanical ventilation or management in High Dependency Unit; and lower in SpO2 and rate of antibiotic treatment previously started. When the decision to admit showed discordance between SSS risk profile and clinical judgement, some elements were often involved: social and welfare aspects, chronic diseases, previous treatment failure, laboratory abnormalities, respiratory failure, chest Xrays characteristics.

Discussion: In the ED, careful clinical judgement is still irreplaceable in decision and management processes, beyond by SSS. New studies will define which parameters to develop to increase the value of some pivotal aspects in the triage process of CAP in the ED, to focus on the real need for hospitalization in the single Patient.

P2491

The influence of respiratory infection on bronchial asthma

Dmitry Ruzanov, Natalya Efimova, Elena Davdovskaya, Tatyana Baranovskaya, Irina Buynevich, Natalya Platonovka, Olga Serdyukova. Department of Pulmonology and TB, Gomel State Medical University, Gomel, Belarus

Acute respiratory infection (ARI) intensify the severity of inflammation reaction of bronchial asthma (BA).

Aim: To study the influence of ARI on the level of the control over BA and the immunology of this combination and the possibilities of treatment.

Method: The clinical monitoring over 316 patients with bronchial asthma for a year, the immunological research and the results of treatment with affine purified antibodies for gamma-interferon of the human (48 cases).

Results: During the observation there were fixed 4,±±0.3 episodes of ARI for each patient. Analyzing the graph of frequency of ARI with BA, some differences with seasonal virus ARI attract our attention. There is no traditional apex of seasonal virus ARI in the February, the reduction of tension is seen only by May, with seasonal virus ARI attract our attention. There is no traditional apex of seasonal virus ARI in the February, the reduction of tension is seen only by May, with seasonal virus ARI attract our attention. There is no traditional apex of seasonal virus ARI in the February, the reduction of tension is seen only by May,
the cellular immunity, the increase of the level of IgG to 9.88±0.41 I/ml with the following return to the previous level, and also the real reduction of the level of IgE to 69.2±6.5 mg/ml among the patients with exogenous asthma.

P2492

Risk factors, etiology and prognosis of adult patients with hospital-acquired pneumonia in Shanghai

Ning Li, Qijian Cheng
Department of Respiratory Diseases, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Objective: To investigate clinical features, risk factors, drug resistance, and clinical outcomes of hospital-acquired pneumonia (HAP) in Shanghai.

Methods: From November 2007 to December 2009, HAP was observed and prospectively studied in Shanghai seven large general hospitals. Clinical data and etiology of pneumonia were recorded. Blood and sputum cultures, identification of bacteria in specimen and drug sensitivity test were performed.

Results: We included 204 patients (mean age 68.07±16.61 years (± SD), 58.3% more than 70 years old) mainly from surgical wards, surgical ICU, medical wards, and medical ICU. Patients were complicated with cerebral vascular disease (19.61%), diabetes mellitus (14.22%), or abdominal surgery (11.76%). Ventilator-associated pneumonia were demonstrated in 20.6% of the cases. Total mortality was 15.69%. Increased heart rate, decreased arterial PH, hypoxia, high glucose, increased plasma creatinine and vasopressor use were associated with the poor outcome in patients with HAP. In all bacterial isolates from HAP, 64.90% were gram-negative bacilli bacteria, including Acinetobacter baumannii, Pseudomonas aeruginosa, Klebsiella pneumoniae, and Escherichia coli. 26.5% of the isolates were Staphylococcus aureus and the rate of MRSA was 65.4%.

Conclusion: The elderly, cerebrovascular diseases, and diabetes are risk factors of HAP. The major pathogen is the most serious complication associated with poor prognosis of HAP. In this setting, Acinetobacter baumannii, Pseudomonas aeruginosa, Klebsiella pneumoniae, Escherichia coli, and Staphylococcus aureus (MRSA 60%) should be considered as the common etiologic pathogens of HAP.

P2493

Bacteriological analysis of lower respiratory tract in patients with rheumatoid arthritis complicated with either colonic or pulmonal diseases

Kentaro Akata, Shuya Nagata, Takashi Kido, Kei Yamazaki, Toshinori Kawanami, Hiroshi Ishimoto, Kazuhiro Yatera, Hiroshi Mukae
Department of Respiratory Medicine, University of Occupational and Environmental Health Japan, Kikuyun, Fukuoka, Japan

Background: Lower respiratory tract infections (LRTI, bronchiectasis, bronchitis and broncholithis) are common comorbidities in patients with rheumatoid arthritis (RA). According to the recent advances of the treatment modalities of RA and other collagen vascular diseases (CVD) including anti-inflammatory biological agents, an aggressive diagnosis of LRTI including non tuberculous mycobacteriosis (NTM) is becoming more important.

Patients and methods: From April 2008 to August 2011, patients with RA and other CVD with suspicion of NTM were enrolled. Additionally, patients with non-CVD with suspicion of NTM were also enrolled as controls. Bronchial washing were performed. Scores, biomarkers and risk factors in respiratory infections

265. Scores, biomarkers and risk factors in respiratory infections

P2494

CUREB 65 or CURB (S) 65 for community acquired pneumonia?

Sakine Naziz, Nazran Kokwar, Ayse Bahar, Nuram Ekim
Pulmonary Medicine, Gazi University School of Medicine, Ankara, Turkey

The CURB-65 score (confusion, blood urea >42.8 mg/dl, respiratory rate >30/min, blood pressure <90/60 mm Hg, age >65) is quite a practical method for determining the need for hospitalization in community-acquired pneumonia. On the other hand, it is a known fact that CURB-65 is rather more sensitive for determining patients with severe illness, and lacks sensitivity towards other factors dealing with milder cases. The purpose of this study is to investigate factors that determine the need for hospitalization in patients not requiring hospitalization according to CURB-65.

The study was undertaken on 54 patients diagnosed with pneumonia and were recorded to the TTD pneumonia database between 2010-2012. Nineteen (35.2%) of the patients were female while 35 (64.8%) were male. The mean age was 67.5. The total treatment time, duration of hospitalization, saturation (SpO2), partial arterial oxygen pressures (PaO2) and mean pneumonia severity index (PSI) values were compared between 15 patients receiving 0.1 CURB-65 points (27.8%) (Group 1) and 39 patients receiving 2 or more CURB-65 points (72.1%) (Group 2). According to the data, the mean PSI score in Group 1 (74.93±30.45) and in Group 2 (106.61±37.41) were statistically different (p<0.003) even though their SaO2, paO2, hospitalization and treatment time were similar (Group 1 SaO2: 89.8±8.45, PaO2: 53.8±6.72, Group 2 SaO2: 89.23±5.94, PaO2: 54.6±8.48; p<0.05).

The study shows that although the PSI are different, low SaO2 levels in both groups show that hypoxemia is the main factor for hospitalization in patients with CURB65 indexes. Therefore we propose that the CURB(S) 65 hypotetic index is a better determinant than CURB 65 for hospitalization.

P2495

Do physicians use urinary pneumococcal antigen test (UPAT) appropriately?

Vindol Paliwar, Ajay Kamath, Catherine Tremlett
Respiratory Medicine, Norfolk and Norwich University Hospital, Norwich, Norfolk, United Kingdom

Introduction: UPAT is a useful test to identify the pneumococcal aetiology of pneumonia. The specificity and sensitivity are high in moderate to severe pneumonia. Most common antibiotic regimen guided by the results. We did this study to look at the utility of the test and how it altered clinical management.

Method: We conducted a retrospective analysis of medical records of all patients who had UPAT in a 6-month period between December 2007 and May 2008. The study was performed in a 1000 bed tertiary teaching hospital in United Kingdom. BTS CURB-65 scoring was used as a measure of severity of pneumonia.

Results: One hundred and eighteen patients had the test in the 6-month study period but only 37 patients met criteria for moderate to severe pneumonia (MSP). Rest of the patients had non-severe pneumonia, infective exacerbation of asthma and COPD. The most important use of the test is in modifying the antibiotic regimen according to the result. We analysed the test results and how it altered clinical management.

Conclusion: UPAT is used inappropriately and the test results are not effectively used in modifying management.

P2496

A clinical, radiological and microbiological profile of lung abscesses

Maria Malik, Shasia Ghazal, Ashok Kumara, Nadeem Rizvi
Chest Medicine, Jinnah Post Graduate Medical Centre, Karachi, Pakistan

Introduction: Lung abscesses continue to be a frequent presentation for physicians in Pakistan With little local data available on the clinical correlations of the disease, there is a pressing need to describe the various factors associated with the condition.

Objectives: To evaluate the clinical,radiological and microbiological profile of lung abscesses.

Methods: A retrospective case study was done through studying hospital records of 41 patients admitted with lung abscess at a tertiary care hospital in Karachi, Pakistan. Demographical data, clinical symptoms, risk factor assessment, radiological findings and culture reports were studied to outline a relevant profile.

Results: Over half the cases comprised of adult, male patients. Clinically, 90.2% presented with productive cough, followed by 82.9% with fever, and 58.5% with haemoptysis. A significant association of 65.3% was found with smoking. Among other risk factors, poor oral hygiene was found in 50.6% of the cases, diabetes mellitus in 43.9%, pneumonia in 22%, and malignancy was diagnosed in 4.9%. Radiographically, 56.1% showed bilateral and 51.2% had right lower lung zone involvement. Sputum Gram staining revealed Gram negative rods and Gram positive cocci in 36.6% of the cases. ABF smear was positive in 22%. Sputum cultures showed Pseudomonas aeruginosa was present in 29.3%. No growth on blood cultures was seen in 86.6% and only 9.8% exhibited growth of E. coli.

Conclusion: Lung abscess was found to be more common in adult men,and was significantly related to smoking. The other common risk factor was found to be poor oral hygiene,while the right lower lung zone was the main site of abscess formation. Pseudomonas aeruginosa was the major pathogen implicated on sputum cultures.

The comparison of different methods of etiologic diagnosis of community-acquired pneumonia
Kirlil Zeybek1, Anna Rtvacheva1, Elena Kaznacheeva1, Alexey Pustovalov1, Galina Khaptkhaeva2, Alexander Chuchalin2, Evgeniy Sokolov3.
1. Laboratory of Pulmonology, Moscow Medico-stomatological University, Moscow, Russian Federation; 2. Clinical Department, Institute of Pulmonology, Moscow, Russian Federation.

The aim of our study was to compare different laboratory methods of the CAP etiological factor identification. 30 patients (20 male and 10 female) with non-severe CAP were enrolled in the study (50,5±3,4 years). We have performed: microbiological test and polymerase chain reaction (PCR)-based study of induced sputum and peripheral blood samples, serological tests to evaluate the level of IgM and IgG antibodies to C.pneumoniae and M.pneumoniae in peripheral blood.

Results: With all laboratory tests the etiologic agents were determined in 76,7% of patients, mostly of S.pneumoniae. In sputum there were 30 positive results in PCR and 19 - in microbiological study. PCR study of sputum revealed in 10 patients monobacterial flora, 5 - bacterial mixture, 4 - virus-bacterial mixture while in microbiological study in all 19 patients there was monobacterial flora. The frequency of S.pneumoniae was comparable both in the PCR study, and in microbiological studies (46.6%). Frequency of K.pneumoniae and H.influenzae identification was the highest in the PCR study of sputum (13,3 and 26,7%).

Conclusion: The comparison of different methods of etiologic diagnoses is the most appropriate way for non-severe CAP.

P2498
Prevalence of MRSA nasal carrier rate in hematology patients of Benghazi Medical Center using PCR-based method; first study in Libya
Khalid A. Ghabbi1, Wail A. Eldukali2, Fathi S. Al-Jehani2.
1. Medicine, Benghazi Medical Centre, Benghazi, Libyan Arab Jamahiriya; 2. Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Ewha Womans University, School of Medicine, Mokdong Hospital, Seoul, Republic of Korea.

Introduction: Carriers of multi drug resistant staphylococcus aureus (MRSA) may spread or develop infections if not discovered and properly treated. Knowing MRSA carrier status would be useful especially for hematology patients on chemotherapy.

Aim and objective: The aim of the study was to determine prevalence of nasal MRSA carrier rate in hematology patients of Benghazi Medical Center (BMC).

Method: Hematology patients admitted to hospital or under regular follow up in clinic were included and consent obtained. Nasal swabs (AFTACA) were taken in standard way. Samples were analyzed for the presence of MRSA by using PCR based system (Gene expert machine-GXMRSA-120). The following data were collected: age, gender, weight, height, underlying hematological diagnosis, history of chemotherapy, hospital admission or MRSA swab in the previous 6 months and long term intravenous device insertion.

Results: 107 patients were screened. 49 (45.7%) were males. Mean age was 48 years. The race index was 25 kg/m². 5 out of 107 patients tested positive for nasal MRSA. 4 out of 5 had lymph proliferative disorders and all received chemotherapy. The rest of results are outlined in table.

Conclusion: 4.5% of patients screened in hematology department of BMC were nasal carriers for MRSA. This is the first study in Libya using PCR based method.

P2499
Influence of age in the clinical differentiation of atypical pneumonia in adults
Nynsuki Miyashita1, Yasuhiro Kawai2, Mika Kubo2, Kazumaru Ouchi3.
1. Department of Internal Medicine I, Kawasaki Medical School, Okayama, Japan; 2. Department of Pediatrics, Kawasaki Medical School, Okayama, Japan.

Background and objective: The Japanese Respiratory Society (JRS) scoring system is a useful tool in the early and simple presumptive diagnosis of atypical pneumonia, Mycoplasma pneumoniae and Chlamydia pneumoniae pneumonia. However, it has been suggested that it seems to be difficult to diagnose atypical pneumonia in the elderly using this system. In the present study, we evaluated the accuracy and usefulness of the JRS scoring system in the different age groups.

Methods: We analyzed 262 cases of M. pneumoniae, 98 cases of C. pneumoniae and 364 cases of common bacterial pneumonia.

Results: The comparison of co-morbid illnesses and higher risk classes in the elderly (age ≥60 years) group was significantly higher than those of non-elderly patients (age <60 years) in both atypical pneumonias. One or more additional etiological factors were found more frequently in the elderly group than in non-elderly patients. The diagnostic sensitivity and specificity for atypical pneumonias were 39% and 88% for the elderly group and 86% and 88% for age non-elderly group, respectively. When the diagnostic sensitivity was analyzed for different ages stratified into 10-year groups, the sensitivity was highest in the 18-29-year-old group and decreased in order from the youngest to the oldest age group.

Conclusions: Our results indicate that it is difficult to distinguish between atypical pneumonias and bacterial pneumonias in the elderly using the JRS scoring system. When treating patients aged ≥60 years, physicians should choose fluoroquinolones or β-lactams + macrolides as empirical first-choice drugs, so as to always include potential antibiotic cover for atypical pathogens.

P2500
Clinical features and prognostic factors in elderly patients with aspiration pneumonia
Seo Woo Kim1, Yong Ju Ryu2, Seok Jung Lee1, Jin Hwa Lee1, Jung Ryeol Chang1, Sung Shme Shim1.
1. Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Ewha Womans University, School of Medicine, Mokdong Hospital, Seoul, Republic of Korea; 2. Radiology Department, Ewha Womans University, School of Medicine, Mokdong Hospital, Seoul, Republic of Korea.

Background: The aims of this study were to investigate the clinical features, risk factors, and outcomes of patients with aspiration pneumonia and to identify the prognostic factors contributing to mortality in these patients.

Method: Following a retrospective review of clinical data and radiographic findings between 2006 and 2010, 176 patients were enrolled in this study.

Results: The median age of patients was 75 years (range, 66-81), and 125 (71%) patients were male. 89 (51%) were admitted to the medical ICU and their clinical course was fulminating as a result of acute respiratory failure requiring mechanical ventilation in 79 (45%), septic shock in 36, ARDS in 20, and multi-organ failure in 26. Overall in-hospital mortality was 22.7% (40/176) with a median survival of 18 (range 9-43) days. Comorbidities or risk factors associated aspiration included cerebrovascular accidents (n=79), bedridden (n=57), malignancy (n=29), dementia (n=25), alcoholism (n=18) and Parkinson’s disease (n=14). The leading pathogen considered to be associated with pneumonia in patients (n=60), followed by A. baumannii (n=24), K. pneumonia (n=19), and P. aeruginosa (n=17). Independent predictive factors of in-hospital mortality included septic shock (HR 7.1, 95% CI, 2.6-19.3, P<0.001), dyspnea (HR 5.3, 95% CI, 1.5-19.1, P=0.030), hypoxemia (serum albumin ≥2.5 g/dl) (HR 2.7, 95% CI, 1.1-6.9, P=0.038), and CVA (HR 2.6, 95% CI, 1.1-6.5, P=0.036).

Conclusion: Aspiration pneumonia has a high mortality rate and poor prognosis, particularly in patients with septic shock, dyspnea, hypoxemia, CVA.

P2501
Incidence of ventilator associated pneumonia (VAP) and assessment of sereral estimation of procalcitonin levels as a prognostic marker in cases of VAP in a tertiary centre in India
Vikas Sikri1, Rajesh Chawla1, Ramon Sardana2, Ashish Jain1. 1. Respiratory & Critical Care, Indraprastha Apollo Hospitals, New Delhi, India; 2. Microbiology, Indraprastha Apollo Hospitals, New Delhi, India.

Introduction: Patients developing VAP have higher mortality rates and longer ICU stays. Various markers have been used for prognosis in patients who develop VAP. We studied serial estimation of procalcitonin (PCT) levels in VAP as a prognostic marker.

Aims & objectives: To calculate incidence of VAP per 1000 ventilator days and assess role of PCT as a prognostic marker in VAP.

Material & methods: All consecutive patients intubated in the ICUs were assessed for development of VAP using CPIS score. In patients who developed VAP during the study period, there serum PCT levels were collected on day 0, 3 and 7 of developing VAP.

Results: We studied 351 patients, 25 developed VAP. Incidence of VAP was 63.3/1000 ventilated days. (Incidence/1000 ventilator days= No. of VAP cases/Total ventilator days C 1000). Patients having higher initial levels of & in whom the levels decreased subsequently showed better survival as compared to less initial values and a marginal fall/rise in subsequently values. Mean value of PCT in survivor group on 0.3 & 7 days were 45.72, 21.01 and 7.26 respectively (standard error of mean of 34.71, 15.28 & 4.95) while the levels in non-survivor group were 1.94, 2.11 & 1.99 respectively (standard error of mean of 0.72, 0.80 & 1.25). The PCT levels remained low/steady on serial monitoring in the non survivor.

Conclusions: Our study further re-enforces the role of serial estimation of PCT as a prognostic marker in patients with VAP. Though further studies with larger number of patients is required to make its estimation as a standard protocol.
P2502
Procalcitonin and proadrenomedullin in COPD patients: Stable state versus exacerbation difference in mortality rate?

M.C. Telgen 1,2, M.G.J. Brusse-Keizer 1, P.D.L. van der Valk 1, J. van der Palen 1,2, H.A.M. Kerstjens 1, M.G.R. Hendriks 3

1 Department of Pulmonary Medicine, Medisch Spectrum Twente, Enschede, Netherlands; 2 Department of Internal Medicine, Medisch Spectrum Twente, Enschede, Netherlands; 3 Department of Medical Microbiology, Regional Laboratory of Public Health, Enschede, Netherlands; 4 Department of Pulmonary Medicine, University Medical Centre Groningen, and University of Groningen, Netherlands; 5 Department of Research Methodology, Measurement, and Data Analysis, University of Twente, Enschede, Netherlands

Rationale: Little is known about proadrenomedullin (pro-ADM) and procalcitonin (PCT), biomarkers in COPD, in relation with mortality. Stolz. D et al. (Chest 2008;134:263-272) suggested that pro-ADM at hospitalization for an acute exacerbation of COPD (AE-COPD) predicts survival. In our cohort of well defined COPD patients (the COMIC study) we wanted to study the association between PCT and pro-ADM levels in stable state and at hospitalization with mortality.

Methods: PCT and pro-ADM levels were determined in 187 patients who provided a plasma sample during stable state and at hospitalization for AE-COPD. The mean follow-up after inclusion was 46 months ±20. Date of death was verified from the municipal administration.

Results: The PCT and pro-ADM levels were significantly increased at hospitalization compared to stable state. Patients who died had a significantly higher level of PCT and pro-ADM both during stable state and hospitalization.

Table 1. Pro-ADM and PCT results

<table>
<thead>
<tr>
<th>Pro-ADM nmol/l (mean ± (SD))</th>
<th>PCT ng/ml (median (IQR))</th>
</tr>

Conclusions: Both PCT and pro-ADM could be a marker for mortality in COPD.

P2504
Plural fluid C-reactive protein concentration in discriminating uncomplicated from complicated parapneumonic pleural effusion

Sanja Petruševska Marjanović 1, Irena Konđova Topuzovska 1, Zvonko Milenković 1, Goran Kondovi 1, Aninka Anastasovska 1, 2 Respiration Diseases, University Clinic of Infectious Diseases and Febrile Conditions, Skopje, Macedonia, The Former Yugoslav Republic of; 2 ThoracoCardiovascular Surgery, University Clinic, Skopje, Macedonia, The Former Yugoslav Republic of

Parapneumonic pleural effusions (PPE) are the second most common cause of exudates after malignant effusions. The early discrimination between uncomplicated parapneumonic effusions (UPPE) from complicated parapneumonic effusions (CPPE) is important for adequate management of PPE. Oversight in distinction between these two groups with classical recommended markers (pH, lactate dehydrogenase (LDH) and glucose) require alternative tests. The aim of this study was to determine the role and value of plural fluid C-reactive protein (CRP) in discrimination between UPPE from CPPE. The study was including 60 patients: 30 with UPPE and 30 with CPPE. CRP concentration was measured with Ektachem Clinical Chemistry tests on analyzer Vitros 250. LDH and glucose were performed on analyzer Vitros 350. Pleural fluid was aspirated from pleural cavity with ultrasound guidance. Receiver-operating curve were to assess the sensitivity and specificity of plural biochemical parameters. CRP was statistically higher in CPPE (118.97±31.04 U/L) than in group with UPPE (40.24±22.30 U/L) (t=11.26; p<0.005). According to Spearman’s correlation, positive correlation was between levels of plural CRP concentration and CRP in serum (r=0.635; p<0.01). Positive correlation was between pleural concentration of CRP and LDH (r=0.811; p<0.01). Significant negative correlation was between levels of CRP and pH (r=-0.813; p<0.05), and of CRP and glucose in pleural fluid (r=-0.826; p<0.01). The CRP cut-off value of 73.43 mg/l differentiated CPPE from UPPE with a sensitivity and a specificity of 100%.

Conclusion: CRP may be used as a good marker in discrimination from UPPE from CPPE and management of patients with PPE.

P2505
Lung and serum biomarkers of tissue lesions due to acute exacerbation of COPD

Kornelia Mise, Željko Ivančević, Ivan Gudelj, Slava Kotarac, Jasminka Svalina-Genčsa. Clinic for Lung Diseases, Clinical Hospital Center, Split, Croatia Clinic for Lung Diseases, Clinical Hospital Center, Split, Croatia

Introduction: In COPD are common respiratory tract infections, resulting in exacerbation of disease. Laboratory findings are normal or slightly abnormal, such as inflammatory biomarkers: WBC, CRP, LDH, ALP. What is going on with pathological processes in lung tissue? Aim: Analyze tissue damage topical and serum biomarkers.

Methods: 56 COPD pts in exacerbation underwent bronchoscopy. Tissue damage topical biomarkers (LDH, CRP, ALP, bronchus pH acidity) were analyzed from the bronchial aspirate.

Results: Average pts age is 64.6 y. Lung LDH mean value (L-LDH) was 150.88±18.4, and in serum 181.66±79.64 U/L. Lung ALP mean value was 58.5±37.75 U/L, and in serum (S-ALP) 78.76±28.66 U/L. Lung CRP mean value (L-CRP) was 0.06±0.78 mg%, and in serum 56.54±17.45 mg%. L-CRP was detected in 10 pts only (in 76 not).

Mean lung acidity (pH) was 7.89±0.82. The most common organism causing COPD exacerbation was: H. influence, with biomarker values of L-LDH X=1746.30 U/L, and S-LDH=188.4 U/L. The second most common was P aeruginosa, with biomarker values of L-LDH X=1456.61 U/L, and S-LDH=201.8.

Conclusion: In pts with COPD, serum inflammatory biomarkers are not consistent index of COPD exacerbation, nor its severity. Lung LDH values are extremely increased, and serum LDH values are rarely pathological. These facts indicate severe lung tissue damage, although S-LDH values are not significant for pathological process. In contrast, L-CRP was found only in trace in few pts, whereas serum values are always increased. In bacterial lung inflammation pH is alkaline (X=7.89), however, it is not comparable with blood pH values, since the measuring method was different.

P2506
Elevated creatinine is a sensitive severity marker in community acquired pneumonia

Joanne Sloan, Janet Wilson, Carly Griffin, Morven Wilkie, James Chalmers, Stuart Schember. Respiratory Department, Ninewells Hospital, Dundee, United Kingdom

Background: It is recognised that acute kidney injury (AKI), as classified by the International Kidney Disease Group Improving Global outcomes staging classification, is associated with increased 30-day mortality in patients with community acquired pneumonia (CAP). This study aimed to determine if increases in serum creatinine not meeting the criteria for AKI were associated with increased 30-day mortality.

Methods: A retrospective study of patients admitted over a 6 month period, with radiologically confirmed CAP. Baseline creatinine, admission creatinine, AKI severity and 30-day mortality were recorded.
Results: 210 patients (52% male, 48% female) were included in the study with a median age of 76 years. 26 (12.4%) patients met the criteria for AKI. 57 (27.1%) patients had rises in creatinine above baseline, but not meeting AKI criteria. As expected AKI scoring was associated with increased 30 day mortality.

Table 1. Incidence of AKI and 30 day mortality rates

<table>
<thead>
<tr>
<th>AKI staging</th>
<th>Number of Patients</th>
<th>30 Day Mortality</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</tbody>
</table>

Greater than 20% rises in creatinine above baseline were strongly associated with a higher 30 day mortality rate.

Figure 1: Elevated creatinine and 30-day mortality.

Log rank test p<0.002.

Conclusions: Creatinine rises as low as 20% above baseline in patients with CAP are associated with higher 30 day mortality rates than for patients without creatinine rises.

P2507
Admission hyperglycaemia is associated with increased risk of diabetes mellitus following hospitalisation with community acquired pneumonia

Aran Singanayagam1, Gillian Fleming2, Ahsan Akram3, Adam Hill2, James Chalmers2

1Respiratory Medicine, St. Mary’s Hospital, London, United Kingdom; 2Department of Respiratory Medicine, Royal Infirmary of Edinburgh, United Kingdom

Background: Hyperglycaemia has previously been shown to correlate with adverse outcome in community acquired pneumonia (CAP). The aim of this study was to assess whether hyperglycaemia is associated with increased risk of diabetes mellitus (DM) following admission with CAP.

Methods: We conducted a prospective observational study of patients who had survived hospitalisation with CAP. All patients had random serum glucose measured on admission and were categorised into normoglycaemia (4.0-6.0 mmol/L), mild hyperglycaemia (6.1-7.0 mmol/L), moderate hyperglycaemia (7.1-14.0 mmol/L) and severe hyperglycaemia (>14.0 mmol/L). Patients with pre-existing DM or those who were hyperglycaemic on admission were excluded. The outcome of interest was diagnosis of diabetes mellitus within one year of hospital discharge.

Results: 1202 patients were included with 85 (7.1%) diagnosed with DM within one year of follow-up. Rates of diabetes diagnoses according to admission glucose level and normoglycaemia group 3.9%, mild hyperglycaemia group 6.4%, moderate hyperglycaemia group 9.8% and severe hyperglycaemia group 64.7%. On multivariable analysis, adjusting for age, gender, smoking status, cardiovascular disease and pneumonia severity, there was a graded increase in association of hyperglycaemia and subsequent diabetes diagnosis: mild hyperglycaemia (OR 1.55 (0.78-3.09) p=0.2), moderate hyperglycaemia (OR 1.69 (1.25-2.29) p=0.0007), severe hyperglycaemia (OR 3.0 (2.04-4.46) p<0.0001).

Conclusions: Moderate to severe hyperglycaemia on admission with CAP is associated with increased risk of subsequent DM diagnosis within one year of hospital discharge.

P2509
Study on human tracheal bronchial epithelial cells secreting cytokines in vitro by nontypeable haemophilus influenzae

Liamne Qian1, Chunxue Bai1, Guifang Wang1

1Department of Pulmonary Disease, Zhejianghong Hospital, Shanghai, China; 2Department of Internal Medicine, The Traditional Chinese Medical Hospital in Kunshan, Kunshan, Jiangsu Province, China

Obstructive To study the interaction of nontypeable haemophilus influenzae strain ATCC49247 with primary human bronchial epithelial cells (HBEc) and the NTHi-induced release and expression of proinflammatory cytokine in the HBEc.

Methods: HBEc were isolated by low temperature protease digestion and cultured in serum-free medium. Confluent epithelial cell cultures were incubated with NTHi, NTHi + erythromycin(0.1mg/L), NTHi + gentamicin(100mg/L), NTHi + dexamethasone(100µM)and normal untreated control cells after 24h. Release of IL-8 and TNF-a into the supernatant was assayed by enzyme-linked immunosorbent assay. The expression of ICAM-1 was examined by immunohistochemistry staining.

Results: (1) Some HBEc's were transformed and died after 24h. (2) HBEc: NTHi-induced cells released significantly greater amounts of IL-8 and TNF-a (p<0.001). (3) NTHi + erythromycin(0.1mg/L), NTHi + gentamicin(100mg/L), NTHi + dexamethasone(100µM) significantly reduced the total number of ICAM-1 positive cells from 10±5% (in control untreated cultures) to 8±3% (p<0.001). Similarly, incubation of HBEc with 0.1mg/L erythromycin and gentamicin significantly induced release of IL-8, TNF-a and the expression of ICAM-1, which was blocked by 10µg/ml erythromycin and 100µM dexamethasone.

Conclusions: HBEc can release IL-8 and TNF-a. NTHi may increase significantly release and expression of proinflammatory cytokine. Gentamicin have no anti-inflammatory effects. Erythromycin may have anti-inflammatory effects. Dexamethasone has distinct anti-inflammatory effects.

P2510
Comparision of procalcitonin and CURB-65 in pneumonia

Sawg Orsu, Ismail Yilmaz, Yasin Abdul, Funda Öztuna, Yilmaz Bulbul, Nevzat Giller

Department of Pulmonary, Kars University Faculty of Medicine, Trabzon, Turkey

CURB-65 score, pneumonia and hospital admission decision as well as useful and simple clinical scoring model for prediction of pneumonia. CURB-65 score, =+2 is recommended for patients with inpatient treatment. The other hand, procalcitonin (PCT), a marker for determining prognosis of pneumonia. CURB-65 score and PCT levels were compared in this study.

In this study 58 patients were admitted to our clinic due to common acquired pneumonia. Patients, the clinical and laboratory findings were recorded. CURB-65 score was calculated. CURB-65 score in patients with Group-I (score, <+2) and Group-II (score, >=+2) as divided into 2 groups. (Normal value: Procalcitonin<0.1, CRP <0.5).

In our study, median age 68 (18-96) was found. The most frequent clinical symptoms were cough (83%), dyspea (71%) and fever (67%), respectively. In group-I, mean PCT level was 3.6±7.7, in Group-II PCT was 9.2±0 (p = 0.028). The average white blood cell was 12±8.6 and was 13±6.2 ± 2. (p > 0.05). CRP level of 18±4.1, and 19±4.1 (p > 0.05), respectively. Total 11 (19%) patients died. The median value of PCT was significantly higher in patients who died (2.2 ± 0.45, p = 0.012). Similarly, CRP was significantly higher in patients who died (33 vs. 14, p = 0.016). PCT levels were positively correlated with the CURB-65 score (r = 0.296, p = 0.024).

As a result, PCT levels correlated with a CURB-65 score in pneumonia. Initial PCT level may be considered in patients with pneumonia.
P2511

Bacterial infection in acute exacerbations of chronic obstructive pulmonary disease
Fatema Chermiti Ben Abdallah, Wafa Bouhawel, Inmen Sahnoun, Ridaa Mabonouchi, Amel Chitourou, Sofia Taktak, Ali Ben Kheder. Pneumology Department, Abderrahmen Mami Hospital, Ariana, Tunisia

Introduction: Infections are major causes of acute exacerbations (AE) of chronic obstructive pulmonary disease (COPD) which increase mortality rate and impair quality of life of patients.

Aim: Determine the bacterial profile in patients hospitalized in our department for AE of COPD caused bronchopulmonary-infection.

Methods: Retrospective study including 100 patients hospitalized for AE of COPD. Bronchopulmonary infection was considered because of clinical, radiological and/or bacteriological criteria.

Results: Mean age of patients was 63 years and mean duration of the disease was 11 years. Regarding to GOLD classification, 63% of patients had COPD stage II, 34% stage III and 3% stage IV. Infection agent was identified in 69 patients with sputum culture. Isolated pathogens were: Haemophilus Influenzae (28), Streptococcus Pneumoniae (8), Streptococcus (3), Enterobacter (12). Pseudomonas Aeruginosa (10), serratia (2), Klebsiella (2) and 4 patients had mixed infections (staphylococcus and Haemophilus). Modification of sputum colour is the most parameter correlated with bacterial infection. Duration of COPD more than 10 years, severe dyspnea and impaired respiratory function (FEV1 < 35%) were significantly associated with more aggressive pathogens (negative gram bacilli).

Conclusion: Bacterial infection is major cause of AE of COPD and is considered as a worsening lung function factor. In patients with lower FEV1, AE is caused by more aggressive pathogens.

Influence of lung infection on the course and outcome in patients with stroke
Dragana Radanovic, Simsa Ristic 1, Ivana Marinkovic 1, Ines Vestanicova 1,2
1Institute of Pulmonary Diseases, Institute of Pulmonary Diseases, Niš, Serbia; 2Department of Neurology, University Clinical Centre, Niš, Serbia; 3Medical Faculty of Niš, Medical Faculty of Niš, Niš, Serbia; 4University Clinical Centre, Surgery Clinic, Niš, Serbia

Purpose: Occurrence of acute bacterial lung infections affects the course of disease and outcome in stroke patients. Aim of the study was to explore the frequency of hypostatic and aspiration pneumonia, their risk factor and their effect on outcome in patients with acute stroke.

Methods: In this retrospective study, we evaluated patients with stroke who were hospitalized in the Department of Neurology in Niš, between January - December 2011. There were a total of 1312 patients with stroke. 824(62.80%) had ischemic stroke, and 488 (37.20%) had haemorrhagic. Patients were evaluated and had the same investigations with anamnestic, clinical, neurological, biochemical analyses, physical examination by a specialist for pulmonary diseases, lung X-ray, Doppler of the neck blood vessels, EEG, CT of lung, CT/MRI of brain, MRA angiography.

Results: Of a total of 1312 patients with stroke, 59 patients (4.49%) of them had pulmonary complications within 10 day from the event. There were 36 male and 23 female patients, age from 41 to 82 years. Pulmonary infections in all of the patients was confirmed by x-ray imaging and biochemical analyses. 28(47.46%) patients had lobar pneumonia, 23(38.98%) had bilateral broncho pneumonic changes and 13(5.56%) had pleural effusion. All of the patients were highly febrile, with increased sedimentation and leucocitosys with dominant neutrophiles. Despite the intensive antibiotic treatment, using two or more antibiotics in combination, 14 patients have died.

Conclusion: Hypostatic and aspiration pneumonia are frequent complications of stroke associated with poor outcome. Regarding to this fact, an intensive prevention of complications is necessary immediately after hospitalization.

Nontypeable haemophilus influenzae leads to activation of the NLRP3 inflammasome – A possible trigger of chronic bronchial inflammation in COPD
Johannes Rotta detto Lora 1, Kristina Rohmann 1, Daniel Drömann 1, Jan Rupp 1, Torsten Goldman 1, Klaus Dalhoff 1, 2Medical Clinic III, University of Luebeck, Germany; 1Institute of Medical Microbiology and Hygiene, University of Luebeck, Germany; 2Medical Clinic, Research Center, Borstel, Germany

The inflammasome is a cytosolic protein complex which is involved in a variety of inflammatory diseases. Since it represents a heterogeneous group of proteins, we elucidated which specific set of proteins is recruited after stimulation with nontypeable Haemophilus influenzae (NTHi). In view of the fact that IL-1β is a central early phase inflammatory cytokine, we investigated whether inflammasome inhibition affects other cytokines like IL-8 and TNF-α.

Murine macrophages and human lung tissue were stimulated with NTHi 10 cfu/ml for 24-48h. To assess the relevance of the inflammasome for the inflammatory response, a caspase-1 inhibitor (CI) was added after in vitro stimulation. The inflammatory response was measured by cytokine ELISA and Western Blot. Western Blot analysis showed the activation of caspase-1 after NTHi infection and moreover the expression of the NO-like receptors NOD1 and NLRP3. In cell culture and human lung tissue experiments IL-1β production was significantly induced (RAW control 24h beneath lowest standard vs. NTHi 24h 408±546 pg/ml, n=6, p<0.01). The inhibition of caspase-1 led to a significant reduction of IL-1β levels and also to a decrease of IL-8 and TNF-α production (IL-8: NTHi 24h 408±64 pg/ml vs. NTHi+CI 24h 174±12 pg/ml, n=6, p<0.05). For the first time we demonstrated the participation of the NLRP3-inflammasome in NTHi-induced inflammation in pulmonary cells and tissues. Our findings concerning caspase-1 mediated IL-1β-suppression emphasize the role of the inflammasome in respiratory tract infections. These results may provide new insights into the pathogenesis of persistent airway inflammation in COPD.

P2514

The role of galactomannan in exhaled breath condensate in detecting pulmonary aspergillosis in patients with exacerbated COPD
Cristina Felisi 1, Laura Trovato , 2 Raffaele Campisi 1, Salvatore Oliveri 2, Giuseppe Di Maria 1, 3, Dipartimento di Medicina Bio-molecolare e Clinica, Università di Catania, Italy; 2Dipartimento di Scienze Biomediche, Università di Catania, Italy

Introduction: Growing evidence suggests that patients with severe COPD are at a higher risk of pulmonary aspergillosis (PA), especially during an acute exacerbation. The levels of GM in exhaled breath condensate (EBC) might allow earlier diagnosis and extend the diagnostic yield of noninvasive mycological tests.

Methods: Evaluate the role of GM in EBC for early diagnosis of PA in severe COPD patients at exacerbation.

Methods: Serum and EBC were collected from 15 severe or very severe COPD patients at exacerbation and tested for GM using a Platelet® Aspergillus Ag test. Sensitivity of EBC fluids with an index >0.5 were considered positive. Double diffusion in agrose gel (DD) for antibody response to Aspergillus was also determined.

Results: Two patients had probable, 7 possible and 6 had no evidence of PA according to the criteria proposed by Bulpa. Serum positive GM assay was observed in two samples of the patients with probable PA and in one sample of two patients with possible PA. In patients with probable PA also serum precipitins was positive (A. fumigatus). EBC analysis yielded GM positive results (range, 0.8–7.5 pg/ml). In one patient with probable PA and in 2 patients without PA. In a patient with probable PA, positivity of the GM in EBC, preceded that of the serum of 4 days. GM in EBC was negative in 5 out of 7 cases with possible PA and in 5 out of 6 without PA. The sensitivity of GM in EBC was lower for the diagnosis of probable and possible PA compared to serum GM. However, considering the discordant results in serum and in EBC of four patients with possible PA we suggest that EBC GM levels can expand the diagnostic yield of PA.

P2515

Clinical features of patients with pneumococcal urinary antigen positivity, in a cohort of hospitalised community acquired pneumonia
Chamra Rodríguez, Thomas Bewick, Sonia Greenwood, Wei Shen Lim. Respiratory Medicine, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Streptococcus pneumoniae accounts for up to 50% of hospitalised community acquired pneumonia. Diagnosis of pneumococcal disease has always been a challenge. Urinary antigen testing provides a non-invasive, sensitive and specific diagnostic tool. We investigated the clinical features of patients with pneumococcal urinary antigen positivity in patients admitted with community acquired pneumonia. We conducted an observational, prospective cohort study in two large UK teaching hospitals, from September 2008 to September 2010. Consecutive adult patients (aged over 16), admitted with community acquired pneumonia (CAP) were recruited. A standardised proforma was used to collect clinical information. Urine samples were tested using the Binax NOW® immunochromatographic test. A total of 920 urine samples were available for analysis. 205(22.3%) had a positive antigen test.

Patients with a positive antigen test were more likely to be hypertensive (16.8% of antigen positive vs. 6.8% of antigen negative patients, OR 2.8, 95% CI 1.7-4.8, p<0.05) and tachypnoeic at presentation. Incidence of parapneumonic effusion and critical care admission rates (OR 2.2, 95%CI 1.4-9.3, p<0.01) were also higher in the antigen positive group. These associations were maintained when adjusted for age and pneumonia severity. Patients with a positive pneumococcal antigen test were more unwell at presentation with a greater likelihood of complications. This is likely to be due to the higher bacterial load in patients with a positive antigen test. Thus, urinary antigen testing appears to add prognostic value in addition to its diagnostic capabilities, when used in pneumococcal disease.
P2516
Effect of Cryptococcus neoformans on the immune system of immunocompetent patients
Jinhui Wang, Yingfeng Luo, Xiaoqiu Wei, Yangping Zai, Shuyue Li. The State Key Laboratory of Respiratory Disease, Guangzhou Institute of Respiratory Disease, Guangzhou, Guangdong, China

On one hand the host immune system regulates the susceptibility and resistance to cryptococcal infection, on the other Cn can also affect T-cell activation and polarization during infection. Cn may potentially interfere with the differentiation of Th1 cells, which may be an escape mechanism of evade host defense and contribute to the cryptococcal infection in immunocompetent patients. However, most of these effects on T-cell biology were only found in cell and animal studies so far.

Objectives: To determine the effect of Cn on the immune system of immunocompetent patients.

Methods: Twenty immunocompetent patients with pulmonary cryptococcal infection were enrolled. Blood plasma concentrations of IFN-γ, IL-4 and IL-12 were measured using Elisa. PBMC were then isolated and incubated with or without Cn (3×10⁶ CFU/mL) for 6 and 24 hours, followed by the assay of IFN-γ and IL-12 concentration in the supernatant.

Results: Plasma IFN-γ was greatly decreased in the patients when compared to the healthy controls. No significant differences in plasma IL-4 and IL-12 were observed between these two groups, the increment for cryptococcal infection patients was much lower (3.1-fold) compared with that from healthy controls (7.4-fold). IL-12 treatment had no observed effect on the IL-4 production of PBMC.

Conclusions: Cryptococcal infection can damage the host immune system, leading to a deficient response to the IL-12 stimulation and an impaired Th1 polarization. This may explain the persistence of Cn in the immunocompetent patients.

P2517
Exhaled breath biomarkers in patients with ventilator associated pneumonia (VAP)
Ulrike Grigat, Philipp Tretz, Patricia Fucs, Jochen Schubert, Wolfram Mieckisch. Anaesthesiology and Intensive Care Therapy, University of Bostock, Germany

Volatile organic compounds (VOC) in breath have been described as biomarkers of metastatic, oxidative stress and cancer. This pilot study was intended to find out whether VAP related breath biomarkers could be recognized by means of a smart and rapid combination of VOC sample preparation and analysis.

20 mechanically ventilated patients (10 with pneumonia, 10 controls) were investigated. In NTME, 1.0 μL of alveolar gas were withdrawn from the respiratory circuit. VOCs were pre-concentrated by means of needle trap micro extraction (NTME) at the bedside and identified/quantified by means of gas chromatography-mass spectrometry (GC/MS). Results were analysed using ANOVA on ranks. Expired concentrations of VOCs ranged from (400 pptV to 3000 pptV (0.02 to 14.2 nmol/L). Exhaled acetone concentrations were higher in control patients (median 2895 pptV vs. 187 pptV, p=0.037). VAP patients exhaled lower concentrations of CS aldehydes (median 2.061 pptV vs. 19.683 pptV, p=0.013) than control patients. Exhaled pentane showed a tendency to higher concentrations in VAP patients (median 9.507 pptV vs. 6.040 pptV).

The NTME-GC/MS assay enabled reliable detection of volatile substances from ventilated patients in trace amounts. Elevated pentane concentrations indicate oxidative stress in VAP, reduced aldehyde concentrations may be due to chemical quenching of ROS in NTME. NTME appears to be a promising tool for pneumonia patients.

Analysis of exhaled oxygenated compounds bears the potential of non invasive monitoring and recognition of pathological pulmonary processes.

P2518
Copetin predicts early clinical deterioration and persistent instability in community-acquired pneumonia
Marin Koljac1, Michael Halank 1, Bernhard Schulte-Hubbert1, Sybille Bergmann1, Steffen Albrecht1, Gert Hoffken1. 1Division of Pulmonology, Medical Department 1, University Hospital Carl Gustav Carus, Dresden, Germany; 2Institute of the Clinical Chemistry and Laboratory Medicine, University Hospital Carl Gustav Carus, Dresden, Germany; 3Department of Gynecology and Obstetrics, University Hospital Carl Gustav Carus, Dresden, Germany

Optimal risk prediction of early clinical deterioration in CAP remains unresolved. We prospectively examined the predictive value of the new biomarkers copeptin and proadrenomedullin (MR-proADM) in comparison to clinical scores and inflammatory markers to predict early high risk prognosis in CAP.

Methods: 51 consecutive hospitalised adult patients were enrolled. We measured CRP-65- and P5I-scores, the ATS/IDSA 2007 minor criteria to predict ICU admission and the biomarkers CRP, procalcitonin, copeptin and MR-proADM on admission. Predetermined outcome parameters were combined mortality or ICU admission after 7 days and clinical instability after 72 hours.

Results: Copetin was the only biomarker significantly elevated in patients with either adverse short term outcome (p<0.003). In ROC-curve analysis copeptin predicted ICU admission or death within 7 days (AUC 0.81, cut-off 35 pmol/L, sensitivity 78%, specificity 79%) and persistent clinical instability after 72 h (AUC 0.74). In Kaplan-Meier-analysis patients with high copeptin showed lower ICU-free survival within 7 days (p=0.001). The diagnostic accuracy of copeptin was superior to the CRB-65 score and comparable to the PSI-score and the ATS/IDSA minor criteria. If copeptin was included as additional minor criterion for combined 7-day mortality/ICU-admission, the diagnostic accuracy of the criteria was significantly improved (AUC 0.85, p=0.045).

Conclusion: Copeptin predicts early deterioration and persistent clinical instability in hospitalised CAP and improves the predictive properties of existing clinical scores. It should be evaluated within a biomarker guided strategy for early identification of high risk CAP patients.

P2519
Correlation of Mycobacterium tuberculosis-specific and non-specific quantitative T cell IFN-γ responses with mycobacterial load in a HIV-prevalent high burden setting
Grant Theron, Jonny Peter, Laura Lenders, Richard van-Zyl Smit, Richard Meldau, Ureshnie Govender, Keertan Dheda. Medicine, University of Cape Town, Western Cape, South Africa

Background: Measures of bacillary load in patients with tuberculosis (TB) may be useful for predicting and monitoring response to treatment. The relationship between quantitative T-cell responses and mycobacterial load is poorly studied. We hypothesised that, in a high burden setting, the magnitude of mycobacterial antigen-specific and non-specific T-cell IFN-γ responses would correlate with (a) bacterial load and (b) culture conversion in patients undergoing treatment.

Methods: We compared the magnitude of purified-protein derivative (PPD) and RD1-specific (TSPOT.TB and QFT-GIT) peripheral blood IFN-γ T-cell responses with associations of sputum bacillary load [liquid culture time-to-positivity, smear microscopy grade, Xpert-MTB/RIF] and the presence of cavities on a chest radiograph in 513 individuals with suspected TB in Cape Town, South Africa. Serial IGRA responses were evaluated at 2 (n=35) and 6 months (n=13) post treatment initiation.

Results: PPD and RD1-specific IFN-γ responses were not associated with culture TTP (p-values for TSPOT.TB, QFT-GIT and PPD of 0.11, 0.07 and 0.09), smear-grade (0.42, 0.08, and 0.85), Ct values (0.70, 0.91, and 0.49) or the presence of cavities on the chest radiograph (0.12, >0.05, and 0.08). 2-month IGRA conversion rates (positive to negative) were negligible (<10% for TSPOT.TB (3/28) and QFT-GIT (1/29)) and lower compared to culture [60% (21/35); p<0.01].

Conclusions: In a high burden setting M. tuberculosis-specific and non-specific antigen-driven IFN-γ responses do not correlate with bacillary load and are not useful for prognostication or treatment monitoring.

P2520
LL-37 is produced intrapleurally in infectious pleural effusion
Carlos Antonio Amaya1, Javier Villalba1, Mayte Garcia-Urrutia1, Juan Jose Ruiz-Cubillán1, Alejandro Daly1,Beatriz Abscal1, Diego Ferrera1, Francisca Santos2, David Ibarre1, Ramón Aguierto1. 1Neumology, Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, Spain; 2Biochemistry, Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, Spain

LL-37 is an antimicrobial peptide produced by neutrophils, respiratory epithelial and mesothelial cells that has been studied for its broad spectrum activity against microorganisms. It also recruits inflammatory cells and promotes immune responses. It has never been measured in pleural fluid.

Aims and objectives: The objective of our study is to measure the pleural and serum levels of LL-37 in pleural effusion patients, and to compare these levels and the pleural-to-serum LL-37 ratio among pleural fluids of three frequent etiologies: infectious, malignant and congestive heart failure (CHF).

Methods: We obtained 42 pleural effusions and divided them into 3 diagnostic categories. LL-37 was measured in the pleural fluid and serum of 23 infectious effusions, 10 malignant effusions and 9 CHF effusions by ELISA. Statistical analyses were performed using software SPSS 17.0.

Results: Results are presented: mean ± Std. Deviation (median, minimum, maximum).

Pleural Fluid LL-37 levels: Infectious 3.77±4.81 ng/ml (1.64, 0.38-19.4) malignant 2.58±4.17 (0.87, 0.09-13.5), CHF 1.59±1.02 (0.99, 0.47-3.3) (p=0.04)

Serum LL-37 levels: Infectious 2.09±1.42 ng/ml(0.98, 0.06-16.5), malignant 3.44±4.1 (1.19, 0.17-12.6), CHF 3.44±4.3 (0.22, 0.6, 0.71-10.3) (p=0.13)

Pleural fluid-to-Serum LL-37 ratio levels: Infectious 1.33±1.88 (1.29, 0.10-4.3) malignant 0.60±0.92 (0.72, 1.11-2.1) CHF 0.46±0.93 (0.44, 1.12-2.4) (<p=0.001). Infectious vs malignant p=0.002, infectious vs CHF p<0.001, malignant vs CHF not examined the p value.

Conclusions: Pleural fluid-to-Serum LL-37 ratios are significantly elevated in infectious pleural effusions in comparison with malignant or CHF pleural effusions, suggesting that LL-37 is actively produced intrapleurally in infectious effusions.
Conclusion: Several new risk factors have been identified that may help identify exacerbation patients who are at risk of failure despite adequate antibiotics. These patients should be closely monitored during and after treatment of their exacerbation.

P2524
Colonization in advanced chronic obstructive pulmonary disease
Jessica Rademacher, Hendrik Suhling, Günter Auenhammer, Jens Gottlieb, Tobias Welte. Respiratory Medicine, Medical School, Hannover, Germany.

Background: Isolation of potentially pathogenic organism from the sputum is associated with at least one hospitalization for COPD exacerbation (Martinez-Garcia et al. Chest 2011; 140: 1130-1137). But there is still a lack of examinations in larger populations of patients with COPD and pathogenic colonization. Aims: This examination was performed to evaluate the colonization in patients with advanced COPD. Methods: In this single-center evaluation, 379 patients with advanced COPD (GOLD III and IV) in our pre-transplant outpatient clinic were screened between October 2008 and 2011 by lung function, exacerbation rate within the last 12 month and sputum analysis. Results: The median exacerbation rate within the last 12 months was 2 (IQR 1-3), 51.7% of the patients had expectation and 40.9% had none (7.4% remains unknown). We analyzed the sputum of 186 patients and had a positive sputum culture in 31.6% of the patients, which is 16.4% of the whole examination group. Patients with a positive sputum culture were significantly more often hospitalized due to exacerbation (p=0.02). 94 patients (24.3%) underwent lung transplantation in the observation period. 19% of the explanted lungs had a proof of pathogenic organism. In 71 patients (75.5%) analysis of the sputum before transplantation was concordant with the results of the explanted lung. 11 patients (11.7%) had a proof in the explanted lung and no positive sputum or expectation before. Conclusion: Even in patients with end stage COPD chronic bacterial colonisation does play a role only in a minority of the patients (16%). The proof of pathogenic organism correlates with significant more hospitalization due to exacerbations.

Biomarkers and severity in community-acquired pneumonia (CAP)
Sergio Fundo1, Elsa Mincholle2, Ana Lasierra1, Ana Simon1, Carolina Pandera1, Guillermo Hernandez1, Francisco De Pablo1, Sandra Garcia1, Carlos Lapresta1, Salvador Belío1, Palmonology, Hospital Miguel Servet, Zaragoza, Spain, 2Biochemistry, Hospital Miguel Servet, Zaragoza, Spain.

Introduction: To evaluate the prognostic value of biomarkers in community-acquired pneumonia (CAP), we studied the correlations between C-reactive protein (CRP), procalcitonin (PCT), leukocyte count (WBC) and pradefomedemulin (proADM) with the widely used PSI severity score.

Conclusion: Several new risk factors have been identified that may help identify exacerbation patients who are at risk of failure despite adequate antibiotics. These patients should be closely monitored during and after treatment of their exacerbation.

P2523
Prognostic factors for short and long term outcomes of outpatient exacerbations in moderate-to-severe COPD
Rob Wilson1, Antonio Anzueto2, Marc Miravitlles3, Pierre Arvis4, Tobias Welte. Respiratory Medicine, Medical School, Hannover, Germany.

Introduction: Older patients with severe COPD, frequent exacerbations and co-morbidities are at higher risk of poor outcomes. Additional risk factors for short and long term outcomes are yet to be fully identified.

Methods: In the MAESTRAL study, COPD patients treated with 5-day moxifloxacin or 7-day amoxicillin/clavulanic acid for an Anthonisen type I exacerbation, stratified to oral corticosteroid treatment at the physician’s discretion. Predictive factors for clinical failure at end-of-therapy (EOT) and 8 weeks post-EOT were compared by post-hoc multivariate stepwise logistic regression analysis.

Results: Patients with frequent exacerbations, paroxysm, higher respiratory rate, low body temperature and bacterial resistance to study drug had a higher risk to fail at EOT. While patients who, in addition to frequent exacerbations and low body temperature, required systemic corticosteroids for their current exacerbation, were on LABA, suffered from sleep disturbances, had longer duration of chronic bronchitis, increased heart rate, low FEV1, low BMI and positive sputum culture at EOT were more likely to fail up to 8 weeks post-therapy.

P2522
Pseudomonas aeruginosa exacerbations in COPD patients
Isabelle Raul, Vincent Jouineaux, Claire Andrejak. Respiratory Diseases, Teaching Hospital, Amiens, France.

Background: Pseudomonas aeruginosa is found in COPD patients sputum in 4-15%, mainly in those with advanced disease and/or in those requiring mechanical ventilation. Currently, there are no data to justify an empiric antibiotic therapy against Pseudomonas aeruginosa when a new COPD exacerbation occurs in a patient with a previous Pseudomonas aeruginosa exacerbation.

Methods: We conducted a retrospective study to analyse microbiological ecology exacerbations in COPD patients with at least one Pseudomonas aeruginosa exacerbation.

Results: Among the 243 COPD patients hospitalized during the study period (2007-2011), only 23 (9.5%) had at least one Pseudomonas aeruginosa exacerbation (exacerbations per patient: 1.1). They presented a new Pseudomonas aeruginosa exacerbation in 54% of cases. From one to other exacerbation, the Pseudomonas aeruginosa susceptibility changed, with a wild type Pseudomonas aeruginosa in 58% of cases during the first exacerbation and 42% during the next one. COPD patients with GOLD stage IV were rarely hospitalized for a wild Pseudomonas aeruginosa exacerbation (p = 0.01, 15% vs. 83% in GOLD stage II and III patients).

Conclusion: In this pilot study, the microbiological ecology of COPD exacerbation differed from one exacerbation to another, contrary to that observed in cystic fibrosis patients.

P2521
Usefulness of procalcitonin as a diagnostic marker of pleural effusion
Isabelle Raul, Ruma El-Helbawy, Anur Darwish, Heba Fathy, Neurin El-Hel, Minoufiya University, Shebin El-Kom, Minoaffya, Egypt, 2Biochemistry, Minoufiya University, Shebin El-Kom, Minoaffya, Egypt.

Pleural effusions are common and are associated with many diseases. We investigated the usefulness of procalcitonin (PCT) as a diagnostic marker for the cause of pleural effusion. The study was carried out on 54 patients with pleural effusions divided into groups: transudate (n=6), empyema (n=9), T.B (n=8), parapneumonic effusions (PPE) (n=9) and malignan exacerbations (n=22). Levels of procalcitonin were measured both in serum & pleural effusions. Pleural fluid PCT was highest in empyema 1.7±0.86 ng/ml, next highest in PPE (0.57±0.56 ng/ml), & lowest in transudative effusions (0.06±0.03 ng/ml). Pleural fluid & serum procalcitonin levels positively correlate in both empyema & PPE. The optimal discrimination of patients with empyema could be performed at a cut-off point of pleural fluid procalcitonin 0.09 ng/ml with area under the curve (AUC) of 0.93 (sensitivity 80%,specificity 60%). However, the optimal discrimination of PPE levels positively correlate in both empyema & PPE. The optimal discrimination of patients with empyema could be performed at a cut-off point of pleural fluid procalcitonin 0.07 ng/ml (sensitivity 78%, specificity 51%) and at a serum procalcitonin 0.07 ng/ml with AUC of 0.74 (sensitivity 89%,specificity 69%).The optimal discrimination of patients with PPE could be performed at a cut-off point of pleural fluid procalcitonin 0.065 ng/ml (sensitivity 78%, specificity 33%). The optimal discrimination of patients with (empyema & PPE) could be performed at a cut-off point of pleural fluid procalcitonin 0.075 ng/ml (sensitivity 83%,specificity 58%) and at a serum procalcitonin 0.07 ng/ml (sensitivity 83%,specificity 47%). In conclusion: Pleural fluid PCT is a good and early marker of infection in the pleural space and correlates with the serum PCT in patients with PPE or empyema. Pleural PCT had better diagnostic accuracy than the serum PCT in cases of PPE & empyema.
**Material and methods:** We prospectively studied 282 immunocompetent adults; patients hospitalized with CAP, calculated their PSI score and measured on admission the mentioned four blood biomarkers. Subsequently, we established the ROC curves to determine which of the biomarkers had a better discriminating power from mild CAP (PSI 1-3) to severe ones (PSI 4-5).

**Results:** PCT and proADM significantly discriminated severe from mild CAP, although the area under curve was significantly higher for proADM (0.757 vs. 0.581). The other two biomarkers did not reach statistical significance.

**Background:** Bronchiectasis (B.) is induced by different mechanisms, one of these is primary ciliary dyskinesia (PCD). Genetic aberrations lead to a lack of mucociliary clearance. The bacterial biofilm in B. of patients with PCD in comparison to CF was studied by fluorescence in situ hybridisation (FISH).

**Material and methods:** An explant and 2 middle lobe resections of 3 patients (age between 5 and 50 years) were investigated using conventional histology. Diagnosis of PCD was confirmed by transmission electron microscopy. For comparison 10 explants of CF patients were available. Of all cases, at least 2 locations were studied by FISH using a pan-bacterial and a Pseudomonas-specific probe.

**Results:** Histology revealed typical B. In all 3 PCD cases no bacterial biofilms were detected by FISH, although at least one case Ps. was detected by culture previously. In comparison all CF cases showed colonization with Ps.

**Conclusions:** Significant differences exist concerning bacterial biofilms in PCD versus CF. This might be of relevance for the clinical practice.
Inflammatory cells composition of bronchial brush-biopsies in dependence on least injured effects. *H.*influenzae, *Ch.*pneumoniae have more injured effects and *M.*catarrhalis infection (33.7 ± 0.7%). Dystrophical cells count was reliable high (p < 0.05) in *H.*influenzae, *Ch.*pneumoniae, *M.*pneumoniae infection (6.3 ± 1.0%, 7.4 ± 1.4%, 7.4 ± 1.6%) as compared with *S.*pneumoniae, *M.*catarrhalis infection (2.5 ± 0.9%, 2.2 ± 0.7%). Dystrophical cells count was reliable high (p < 0.05) in *H.*influenzae, *Ch.*pneumoniae infection (50.3 ± 1.5%, 50.2 ± 2.1%) than *S.*pneumoniae, *M.*pneumoniae *M.*catarrhalis infection (49.6 ± 3.0%, 47.4 ± 3.5%, 39.8 ± 4.3%). Macrophages quantity was reliable high (p < 0.05) in *M.*pneumoniae infection (55.1 ± 1.6%) as compared with *S.*pneumoniae, *H.*influenzae, *Ch.*pneumoniae, *M.*catarrhalis infection (33.7 ± 3.7%, 27.4 ± 3.0%, 25.2 ± 3.5%). Infection agent species influence on degree of bronchial mucosa damage. *H.*influenzae, *Ch.*pneumoniae have more injured effects and *M.*catarrhalis have least injured effects.

Cellular composition of bronchial brush-biopsies at COPD exacerbation age, mortality and hospital costs were higher compared to culture negative group. *Acinetobacter* was the most common isolated microorganism. In hospitalised COPD patients in our clinic, *Acinetobacter* infection (48.8%). Taking into account the results of received data there have been developed and carried out special NPCP aimed to increase the LMSK (lectures, discussions, printed issues). Comparative exercise was repeated 1.5 yrs later. Test showed the increase of LCA up to 60% (p < 0.05). We determined that NP-rate was statistically decreasing during NPCP (p < 0.05). It was fixed that the most difficult questions were the following: sources of NI agents, risk factors of NI, rationale antibiotic use, hand-hygiene and other NI-preventive measures, mortality rates under NI.

Conclusions: There is a necessity to carry out NPCP among surgeons in GSD to increase LMSK and to decrease NP level. Therefore, the most difficult questions require to be studied more deeply.

**Distinct bacterial species: Escherichia coli and staphylococcus aureus have specific microcalorimetric patterns**

Alexandra Streza1, Dragos Zaharia1, Alexandru Muntean1, Octavian Balint1, Miron Bogdan2, Mircea Popa2, Vlad Popa2

*1 University, Medicine and Pharmacy “Carol Davila”, Bucharest, Romania; 2 Microbiology, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania*

**Material and method:** Series of experiments were conducted for *E.Coli* (15 experiments) as well as for *S.Aureus* (13 experiments) and the obtained thermograms were then compared. Several heatflow curve parameters were identified and then used for comparison.

**Results:** The obtained microcalorimetric curves present 2 peaks, each curve providing different recorded parameters.

**Conclusion:** Microcalorimetry represents a method which can be used to objectively differentiate the 2 species (with differences being statistically significant). In our opinion, these parameters could allow a primary microcalorimetric characterization of the bacterial growth. Furthermore, by using this method, identification of bacterial species could be possible in the near future.

**Induction of protective T cell immunity against influenza using a novel peptide vaccine**

Tom Wilkinson1, Olga Piegzaucza2, Stuart Robinson2, Gregory Stolf2, Rob Lambkin-Williams2, John Oxford2, Alex Mann3, Anthony Gilbert3, Wilson Caparros-Wanderley2

*1 Clinical and Experimental Sciences, University of Southampton Faculty of Medicine, Southampton, United Kingdom; 2 Seek, London, United Kingdom; 3Clinical Trials Team, Retroscreen Virology, London, United Kingdom*

Influenza vaccination remains an important cause of global morbidity in spite of current vaccine strategies which generate antibody responses to surface viral proteins. Recent studies have established that naturally occurring T cells which recognize highly conserved core viral proteins and limit illness against a range of viral strains. We aimed to demonstrate that induction of T cell memory using a novel peptide vaccine (Flu-V) could limit influenza severity using a human viral challenge model. 32 seronegative healthy males were randomised to receive 500μg of peptide vaccine or placebo. All subjects were challenged by nasal instillation of live A/Wisconsin/67/2005 (H1N2). Safety, tolerability, influenza severity and cellular immune data were collected.

---

**Monday, September 3rd 2012**

---

464s
The vaccine was safe and well tolerated. No pre-existing T cell responses to the novel Flu-V vaccine were seen at baseline by IFN-γ release assay. All subjects in the treatment arm demonstrated strong induction of the peptide specific cellular response (fold rise 8.2±1.9 (Range 5.0–10.6) p<0.0005). The length of the induction of T cell response to Flu-V inversely correlated with influenza illness severity -symptoms r=-0.786, p=0.02 and viral shedding r=-0.821, p=0.01. Furthermore the peptide specific induced strong cellular responses against heterogenous strains, including H1N1pdm in vitro. Peptide vaccination can induce cellular immunity to influenza which correlates closely with disease protection in humans. T cell responses can be induced against a range of strains and therefore this approach carries potential for the induction of broad heterologous immunity required to protect against future pandemics.

**Results:**
During 2011, 217 sera samples were examined. Antibodies on Adenovirus were detected by Indirect Immunofluorescent Assay –Pneumoslide IgM.

**Material and methods:**
The clinical episodes of 141 non-immunosuppressed outpatients with seasonal influenza A during winter season 2010/2011, including 67 patients IgM and 74 patients IgG with a neuraminidase inhibitor alone and 74 treated with the combination therapy (mean age: 30 and 31 years, respectively), were analyzed.

**Conclusion:**
Although the effect of clarithromycin in non-elderly patients with seasonal influenza A was limited, further studies might be needed to determine the additional or preventive effect of clarithromycin during influenza virus infection for elderly subjects or patients complicated with serious underlying diseases.
We report underlying malignancy and chronic corticosteroid therapy in a multivariate analysis of community-acquired pneumonia (CAP) as independent risk factors for mortality.

Results: A total of 223 patients had been included, 89 (40.3%) with CAP and 132 (59.7%) with HCAP. Statistically significant differences favoring HCAP were observed in the following variables: older age (75.6 yrs, p < 0.001), presence of cerebrovascular disease (74.1%, p = 0.039), poor functional status (37.5%, p = 0.039), previous antibiotic treatment (53.9%, p < 0.001), higher mortality rate (68.4%) and initial empiric therapy (piperacillin/tazobactam plus aminoglycoside, 63.2%).

Conclusions: Our results confirm the greater severity and worse prognosis of HCAP. In this group the most frequent agents were the gram negative bacteria. Accordingly, the empirical antibiotic therapy should cover not only the usual CAP agents, but also the causative agents associated with nosocomial pneumonia.

We compared HCAP vs CAP regarding clinical and epidemiological characteristics, comorbidities, functional status, previous antibiotic treatment, risk stratification by Pneumonia Severity Index (PSI) and CURB 65 score, etiologic agents, therapeutic regimens, hospital length and mortality.

Background: Nocardia pneumonia has emerged as an important cause of mortality and morbidity in both immunocompetent and immunocompromised hosts. In this study, risk factors, clinical features, outcomes and factors associated with mortality in Nocardia pneumonia were reported.

Materials and methods: Clinical records of all cases diagnosed with nocardia pneumonia during 2001-2010 were reviewed. Identification of Nocardia species was based on positive Gram stain and positive modified acid-fast stain results, colonial morphology, and conventional biochemical reactions. Data was analyzed using SPSS version 17. Factors associated with mortality was assessed by univariate and multivariate analysis.

Results: Fifty Five cases were identified. Fever, cough and dyspnea were the most common presentations. Most important risk factors were chronic steroid administration (69%) and an underlying malignancy (24%). Most common complications observed were respiratory failure (27%) and septicemia (27%) 19(34.5%) patients died. Factors associated with mortality were smoking (p = 0.01), decreased appetite (p = 0.007), leukocytosis (t = 0.006), mechanical ventilation (p < 0.001) and septicemia (p < 0.001). Septicemia (OR 20 [95% CI 3.13 -130]) was found to be independent risk factor for mortality in multivariate analysis.

Conclusion: We report underlying malignancy and chronic corticosteroid therapy as a risk factor for development of nocardiosis in our patients. High mortality rate in this cohort were observed. Septicemia was found to be independent risk factor for mortality. Clinicians should keep a high index of suspicion for early diagnosis and management to decrease mortality.

Conclusions: We provide data on the etiology and clinical features of patients with nocardiosis. The most frequent agents were the gram negative bacteria. The relative risk of lethal outcome in those patients was 24.4 (95% CI 10.5 and 52.1). The diagnosis was delayed and the mortality was high. The results confirm the greater severity and worse prognosis of Nocardia pneumonia.

Background: Cytokines are important mediators in the host response to infection. Responses in patients with non-severe and severe CAP and to correlate these with pneumonia severity index (PSI) and other clinical parameters.

Methods: In a prospective study, 20 CAP patients and 10 healthy individuals were included. Upon admission, levels of interleukin (IL-6), IL-10, IL-1β, tumor necrosis factor (TNF), interferon (IFNy), IL-22, IL-17A and IL-4 were determined in bronchoalveolar lavage (BAL) fluid and serum by enzyme-linked immunosorbent assay (ELISA). Systemic cytokine levels were also measured on days 7 and 30.

Results: IL-6 and IFNy were significantly increased compared with healthy individuals, but no correlations with disease severity were found. Systemic levels of IL-6, IL-10 and IFNy were significantly higher in severe CAP patients than in non-severe CAP patients and healthy individuals. Moreover, these cytokines showed a strong correlation with the PSI. In the total group of CAP patients IL-6 and IL-22 levels were also increased compared with healthy individuals.

Conclusions: IL-6 and IFNy are important cytokines in both the local and systemic inflammatory response in CAP. Differences in disease severity upon admission are however only reflected by the systemic levels of these cytokines and IL-10.

Background: Acute respiratory distress syndrome (ARDS) – Manifestation of onset in an immunocompromised patient with pleuropulmonary tuberculosis (TB) has been reported. The aim of this study was to describe the active pleuropulmonary TB and compare the clinical and laboratory findings with previous reports.

Methods: The authors present a clinical case of pleuropulmonary TB and ARDS.

Results: Young patient, 38 years, smoker (25 pack-year), was hospitalized in emergency with fever 39.8 °C, tachycardia (heart rate = 120/min), left thoracic stabbing. Admission chest Xray: opacities highlight ulcerated nodular infiltrative nature and opacity right upper lobe and parietobronzial fluid excluded on left. At 6 hours after admission, the general condition worsens (SaO2 = 40%, PaO2 = 35mmHg), and chest Xray and CT scan shows multiple pulmonary infiltrates ("white lung"). Sputum exam for tuberculosis is negative in microscopy and culture is positive. Pleural biopsies reveal the presence of tuberculosis folicles. Test for HIV was negative. The patient was intubated and mechanically ventilated for 3 days, then improved clinical course and radiological image become the same as admission. After biopsy confirmation of TB patient received tuberculostatic treatment with favorable clinical and radiological evolution.

Conclusions: To improve the prognosis of ARDS of unknown cause we should think of tuberculosi syndrome, especially in patients with impaired immunity.
The clinical evaluation of respiratory tract infection caused by MRSA
Keri Nakashima1, Yoshitomo Osuka2, Haruki Kobayashi2, Naoko Katsurada1, Nobuharu Asai1, Hideki Makino3, Masatumi Misawa1, Yoshitomo Ohkumi1, Norihiko Kaneko1, Masahiro Aoshima1.
1Pathology, Kameda Medical Center, Kamogawa, Chiba, Japan; 2Laboratory Medicine, Kameda Medical Center, Kamogawa, Chiba, Japan

Background: Most of the MRSA detected in respiratory specimens were colo-
ized. However pneumonia due to MRSA becomes severe and improvement of outcomes were important.

Methods: Medical records of 11 MRSA pneumonia patients among 106 patients with MRSA detected in respiratory specimens from June 2010 to May 2011 at Kameda Medical Center were reviewed retrospectively. The following variables were studied: patient background, hospitalization, drug susceptibility, outcomes.

Results: Mean age was 73.5 ± 5.0. Eight patients were male, 3 were female. Eight were HAP, 3 were NHCAP (Nursing and healthcare associated pneumonia). Four patients have Chronic kidney disease, 3 have neurological disorder and 2 were under steroid administration. Nine patients (81.8%) were detected through microbial subsetting. Period from admission to detection was 41.9 ± 1.2 days, period from antimicrobail initiation to detection was 23.1 ± 2.1 days, numbers of antimicrobial agents were 2 ± 0.2. Nine patients (81.8%) have polymicrobial detection. Paeruginosa, 5. malophilia, K pneumonia were detected in 4 ± 3, 2 patients frequently. All of the anti MRSA agents administered were VCM. MIC of VCM were 1 with 2 patients, 0.5 with 1 patients, unexamined with 1 patients in the 4 patients at the introduction of broth microdilution method. Duration of administration was 12.8 ± 4.5 days on average. In 9 patients (84.6%) beta-lactum agents were administered in combination. Duration of hospitalization was 124.8 ± 7.2 days on average, 5 patients (45.5%) were died.

Conclusion: Use of MRSA detected in respiratory samples was HAP and polymicrobial detection. MRSA caused the prolonged hospitalization and poor prognosis.

P2545
Community-acquired pneumonia during the influenza pandemic A(H1N1) pdm09 and post-pandemic period in hospitalized patients, Russia
Zania Bobyleva1, Igor Leshchenko2, Natalia Ponamareva1, Yulia Morezova1.
1Pediatrics Chair, Russian State Medical Academy of Postgraduate Education, Moscow, Russian Federation; 2Laboratory of an Aetiology and Epidemiology of Influenza, Ivanovsky Research Institute of Virology, Moscow, Russian Federation

Background: This was a retrospective study including all adults with CAP admitted to the Hospital Regional Hospital 1 during an influenza A(H1N1) pdm09 between November 1, 2009 and January 15, 2010 (group A) and post-pandemic period between January 1 and April 20, 2011 (group B). Group A: 94 patients, mean age 36.1 ± 13 (men, 39%), Group B: 109 patients, mean age 43 ± 15 (men, 46%).

Methods: Patients with laboratory confirmed influenza A(H1N1) pdm09 (gr. A) 45% vs (gr. B) 28% (p = 0.02). In gr. B compared with gr. A: were hospitalized less often (30% vs 58%, p = 0.003), decreased the proportion of obese patients (14% vs 25%, p = 0.05), less lung injury: 2-way process (55% vs 82%, p = 0.000) and lung injury: 2-way process (55% vs 82%, p = 0.000) and decreased the proportion of obese patients (14% vs 25%, p = 0.05), less lung injury: 2-way process (5% vs 82%, p = 0.000) and lung injury (6% vs 80%, p = 0.000) and rarely detected “glass matte” (2% vs 11%, p = 0.03). In gr. B decreased need for admitted in the ICU 40% vs 60% (p = 0.002), with a smaller proportion of them are pregnant (9% vs 49%, p = 0.01). The length of stay in the ICU, the need for mechanical ventilation and the patients with laboratory confirmed A(H1N1) pdm09 not significantly different. The frequency of deaths in the groups did not differ significantly and was 18% (gr. B) vs 21% (gr. A).

Conclusion: Among in-patients with CAP in post-pandemic period decreased: the numbers of patients infected with the virus A(H1N1) pdm09, the need for admitted in the ICU with a tendency to reduce the incidence of CAP in pregnant.

Prevention of the recurrent acute respiratory viral infections in children Andrey Zaplatnikov1, Nina Korovina1, Irina Zakharova1, Elena Burtsveva2, Gulina Mingleamova1, Ludmila Zaplatnikova1, Irina Zak1, Lucia Vezzoli1, Chiara Paladini3,4.
1Pediatrics, Paeview Russian State Medical Academy of Postgraduate Education, Moscow, Russian Federation; 2Laboratory of an Aetiology and Epidemiology of Influenza, Ivanovsky Research Institute of Virology, Moscow, Russian Federation

Background: It is known that recurrent episodes of acute viral respiratory infec-
tions (recurrent ARVI) are common for children attending nursery school.

Methods: To evaluate the efficacy and safety of interferon inducer (IFN-i - “Anaferon”) in prevention of recurrent ARVI in children.

Patients with laboratory confirmed influenza A(H1N1)pdm09 (gr. B) 45% vs (gr. A) 28% (p = 0.02). In gr. B compared with gr. A: were hospitalized less often (30% vs 58%, p = 0.003), decreased the proportion of obese patients (14% vs 25%, p = 0.05), less lung injury: 2-way process (5% vs 82%, p = 0.000) and lung injury: 2-way process (5% vs 82%, p = 0.000) and decreased the proportion of obese patients (14% vs 25%, p = 0.05), less lung injury: 2-way process (5% vs 82%, p = 0.000) and lung injury (6% vs 80%, p = 0.000) and rarely detected “glass matte” (2% vs 11%, p = 0.03). In gr. B decreased need for admitted in the ICU 40% vs 60% (p = 0.002), with a smaller proportion of them are pregnant (9% vs 49%, p = 0.01). The length of stay in the ICU, the need for mechanical ventilation and the patients with laboratory confirmed A(H1N1) pdm09 not significantly different. The frequency of deaths in the groups did not differ significantly and was 18% (gr. B) vs 21% (gr. A).

Conclusion: Among in-patients with CAP in post-pandemic period decreased: the numbers of patients infected with the virus A(H1N1) pdm09, the need for admitted in the ICU with a tendency to reduce the incidence of CAP in pregnant.

Purpose: The aim was to conduct a systematic review of randomized controlled trials (RCTs) of single-dose PFCE (pentaerythrityl tetraacetate) therapy and chronic intermittent PFCE therapy in transgenic sickle cell and control mice infected with Streptococcus pneumoniae (strain D39).

Methods: Mice were injected intravenously with single dose of saline or PFCE (3 ml/kg) +/- S. pneumoniae strain (D39) and harvested at 72 hours or on showing signs of 2+ lethargy. A second group of mice were injected with PFCE daily for 1 week. Histological analysis of lungs was performed using H&E sections and light microscopy. In addition, white blood cell analysis was performed using flow cytometry.

Results: S. pneumoniae-infected mice treated with PFCE died earlier than those treated with vehicle and were less able to clear S. pneumoniae from the bloodstream. In the absence of infection, mice treated with a single dose of PFCE showed mild inflammation changes in the lung. However, mice treated with PFCE for 1 week did not show any histological abnormalities. The inflammatory response in healthy mice injected with PFCE was significantly higher compared to sickle cell mice.

Conclusions: Single-dose PFCE therapy causes lung injury mice whereas chronic PFCE therapy does not. In addition, the inflammatory response to PFCE therapy is different in healthy and sickle cell mice. Further studies are required to determine mechanisms of inflammatory responses in sickle cell mice and whether supplemental oxygen therapy improves outcomes in mice infected with S. pneumoniae and treated with PFCE.
Prevalence and risk factors for pneumonia in a cohort with clinical suspicion of influenza A (H1N1)

Mirta Vella1, Silvia Crispilla2, Gema Navarro3, Eduard Moms4, Carles Gimeno1, Miguel Gallego1

1. Pneumology, Corporació Sanitaria Parc Taulí, Sabadell, Barcelona, Spain; 2. Microbiology, Corporació Sanitaria Parc Taulí, Sabadell, Barcelona, Spain; 3. Epidemiology, Corporació Sanitaria Parc Taulí, Sabadell, Barcelona, Spain

Due to the potentially life-threatening of H1N1 infection, mainly influenza pneumonia (IP), distinguishing IP from non-influenza pneumonia (NIP) is crucial to adequate the appropriate treatment.

Aim: 1. To determine the prevalence of IP and NIP in a cohort with suspected pandemic H1N1.

2. To evaluate the presence of risk factors for pneumonia in both groups.

Methods: Retrospective observational study undertaken in patients with clinically suspected influenza admitted to emergency room, from August to December of 2009. Nasopharyngeal swabs were obtained from patients and RT-PCR was performed. Episodes in patients under age 18, nosocomial acquisition and infections in health-care workers were excluded. Demographic variables, comorbidities, final diagnosis and administered treatment were recorded.

Results: 326 episodes were evaluated (59.8% women). In 141 cases (43.2%) pandemic H1N1 was confirmed. IP was diagnosed in 33/326 (10.1%) and NIP in 86/326 (26.4%). 84.8% of IP episodes required hospital admission (27.3% in ICU).

On the other hand, 79.1% of NIP needed hospitalization (17.4% in ICU). 24% of IP were classified as PSI class IV/V vs. 44.2% of NIP (p=0.04). Mortality in both groups was 9.1% vs. 10.5% respectively. Regarding to risk factors, statistical significant differences were found in age (47.5±15.9 vs. 58.7±19.5, p=0.002), asthma (18.2% vs. 5.8%, p=0.037) and COPD (9.1% vs. 30.2%, p=0.016). Obesity and pregnancy did not show significant differences.

Conclusions: 1. - The overall prevalence of pneumonia was 36.5% (10.1% for H1N1).

2. - Older age and COPD were risk factors associated with non-influenza pneumonia while asthma was associated with influenza pneumonia.

Nebulised therapy in pregnant with acute respiratory viruses infections (ARVI)

Janna Pahomova

Nebulised therapy in pregnancy did not show significant differences.

Results: 22 cases were found influenza A virus positive via DIEFA with a positive rate of 55%, while 12 cases were found influenza A virus positive via GICA with a positive rate of 30%. Compared with qRT-PCR detection, the specificity, sensitivity and consistency of DIEFA were 85.7%, 78.9% and 82.5% respectively, while the GICA’s sensitivity, specificity and consistency were 42.8%, 84.2% and 62.5% respectively. The data showed that DIEFA had apparent superiority of sensitivity over GICA in rapid influenza A virus detection.

Conclusions: DIEFA can be an optimal approach for rapid detection of influenza A virus with the advantage of higher sensitivity and specificity, adapting for screening influenza A virus rapidly in influenza A virus epidemic conditions.

268. Management of pneumonia due to hospital pathogens

P2553

The role of inflammatory markers in the diagnosis and management of patients with community-acquired pneumonia

Institute for Biochemistry and Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic of

The aim of this study was to determine whether there is a significant difference between the values of C-reactive protein (CRP) and white blood cells (WBC), in patients with serological proved atypical pneumonia and in serological negative atypical pneumonia.

Materials and methods: A total of 403 adult hospitalized patients with clinical and radiographic findings of pneumonia. Diagnosis of acute atypical pneumonia was established by serological confirmation of IgM and IgG antibody against Mycoplasma pn., Coxiella burnetii, Chlamydia pn. and Legionella pn. There were compared the values of the age, sedimentation, WBC, lymphocytes, neutrophils, CRP and aminotranspherases in patients with pneumonia with atypical infection (n=145) and in serological negative for atypical pathogen (n=258).

Results: The mean age of patients was 49.86 years, 209 (51.86%) were male and 194 (48.14%) females. Acute atypical infection was in 145 (35.98%), in 10 (2.48%) mixed etiology and 248 (61.54%) were negative for atypical pathogen.

The main value of the age in patients with positive result for atypical pathogen was statistically significance lower (t=4.43, p<0.05). The concentration of CRP was statistically higher in the group with negative result for atypical pathogen (146,7mg/l) then in atypical positive group (71.1mg/l) (t=4.46, p<0.05), while there was not statistical significance in value of WBC between the two groups (t=1.09, p=0.28).

Conclusion: Although nonspecific C-reactive protein as a parameter of inflammation, within the whole diagnostic protocol in patients with pneumonia, can be useful in their initial differentiation on atypical or not atypical.

P2554

Comparison of laparoscopic sleeve gastrectomy pulmonary complications comparing to laparoscopic adjustable gastric banding

Olg'a Talkar, David Shuva

Moncloa, Pneumology, Meir Medical Center, Kfar Sava, Israel

Introduction/rationale: Major changes in gastric anatomy and physiology following Laparoscopic adjustable gastric banding (LAGB) and laparoscopic sleeve gastrectomy (LSG) may increase the risk of esophageal regurgitation, increasing possibility of long-term pulmonary complications.

Methods: A retrospective case-control study was performed including all patients undergoing bariatric surgery, LAGB or LSG, over a 10-year period (2000-2010) at Meir Medical Center, Israel. Two groups were defined: patients who underwent LAGB or LSG. Data included all perioperative management and were recorded in hospital computer database. All patients were thoroughly examined and questioned about pulmonary complaints, such as: shortness of breath, persistent cough, pneumonia, infected bronchietasis. The data were analyzed using Mann Whitney test for independent samples and Chi square test, with p < 0.05 considered significant.

Results: The patients underwent either LAGB (n=193, mean age 43.1 yrs., +11.3 yrs., 144 (76.6%) females, 21(10.5%) with previous lung disease) or LSG (n=114, mean age 45.5, ±11.3 yrs., 83 (73%) females, 12 (10.5%) with previous lung disease). The LSG patients had significantly lower rates of mencing cough and postprandial cough than did the LAGB patients: 14 (12.3%) vs. 115 (59.6%), p<0.001, 12 (10.5%) vs. 112 (58.0%), p<0.001, respectively, similar rate of complications (2 cases in each group) was noted follow the surgery. Mortality was zero.

Conclusions: Follow-up data demonstrated relatively less postoperative pulmonary complications after LSG comparing to LAGB. Additional follow-up is required to define long-term safety.
A retrospective infection in intensive care unit: Enterococci
Mohammed Emran Akkovayn1, Yasemn Akkovayn2, Tarun Adani3
Method: This study investigated direct costs and related factors for hospitalised CAP. Patients hospitalised with CAP major determinants of costs were length of hospital stay, use of antimicrobial antibiotic combination, use of antibiotic within 3 months and two or more hospitalisation days within 3 months.

Comparison of invitro antimicrobial susceptibility tests of patients admitted in a tertiary respiratory center intensive care unit with their clinical symptoms related to ventilator associated pneumonia (in vivo results)
Mahb Malkomehmad1, Mohammadreza Hashemian1, Parisa Adimi Naghan2, Helenar Fajraliszadeh1,2, Makan Sadr3, Hamidreza Jamaati1.

Background: Ventilator associated pneumonia (VAP),is the most common nosocomial infection in ICU admitted patients. There is no study about comparison of clinical response to routine VAP treatment and susceptibility of microorganism to antibiotics in VAP suspected patients.
Methods: In this cross-sectional retrospective study, the files of 99 mechanically ventilated patients in a respiratory center ICU were assessed. Patients demographic data, underlying diseases, Clinical Pulmonary Infection Score (CPIS), in vitro (culture) results, antibiogram and antibiotic regimen were recorded.The change in CPIS was considered as positive in vivo. The result of culture of secretion (especially tracheal secretion) was considered as in vitro result.
Results: From 99 patients, 59 (60%) were male with a mean age of 42 years.14 patients (14%) had positive in vivo result and 19 patients (19%) had positive in vitro result. 60% of patients had given VAP antibiotic regimen. Comparison between results are seen in 56% of patients with both positive results of in vivo and in vitro had resistant antibiotic susceptibility test in antibiogram. Near to half of patient with both negative results of in vivo and in vitro had given antibiotic regimen for VAP.
Conclusion: More attention to clinical condition of patients (CPIS) than laboratory results is necessary for beginning of VAP antibiotic treatment.
P2560  
Microbial contamination of single- and multiple-dose vials after opening in a pulmonary teaching hospital  
Shadi Eshraghi, 1 Atisa Doroudinia, 1 Mandana Mobahran, 2 Fanak Fahimi  
1 Virology Research Center, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran; 2 Pathology Department, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran; 3 Chronic Respiratory Disease Research Center, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran  

Introduction: Intravenous therapy is a complex procedure usually requiring the preparation of the medication in the clinical area before administration to the patient. Breaches in aseptic technique may result in microbial contaminations of vials which is a potential cause of different avoidable infections.  

Aims: We aimed to investigate the prevalence and pattern of microbial contamination of single- and multiple-dose vials (SDVs and MDVs) in the largest pulmonary teaching hospital in Iran.  

Methods: In a period of 2 month, opened SDVs and MDVs from different wards were collected by a pharmacist. The name of the medication, ward, labeling of the vials, date of opening, and storing temperature were recorded for each vial. Remained contents of each vial were cultured using appropriate bacterial and fungal growth media.  

Results: Microbial contamination was identified in 11 of 205 (5%) of vials. The highest contamination rate was 14.29% for vials used in interventional bronchoscopy unit. The most frequent contaminated medications were Insulin and potassium chloride. Gram-positive bacteria (81.82%) were more significantly involved than gram-negative ones (9.09%) and fungi (9.09%), with the highest frequency for Staphylococcus epidermidis.  

Conclusions: Use of safe injection practice is critical to prevent microbial contamination of these medications. A training program for health care workers in aseptic techniques and written guidelines for aseptic handling of intravenous solutions are required.

P2561  
Comparison of scoring systems use for estimation of severity of community acquired pneumonia  
Marina Rolandskienė Milevičienė, 1 Marija Mitic Milikic 1, Mihailo Stepanovic  
1 Clinic for Pulmonology, Clinical Center of Serbia, Belgrade, Serbia; 2 General Practice, Hospital Komunerus, Belgrade, Serbia  

Introduction: Estimation of Community acquired pneumonia (CAP) severity is important for patient management. Some scoring systems for estimation are: Pneumonia severity index-PSI, CURB, CURB-65 and CRB-65 index and A-DROP system.  

Aim: Aim of this study was to compare predictive values of these scoring systems regarding severity of CAP.  

Method: Study was done at Clinic for pulmonology, Belgrade, in 100 hospitalized patients with an admission diagnosis of CAP, which were categorized into PSI, CURB, CURB-65 and CRB-65 index and A-DROP system.  

Results: The study included 100 patients (men 65, women 35), age range 23-87 years. The patients rates with PSI risk class I, II, III, IV and V were 15%, 16%, 21%, 28%, 14% respectively. Using CURB index rates were 34%, 49%, 9%, 6% and 2% for scores 0, 1, 2, 3, 4 respectively. CURB-65 index was 36%, 31%, 34%, 6%, 2%, 1% with score 0, 1, 2, 3, 4 and 5 respectively. Patients rates for CRB-65 scores 0, 1, 2, 3 and 4 were 44%, 43%, 9%, 3%, 1% respectively. The patients rates for A-DROP characteristics were 24%, 30%, 36%, 13%, 2%, 1% for scores 0, 1, 2, 3, 4, 5 respectively. 9% of patients were died. 28% of patients had chronic obstructive pulmonary disease (COPD).  

Conclusions: Patients were hospitalized more common then that was indicated by scoring systems (some were hospitalized for social reasons). PSI is more additive for estimation of CAP severity, but CURB, CURB-65, A-DROP and especially CRB-65 have the benefit of being easy to calculate and simple to use. CURB-65 and A-DROP show similar results for estimation of degree of the disease. Neither of these scoring systems use COPD as category for assessment (PSI and A-DROP only include arterial blood gas analyses).

P2562  
Community acquired pneumonia: Can physiotherapists and occupational therapists help reduce the length of stay?  
Arun Khanna, Abhar Almulla. Respiratory Medicine, Great Western Hospital, Swindon, United Kingdom  

Introduction: Community Acquired Pneumonia (CAP) places a significant burden on healthcare budget. With an increasingly ageing population, an unmet need for measures to cut down on length of stay (LOS) from this diagnosis exists.  

Methods: We retrospectively analysed all cases of CAP admitted to our hospital for a period of six months. After adjusting for co-morbidities with charlson index, 40 cases of LOS over and above the expected LOS were identified. Their case notes were analysed in detail to identify potential remediable factors to help reduce overall LOS.  

Results: All of the 40 cases received timely diagnosis, review by senior clinicians and appropriate treatment in keeping with national guidelines. The average age was 79 years. Higher Charlson index correlated well with increased LOS. Overall, 42% (n=17) developed complications of pneumonia resulting in increased LOS. Out of these, 23% (n=4) continually deteriorated resulting in an overall mortality of 10%. Unmet occupational and physiotherapist needs resulted in an increased LOS in 45% (n=18) after time to clinical stability (TCS). In 10% (n=4) increased LOS was attributable to ongoing social needs whilst no documented cause could be ascertained in the last remaining case.  

Conclusions: Early institution of physiotherapy and occupational therapy interventions can potentially help reduce LOS from CAP and reduce economic burden on healthcare budget. A multi-disciplinary team approach to CAP, especially in elderly patients, should be considered.

P2563  
Smoking, haemophilus influenzae and hospital readmission  
Rajesh Kumar Yadavilli, Rosalind Benson, Edjiah Matovu, Madhur Vardhan, Sanjeev Agarwal. Respiratory Medicine and Microbiology Dept, Whiston Hospital, Prescot, Merseyside, United Kingdom  

Background: Patients with chronic lung diseases are well known to have colonisation of lower respiratory tract with Haemophilus Influenza (HI). D Roberts et al have demonstrated increased growth of HI inviron the presence of nicotine. However, it is not known if that leads to increased risk of clinical infection requiring hospital readmission.  

Hypothesis: Smoking increases the risk of acute clinical infections and hospital readmission due to HI.  

Methods: Retrospective study of adult patients admitted with acute HI infection over a 2 year period in an acute teaching hospital setting.  

Results: N=133, mean age 60 years, male 57%, smokers 89%; Respiratory co-morbidities 83% (COPD 79%, Bronchiectasis 7%, Asthma 7% and Combined 7%).  

Current smokers had increased risk of recurrent admissions 17/29(59%) compared to Ex-smokers 33/89(37%).  
P = 0.05 Fisher’s exact test.  

Patients with >40 pack years smoking history had increased risk of recurrent admissions 34/6(54%) compared to <40 pack year group 15/30(50%). P=0.01 Fisher’s exact test.  

Smokers with background chronic lung disease had a tendency to have a higher number of recurrent admissions (46% vs 25%), but this was not statistically significant. P=0.09 Fisher’s exact test.  

Conclusions: This study shows a significant association with smoking and increased HI related hospital readmissions. Smokers should be informed of this risk and strongly advised to quit smoking.

P2564  
Community-acquired complicated parapneumonic effusions in adults without associated comorbidity – A study from India  
B N B Mahaveera Prasad, C A. Tukaram, Medicine, MH Wellington, The Nilgiris District, Tamilnabad, India Medicine, MH Wellington, The Nilgiris District, Tamilnabad, India  

Methods: Retrospective analysis of clinical, radiological, bacteriological, pleural fluid A-DROP scores and outcome of surgical intervention. The entry criteria for surgery was pleural fluid characteristics and treatment outcome of cases managed at a multispeciality hospital in rural India.  

Results: 17 cases in this study had 15 males and 2 females between 21 to 53 years of age. All presented with acute onset of fever, chest pain, pulmonary consolidation and leucocytosis. Mean duration of symptoms averaged 6 days prior to hospitalisation. 2 had mild effusion while moderate effusions was observed in the remaining 3 with them having multiloculation. Pleural fluid grew streptococcus pneumoniae in 5 and staphylococcus aureus in 2 cases. Blood and sputum grew streptococcus pneumoniae in 2 cases. Pleural pus was present in 11 cases and in the remaining pleural fluid revealed polymorphonuclear leucocytosis with glucose below 50 mg/dl. Pleural fluid gram stain was positive in 8 cases. All cases received appropriate antibiotics. Pleural drainage with 24 F chest tube was instituted in 11 cases while in the remaining with 12 F pigtail catheter. 3 cases with multiloculation required instillation of intrapleural streptokinase and placement of pigtail catheters at two different sites for an effective pleural drainage. Amount of pleural fluid drained varied from 450 ml to 2400 ml with mean chest tube dwell time of 6.5 days. All patients responded well to therapy. 2 cases had residual pleural thickening without functional abnormality.  

Conclusions: ACCP category 4 effusion was the commonest with infection by streptococcus pneumoniae predominating among them. Early institution of pleural drainage along with appropriate antibiotic therapy resulted in excellent outcome.
P2565 Multilobar x-ray shadowing is an independent predictor of community-acquired pneumonia severity and mortality
Carly L. Griffin, Joanne M. Sloan, Janet R. Wilson, James D. Chalmers, Morven E.M. Wilkie, Stuart Schembri. Ninewells Hospital, NHS Tayside, Dundee, United Kingdom

Introduction: National guidelines for community-acquired pneumonia (CAP) recommend the CURB65 score to assess severity and determine antibiotic therapy. CURB65 does not factor the radiographic extent of consolidation on chest x-ray. The aim of this study was to determine the prognostic value of classifying CAP into unilobar and multilobar consolidation.

Methods: A retrospective study of patients admitted with CAP was performed over 6 months. CAP was confirmed as a new radiographic infiltrate. The primary outcome of the study was the 30-day mortality.

Results: 210 patients (52% male) were included. Median age was 76 years. 62% (no=131) were classified as unilobar pneumonia compared to 38% (no=80) with multilobar CAP. A positive correlation was observed between multilobar consolidation and mortality by Kaplan meier analysis (p=0.01 by log rank test).

Conclusion: Multivariable analysis, after adjusting for confounders, revealed that multilobar consolidation was independently associated with 30-day mortality (odds ratio 2.25 95% CI 1.03-4.92, p=0.02). This relationship persisted for 90-day mortality (odds ratio 1.99 95% CI 1.01-4.02, p=0.04).

P2566 Nitric oxide (NO) in exhaled breath helps to distinguish the origin of lung infiltrate
Natália Voikenska1, Julia Voichevská2, Grigorij Orłıkov3
1Allergology/Pulmonary Department, Paul Stradins Clinical University Hospital, Riga, Latvia; 2Internal Diseases Department, Riga Stradins University, Riga, Latvia; 3Internal Diseases Department, Riga Stradius University, Riga, Latvia

Introduction: Determination of pulmonary infiltrates is necessary not only to evaluate the general condition of a patient, but also to determine needs and duration of antibiotic therapy. Well-recognized methods of diagnosis (physical examination, blood tests and x-rays) are not enough helpful in determination of the pulmonary infiltrate’s origin.

Objective: To distinguish the origin of lung infiltrate using NO in the exhaled breath.

Materials and methods: Prospective non-randomized study was carried out in the Centre of pulmonology and allergy, Paul Stradins Clinical University Hospital, Riga, Latvia. The study is approved by Riga Stradins University Ethics Committee. Patients with lung infiltrate of inflammatory (due to pneumonia) and congestion (heart failure) origin were involved to the study. Community-acquired Pneumonia/CAP was confirmed in 6 (from 10) patients. Heart failure (HF) with small blood circuit congestion and lung infiltration was confirmed in 4 patients. Exhaled NO, X-Ray, clinical pattern were processed. The NO level was measured by chemiluminescence’s analyzer (Aerocrine). The data were processed under SPSS 20.0 for Mac.

Results: CAP patients (no=7) demonstrated 24.67 ppb. HF patients (no=4) demonstrated 3.65 ppb (p<0.05). Normal range for exhaled NO is less than 4 ppb.

Conclusion: The data show that is increased NO production in pneumonia patient. The lung infiltrate origin might be evaluated using NO in the exhaled breath.

P2567 Community acquired and health-care associated pneumonia: Should we own follow guidelines?
María Carrabba, Marina Zarantonello, Cinzia Hu, Giovanna Fabio. Internal Medicine, Università degli Studi & Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milano, Italy

Treatment of healthcare-associated pneumonia (HCAP) according to published guidelines recommend initial broad-spectrum antibiotics and de-escalation based on culture results.

This study aims to investigate the in-hospital and 30-day mortality and LOS in both CAP and HCAP non-immunocompromised (NIC) and HCAP immunocompromised (IC) related to the empirical antibiotic therapy started at admission, before microbiological data availability. All patients admitted to a university tertiary care hospital in Milan with a diagnosis of pneumonia from 2005 to 2011 were prospectively enrolled. CAP, HCAP and immunocompromised were identified on the basis of the existing criteria. Therapies of two periods (T1: 2005-2007 and T2: 2010-2011) have been compared.

Ongoing Results
A total of 275 patients, 135 HCAP, were included in the analysis. T1 accounted for 240 CAP, 40 HCAP-NIC and 80 HCAP-IC. T2 (partial results) accounted for 20 CAP, 4 HCAP-NIC, 11 CAP-IC.

During T1, culture positive were 23.3% and culture negative 55%. The majority of CAP was started with monotherapy (51.7%), while the most of HCAP with dual-therapy (NIC 45%, IC 41.3%). Triple-therapy was addressed for 9.2% of CAP, 12.5% of HCAP-NIC and 25.0% of HCAP-IC. During T2, culture positive were 17.1% and culture negative 80%. The majority of CAP and HCAP-IC started a dual-therapy (55% and 54.5%), while 50% of HCAP-NIC had a monotherapy. Triple-therapy was started in 5% of CAP, 25% of HCAP-NIC and 18.2% of HCAP-IC.

In CAP of both periods none of the patients treated with triple-therapy died, and there were no differences for mortality between mono and dual-therapy. HCAP with dual therapy had less mortality than both monotherapy and triple-therapy.

P2568 Multidrug-resistant bacteria: a serious growing public health threat.
Maria Anciles, Susana Carreira, Cecilia Nunes, Fernanda Oliveira. Pulmonology II - Respiratory Insufficiency Unit, Hospital Padulo Valente, Lisboa, Portugal

Introduction: Multidrug-resistant bacteria (MRB) are a seriously growing public health threat.

Objectives: Characterize patients with MRB isolations, namely their risk factors. Evaluate frequency of MRB species. Assess influence of antibiotic (AB) therapy towards length of hospital stay (LOS) and mortality.

Methods: Retrospective identification of patients with MRB isolations admitted to Respiratory Insufficiency Unit (RIU) from Feb/10 to Jun/11, followed by medical records’ analysis.

Results: MRB were isolated from 32 patients: male sex – 56.3%; mean age – 74.5 years; chronic respiratory disease – 81.3%; comorbidities – 93.8%; of which 65.6% were immunocompetent. Some (37.5%) were transferred to RIU with an average previous LOS of 42.3 days. At RIU admission 96.9% were under treated on AB and 40.6% had been discharged, in the previous month. 71.9% underwent invasive techniques. There were 44 MRB isolations: MRSA – 45.5%; Acinetobacter baumannii – 29.5%; Escherichia coli; Klebsiella pneumoniae, Pseudomonas aeruginosa and Enterococcus faecium – 9.1% each. Pathogen directed-AB was introduced in 29 isolates (65.9%), but only 11 (37.9%) underwent post-AB control and only 3 of these (27.3%) became negative. There were 14 (43.8%) deaths, 78.6% due to infectious causes, of which 54.5% were attributed to MRB. We found no statistically significant differences between death and survival groups, however LOS was significantly longer in patients who had >1 isolation and whose post-AB control remained positive.

Conclusions: Every patient had at least 1 risk factor for infection. MRSA predominated. MRB were difficult to eradicate and responsible for a high mortality rate.

P2569 Implementation of IDSA/ATS and national guidelines for community acquired pneumonia by Greek chest physicians
Chiralampous Triantafyllidis1, Vasilios Kaporelis2, Georgios Papaetis1, Dora Orfanidou1, Maria Apostolidou1, Ioannis Nikolopoulos1, Elissavet-Christina Filippidou1, Angelos Pefanis1
13rd Department of Internal Medicine, National and Kapodistrian University of Athens, Medical School, “Sotira”; 2General Regional Hospital for Thoracic Diseases, Athens, Attica, Greece; 3Centre for Respiratory Failure and Intensive Care Unit, “Sotira” General Hospital for Thoracic Diseases, Athens, Attica, Greece; 41st Department of Respiratory Medicine, Kavala General Hospital, Kavala, Greece

Background: The implementation of practice guidelines for CAP by Greek physicians and their impact on cost and patients’ outcome remain unknown.

Material & methods: A prospective observational study incorporating 350 immunocompetent hospitalized pts with CAP. The aim was to investigate whether the 2007 IDSA/ATS and the Greek national guidelines for CAP are implemented by chest physicians in “Sotira” General hospital in Athens, Greece. We: a) assessed whether the decision of hospital admission was correct or not and b) evaluated whether the administered antimicrobial regimen was in accordance to guidelines. Fine score (PSI) was applied by the authors to determine the severity of CAP.

Results: The mean age was 56.3±22.2years and the duration of hospitalization 10.9±11.8days. 218 (62.2%) pts were male and 132 (37.7%) female. The mortality rate was 12.29%. 167 (47.71%) pts were admitted to the hospital, despite they were classified as risk class I or II and therefore could be treated as outpatients. Implementation of CAP guidelines as far as the initial antimicrobial regimen is concerned was poor (211pts, 60.29%). Patients treated with an initial antimicrobial in accordance to guidelines performed statistically significant lower mortality and
a trend towards shorter length of hospitalization compared to pts receiving initial regimen in discordance to guidelines (p=0.04 & p=0.006 respectively).

Conclusion: The implementation of CAP guidelines by chest physicians in the major Greek hospital for thoracic diseases is poor. Improvement of adherence may improve patients’ outcome, shorten the length of hospitalization and reduce the financial burden for the national health system.

P2571
Clinical presentation and evolution of community acquired pneumonia in older patients
Adamantia Liapikou1, Johann Maliou1, Panagiotis Petras1, Maria Kasilas1, Andreas Anastasiopoulos1, Michalis Volonakis1, Dimitra Chaimala1, Katerina Dimakou1, 11st Respiratory Department, Sotiria Chest Hospital, Athens, Greece; 2nd Respiratory Department, Sotiria Chest Hospital, Athens, Greece

Introduction: Community-acquired pneumonia (CAP) is an important threat to the health of older adults with almost 40% of them requiring hospitalization. CAP in the elderly has a different clinical presentation and evolution than CAP in other age groups.

Aim: Comparing the characteristics, severity and outcomes of CAP in elderly and younger patients (control group).

Methods: An observational, retrospective study of consecutive CAP patients >65 years old was performed during two years in two respiratory clinics. Exclusion criteria were immunosuppression and suspicion of aspiration.

Results: Of 180 cases of CAP, 116 patients were >65 years old, with a mean age 75±10.3 years. Most elderly patients (76%) had comorbid conditions, including cardiac (35%), COPD (42%), diabetes mellitus (27%) and neurologic diseases(17%). Two-thirds (68%) of elderly patients belong to CURB65 III -IV classes comparing to 12% of the controls. An acute altered mental status was included in 30% of elderly patients comparing to 11% of the others and 80.5% classes comparing to 12% of the controls. An acute altered mental status was detected in 53.6 days.

Period: 1 month and microbiological initiation to detection was 40.6 days. The numbers of antimicrobial agents were 3.5 on average. MDRP were detected in 6 patients with hematological disorders. Sixty three patients have polymicrobial detection. S.marcenses, MRSA, MSSA, K pneumoniae were detected in 12, 12, 11, 11 patients frequently. Fifty nine were judged as colonization. Forty one were causative organism of pneumonia. Three were CAP.

Conclusions: Paeruginosa were detected in patients with chronic respiratory disease and long hospitalization. More than half of detections were bacterial colonization. HAP were frequent and Paeruginosa caused the prolonged hospitalization and poor prognosis.

P2572
The clinical evaluation of patients with Pseudomonas aeruginosa detected in respiratory specimens
Ket Nakahima1, Yoshitomo Otsuka2, Haruki Kobayashi2, Naoko Kastasrada1, Nobuo Asai3, Hideki Makino1, Masafumi Misawa1, Yoshihiro Ohkuni1, Norihito Kaneko1, Masahito Aoshima1, Department of Pulmonology, Kameda Medical Center, Kamogawa, Chiba, Japan; 2Department of Laboratory Medicine, Kameda Medical Center, Kamogawa, Chiba, Japan

Introduction: The present study aims to clarify the clinical picture of patients with Pseudomonas aeruginosa detected in respiratory specimens.

Methods: Medical records of patients with Pseudomonas aeruginosa detected in respiratory specimens from April 2010 to March 2011 at Kameda Medical Center were reviewed retrospectively. The following variables were reviewed: patient background, duration of hospitalization, drug susceptibility, outcomes.

Results: One hundred patients were detected with P. aeruginosa in respiratory specimens totally. Mean age was 75.0 y.o. Sixty seven patients were male, 33 were female. Twenty eight patients have chronic respiratory disease. Fifty three patients were detected through microbial substitution. Period from admission to detection of P. aeruginosa was 53.6 days. Period: 1 month and microbiological initiation to detection was 40.6 days. The numbers of antimicrobial agents were 3.5 on average. MDRP were detected in 6 patients with hematological disorders. Sixty three patients have polymicrobial detection. S.marcenses, MRSA, MSSA, K pneumoniae were detected in 12, 12, 11, 11 patients frequently. Fifty nine were judged as colonization. Forty one were causative organism of pneumonia. Three were CAP.

Conclusions: Paeruginosa were detected in patients with chronic respiratory disease and long hospitalization. More than half of detections were bacterial colonization. HAP were frequent and Paeruginosa caused the prolonged hospitalization and poor prognosis.

P2573
Serum level of vitamin D3 before and after treatment in pulmonary tuberculosis
Young-Jae Cho1, Hyo-Jeong Lim1, Jong Sun Park1, Ho Il Yoon1, Choon-Taek Lee1, Junghun Song1, Jae Ho Lee1, Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea

Vitamin D3 is known to have potent immunomodulatory effect and it has been suggested that the low serum level of vitamin D3 increases the risk of tuberculosis. Serum levels of 25 hydroxyvitamin D3 (25HOD3) were measured in 168 drug sensitive pulmonary tuberculosis (PTB) before and about 6 months after the treatment by using high performance liquid chromatography, and were compared with those of 197 healthy normal controls (HNC). Deficiency of vitamin D was defined by the serum level below 15 ng/mL of 25HOD3. The sputum AFB smear grade was quantified from 1 to 4 according to ATS criteria. Heavy AFB smear was defined as 3 and 4 grades.

The mean level of 25HOD3 in PTB before treatment was significantly low compared with HNC (18.7±8.33 vs. 13.1±8.6 pg/mL, p<0.05). The mean level of 25HOD3 in PTB after treatment was also significantly low compared with HNC, but did not show difference compared with the level before treatment. The numbers of vitamin D deficiency before treatment were significantly higher in the PTB compared with HNC, and the numbers did not show significant change after treatment. The numbers of heavy AFB smear were also significantly higher in the vitamin D deficiency patients in the PTB (p<0.05).

These results strongly suggest that vitamin D deficiency increases the risk of tuberculosis, and is related with more severe form of PTB.

P2574
Supplementary cholecalciferol in recovery from pulmonary tuberculosis
Hisaaki Oda1, Yoshihiro Asanuma2, Satoshi Hatano2, Katsuo Saito1, 1Department of Pulmonology, Ohu Institute of Chest Diseases, Kashiwa, Japan; 2Department of Pulmonology, Aga Khan University, Karachi, Pakistan

Vitamin D is known to have important for immune homeostasis. In vitro work suggests that l-alpha-25-(OH)2-D modulates host cell responsiveness to the T cell cytokine, interferon gamma (IFNγ). IFNγ is one of the key mediators of protective immunity against Mycobacterium tuberculosis infection therefore; vitamin D may enhance the host immune responses against the pathogen. The objectives of this study were to determine whether supplementation of vitamin D in patients with Tuberculosis could impact recovery.

Methods: 266 patients were randomized to receive either 600,000 IU of Intramuscular vitamin D3 or placebo for 2 doses. Clinical assessments were done...
at 4, 8 and 12 weeks from baseline. Blood samples were obtained at 0 and 12 weeks. Statistical comparisons between outcome variables at 0 and 12 weeks were performed:

**Main Results:** 259 patients completed the study. At the end of 12 weeks, the vitamin D arm demonstrated significantly greater mean weight gain: + 4.02 (95% CI 3.38,4.86) v/s + 2.61 (95% CI 1.99,2.23); p = 0.007 and increases in BMI: + 1.48 (95% CI 1.17, 1.78) v/s + 0.96 (95% CI 0.72,2.10); p =0.008 as compared with the placebo arm. There was a significant difference in chest radiographic improvement in the vitamin D group; number of zones involved -2.21 (95% CI -1.91, -2.51) v/s -1.77 (95% CI -1.51, -2.03); p = 0.01 and resolution of cavitation 73(65.7%) v/s 60 (55%) v/s 60, p = 0.05.

No differences were seen in TB score or sputum smear conversion. At follow up Conclusions: Vitamin D supplementation significantly impacted clinical improvement in patients with pulmonary TB.

P2575

**Prevalence of hypovitaminosis D in TB patients in an East London population**

Muhammad Tufail1, Philip Coakley1, Ashlin Harper1, Pandina Kwong2; Stuart Jones2, Bridget Hall1; Angela Hauser1, Ajitha Jayaratnam1, Michael Apps3, 1Respiratory Medicine Department, King George Hospital-Barking, Havering and Redbridge Hospitals NHS Trust, London, United Kingdom; 2Biochemistry Department, King George Hospital-Barking, Havering and Redbridge Hospitals NHS Trust, London, United Kingdom

**Introduction:** There is a well-established link between vitamin D (25(OH)D) deficiencies and TB, although in vivo association is still contentious.

**Aims:** This retrospective case control study aimed to compare the prevalence of hypovitaminosis D in cases diagnosed with TB in 3 East London boroughs to controls, who were defined as non-occupational inpatients who were not on vitamin D supplements and in whom 25(OH)D assay was performed during the study period.

**Methods:** We compared 25(OH)D levels in patients diagnosed with active TB with controls during a twelve month period from 01/09/10-31/08/11. Hypovitaminosis was defined by two thresholds for 25(OH)D concentrations: deficiency < 30nmol/L and insufficiency 30-79 nmol/L.

**Results:** There were 211 TB cases of whom 75 (35%) had 25(OH)D levels measured. All 75 had hypovitaminosis D of whom 60 (80%) had 25(OH)D deficiency and 15 (20%) were insufficient in 25(OH)D.

There were 323 controls, 87 of whom were taking supplements and so were excluded. Of the remaining 236 controls, 6.8% were vitamin D replete (vs. 0% in TB cases), 52.1% had vitamin D deficiency (vs. 80% in TB cases) and 41.1% were vitamin D insufficient (vs. 20% in TB cases). Mean 25(OH)D levels were significantly lower in the study group as compared to the control group (18.11 nmol/L vs 34.98 nmol/L, p < 0.001).

**Conclusions:** The prevalence of hypovitaminosis D in both the study as well as the control groups is alarmingly high but importantly 100% of TB cases who had 25(OH)D levels checked were either deficient or insufficient. We hypothesize that this may be a unique finding in our ethnically-diverse population and thus may have implications for nutritional supplementation offered to active TB patients.

P2576

**Factors influencing change in baseline vitamin D level in mycobacterial infection**

Gemma Hawthorne1, Alice Turner1, Heinke Kunst1, Martin Dedicoat2

1School of Clinical and Experimental Medicine, University of Birmingham, United Kingdom; 2Department of Respiratory Medicine, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

**Background:** Vitamin D may be an agent, of broad relevance in the treatment of infectious disease because of its immunomodulatory properties.**Methods:** In an ongoing open label observational trial, baseline bloods, vitamin D levels, sputum smear and culture results, radiological changes and TB score were recorded in patients with mycobacterial infection. Each patient was supplemented with 100,000 units of cholecalciferol at 0, 8 and 16 weeks.

**Results:** The mean age of patients recruited (n=42) was 36 years (M:F 27:15), 16 weeks. The mean age of patients recruited (n=42) was 36 years (M:F 27:15), with pulmonary disease (n=29) or extra pulmonary disease (n=13). There was a significant difference in vitamin D levels between the groups. Pre supplementation median vitamin D levels were 11.9 nmol/L (mean 16.96 nmol/L, 92.9% with 25(OH)D levels <50nmol/L. At week 8 post supplementation levels had risen to median 44nmol/L (mean 43.9 nmol/L). There was a significant difference in vitamin D levels pre and post supplementation (p=0.00), with a significantly higher percentage rise in vitamin D levels in patients who were severely deficient (<20nmol/L) (p=0.01).

There was no correlation between vitamin D and DBP, antimicrobial product (LL37) levels or TB score at baseline measurement.

**Conclusions:** Supplementation with 100 000 units of cholecalciferol does not result in sufficient levels (>50nmol/L) at 8 weeks in all patients with just 65% attaining levels >50nmol/L. However, there is a statistically significant rise in levels of vitamin D in those supplemented between week 0 and week 8.

Patients with mycobacterial infection with vitamin D deficiency may benefit from higher initial doses to obtain sufficiency.

P2577

**Does relationship exist between severity of vitamin D deficiency and development of active TB?**

Adeel Tariq Sahal, Joyutpal Das, Sushil Agarwal, Karunvir Singh, Martin Dedicoat, Alice Turner, Heinke Kunst

Respiratory Medicine, Heart of England NHS Trust, Birmingham, United Kingdom

**Introduction:** Deficient serum vitamin D levels have been associated with impaired mycobacterial immunity and incidence of active tuberculous (TB). However, the significance of level of vitamin D in LTBI and the risk of progression to active disease is less clear.

**Methods:** A retrospective review of vitamin D levels of all patients with active TB and LTBI was undertaken between January 2010 and December 2010 at Heart of England NHS foundation trust, Birmingham. We compared vitamin D levels in cases with active and latent TB to explore a relationship between severity of vitamin D deficiency and incidence of active/latent TB.

**Results:** 148 cases with LTBI and 113 with active TB were included in the study. 117 out of 148 patients with LTBI and 108 out of 113 active TB cases had a Vitamin D level performed. Median Vitamin D level in patients with TB was 5.7ng/ml (Range 2-46.4). Median Vitamin D level for LTBI was 7.8ng/ml (2.95-30). The difference in Vitamin D levels between latent and active TB cases was statistically significant with P =.003 (calculated Using Mann Whitney U Test). Subgroup analysis, Median Vitamin D levels of non-white TB and LTBI population were 5.2 (Range 2.00 - 36.20) and 6.5ng/ml (Range 2.00 - 43.40) respectively, P value 0.01. Median Vitamin D levels of white TB and LTBI cases were 17.0 (Range 2.50 - 46.40) and 22 ng/ml (Range 7.30 - 95.30) respectively, P value 0.29 (cohort of white population much smaller than non-white).

**Conclusions:** Vitamin D levels were significantly lower in active compared to latent tuberculosis cases suggesting that degree of vitamin D deficiency may influence development of active TB. We feel prospective study is needed to evaluate it further.

P2578

**Ethnic differences in the vitamin D levels of foreign-born tuberculosis patients in south London not reflected in patients born in the UK**

Nicole Penn1, Sharenja Ratnakunar1, Jessie Randhawa2, Heather Milburn2, 1School of Medicine, King’s College London, United Kingdom; 2Respiratory Medicine, Guy’s and St. Thomas’ Trust, London, United Kingdom

Vitamin D deficiency is more common in tuberculosis (TB) patients, and within certain ethnic groups. 70% of TB in the UK occurs in foreign-born persons. We investigated the roles of ethnicity and immigration on the vitamin D levels of TB patients in south London.

We analysed the vitamin D levels of all patients at the time of diagnosis. We compared results by country of birth, ethnicity, age and length of residency in the UK.

There were 470 patients; the mean serum 25(OH)D level was 29.1nmol/L (95% CI 27.2-31.0) and 90.6% had insufficient (<30nmol/L) 25(OH)D levels. Patients born in the Horn of Africa and Indian subcontinent had significantly lower vitamin D levels compared to patients born in the rest of Africa (P<0.001) and Asia (P<0.01). Patients born in Europe had significantly higher vitamin D levels than patients born in Africa (P<0.05) and Asia (P<0.05). Children born in the UK had the highest vitamin D levels (mean 57.4% 95% CI 45.6-69.2); this was significantly more for than children born outside of the UK (mean 19.5% 95% CI 12.5-26.5, P<0.001).

**Mean Serum 25(OH)D by country of birth showing particularly low levels in those from the Horn of Africa and the Indian Subcontinent [normal value >50nmol/L]**

TB patients born in the horn of Africa and the Indian subcontinent have an increased risk of very low vitamin D levels. As there is little difference in ambient sunshine this raises the possibility of significant differences in diet or genetics. Children born in the UK had high levels of vitamin D not attributed to ethnicity.
Conclusion: We found that majority of the LTB patients had low 25[OH]D levels. In general, patients with low 25[OH]D levels tend to react more strongly during TST. One limitation of our study is that the impact of BCG vaccination was not taken into account. Nevertheless, this study further highlights the impact of 25[OH]D as an immuno-regulator in vivo.

P2582
Adverse drug reactions and outcomes of tuberculosis treatment using fixed-dose combination drugs

Methods: Clinical analysis of adverse reactions to second line anti TB drugs

Aim: To assess the effect of 25[OH]D level on the size of tuberculin skin test in household contacts of patients with active tuberculosis.

Methods: We performed a retrospective analysis of 25[OH]D levels and induration sizes during TST in 212 TST cases from 10/2009-10. 146/212 cases had both values (25[OH]D level and the induration size during TST) recorded. Only 3% (5/146) of them had normal 25[OH]D level (<20ng/ml) and normal induration size during TST. We also observed that the average increase of 25[OH]D levels with Adcal-D3, ergocalciferol and combination of these two agents were 14.6±5.4, 20.6±8.9 and 25.8±5.3 respectively. We found that the increase of 25[OH]D level with combination of two agents were greater than Adcal-D3 alone (p<0.001).

Conclusions: Does vitamin D level influence the size of tuberculin skin test in household contacts with latent TB infection?

Methods: Clinical analysis of adverse reactions to second line anti TB drugs

Introduction: Adverse reactions to second line anti TB drugs not only leads to permanent system damage and discontinuation of therapy, but also MDR/XDR treatment failure. This study was conducted to evaluate the impact of 25[OH]D levels on the size of tuberculin skin test (TST).

Objective: Evaluation of vitamin D replacement in the tuberculosis patients

Methods and results: We reviewed 113 TB cases from 2010 in our retrospective study. The study population was consisted of 68 males and 45 females. 25[OH]D levels were checked in 96% (65/68) and 98% (44/45) of male and female patients respectively. 25[OH]D levels were 25[OH]D deficient. 53/56 males and 38/40 females, who were 25[OH]D deficient, received 25[OH]D replacement therapies with Adcal-D3 (cholecalciferol, vitamin D3), ergocalciferol (ergocalciferol, vitamin D2) or combination of these two agents. We then assessed the effect of these agents on the 25[OH]D level. Only 76% (20/26) of males and 87% (46/53) of females who received replacements, had their 25[OH]D levels repeated in 3-6 months. In both genders, 25[OH]D levels increased with the treatment (p<0.0001 in both genders). We also observed that the average increase of 25[OH]D levels with Adcal-D3, ergocalciferol and combination of these two agents were 14.6±5.4, 20.6±8.9 and 25.8±5.3 respectively. We found that the increase of 25[OH]D level with combination of two agents were greater than Adcal-D3 alone (p<0.001).

Conclusions: Consistent with other studies, we have noticed that most of the TB patients had low 25[OH]D levels. Majority of these patients responded to supplementation, regardless of the gender or the therapeutic agent(s).

P2581
Does vitamin D level influence the size of tuberculin skin test in household contacts with latent TB infection?

Methods: Clinical analysis of adverse reactions to second line anti TB drugs

Introduction: Adverse reactions to second line anti TB drugs not only leads to permanent system damage and discontinuation of therapy, but also MDR/XDR treatment failure. This study was conducted to evaluate the impact of 25[OH]D levels on the size of tuberculin skin test (TST).

Objective: Evaluation of vitamin D replacement in the tuberculosis patients

In both genders, 25[OH]D levels increased with the treatment (p<0.0001 in both genders). We also observed that the average increase of 25[OH]D levels with Adcal-D3, ergocalciferol and combination of these two agents were 14.6±5.4, 20.6±8.9 and 25.8±5.3 respectively. We found that the increase of 25[OH]D level with combination of two agents were greater than Adcal-D3 alone (p<0.001).

Conclusions: Consistent with other studies, we have noticed that most of the TB patients had low 25[OH]D levels. Majority of these patients responded to supplementation, regardless of the gender or the therapeutic agent(s).
ing incidence. TB meningitis (TBM) is a rare form of extra-pulmonary TB, which carries disproportionately high mortality and morbidity rates. Barking, Havering and Redbridge University Hospitals Trust (BHRUT) serves an area in East London with a high incidence of TB. This study aims to evaluate the epidemiology, clinical presentation and outcome of patients diagnosed with TBM.

**Methods:** Individuals diagnosed with TBM between 2000 and 2010 were identified using the London TB Register. A prospective observational study was conducted reviewing medical notes, microbiology results and radiology. Data was collected for epidemiology, clinical features, risk factors, treatment regimens and outcome.

**Results:** 50 patients with TBM were identified and notes were available for 42. 82% were born outside the UK with the highest incidence seen in patients born in India. All patients were treated for at least 12 months with 92% receiving concurrent steroids. Other information is shown below.

**Conclusion:** TBM has a high mortality rate in East London with a high proportion of patients requiring treatment in intensive care or suffering long-term neurological sequelae. Confirming diagnosis is challenging as presentation is non-specific, potentially leading to treatment delay. Development of a diagnostic scoring system using clinical features, risk factors and CSF data to aid early diagnosis would prove extremely valuable.

**Miliary tuberculosis during treatment with anti TNF alpha – A report of three cases**

Liliana Alexandrina Grigoriu, Cristina Iacobescu, Ana Maria Sasu, Stefan Dumitrache-Rujinski, Miron Alexandru Bogdan. Pneumology, Maria Nica Institute of Pneumology, Bucharest, Romania

The anti-TNFs have proven very effective in the treatment of rheumatoid arthritis, ankylosing spondylitis, psoriasis, Crohn’s disease. Among the side effects is well known the risk of developing infections, particularly tuberculosis. We present three cases of miliary tuberculosis with mediastinal lymphadenopathy which occurred during treatment with anti-TNFs. Two male patients aged 56 respectively 41 years, were treated with infliximab for ankylosing spondylitis. One male patient aged 32 years was treated with adalimumab for psoriasis. All patients performed chest X-ray, tuberculin skin test, quantiferon TB test for latent TB. The clinical signs of disease were febrile syndrome, dyspnoea, cough and weight loss. In the first case, the positive diagnosis was concluded on lung biopsy and culture positive for BK in sputum. In the second case, were revealed AFB in bronchial aspirate. In the third case, the diagnosis was concluded on lung and mediastinal lymphnode biopsy.

In all cases we observe an aspect of miliary and mediastinal lymphadenopathy on chest CT. In the first case, we find a pulmonary embolism. All three patients developed hepatic cytolytic during anti TB treatment, requiring discontinuation in two cases. The evolution was slowly favorable after the reintroduction of treatment.

**Conclusions:** All three cases are severe forms of miliary tuberculosis associating necrotic mediastinal lymphnodes occurred during treatment with anti-TNFα.

A dilemma of skeletal tuberculosis diagnosis

Parvaneh Baghaei Shiva, Majid Marjani, Payam Tabarsi, Mohammad Reza Masjedi. Clinical Tuberculosis and Epidemiology Research Center, NRTLD, Tehran, Islamic Republic of Iran

**Objectives:** Skeletal tuberculosis reports 1-5% of all TB cases. The most common sites of involvement are spine, knee and hip. The diagnosis of extra-pulmonary TB is difficult. The aim of this study was to show up the different way of diagnosis and report this kind of TB in Iran.

**Method:** This study was done in Masih Daneshvari Hospital, a referral center of TB in Iran, from 2003 to 2011. In this retrospective study, we extracted all skeletal TB. Demographic information, the method of diagnosis, and other information were evaluated.

**Results:** Of 426 extra-pulmonary TB, 58(13.6%) patients were skeletal TB. The mean age was 45.72±20.26yrs. 31(53.4%) patients were male. One patient was HIV positive. New cases of TB, relapse and history of TB treatment were 51, 4 and 3 respectively. Median of duration of symptoms was 7 months. 28 patients had pulmonary TB (sputum smear or culture was positive). The kind of skeletal TB was: 2patients with pleural, one patient with CNS, one patient with lymph node concomitant with spine and 52 patients just spine. Two patients were arthri-tis (knee) tuberculosis. Diagnostic method was: positive granuloma 43.7%, PCR positive 31.2%, positive smear and culture 22%, positive sputum for TB 31% and diagnosed by clinical/magnetic resonance imaging 13.7%.

**Conclusion:** The diagnosis of skeletal TB is difficult and it will take time to detect it. Investigation of other involved site such as lungs, pleura or lymph nodes can help us early TB diagnosis.

P2588

Obstructive airway disease in pulmonary tuberculosis cases in relation to smoking

Shiv Sagar Gupta, Nishish Kumar. Pulmonary Medicine, Era’s Lucknow Medical College, Lucknow, UP, India

**Introduction:** Tuberculosis (TB) is a long-standing & expanding threat to public health. People with treated pulmonary tuberculosis (PTB) are left with significant changes in lung anatomy & are at higher risk of pulmonary sequelae. Smoking is the major risk factor for airflow obstruction. Recent & early studies suggest association of prior TB with development of COPD. But whether smoking modifies this relationship is unclear.

**Aims:** 1) To study the effect of smoking & prior PTB on airflow obstruction 2) To assess the severity of obstructive abnormality in smoker versus non smoker patients of prior PTB. Settings: Tertiary care Institute in Lucknow, India. Period: From Jan 2011 to Jan 2012.

**Material & method:** 100 patients who visited OPD with history of prior PTB were divided into different categories on the basis of sex, smoking history, age etc. All patients were subjected to spirometry, sputum examination for acid fast bacilli, chest X-ray & their history were also evaluated. Diagnosis of COPD was based on GOLD criteria.

**Results:** Out of total 100 patients 53 were smokers and 47 were non-smokers.
Out of 53 smokers 38 (71.69%) had obstructive abnormality while out of 47 non-smokers 23 (48.93%) had obstructive abnormality (p<.05). Smoker with prior PTB developed more severe airflow obstruction (Mean FEV1 40.03%) as compared to non-smoker with prior PTB (Mean FEV1 45.43%).

Conclusion: Prior PTB is an independent risk factor for airflow obstruction irrespective of smoking status which may explain the higher prevalence of COPD in India. Prior PTB along with smoking is associated with more severe form of airflow obstruction.

P2589
Prevalence, features of the course and treatment efficacy airway obstruction in patients with newly diagnosed pulmonary tuberculosis

Airway obstruction (AO) is an important factor for ineffective treatment of pulmonary tuberculosis. The aim of research was studying prevalence AO, features of treatment and inhalation therapy in patients with newly diagnosed pulmonary tuberculosis (TB).

Methods: In a prospective study was examined by spirometry among 311 patients of 18-75 with TB. The effectiveness of treatment was identified among 125 patients by randomization. The first group consisted of 31 patients, who, besides chemotherapy, got ipratropium bromide and fenoterol (1 month); the second group consisted of 32 patients, who got fenoterol. The Control Group included 32 patients, who got only standard chemotherapy. Quality of life (QL) was evaluated using Short Form-36 (SF-36) at baseline and 1 month.

Result: The prevalence of AO among patients with TB was 62.70%. AO associated with greater frequency of shortness of breath (odds ratio (OR) = 11.78) and cough (OR=10.56) compared patients with non-obstructive pattern (p=0.01). The relative risk of developing endobronchial pathology in patients with AO is 2.01 times greater than without AO. In patients treated with inhalation therapy was observed greater improvements in HRQL by 5.6 scores for the physical component of SF-36, microscopic conversion of sputum to 16.17% cases and X-rays cavity closure to 11.81% cases more frequently compared with the Control group (p<0.05).

Conclusions: TB is often complicating by AO, short course of inhaled bronchodila-
tors and/or glucocorticoids improve results of a treatment for such patients.

P2590
Effect of tobacco on the pulmonary tuberculosis

Samiy Farah1, Manel Hadji2, Chiraz Aichaoui3, Manel Hdiji2, Chiraz Aichaouia3, Salsabil Dabboussi4, Zied Moetaattar1, Samira Mhamdi1, Abderrazek Haddaoui5, Moreh Khadraoui6, Rzek Cheikh9.

Introduction: Tobacco increases the risk of pulmonary infection, especially tuberculosis.

Objective: To determine the effect of pulmonary tuberculosis on clinical expression of the tuberculosis and its delay diagnosis.

Material and methods: It’s a comparative study between two groups of patients hospitalized in our department between January 2008 and June 2010.

Results: The first group was made of 37 smokers patients hospitalized because of confirmed pulmonary tuberculosis. The second group consists of 32 non smokers patients and also hospitalized because of confirmed pulmonary tuberculosis. Delay of diagnosis was shorter in the group of smokers (42 days versus 78 days). Cough and dyspnea were more found at the smoker’s (86% versus 82%). The biological investigations showed a high level of white blood cells with predominance of neutrophils especially in smokers (20 versus 10) and smokers were more likely to be smear-positive (21 versus 17). Chest X ray showed essentially nodules in both groups. These nodules were bilateral in the group of smokers (22 versus 14). The duration of the treatment was longer at the smokers (7 months versus 6, 5 months). Evolution after antituberculosis treatment was favourable for all patients. The complications as the lung fibrosis (2 versus 1) were more among smokers than non-smokers.

Conclusions: The Smoking was not associated with delay in the diagnosis and treatment of tuberculosis.

P2591
Anxiety and depression in tuberculosis hospitalized patients in comparison to healthy individuals

Ionela Ionel1, Dorin Vancea1, Zeno Flratia1, Ovidiu Buralcav2. 1Clinic of Pneumology, Victor Babes Hospital, Timisoara, Timis, Romania; 2Thoracic Surgery, Emergency Municipal Hospital, Timisoara, Timis, Romania.

Introduction: Very little is known about the psychiatric comorbidities in tuberculosis (TB), which must be recognized and managed in order to improve adherence to the treatment.

P2592
Screening and monitoring of tuberculosis in patients on biologics treatment

Sameh Farah1, Galina Lukina2, Lydia Gumapov2, Kochetkov Yakov1.

Background: The new class of drugs - biologics (B) - is high effective, but its use is limited due to different degree the risk of tuberculosis (TB).

Methods: 600 pts (rheumatoid arthritis - 264, ankylosing spondylitis - 257, psoria-
sis - 50, other - 29), 303 male and 297 female, 15-80 y.o. (95/CI 42,2, 43,3) were examined before (377 pts) and during (286 pts: infliximab - 159, adalimumab - 58, etanercept - 17, certolizumab - 28, abatacept - 11, tocilizumab - 21; 20 pts receive more then one B consecutively) B treatment. Clinical examination, X-ray (CT in any abnormalities), tuberculin skin test (TST), interferon-gamma release assays (IGRA), skin test with recombinant protein ESAT-6/CFP10 (developed in Russia as DIASKINTEST - DST) were performed.

Results: In all cases by primary screening active TB was rejected, but positive TST was obtained in 82.6%, IGRA in 34.6%, and DST - in 25.8%. Preventive TB treatment (PT) was administered in patients with residual TB changes (49) or defined latent TB infection (LTI) (positive both NST and IGRA/DST). During the B treatment active pulmonary TB was detected in 8 pts (all - on TNF-alpha inhibitors: etanercept - 17, certolizumab - 12, rituximab - 28, abatacept - 11, tocilizumab - 21; 20 pts receive more then one B consecutively) B treatment. Clinical examination, X-ray (CT in any abnormalities), tuberculin skin test (TST), interferon-gamma release assays (IGRA), skin test with recombinant protein ESAT-6/CFP10 (developed in Russia as DIASKINTEST - DST) were performed.

Conclusion: The procedure of TB screening and monitoring is the essential part of the B treatment program. The tests based on specific M tuberculosis antigens are very useful as the tools for LTB monitoring and enable to reduce PT at least three times.

P2593
Predictive factors of relapse in pulmonary tuberculosis

Sonia Habibeb1, Ines Zendah, Nhadja Ayed, Leila Bayahi, Ibtihel Kouaja, Habib Chenitra. Respiratory Department I, Abdourhamen Mama Hospital of Respiratory Diseases, Ariana, Tunisia.

Background: Pulmonary tuberculosis (TB) relapse is a life-threatening condition. Revealing the factors that lead to relapse may help developing preventive measures.

Aim: The aim of this study is to reveal the main predictive factors of relapse in patients with pulmonary TB.

Methods: We compared the data reported during the first episode of TB of 22 non-HIV patients treated for pulmonary TB and who had a relapse with those of 36 non-HIV patients treated for the same disease without relapse. Files were selected if the follow-up period exceeds 3 years. Results are expressed as a percent or a mean with (C.I.95).

Results: Patients with relapsing disease, as compared to patients without relapse, are older (61[56-65] vs 37[33-41] years-old), with history of heavier smoking (40[29-51] vs 18[10-26] Pack-Years) and a lower proportion of TB-vaccinated patients (40% vs 80%; p=0.05). The 2 last findings are likely to be correlated to age. But independently of age, in patients with relapse, we found a higher proportion of patients who have a close contact with another TB-patient (63% vs 38%; p=0.01) and a more frequent right lung involvement (50% vs 36%; p=0.05).

Conclusion: From our data, relapse of pulmonary TB is more likely to occur in older patients, those exposed to contagious persons and those with a right lung involvement during the first episode of TB.

Relapse rate of tuberculosis and related factors in Korea; by using the nationwide tuberculosis notification data
Hyungmin Lee1, Yoosung Park1, Sang-suk Shin1, Eun-hee Cho1, Sung-suk Shin1, Bo Youl Choi1, Division of HIV and TB Control, Korea Centers for Disease Control and Prevention, Osong, Korea, 2Department of Internal Medicine, College of Medicine, Catholic University, Seoul, Korea, 3Department of Preventive Medicine, College of Medicine, Hanyang University, Seoul, Korea

Background: The relapse rate of tuberculosis(TB) was one of the indicators that assess indirectly the level of TB control. In Korea proportion of relapse TB was reported in about 12%.

Aims: To estimate the relapse rate of TB and investigate the related factors with relapse of TB by using the nationwide TB notification data in Korea.

Materials and methods: Data source was the nationwide TB notification data in 2005. For them to check that TB patients had been reported again from 2006 to 2010. Related factors were analyzed by using multivariate logistic regression.

Results: Of 45,434 TB patients in 2005, 4.371(9.6%) were reported with TB again and 564 were reported two or more. So the cumulative relapse cases were 5.072(11.2%). A relapse rate was 4.8% in 2006, 2.4% in 2007, 1.6% in 2008, 1.4% in 2009, and 1.0% in 2010.

Conclusion: The five-year relapse rate was 9.6%. It was likely to be underestimated for death after failure or default were related strongly.

TAF = treatment after failure, TAD = treatment after default, TI = transfer in, pul = pulmonary.

P2596
Safety and benefit of adjunctive systemic corticosteroid therapy in the management of severe, smear positive pulmonary tuberculosis (SSP-PTB): an interim analysis of a randomized controlled trial
Dushantha Madegedara1, Dhammika W. Yasaratne2, Dushanka Madugedara1, Chanchala Kalathunga1, Suvinitha Wijesinghe3, Sunil Alwis4, Department of Respiratory Medicine, Teaching Hospital, Kandy, Sri Lanka, 2Department of Radiology, Teaching Hospital, Kandy, Sri Lanka, 3National Programme for Tuberculosis Control and Chest Diseases, Ministry of Healthcare and Nutrition, Colombo, Sri Lanka

Objective: To assess the safety and benefit of adjunct steroid therapy in SSPPTB.

Methods: SSPPTB patients were randomized to 2 groups. All were given standard category 1 anti-tuberculosis therapy (ATT). Test group was given a tapering 3 week course of oral prednisolone. Interim analysis done at 8 weeks.

Results: Steroid arm had 38 (36 males; mean age 49y) while control arm had 26 (19 males; mean age 46y) patients.

Conclusions: Adjuvant therapy with prednisolone in patients with severe, smear positive pulmonary tuberculosis is safe and obtainable cost-effective.

P2597
C-reactive protein in pulmonary tuberculosis-correlation with extent and severity of the disease
Nelson Trevisan1, Hans Dabó1, Isabel Gomes1, Agostinho Marques1, 2.Pneumology, Hospital São João, Porto, Portugal, 2Faculty of Medicine, University of Porto, Portugal

Background: Pulmonary tuberculosis (PT) presents a broad clinical spectrum. C-reactive protein (CRP) has been identified as a possible marker of severity in this disease.

Aims: To assess the role of CRP in patients admitted for PT and its relation with radiological extent, bacterial load, hospital stay and mortality.

Methods: We retrospectively evaluated 201 adult patients admitted in a tertiary hospital for PT without HIV infection (2007-2011). Demographic, clinical, analytical and radiological data as well as hospital evolution were studied. Patients were categorized according to radiological extent (National Tuberculosis Association classification) and initial bacterial sputum load (ATS criteria). For statistical analysis, Spearman correlation coefficient, analysis of variance ANOVA and Bonferroni test were used, with SPSS18 support.

Results: Most were male (74%), mean age 53.5 yrs. Sputum smear on admission was negative in 39.8%; in these, CRP was significantly lower (mean: 82.1 mg/L) than in smear-positive patients (mean: 114.5 mg/L), p=0.003. However, CRP did not increase with higher bacterial load (p=0.113). CRP values increased significantly with more extensive disease on chest X-ray (Est.I: 61.7mg/L, Est.II: 109.9mg/L, Est.III: 170.8mg/L), p=0.000. A positive correlation between CRP value and hospital mortality was found (r=0.141, p=0.027) but not with duration of hospitalization (p=0.065).

Conclusions: CRP may play an important role as an indicator of the extent and severity of PT and showed prognostic value for short term mortality of the disease.
Studies including ambulatory patients may help defining its role in identifying those who need to escalate health care.

P2598

diagnosing value of closed-pleural biopsy in pleural tuberculosis

Basma Hamdi, Chiraz Aichoua, Samira Mhandi, Zied Mostami, Sahsab Daboussi, Sameh Farah, Mohsen Khadhraoui, Raïzeï Cheikh.

Pulmonary Department, Military Hospital, Tunis, Tunisia

Introduction: Thoracoscopy is the gold standard for diagnosis of pleural tubercular (PTB). However, pleural biopsy (PB) is a blind technique of investigation of simple first intention designed to make the histological diagnosis.

Aim: To evaluate the contribution of PB in the histological diagnosis of PTB.

Method: We study retrospectively 49 patients in whom PTB were diagnosed in our military department. PB was sent for culture and histopathological examination. Patients were excluded if they had positive bacilloscopy.

Results: The mean age was 32 years (12 to 78). 81% were male. A past medical history of tuberculosis was found in 25% of cases. The most frequent symptoms were chest pain, cough and constitutional symptoms. The TB effusions were all exudative with a mean lymphocyte fraction of 80%. PB was done in 89% of cases with a mild number of fragments was 4.5. Diagnosis was confirmed by closed-PB in 61.9% of cases, bones from the first biopsy in 53.3% of cases. Thus the sensitivity of the PB is 53%. No complications of PB were noted. The thoracoscopy confirm the diagnosis in 24.4% of cases. 4.4% of cases was histologically non diagnostic. Pleurisy is noted in 77.5% of cases associated with pericardial disease in 6.1% of cases. Histology found a tuberculous granuloma in 69% of cases with caseous necrosis in 50% of cases. Culture of pleural fragment was positive in 3 cases. In other cases the diagnosis is retained on elements of presumptions.

Conclusion: Necessity of PB depends on the extent of lesions and the experience of the operator. The PB is a minimally invasive and cost effective procedure for the early diagnosis of pleural tuberculosis before considering more invasive examinations.

P2599

Atypical pulmonary tuberculosis

Wizam El-Akkad, Abdelaziz Aichane, Zineb Berrada, Hicham Alfi, Zoubida Bouayad.

Pneumology, Hospital "20 Août", Casablanca, Morocco

Introduction: Tuberculosis remains a common disease, but despite this, it is often diagnosed with long delay due to some atypical presentations. The aim of our work is to know unusual shapes because they may pose problems of differential diagnosis especially with malignant diseases.

Methods: We report 50 cases of pulmonary tuberculosis atypical between 2000 and 2009: 15 cases of endobronchial tuberculosis, 16 cases with basal localization and 19 cases of pseudotumoral form.

Results: The average age is 37 years. Smoking is found in 17 cases and diabetes in 12 cases. The clinical picture is dominated by bronchial syndrome. The chest rays show basal opacity in 16 cases, a pseudo-tumor opacity in 19 cases and a retraction opacity in 15 cases. Bronchoscopy visualizes endobronchial granuloma in 6 cases, tumor buds in 5 cases and bronchial stenosis with extrinsic compression in 8 cases. CT show suspected tubular process in 19 cases, mediastinal lymphadenopathy assessed in 12 cases and avascular opacity in 5 cases. Pulmonary tuberculosis is confirmed by bacteriology in 23 cases, bronchial biopsies in 8 cases, transmural biopsy in 7 cases, by thoracotomy in 6 cases and by lymph node biopsy in 2 cases. Antitubercular treatment was prescribed in all cases with good evolution in 36 cases (72%).

Conclusions: Pulmonary tuberculosis may mimic atypical, mainly malignancy hence the interest to recognize its various unusual shapes.

P2600

Features and treatment outcome in cavitary pneumonia

Evelina Lesne, Olga Caraiani, Vasile Zlepca. Pneumophysiology, State Medical and Pharmaceutical University "Niculice Teodora Tita", Chisinau, Republic of Moldova

Cavitary pneumonia is a clinical X-ray form of infiltrative TB or a complication of the acute progression of fibro-cavitary TB. Aim of study is evaluation of features and treatment outcome in CP. A retrospective study included 95 patients with CP. Most of them (84%), were new cases of infiltrative TB and 16% fibro-cavitary TB. New-onset TB were 70% cases, relapse cases were 21% after treatment failure 21% and after default 2%. Male/female ratio was 2/1, average age 42.6 yrs, unemployed 64%, diabetes 11%, with bad living conditions 72%, homeless 10%, with medium level of education 59%. Regarding the way of detection, all were detected passively, 63% were late detected (average time 6 weeks). Regarding clinical picture, 77% had well-defined respiratory syndrome and 85% intoxication syndrome. Co-morbidities had 40% (alcoholism 19%, hepatitis 7%, diabetes 7%, HIV-infection 4%). Hematological parameters included anemia in 61% cases, lymphocytosis 48%, lymphopenia 51%, increased ADA 42%. Radiological were revealed destructive lesions in 90% with bilateral localization in 89%, involving more 3 lobes in all cases. At the detection, smear positive for acid-fast bacilli were 85%, culture positive 84%. Primary drug resistance was identified in 34% cases. Conversion rate of smear positive patients at 2 months of treatment was 56%. DOTs received 91%, individualized treatment 9%, compliant with treatment were 84% cases. Treatment outcome: anti-TB treatment completed 61%, dead 23%, treatment failure 12%, default 4%. Features that affect the outcome of CP are: late detection, co-morbidities (especially for low economical status), previous anti-TB treatment, high rate of primary resistance, bilateral involving.

P2601

How do we diagnose tuberculosis in early childhood?

Jins Ladeira, Ana Correia, Isabel Carvalho, Aurora Carvalho, Raquel Duarte.

*Pneumology, Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE, Vila Nova de Gaia, Portugal; 1Departamento de Saúde Pública, ARS Norte, Porto, Portugal; 2CDP, Centro de Diagnóstico Pneumológico de Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 3Departamento de Epidemiologia, Medicina Preventiva e Saúde Pública, Faculdade de Medicina da Universidade do Porto, Portugal

Children are a special group when considering Tuberculosis(TB) diagnosis: they can develop disease quickly after primary infection, present severe forms and there is a lack of standardized case definition and difficulties in establishing a definitive diagnosis.

Aims: Understand reasons to initiate TB treatment in children under 6 years old and identify risk factors associated with treatment in the absence of laboratory criteria.

Methods: We reviewed TB records of patients younger than 6y reported in North-ern Portugal in 2000-09. Epidemiological, clinical, radiological, microbiological and treatment information were analyzed (univariate/multivariate analysis) using SPSS19.0 (p<0.05).

Results: In the last 10 years 132 children under 6y were diagnosed with TB; 60% male. Six children had co-morbidities: five HIV-positive and one diabetic. 90% were BCG vaccinated. Information about TB detection known in 130: 104 had symptoms (78.8%) and 26 were screened during contact investigation (19.7%). Laboratory criteria for TB obtained in 73 (56.2%): 31 culture-positive (23.7%). Having normal SPSS19.0 (C 1.45-15.45), positive tuberculin skin test-TST (OR 5.26, CI 1.92-14.29) and not having performed invasive tests-bronchoscopy/gastric fluid analysis (OR 5.95, 1.89-16.67) were independently related to the decision to treat without laboratory criteria. History of TB contact, existence of symptoms and co-morbidities were not associated to that decision.

Conclusion: Our confirmation rate among this age group was higher than in Europe (19% in 2009). Decision to treat was neither based on laboratory criteria nor on radiological finding consistent with TB, but on a positive TST. Criteria to initiate treatment in this group must be reviewed in order to prevent loosing cases and over-treatment.

P2602

Gender difference in sputum positive pulmonary TB cases

Venugorapu Kunjupillay, PR. Sreelatha, R. S. Nisha. Health Services, Govt. General Hospital, Alappuzha, Kerala, India.

Material and method: All sputum positive cases registered for two years (ie, 2003 & 2004) were included in the study. Sputum positive grade with gender and age was analyzed. Among the males there were no gender difference reported in this rate so far. Alappuzha district is one of backward district of South India. Females are usually of working class of manual labour group. We are trying to evaluate any difference from usual presentation in gender difference in sputum positive pulmonary TB cases from a backward district of South India.

Introduction: Incidences of tuberculosis among males are considered about dou-ble that of females. There was no geographical difference reported in this rate so far. Alappuzha district is one of backward district of South India. Females are usually of working class of manual labour group. We are trying to evaluate any difference from usual presentation in gender difference in sputum positive pulmonary TB cases from a backward district of South India.

Material and method: All sputum positive cases registered for two years (ie, 2003 & 2004) were included in the study. Sputum positive grade with gender and age was analyzed. Among the males there were no gender difference reported in this rate so far. Alappuzha district is one of backward district of South India.

Results: A total of 260 sputum positive cases registered during the study period. 215 were male and 45 were female. Among the females there were scanty cases and only 3 cases were 1+. 3+ cases were 33 among females and 156 among males.

Conclusion: A high incidence of sputum positive cases among males (1:5) may be due to low reporting of working class females. Late reporting is also common among females in backward areas.

P2603

Risk of serious adverse reactions during the treatment of new tuberculosis patients

Diana Ivanova, Sergey Borisov, Alexander Ryzhov. Clinical Department, Moscow Research and Clinical Center for TB Control, Moscow, Russian Federation

Background: Treatment of tuberculosis (TB) may be complicated by serious adverse reactions (SADR)s. Correct risk assessment before the start of treatment enables to choose the right preventive strategy and thereby to reduce a frequency of SADRs. The aim was to determine the rates of and risk factors for SADRs during treatment of new TB patients.

Methods: 200 HIV-uninfected new pulmonary TB patients admitted to Research
and Clinical Center for TB control 2009 to 2011 were monitored for ADRs during the intensive phase of treatment. The median age was 28.0 (IQR 22-44) yrs, 93 were female, 108 were smear-positive, 172 received only first-line anti-TB drugs. ADRs having NCI CTCAE Grade 3-4 were recorded as serious. Multivariate logistic regression was used for risk assessment.

**Results:** Seventy-six (37.8%) experienced at least one SADR, to a total of 95 events (47 - hepatitis, 19 – allergic reactions, 14 - hyperuricemia, 7 – deafness). Seventy-six (37.8%) experienced at least one SADR, to a total of 95 events (47 - hepatitis, 19 – allergic reactions, 14 - hyperuricemia, 7 – deafness). A cavity diameter (MM) < 32.9 (OR = 2.31, 95%CI: 1.56-3.45) and a history of drug/food allergy (OR = 2.94, 95%CI: 1.33-6.49) were identified as risk factors for developing a SADR.

**Conclusion:** During anti-TB treatment more than the third part of new TB patients experienced SADRs (more often hepatitis and allergy). Female sex, a history of drug/food allergy, low BMI, smear-positive TB and large cavities are the risk factors associated with SADRs.

**P2606**

**Anti-tuberculosis therapy as a reason for ejaculatory disorders**

Ekaterina Kolchavenets, Elena Brzhuzhtayk, Denis Khloston, Alexander Osadchyi.

Introduction: The sexual life is an integral part full and happy life. Patient with tuberculosis (TB) suffers from this disease itself as well as from different complications. The aim was to estimate the frequency of ejaculatory disorders in men suffering from tuberculosis and to determine the effect of TB treatment on the ejaculation.

Material and methods: 98 pulmonary TB patients were enrolled in study. The intravaginal latency time before onset of TB was estimated retrospectively and in 3 months of anti-TB therapy.

Results: Before anti-TB therapy 14.3% of pulmonary TB patients had ejaculatory disorders; 10.2% had premature ejaculation, and 4.1% delayed ejaculation. The rest 85.7% of patients had normal ejaculation.

Conclusion: The months of the therapy with 4 anti-TB drugs (isoniazid, rifampicin, pyrazinamide and streptomycin) the proportion was changed significantly. The share of patients with normal ejaculation decreased to 61.2%. On contrary, frequency of premature ejaculation increased twice (20.4%), and delayed ejaculation – in 4.5 times (18.4%).

**P2607**

**Predictive factors for antituberculosis treatment failure**

Tatjana Lesnjic, Zlepca Vasile. Pneumopathology, State Medical and Pharmaceutical University “Nicolet Testemiten”, Chisinau, Republic of Moldova.

The effectiveness of DOTS achieved 59% in Moldova in 2011. The result of an inadequate treatment is the treatment failure. Its increasing rate (7.5% in 2011) leads to accumulation of MDR sources in the population and puts more problems to the National TB Control Program. Treatment outcome depends by the social categories of patients, TB extension and co-morbidities. Aim of study is evaluation of predictive factors for anti-TB treatment failure (TF).

Methods: We compared risk factors for TF in a study group (SG) of 110 patients with pulmonary TB failed after 5 months of DOTS and a control group (CG) of 100 patients cured with DOTS.

Results: Males 60% SG vs 50% CG, average age 35.6 SG vs 42.5 CG, unemployed 76% SG vs 48% CG, with bad living conditions 63% SG vs 48% CG (p<0.05). Were detected 80% of patients from both groups by passive way with known TB contact 26% SG vs 20% CG. All patients (100%) had destructive forms of TB with positive smear, but bilateral extension had 84% of SG vs 24% in CG (p<0.05). Susceptibility test detected primary resistance in 55% SG vs 12% CG. Co-morbidities had 56% of SG vs 24% in CG, most frequent alcoholism, malnutrition, diabetes, HIV infection, tuberculosis 20% from SG vs 100% compliance in CG. Treatment outcome in SG cured 42, 30% dead, 10% default, 18% continue another treatment regimen vs 100% cured in CG.

Conclusions: Predictive factors for TF: are treatment not adapted to susceptibility testing, noncompliance with treatment, low social status, extensive TB with co-morbidities.

---

**P2608**

**Incremental yield of first, second and third spumum acid fast bacilli smear by microscopy in the diagnosis of pulmonary tuberculosis among patients referred to St. Paul Hospital Iloilo Public Private Mix directly observed treatment programme**

Kristine Kurz Gaven, Amne Lourdes Ponje, Ellice Solis, Rosario Toledo III. Department of Internal Medicine, St. Pauls Hospital Iloilo, Iloilo City, Iloilo, Philippines Department of Internal Medicine, St. Pauls Hospital Iloilo, Iloilo City, Iloilo, Philippines Public-Private Mixed DOTS, St. Pauls Hospital Iloilo, Iloilo City, Iloilo, Philippines Public-Private Mixed DOTS, St. Pauls Hospital Iloilo, Iloilo City, Iloilo, Philippines Department of Internal Medicine, St. Pauls Hospital Iloilo, Iloilo City, Iloilo, Philippines Public-Private Mixed DOTS, St. Pauls Hospital Iloilo, Iloilo City, Iloilo, Philippines

Study included all TB suspects referred to St Paul Hospital Iloilo Public Private Mix DOTS for sputum microscopy who submitted 3 sputum specimens for 2 days before and at least 1 spumum positive for AFB by smear microscopy. 3922 TB suspects submitted 3 specimens each 18.62% suspects fulfilled the definition of having at least 1 positive smear result confirmed by 2nd smear examination.0.27% had at least one positive smear.93.8% of suspects had their first specimen positive for AFB.5.55% were positive on the second specimen but not on the first and 0.65% were positive on the third specimen but not on the previous two. The distribution of smear positives among TB suspects in successive specimens and year, in 2003, 116 TB suspects examined of whom, 28.4% were positive. For 2005, 481 suspects wherein 22.24% were positive. For 2006, 481 suspects, 21% were positive.
2007, 670 suspects,17% were positive. In 2008, 734 suspects,16% were positive. In 2009,401 suspects and 14% were positive. Result showed reliance on the first specimen detect 85% of the sputum positive patients in 2003,94% in 2004,91% in 2005,98% in 2006,95% in 2007,94% in 2008 and 91% in 2009. If the second morning specimen was taken into consideration,then 97% were detected in 2003 and 2004 and 100% were detected from 2005-2009. As shown in this study that almost 7% of cases can be detected with submitting 2 specimens, one of which is the early morning specimen, the DOTS could improve the compliance of sputum submission of the patients as well as reduce the cost.

Presentations and treatment response of pulmonary tuberculosis in type 2 diabetes mellitus
Safaa Wolfs. Chest Department, Assiut University Hospital, Assiut, Egypt

Introduction: The association between diabetes and tuberculosis and their synergistic role in causing human disease has been recognized for centuries. They have serious implications on each other.

Aim: The aim was to study the coexistence between Tuberculosis and Diabetes, and to determine whether diabetes alters the radiological manifestations of pulmonary tuberculosis.

Methods: Patients with both Tuberculosis and Diabetes(28patients), were compared with another TB patients without diabetes(30patients). All were subjected to sputum smear for AFB examination and X ray chest.Bronchoalveolar lavage and tuberculin test were performed in selected cases.

Results: Diagnosed in 48.5% of TB patients. The majority were old females(60.7%) with mean age51.80±11.32.All patients associated with diabetes had type 2 DM. Most of them had diabetes before TB infection(57.5%). TB caused uncontrolled diabetes in 71.4% of cases, while diabetes decreased the response to anti-TB drugs in 32.1%. In diabetic patients lesions of tuberculosis were found to be bilateral in 39.3%, followed by left lung. It was significantly different from control group as it affected either right or left lung. Lower lung zone affection was significantly higher among diabetic patients 71.4% vs 3.3%. Atypical radiological features were significantly common in diabetic patients. Cavitating lesion and pneumonia may delay the proper treatment.

Conclusions: DM and TB had an adverse affect on each other. The atypical radiological images masked the diagnosis of tuberculosis in diabetic patients, which may delay the proper treatment.

The situation of extrapulmonary tuberculosis in Japan: Affected organ and rate of bacteriologically detection
Susumu Hirao, Masaki Ota, Akihiko Ohkado, Kunihiko Ito, Nobukatsu Ishikawa. The Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association, Kiyose, Tokyo, Japan

Introduction: To bacteriologically confirm diagnosis of tuberculosis (TB) is desirable. However, extrapulmonary TB (EPTB) is difficult because collecting samples are not simple like sputum samples, and burden for patients and doctors. In addition, smear examination tend to be negative. In Japan, patients access to examination easily because of health system. That is why, EPTB may be more bacteriologically confirmed in Japan.

Objectives: It is interesting to look into % of EPTBs bacteriologically confirmed by organs, because it would be a good guide for national TB programmes in high-burden countries which type of EPTBs are more likely to be confirmed.

Methods: EPTB data were collected from public health centre from 2008 to 2010 in the whole country. Study variables were affected organ of by age group, gender, nationality, month of diagnosis, prefectural, occupational and treatment history.

Results: The total number of EPTBs in Japan from 2008 to 2010 was 14,711. The most affected organ was pleura (7,043 cases) followed by lymph node excluded hilar lymph node and mediastinal TB (2,882 and 1,433 cases, respectively). Overall 6% of bacteriologically confirmed EPTB was 30.6%. The organ which was highest % of all EPTBs was oculus (4.1%) followed by pleura and hilar lymph node (16.3% and 21.8%, respectively).

Conclusions: Our study demonstrated that 14,711 cases of EPTB were found in Japan from 2008 to 2010. The most affected organ was pleura, however, the % of bacteriologically confirmed pleural TB was only 16.3%.

Culture-positive pulmonary tuberculosis with a normal chest x-ray in the absence of HIV co-infection
James Brown, Graham Bothamley. Respiratory Medicine, Homerton Hospital, London, United Kingdom

Aim: Normal chest x-rays (CXRs) have been found in those with culture-positive pulmonary tuberculosis, even without HIV co-infection. We wished to know how frequently this occurs, how frequently such patients are smear-positive and therefore infectious, whether contacts of these patients had evidence of tuberculosis and whether the site of disease can be identified by CT scan.

Methods: Records from the tuberculosis clinic at the Homerton Hospital, London, were reviewed for the period 2003-2012. All cases of culture positive pulmonary tuberculosis were reviewed and for those with a reported normal CXR the case notes were reviewed.

Results: 13 of 364 cases of culture positive pulmonary tuberculosis had a normal CXR. This included 6 of 34 (18%) with HIV co-infection. The frequency of a normal CXR was 3 of 233 (1.3%) with a negative HIV test. Data from one case without an HIV test and another with ++ smear but no culture are included.

Conclusions: Although 3 sputum samples were usually sent, often only one proved culture-positive. CT scans may not reveal active disease. Two with a positive smear had contacts who had forms of TB suggesting recent infection.

Tuberculosis and tumor necrosis factor alpha antagonist: Our experience
Nuria Maria Reina Martí, Ezpeletxeta Sanee de Tejada, Lidia López, Ana Milena Franco Torres, José Luis Velasco Garrido, Carmen Fernández Aguante, María Victoria Hidalgo Sajuga. Pulmonology Department, Virgen de la Victoria University Hospital, Malaga, Spain

Tumor necrosis factor alpha (TNF-alpha) antagonist are used for the treatment of chronic inflammatory disorders when they are refractory to standard therapy. Among its side effects are tuberculosis infection.

Objective: To evaluate the tuberculosis in patients treated with TNF-alpha antagonist.

Method: A retrospective review of patients treated with infliximab, etanercept and/or adalimumab in our hospital. We obtained 633 potential cases. We included patients with a positive culturing or histologic findings suggestive of Mycobacterium tuberculosis infection. Data collected: sex, age, underlying disease, prior immunosuppressive therapy, tuberculosis screening and prophylaxis, TNF-alpha antagonist used and location of the infection.

Results: Of the 633 patients, three developed active tuberculosis. Two men received prophylaxis with isoniaid and they were affected by psoriatic arthropathy treated with infliximab (previously with methotrexate). One of them, a 39-year-old man, developed pulmonary tuberculosis and the other one, a 53-year-old man, a genitourinary disease with a resistant germs to isoniaid. And a 58-year-old woman with rheumatoid arthritis treated with infliximab (and previously with sulphasalazine, penicillinamide, chloroquine and methotrexate), with unknown screening and prophylaxis, who developed pulmonary tuberculosis.

Conclusions: Screening and prophylactic measures cannot eliminate the risk totally. All the patient that developed tuberculosis disease were undergoing infliximab treatment and all of them suffered rheumatic disease. At least two of the developed tuberculosis diseases were not chemo prophylaxis treated. Two developed pulmonary tuberculosis disease and another one a genitourinary disease.
P2614
The factors associated to pulmonary impairment in patients with treated tuberculosis
Mikhail Chushkin, Valentina Aksenova, Elena Bogorodskaya, Vadim Koroev, Sergey Mandrykin, Dmitry Zhutikov, Eduard Tikhokhod, Sergey Smerdin. 
Phthisiopulmonology, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; 2Rehabilitation, Medical Center, Central Bank of Russian Federation, Moscow, Russian Federation

Tuberculosis is associated with frequent pulmonary impairment. Low lung function is an independent predictor of all-cause or respiratory disease mortality. The aim of the study was to ascertain the factors affecting lung function in patients treated for pulmonary tuberculosis.

Methods: In 302 patients who were treated for pulmonary tuberculosis (188 men and 114 women between the ages of 20 and 82 years) and observed at local dispensaries pulmonary function tests were performed. 

Results: Out of 302 patients, 114 (37.8%) had low lung function (FEV1 < 80% predicted). According to ATS/ERS criteria we classified 8.3% of subjects as having mild impairment; 18.2% of subjects as having moderate impairment; and 11.3% of subjects as having severe impairment. Risk factors for low lung function were positive culture in the past (odds ratio [OR] 4.3; 95% confidential interval [CI] 2.9 to 6.0; p < 0.001), age more than 40 years, recurrence of tuberculosis (OR 2.6; 95% CI 1.3 to 4.9; p < 0.004); education less than 15 yrs (OR 1.7; 95% CI 1.05 to 3.05; p < 0.05). We did not find influence of gender (males vs females, OR 1.36; 95% CI 0.84 to 2.21; p > 0.05), smoking ever vs never (OR 1.21; 95% CI 0.74 to 1.97; p > 0.05).

Conclusion: Risk factors for low lung function were culture-positive pulmonary tuberculosis in the past, age more than 40 years, recurrence of tuberculosis which may increase the prevalence of low lung function in the patients treated for pulmonary tuberculosis.

P2615
Sensitivity and specificity of St. George’s Respiratory Questionnaire in predicting low lung function in patients treated for pulmonary tuberculosis
Mikhail Chushkin, Elena Bogorodskaya, Valentina Aksenova, Vadim Koroev, Sergey Mandrykin, Dmitry Zhutikov, Eduard Tikhokhod, Sergey Smerdin. 
1Pulmonary Physiology, Research Institute of Phthisiopaediatrics, M.I. Sechenov First Moscow State Medical University, Moscow, Russian Federation; 2Rehabilitation, Medical Center, Central Bank of Russian Federation, Moscow, Russian Federation

Tuberculosis is associated with frequent pulmonary impairment. This supports performance of pulmonary function tests in the course of treatment and after a cure but until now pulmonary function testing had not been included in tuberculosis treatment guidelines. The aim of the study was to assess the usefulness St. George’s Respiratory Questionnaire (SGRQ) for predicting low lung function in patients after treatment of pulmonary tuberculosis.

Methods: We investigated 226 patients older than 40 years who were cured for pulmonary tuberculosis (145 males and 81 females). Quality of Life was studied by SGRQ. Pulmonary function was studied by spirometry. Receiver Operating Characteristic (ROC) curve analysis was used for assessment of sensitivity and specificity.

Results: Out of 226 patients, 97 (42.9%) had low lung function (FEV1 < 80% predicted). According to ATS/ERS criteria we classified 8.8% of subjects as having mild impairment; 20.8% of subjects as having moderate impairment; and 13.3% of subjects as having severe impairment. According ROC curve analysis for low lung function, when 29% of Total SGRQ score was chosen as the cut-off, the sensitivity, specificity, positive value and negative value were 57.7%, 83%, 72%, and 72% respectively. Area under the ROC curve (AUC) was 0.75 (95% confidential interval [CI] 0.69 to 0.81; p < 0.001). AUC was a bit bigger in male than in female (0.79 vs 0.69).

Conclusion: Total SGRQ of 29% may be the best cut-off in low lung function detection. Higher Total SGRQ score was associated with higher probability of low lung function.
parameters of both pleural fluid and sputum were measured. Twenty patients showed positive pleural fluid AFB culture results while the other 20 patients were AFB culture negative. Four patients among 38 patients had positive PCR results for tuberculosis and all of them had positive pleural fluid AFB culture results. Thirty five patients (88.5%) were accompanied with pulmonary tuberculosis in chest radiography. Both sputum and bronchial washing AFB culture showed higher positive results in patients with positive pleural fluid AFB culture results (p=0.001) compared to the group with negative culture results. The patients with positive AFB culture in pleural fluid had greater RPT one year after initiation of antitubercular treatment compared with those with negative AFB culture. The mean RPT of pleural fluid AFB culture positive group and culture negative group were 1.5±2.27 and 0.63±2.75 (p=0.046), respectively. There were no differences in pleural adenosine deaminase levels, initial amount of pleural effusion, need for

P2621 Pulmonary tuberculosis presentation – Late diagnosis, advanced disease

Valeria Maria Augusto, Direza Bartolomeu Greco, Margarete Dalcolmo, Marina Augusto Neves, Helena Rachel Wemereich. Clínica Médica, UFMG, Belo Horizonte, MG, Brazil

Pulmonary TB is the disseminating form of the disease. Rates are particularly high in urban areas associated with poverty, crowded living, social instability and HIV infection.

Objective: To describe clinical and radiological manifestations of pulmonary TB in a big Brazilian city and to evaluate the time between beginning of symptoms and diagnosis.

Methods: Prospective descriptive study; patients with positive smear proceeding from the public laboratories of the city of Belo Horizonte were prospectively included between May 2006 and April 2008. Demographic data were investigated. Blood samples were drawn for HIV. Chest radiographs (CXR) – were examined. Sputa were cultured whenever possible.

Results: 224 cases were included, 150 (67.0%) of the male sex. Age was 39.3 (± 13.0). Pulmonary manifestations occurred in almost all cases and systemic manifestations in 90%.

MRTB occurred in 3/158 with culture (1.9%). HIV was positive in 5/222 (2.3%).

Conclusion: Pulmonary positive TB had a late diagnosis in this big Brazilian city. Clinical presentation was of advanced disease with frequent cavitary lesions. In multifocal TB, the radiologic manifestation is not prevalent. Faster diagnosis should become available for high burden cities counties.

P2622 Bacteriological confirmation in a series of patients with exudative pleural

collections, presumed of tuberculous origin

Raúla Daniela Vasilescu, Pneumology I, Hospital for Infectious and Tropical Diseases Dr. Victor Babes, Bucharest, Romania

We analised a series of 23 cases of pleurises diagnosed in 2011 in our pneumology department. There were 23 patients, 14 males and 9 females, aged between 21 and 80.

Pleural fluid analysis: exudate, 100% lymphocytes in 22 cases and with 90% neutrophils one case, with proteins 3.8 – 6.2 g/dl, LDH 274 – 1743 u/l and ADA 47.5 – 196 u/l. Ziehl – Neelsen smears for BAAR from the pleural fluid were negative in all cases.

We obtained bacteriological confirmation in 4 cases from 23 (17,4%) – cultures typical for Mycobacterium tuberculosis.

Bacteriological confirmation coming too late, the criteria for choosing an antituberculous treatment were – epidemiologic, the analysis of pleural fluid (lymphocytic exudate with high ADA) and exclusion of other etiologies after performing CT scans and bronchoscopy.

We administered a standard regimen with Isoniazid, Rifampicin, Pyrazinamide and Ethambutol 7/7 in the first two months continued with HR 3/7. At the end of the hospital stay we obtained important resolution of the pleuritis in all cases and at the end of the treatment - normal chest X-rays at 20 patients, 3 having residual pachypleuritis.

We obtained bacteriological confirmation at one patient with liver cyrosis of viral (HCV) origin, one patient with 4 month pregnancy, one student with no other comorbidity and one patient with the contact.

In conclusion - bacteriological confirmation after cca 45 days of delay did not influence the therapeutic decision and the absence of confirmation didn’t change the type of treatment at that patients with favourable outcome. We must also consider a relative high prevalence of tuberculous pleurisy in a high endemic country as Romania.
P2623 Antituberculosis chemotherapy toxicity reduction
Yevelina Voronkova, Sergey Medvedev, Elena Pushkareva. Clinical Department, Novosibirsk TB Research Institute, Novosibirsk, Russian Federation

Increasing number of TB patients with co-morbidities (including hepatitis) affects the tolerance to treatment and - as a consequence - the efficiency of the treatment.

Purpose: To reduce the toxicity of TB treatment.

Method: A prospective study of 92 patients with pulmonary tuberculosis with drug-sensitive MTR. Study Design: "Case control". TB Patients were treated by standard chemotherapy regimens, including those in the study group (46 patients) - anti-TB medications lecithin-based ultra-emulsion.

Results: The application of anti-TB drugs in form of lecithin-based ultra-emulsion does not reduce the effectiveness of treatment in comparison with the conventional method, while significantly improves patient tolerance to chemotherapy. The analysis of tolerance demonstrated that adverse events were occurring with standard chemotherapy in 19 (41.3%) respectively, the application of the proposed method - only in 3 patients (6.5% < p<0.001, y2). We found that of development hepatotoxic reactions is 9.4 (p = 0.008, y2) in patients with the standard chemotherapy of pulmonary tuberculosis with chronic viral hepatitis. Hepatotoxic reactions were not registered in group with application of anti-TB medications lecithin-based ultra-emulsion.

Conclusion: The proposed method for the treatment of pulmonary tuberculosis prevents development of hepatotoxic complications. The patent of the Russian Federation has been obtained.

P2624 Tuberculosis in immunocompromised hosts: Pathogenic and pathologic peculiarities
Maryna Dzusmikeyeva 1, Dzmitry Gorenok 2. 1Laboratory Department, Republic Scientific and Practical Center for Pulmonology and Tuberculosis, Minsk, Belarus; 2Surgery Department, Republic Scientific and Practical Center for Pulmonology and Tuberculosis, Minsk, Belarus

Fast spreading of HIV-infection is one of the leading reasons of TB incidence increase. HIV-associated immunodeficiency leads to transition TB from infection to disease. Active TB strengthens HIV replication due to rapid synthesis of proinflammatory cytokines. In Belarus, the annual tendency to HIV-associated TB increase is observed. In 2002, a total of 35 HIV/TB patients was registered, whereas 265 in 2009. The purpose of study: to investigate pathogenic and pathologic peculiarities of pulmonary TB in patients with HIV/AIDS.

Methods: Morphological study of HIV/AIDS-associated TB was carried out on autopsy material of 11 patients died in center clinic in 2006-2010. The control group was 10 not HIV-infected TB patients.

The causes of death in HIV-infected patients were generalized TB with extrapulmonary manifestations in 2 cases, cases of pneumonia in 2 cases, acute progressive and disseminated TB in 3 patients. We distinguished following pathogenetic variants of associated HIV/TB pathology: HIV was primary, duration of observation before TB revealing 1-3 years, HIV/TB were revealed simultaneously. Peculiarities of TB course in AIDS patients compared with non HIV-associated TB were: loss of wavy TB coursing signs and specific inflammation features; monomorphism of TB inflammation foci; prevalence of necrotic suppurative foci; absence of productive inflammation elements on foci periphery; absence of localization and organizations signs of TB foci.

Morepathological peculiarities of HIV/TB determine diagnostics complexity and require histobiological study with Ziehl-Nielsen staining.

P2625 Spinal tuberculosis
Waan Ali, Abdelaziz Aichane, Zineb Berrada, Hicham Afif, 1Zoubida Bouayad, 2Department of Phthisiopulmonology, I.I.Mechnikov’ North–West State Medical University, St. Petersburg, Russian Federation; 1Laboratory of Genetic Methods of Research, The Research Institute of Phthisiopulmonology, St. Petersburg, Russia; 2Department of Phthisiopulmonology, I.I.Mechnikov’ North–West State Medical University, St. Petersburg, Russian Federation; 1Department of Phthisiopulmonology, I.I.Mechnikov’ North–West State Medical University, St. Petersburg, Russian Federation; 2Department of Phthisiopulmonology, The Research Institute of Phthisiopulmonology, St. Petersburg, Russian Federation

Introduction: Spinal tuberculosis is rare, but represents the most common form of atypical tuberculous in endemic countries.

Methods: From January 2000 to December 2010, we collected 16 cases of spinal tuberculosis. We analyzed clinical and radiological profile, means of confirmation and treatment.

Results: Spinal and chest pain were the most frequent signs. Four patients had neurological signs. The diagnosis was made by the detection of bacillus in the pus of paravertebral abscess in 6 cases, by histological study of vertebral biopsy in 5 cases, biopsy of another associated lesion in 1 case and in front of clinical and radiological (mainly CT and MRN) arguments with good clinical evolution under antibacterial treatment in 4 cases. The antibacterial treatment associating at least 4 drugs was tolerated and correctly followed by all patients. Surgical drainage was associated in 5 cases. The evolution was good in all cases.

Discussion: Diagnosis of spinal tuberculosis is late when there is no neurological sign. Imaging can make early diagnosis with MRN. Prognosis is good when treatment is early.

P2626 Hepatotoxicity of antituberculosis chemotherapy in patients with liver cirrhosis
Hong Joon Shin1, Chan Woo Park1, Sung Chul Lim1, 2In Jae Oh1, Kyu Sik Kim1, Yu Il Kim1, Young Chul Kim1, Jung Pil Jung1, Young Chun Ko2, Young Soo Kwon1, 1Internal Medicine, Chonnam National University Hospital, Gwangju, Korea; 2Internal Medicine, Gwangju Christian Hospital, Gwangju, Korea

Background: We compared liver cirrhosis (LC) and control patients who were received standard short-course antituberculosis (TB) therapy to evaluate the risk of drug induced hepatotoxicity (DHI) in LC patients.

Methods: Forty two LC patients with newly diagnosed active TB who were received isoniazid, rifampin, ethambutol, and/or pyrazinamide were included in the study. One hundred forty eight patients were selected as control subjects. DHI was defined as a liver transaminase level ≥ 120 IU/L.

Results: Of all LC patients, the etiology of LC consisted of alcoholic in 31 (74%), hepatitis B in 8 (19%), and hepatitis C in 3 (7%). Mean Child-Pugh score of all LC patients was 7.1±1.2 and Child’s A and B were 16 (38%) and 26 (62%), respectively. Pyrazinamide containing regimen were more commonly used in control patients (24 of 42 LC patients [57%] vs. 138 of 148 control patients [93%], p=0.001). Elevated liver enzyme including transient elevation of transaminase was more frequently found in LC patients (31 of 42 LC patients [74%] vs. 69 of 148 control patients [47%], p=0.002). DHI was also more frequently found in LC patients (6 of 42 LC patients [14%] vs. 6 of 148 control patients [4.3%], p=0.016).

In 5 out of 6 LC patients showed DHI, isoniazid and rifampin were successfully readministered and maintained until the end of treatment.

Conclusion: Our data suggested that LC patients with active TB should be closely monitored liver function tests due to more frequent hepatotoxicity during anti-TB treatment including isoniazid and rifampin.
P2629
Smear negative pulmonary tuberculosis in HIV: Over diagnosed or under investigated
Mandar Kubal1, Kavita Mody2, Ravindra Nath Sahay3, Amita Athavale2.
1Department of Medicine, Seth G S Medical College & K E M Hospital, Mumbai, Maharashtra, India; 2Department of Chest & EPRC, Seth G S Medical College & K E M Hospital, Mumbai, Maharashtra, India

Introduction: A significant proportion of HIV infected individuals with respiratory complaints and abnormal chest radiograph are labelled as tuberculosis and started on anti-TB treatment without detailed investigations.

Aims: The aim of the study was to verify the empirical diagnosis of smear negative pulmonary tuberculosis in HIV infected individuals using diagnostic modalities available at a teaching hospital in resource limited settings.

Methods: 50 HIV infected individuals with respiratory complaints, an abnormal chest radiograph, and negative sputum for AFB and labeled smear negative pulmonary tuberculosis underwent detailed history, physical examination, and a series of microbiological investigations. HRCT scans of the chest were performed to verify the chest x-ray findings. In the absence of definitive diagnosis on the initial sputum, the patients underwent bronchoscopy and sampling of respiratory secretions from the affected areas.

Results: Out of the fifty patients enrolled in the study, definitive diagnosis was reached in 47 patients of which 14 patients (28%) had bronchectasis, 13 patients (26%) had Pneumocystis jiroveci pneumonia, 5 patients (10%) bacterial pneumonia, and 8 patients (16%) had fungal pneumonia. 6 patients (12%) had non infective conditions like cardiomyopathy (3 patients), bronchial asthma (1 patient), non small cell carcinoma (1 patient), and interstitial lung disease (1 patient). Only 1 patient was confirmed to have tuberculosis on sputum AFB culture and also on bronchial washings AFB smears.

Conclusion: A wide variety of respiratory conditions other than tuberculosis can be definitively diagnosed in HIV infected individuals if investigated in detail.

P2630
Therapeutic drug monitoring of ionized, rifampin, and pyrazinamide in HIV infected patients with tuberculosis
Shadi Baniasadi1, Kavita Mody2, Ravindra Nath Sahay3, Amita Athavale2.
1Iran; 2India; 3Iran

Results: Twenty HIV-infected patients who received 4 first-line anti-TB drugs for active TB were eligible for the study. Venous blood was obtained 2 h after daily dose of INH (5mg/kg), RIF (10 mg/kg), and PZA (25 mg/kg). Serum levels of anti-TB drugs were analyzed using high–pressure liquid chromatography (HPLC) and compared with published normal ranges.

Conclusion: Of the 20 patients (mean age 36.25 years, range 30-57 years), 18 (90%) had a very low maximum concentration of INH (<1 μg/mL), and 2 (10%) had a low maximum concentration of INH (<2 μg/mL). All patients had a very low maximum concentration of RIF (<7 μg/mL) and 7 (35%) had a low maximum concentration of PZA (<20 μg/mL).

Further description of the study is available in detail.

FcyRI and CR on blood monocytes in differentiation between sarcoidosis and tuberculosis
Anna Dubaniewicz1, Manta Saguldziska1, Monika Wybieralska2, Katarzyna Rogora1, Jan M. Slominski1, Piotr Kowalczykski1, Adam Sterman1.
1Department of Pneumonology, Medical University of Gdansk, Poland; 2Department of Clinical Immunology and Transplantology, Medical University of Gdansk, Poland

Results: Of the 20 patients (mean age 36.25 years, range 30-57 years), 18 (90%) had a very low maximum concentration of INH (<1 μg/mL), and 2 (10%) had a low maximum concentration of INH (<2 μg/mL). All patients had a very low maximum concentration of RIF (<7 μg/mL) and 7 (35%) had a low maximum concentration of PZA (<20 μg/mL).

Conclusion: Low serum concentrations of INH, RIF, and PZA, which may be related to poor compliance, are common in HIV-infected patients. TDM of anti-TB drugs may help to optimize drug therapy and improve TB cure rates.

Results: Of the 20 patients (mean age 36.25 years, range 30-57 years), 18 (90%) had a very low maximum concentration of INH (<1 μg/mL), and 2 (10%) had a low maximum concentration of INH (<2 μg/mL). All patients had a very low maximum concentration of RIF (<7 μg/mL) and 7 (35%) had a low maximum concentration of PZA (<20 μg/mL).

Conclusion: Low serum concentrations of INH, RIF, and PZA, which may be related to poor compliance, are common in HIV-infected patients. TDM of anti-TB drugs may help to optimize drug therapy and improve TB cure rates.

Purpose: We investigated the expression level of thymosin β4 in the various stages of pulmonary tuberculosis. We also examined the expression pattern of VEGF and HIF-1α and compared the expression pattern of thymosin β4 with VEGF and HIF-1α.

Material and method: Ten surgical samples of active pulmonary tuberculosis lesions were immunostained with rabbit polyclonal antibody to thymosin β4 (1:1,000 dilution, ALPCO Diagnostics, Windham, NH, USA), HIF-1α (1:100 dilution, Novus Biologicals, Littleton, CO), or VEGF (1:2,000 dilution, Abcam Inc., Cambridge, MA, USA) at 4°C for overnight. The expression levels were analyzed on the pathological stages of pulmonary tuberculosis.

Result: Thymosin β4 was highly expressed in both alveolar macrophages in granuloma and surrounding lymphocytes in early stage of granulomatous tissues but not expressed in late stages of fibrous tissues. The expression pattern of HIF-1α was similar with that of thymosin β4. VEGF was weakly expressed in alveolar macrophages in granuloma but highly expressed blood vessels surrounding granuloma. The expression pattern of VEGF was co-localized with CD31 (Platelet endothelial cell adhesion molecule, PECAM).

Conclusion: These data suggested that thymosin β4 is highly expressed and associated with HIF-1α and VEGF-mediated inflammation and angiogenesis in the granulomatous lesions of active pulmonary tuberculosis.

Altered imbalance between Th17 and regulatory T-cells and impaired Th1 response in the recovery of multidrug-resistant tuberculosis

Qi Tan1, Rui Min1, Hong Wang1, Weiping Xu1, Zhuhu Xu2, Weiguo Xu3, Xiaoqiang1, Chunyan Shi2, Hongguo Pan1

1Department of Respiratory Medicine, The First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China; 2Department of Chronic Infectious Diseases, Center for Disease Control and Prevention, Jiangsu Province, Nanjing, China; 3Department of Respiratory Medicine, The First Hospital of Jiangnan City, Zhongshan, Jiangsu, China

Objective: Multidrug-resistant tuberculosis (MDR-TB), a lethal global threat today, requires prolonged and expensive second-line drugs of heightened toxicity. A dysregulation of Cyt4 T cell subsets, found in the pathogenesis of TB, is a crucial question still unsolved in MDR-TB. Insights into MDR-TB immune responses are urgent for developing new solutions.

Methods and results: We phenotypically examined circulating TH17/Treg cells, regulatory T cells (Tregs), TH1/TH2 cells by flow cytometric detection in 26 MDR-TB patients, 26 drug-sensitive TB patients (DS-TBs) and 26 healthy subjects (HCs). The levels of circulating T cell subsets were further analyzed during before/post-treatment phase in MTB-TB patients.

Results: We found upregulation of circulating Th17 expression (7.45±1.54%) and decreased ratio of Treg/Th17 (0.42±0.01) in MDR-TB compared to HCs and DS-TBs. More remarkable suppression of Th1 cell activation was detected in MDR-TB patients than in DS-TBs compared to HCs. Although clinical signs of MDR-TB patients did not show obvious recovery after 7 month-chemotherapy, the circulating ratio of Treg/Th17 (0.88±0.13) and level of Th1(15.1±0.90) in MDR-TB patients tended to normal compared to their previous level before treatment (P<0.05).

Conclusions: These data provided evidence for an unbalanced immune status of Treg/Th17 and inhibition of Th1 type immunity in MDR-TB infection, and suggested a specific role of these T cell-induced immunities during the evolution of MDR-TB. Further study on the immune homeostasis restoration of MDR-TB patients may aid in improving adjuvant immunotherapies and developing potential therapeutic strategies.

1Department of Pneumology, Medical University of Gdańsk, Gdańsk, Poland; 2Department of Thoracic Surgery, Medical University of Gdańsk, Gdańsk, Poland

Due to clinical and histopathological similarities between sarcoidosis (SA) and tuberculosis (TB), we try to find some biomarker(s), which allow to a differential diagnosis between these disorders. We recently revealed increased frequencies of receptors for Fc fragment of IgG (FcγRII) and FcγRI (FcγRI) monocytes in both SA and TB but in contrast to SA, monocytes had increased FcγRIII expression with receptors for fragment of complement (CR) CR1 and CR4 deficiency. Abnormal expression of FcγRI and CR may cause of a disorder of the phagocytosis by monocytes and clearance of immune complexes (CIs) with following immunocomplexes, which concentration was higher in SA than in TB. Therefore, we have analyzed the key stages of phagocytosis blood monocytes from 22 patients with SA, 20 patients with TB and 20 healthy volunteers using the PHAGOTEST® kit by flow cytometry. Our study revealed increased percentage of monocytes in SA than in TB and the controls (p=0.003, p=0.002, respectively), but there was no difference between TB and healthy individuals. The percentage of phagocytizing monocytes was increased in SA than in the controls (p=0.03) and it was slightly elevated compared to TB. There was no difference between TB and the controls. In summary, current study revealed increased of phagocytic activity of monocytes in SA than TB and explained previously obtained results regarding higher frequency of FcγRI and CR deficiency on sarcoid than on tuberculosis monocytes. The increased phagocytosing of CIs and high antigen load with following persistent antigenemia may explain the presence persistent complexemia in our patients with SA. This study may be useful for differentiation of both diseases.

Serum and r32kd induced cytokine levels and expression in tuberculosis patients and controls

Lavanya Joshi1, P.S. Raju1, Vijayalakshmi Valluru1,2, Suman latha Gaddam1

1Dept of Immunology, Bhagwan Mahavir Medical Research Centre, Hyderabad, Andhra Pradesh, India; 2Immunology and Molecular Biology, LEPPRA Society-Blue Peter Research Centre, Hyderabad, AP, India; 3Free Chest Clinic-PFMI DOTS, Bhagwan Mahavir Medical Research Centre, Hyderabad, AP, India

Tuberculosis is a disease caused by Mycobacterium tuberculosis (MTB) whose interaction with the host may lead to a cell-mediated protective immune response. Several cytokines, including IL-6, IFN-γ and TNF-α, play important roles in mediating resistance against MTB. The aim was to investigate the candidate cytokines in active pulmonary tuberculosis patients of younger age (15 to 25yrs), their Household Contacts and controls. Levels were estimated by ELISA in pg/ml in serum(n=30) and PBMCs stimulated with r32-kd antigen of M.bovis BCG (n=30). Expression by qRT-PCR in 5 individuals from each group in culture supernatants were studied. In serum IFN-γ and TNF-A concentrations were elevated in patients compared with their contacts and controls(24.51±10.60, 20.45±4.93, 14.14±8.22 at p<0.002, (13.62±8.14, 11.34±5.30, 6.39±4.10 at p<0.003). In contrast, r32kd stimulated PBMCs produced less IFN-γ and TNF-A (36.21±16.9, 45.57±4.91, 56.37±5.37 at P<0.002, (59.74±6.51, 87.28±5.43, 109.2±8.56 at p<0.007), whereas IL-6 concentrations were elevated in controls both in serum and stimulated PBMCs(11.6±4.09, 1.20±0.0018 at 74.94±15.18, 61.21±11.87, 68.66±69.36 at P<0.01). Out of the 30 cases studied 6 contacts behaved similar to the patients in their clinical and Immunological aspects. The cell-associated mRNA in Ag85B-stimulated r32kd-activated PBMCs was significantly depressed in TB patients. On the other hand, Expression of IL-6 was high in patients. Therefore, in conclusion, IFN-γ, TNF-α and IL-6 production to r32-kd antigen could be used as biomarkers for the clinical status of TB patients and early diagnosis of their contacts.

P2637

Serum amyloid A is a sensitive marker of activity of the process in patients with pulmonary tuberculosis

Rajeshvili Kuzag, Kumineya Galina, Oksana Komissarova. Biochemistry Laboratory, Central TB Research Institute of RAMS, Moscow, Russian Federation

Aim: Study level of serum amyloid A (SAA) in blood serum of patients with active pulmonary tuberculosis (TB) and its comparison with level of C-reactive protein (CRP).

Materials and methods: We studied level of SAA and CRP in blood serum of 93 M tuberculosis patients in the age from 18 till 55 years (male – 38 and female – 55). Concentration of SAA was determined by ELISA and CRP by immunoturbidimetric method.

Results: It was established that the level of SAA increased in 99% of patients, whereas rate of CRP was increased in 80.7% of patients. The degree of increase SAA also was much higher: the levels of SAA over 100 mg/l were observed in 68.8% of patients, but CRP - only 11.1% of cases. The degree of increase SAA was directly related with the manifestation of tuberculosis intoxication, the quantity of M tuberculosis (MTB) in sputum, the spectrum of drug resistance of MTB, the extension of the lung process and the presence of destruction in lung tissue. A maximum value of SAA in patients with pulmonary tuberculosis was 247 mg/l. The level of SAA after 3 months of chemotherapy decreased by about half in patients with effective treatment, but remained significantly increased in comparison to the norm. In patients with inefficient of the treatment the level of SAA was not substantially changed.

Conclusion: SAA is a useful marker of activity of the process in patients with pulmonary tuberculosis and its sensitivity is higher than that of CRP.

The usefulness of antimonycytobacterial antibodies detection in TB diagnosis

Elena Ciocanu1, Codrin Popa2, Irina Luciana Dumitru1, Bogdan Gruza1, Cristian Cogorc1 

1Physiology, University of Medicine and Pharmacy “Gr T Popa”, Iasi, Romania; 2Pneumology, Clinic of Pulmonary Diseases, Iasi, Romania; 3Pneumology, University of Medicine and Pharmacy “Gr T Popa”, Iasi, Romania

Aim: Due to the high number of cases, it could be useful a rapid and cost effective test for early diagnosis of tuberculosis. We planned to evaluate if a test based on detection of anti-lipoarabinomannan antibodies in serum is suitable for diagnose the tuberculosis (TB)

Methods: The test used is based on detection of anti-lipoarabinomannan antibodies
from the sample using plastic combs. The test is positive if a colored spot appears on plastic comb. We used a randomized lot of patients addressed to Clinic of Pulmonary Diseases, Iasi, Romania.

Results: We have tested 46 patients from June 2011 to January 2012 from Iasi County. The final bacteriological results are available for 27 patients in present (February 2012). All the data presented below are just for patients with final evaluations. The average age was 45 years. Based on bacteriological tests 10 cases (37%) were diagnosed with TB. From patients with TB, the rapid serum test was positive in 8 cases (80%), 2 cases were negative. The other 17 cases were culture negative for M. tuberculosis. From negative cases 14 (82.4%) were also negative for rapid TB test, and 3 cases were positive. For all 3 cases negative in bacteriology but positive in rapid TB test were observed opacities in upper lobes. Tuberculin test was positive in one case and not performed in others two. The producer revealed that this test has a sensitivity of 70.2% in patients with pulmonary tuberculosis and a specificity of 95.1%.

Conclusion: In the study population, this rapid TB test seems to be interesting for a rapid TB screening. A future study with a larger sample is expected for final evaluation is necessary for a more appropriate evaluation of the utility of this rapid TB test.

P2639 Impact of immunogenetic factors to tuberculosis of intrathoracic lymph nodes in children in northwestern Russia

Severality of the disease depends not only on peculiarities of causative agent but also on genetic profile of patients. The aim of the study: to study the distribution of HLA-DRB1* alleles in children with tuberculosis of intrathoracic lymph nodes in North-Western region of Russia. Totally 188 children from 1 to 15 years old were recruited in Cape Town, South Africa and London. Patients with latent TB infection were also recruited. Whole blood samples were taken before, during, and after, 6 months of standard first line TB drug therapy. Samples were processed for microarray expression using a customized microarray. Changes in transcriptional expression were analyzed. An algorithm to quantify the changes was also devised.

Methods: We have tested 46 patients from June 2011 to January 2012 from Iasi County. The final bacteriological results are available for 27 patients in present (February 2012). All the data presented below are just for patients with final evaluations. The average age was 45 years. Based on bacteriological tests 10 cases (37%) were diagnosed with TB. P2640 A change in blood transcriptional signatures accompanies successful tuberculosis therapy

Chloe Bloom 1, Christine Graham 1, Matthew Berry 2, Katalin Wilkinson 3, Oni Tolu 2, Zhaohui Xu 4, Jose Rossello-Urgell 4, Robert Wilkinson 6, Anne O’Garra 1
1Division of Immunoregulation, MRC National Institute for Medical Research, London, United Kingdom; 2Respiratory Medicine, St. Mary’s Hospital, London, United Kingdom; 3Institute of Infectious Diseases and Molecular Medicine, University of Cape Town, South Africa; 4BIHR, Baylor Research Institute, Dallas, United States; 5Respiratory Medicine, Royal Free Hospital NHS Trust, London, United Kingdom; 6Division of Mycobacterial Research, MRC NIMR, London, United Kingdom

Introduction: Inadequate treatment of patients with active TB leads to worsening disease, infection transmission and drug resistance. Effective anti-TB therapy monitoring is difficult as the best accepted method is the 2-month sputum culture conversion. However this has low sensitivity for predicting an individuals response, and difficult to implement since culture results are not available in 30-50% of patients. No recognised biomarkers of treatment response earlier than 2 months exist.

Aims: Determine if blood transcriptional profiles can be used in early TB treatment monitoring.

Methods: Mtb culture-positive, HIV-uninfected, pulmonary TB patients were recruited in Cape Town, South Africa and London. Patients with latent TB infection were also recruited. Whole blood samples were taken before, during, and after, 6 months of standard first line TB drug therapy. Samples were processed for microarray expression using a customized microarray. Changes in transcriptional expression were analysed. An algorithm to quantify the changes was also devised.

Results: All patients responded successfully to therapy. An active TB transcriptional signature was derived by comparing the untreated active and latent TB patients. A specific treatment response transcriptional signature was derived com-
Introduction: Pulmonary infections due to non-tuberculous mycobacteria (NTM) are a clinical challenge. There are to date no recommendations for the use of potential second line drugs, when first line treatment fails. For Moxifloxacin, in vitro susceptibility could be shown for M. avium-complex (MAC), but almost no data available on its in vitro effectivity against various other NTM species.

Methods: From 100 NTM-positive cultures other than MAC isolated at our center during 2003-2010 (9 M. fortuitum, 2 M. chelonae, 6 M. gordone, 5 M. marinum and 78 M. kansasii), we tested the minimal inhibitory concentrations (MIC) of moxifloxacin and thus the sensitivity (breakpoint ≤ 2 µg/mL). Culturing and resistance testing was performed on solid Middlebrook agar plates (7H11) by agar dilution.

Results: Out of 100 tested NTM-positive cultures, 98 (98%) showed sensitivity to moxifloxacin at. Only two strains (M. fortuitum and M. chelonae) showed higher MIC.

Conclusions: Our study revealed a high sensitivity rate of moxifloxacin against several NTM strains other than MAC in vitro. Despite the absence of clinical treatment studies, we see a potential use of moxifloxacin as a second line drug.

P2645

Molecular characterization of mycobacterium tuberculosis resistant to fluoroquinolones, distributed in Saratov region

Tatiana Morozova, Tatiana Salina. Department of Pathihology, Medical University, Saratov, Russian Federation

Aim: To study the spectrum of mutations of gena gyrA M. tuberculosis, coding for drug-resistance to fluoroquinolones, in the Saratov region.

Methods: We examined 47 samples of sputum patients with active pulmonary tuberculosis. Detection of Mycobacterium tuberculosis (MTB) and determine their drug susceptibility to fluoroquinolones was performed using biological microchips. The results of the reaction were evaluated with the use of hardware-software complex (“Chipdetektor-01”), Technology research, a set of reagents and equipment were developed by staff of the Institute of Molecular Biology (“Chipdetektor-01”, Moscow).

Results: DNA M. tuberculosis were found in 39 (83%) patients. Mutations in the gene gyrA were identified in 22 (56,4%) samples, of which - in 13 (59%) found the mutation in codon 95 Ser (AGC) -> Thr (ACC) due to the natural polymorphism of the gene and do not lead to the development of drug resistance. In 9 (41%) samples identified mutations in 91 (33,3%), 94 (44,4%), 90 (22,2%) codons that encode resistance to fluoroquinolones. Primary drug resistance is set in 5 (12,8%) patients. In 4 cases revealed secondary drug resistance in patients, which received 90-120 doses antibiotic drugs. Of these, 3 cases have double mutations in gyrA (Asp94-Gly + Ala90-Gly), (Asp94-Ala + Ala90-Gly), (Asp94-Gly + Ala90-Val) and in 1 patient was found a combination of four mutations.

Conclusion: In the Saratov region primary resistance to fluoroquinolones at the level of genetic mutations was set in 12.8% cases. Was found the increase in the number of mutations among MTB strains isolated from patients receiving prolonged treatment with anti-TB drugs.

P2646

Expression of P-gP in patients with resistant tuberculosis

Ivan Neves, Maria Cres, Simone Carvalho, Liane De Castro. Farmacogenetics Laboratory - LAFCLIN - Farmacognética, Evandro Chagas Clinical Research Institute - IPE/CIOCRUZ, Rio de Janeiro, RJ, Brazil Clinical Research Laboratory in Tuberculosis - LACIPBUFF, IPE/CIOCRUZ, Rio de Janeiro, Brazil Nursing School - Coordination, Souza Marques Technical Educational Foundation - FTESM, Rio de Janeiro, RJ, Brazil Lapcin- Farmacogenetics, IPE/CIOCRUZ, Rio de Janeiro, Brazil

Background: Resistant tuberculosis (TB) is one important cause of treatment failure. One of the MDR resistance mechanisms is MDR1 gene expression, as P-glycoprotein (P-gP) expressed on cell surface, its related with output of drugs and could modify their biodispomibility.

Objectives: To evaluate P-gP expression in patients with monoresistance (MR) or multi-drug resistance (MDR) tuberculosis.

Methods: A prospective study was performed analyzing blood samples of patients with confirmed resistant TB in treatment at Evandro Chagas Research Institute (IPEC) in Rio de Janeiro, Brazil, since 2010. Flowcytometric analyses of P-gP Activity - For detection of P-gP function as a transporter, Rhb D23, by Sigma, Germany (SG) was used as a fluorescent. Cicloporin-A (SG) was used in this study to reverse P-gP mediated drug resistance and Rifampicin (R) as inductor. Detection P-gP expression - The monocotes P-gP expression was determined using a murine anti-P-gP monoclonal antibody (eBioscience-USA) and anti-Cd14, and analyzed using flowcytometer (EPICS XL-MCL. System II. Beckman Coulter, USA).

Results: The samples of 12 patients were analyzed. Seven men and five women, with ages from 23 to 73 years. The panel of resistance showed: R(2); Rifampicin more isoniazide (RI) (4); RI more streptomycin (S) (3); RI more Ethambutol (E) (2); Rifampicin more isoniazide (RI) and Ethambutol (E) (1). The efficacy activity was identified in 53.8% of patients. The Rifampicin was able to efflux induce in majority of patients Unexpected the monocotes P-gP-expression was found in 57, 7% and 74, 1%, respectively in patients with efflux activity and no efflux activity.

Conclusion: These findings can be involved with resistant TB and future relation with response of treatment must be evaluated.
Conclusion: TB patients with weakly positive smears or with a not purulent sputum property should undergo three sputum smear tests.

P2648
Role of the macrophage-inducible C-type lectin Mincle in the lung host defense against tuberculosis infections in mice
Friederike Behling1, Kathrin Steinwede1, Regina Mauss1, Jennifer Bohling1, Tobias Wehr1, Ulrich Mauss1, Department of Experimental Pneumology, Hannover Medical School, Hannover, Germany; 2Clinic for Pneumology, Hannover Medical School, Hannover, Germany

The macrophage-inducible C-type lectin Mincle has been identified as receptor for the mycobacterial cell wall component trehalose dimyculoside (TDM) of M. tuberculosis. We here examined the role of Mincle in lung protective immunity against mycobacterial pathogens in mice. We found that mice infected with M. bovis BCG responded with a delayed expression of Mincle on alveolar macrophages by days 14-21 post-challenge. In line with this finding, we observed that Mincle KO mice showed significantly reduced proinflammatory cytokine release and alveolar leukocyte recruitment as well as increased mycobacterial loads particularly in lung draining lymph nodes and spleens relative to wild-type mice infected with M. bovis BCG. Importantly, flow-sorted alveolar macrophages of wild-type mice responded with substantially greater proinflammatory TNF-α, KC, CCL2 and CCL5 mRNA levels to infection with M. bovis BCG relative to alveolar macrophages of BCG-infected Mincle KO mice. Together, the current study shows that Mincle exhibits delayed cell surface expression kinetics on alveolar macrophages upon M. bovis BCG challenge, thus acting as a ‘delayed-type’ regulator of proinflammatory macrophage activation during mycobacterial infections.

P2649
Pleural effusion cytokine profiles in HIV/MTB co-infection
Ani Chalmaginyan, Unessh Lalloo, Alina Phulpakhare, Devapreegan Moodley, Kennedy Nyamunde, Aneesh Ambaram. Medical Biochemistry, University of KwaZulu-Natal, Durban, South Africa Pulmonology, University of KwaZulu-Natal, Durban, South Africa

Pleural effusion is a common presentation in HIV/MTB co-infection. During infection, it is composed primarily of an extensive inflammatory cell infiltrate and an as yet poorly characterized cytokine milieu. Previous reports have shown significant expansion of CD4 T cells in pleural compartments of patients with active MTB infection. Both the immune infiltrate, and to a large degree, the pleural cytokine milieu, may augment viral dynamics and as a result, promote HIV replication in co-infected patients. The current study may have implications for clinical management of dually infected patients. To characterize the pleural effluent in HIV/MTB co-infected patients, we used cytokine array-based technology to profile key cytokines. Our data showed significantly elevated levels of IL6 and IFN-γ in pleural fluid from HIV/MTB co-infection compared to MTB alone (MTB/HHV vs MTB: IL6: 90.6pg/ml vs 85.6pg/ml; IFN-γ: 91.9pg/ml vs 85.4pg/ml). This observation may have reflected increases in systemic levels of these cytokines in dually infected patients (IL6: 32.1pg/ml vs 29.5pg/ml; IFN-γ: 85.4pg/ml). We noted moderate inhibition of IL4 production in the regulatory T-cells and high levels of FOXP3 mRNA lead to decreased TNF-α production in dually infected patients. Dually infected patients may have reflected increases in systemic levels of these cytokines in dually infected patients. Taken together, our data suggests that co-infection with HIV may alter TH2 polarization dynamics at pleural sites. The high level of TNF-α at MTB pleural sites, in the absence of HIV, is suggestive of conventional pro-inflammatory, innate responses usually associated with tuberculosis.

P2650
Regulatory T-cells and high levels of FOXP3 mRNA lead to decreased immune responses during HIV-TB co-infection
Andre Loxton, Teri Roberts, Gillian Black, Gerhard Walzl. Biomedical Sciences, University of Stellenbosch, Cape Town, Western Cape, South Africa

Tuberculosis causes 2 million deaths per year and is the most important opportunistic infection in patients infected with HIV. During the co-infection of HIV/TB, natural regulatory T cells down regulate Th1/Th2 responses. We performed direct ex vivo phenotyping of whole blood with antibodies to CD4, CD25, FOXP3, CD38 and PD-1. In a 7-day whole blood assay, diluted blood was incubated with M.tb proteins. The supernatant was removed and analysed for interferon-gamma production by ELISA. The Multiplexed Ligation dependent Probe Amplification technique was used to amplify ex vivo RNA and compare gene expression of 45 genes. We found an increase in the ratio and frequency of regulatory T-cells in HIV/TB co-infected participants. FOXP3 expression was increased in participants infected with HIV or TB alone. The median interferon-gamma responses to control and DOS-R M.tb antigens (ESAT-6/CFP10, TB10.4, Ag85A) was the highest in the control group. The response to p24 was higher in the HIV+ group than the HIV-TB participants. The FOXP3 gene was significantly upregulated in HIV/TB co-infected participants. Participants with HIV/TB co-infection have significantly more regulatory T-cells than those infected with either HIV or TB who were able to dampened immune response to both HIV and TB. Differential gene expression and increased frequencies of regulatory T-cells in the HIV/TB co-infected participants may have important implications for future vaccine designs. A more precise unravel the mechanisms of immune failure which is present during HIV/TB co-infection.

P2651
Genetic markers of multi-drug and extensive drug resistant M. tuberculosis in Kyrgyz Republic
Iainagul Isakovka, Numrira Sovzhonova, Almat Alishayev. Molecular Cell Biology, Institute of Molecular Biology and Medicine, Bishkek, Kyrgyzstan

Tuberculosis (TB) is still a major cause of morbidity and mortality worldwide and also in Kyrgyz Republic. Decades of tuberculosis treatment failures in Kyrgyz Republic led to acquired resistance to the first-line antitubercular drugs, isoniazid (INH) and rifampicin (RIF), resulting in multidrug resistant tuberculosis (MDR-TB) (300-400 cases per year). Switch to second line drugs lead to acquisition of resistance to them and spread of XDR-TB. XDR tuberculosis cases represent about 3 to 10% of MDR cases in the countries like Kyrgyz Republic. The aim of this study is the identification of mutation in rpoB, katG, inhA, aprC and gyrA genes in MDR-TB cases in Kyrgyz Republic. Materials and methods: DNA samples of M. tuberculosis (M Tb) were collected from 99 sputum samples from adult patients with primary MDR-TB. Mutations associated with resistance to rifampicin, isoniazid and fluoroquinolones were analyzed by biopsis assay. Results: We have demonstrated that in the rpoB gene of MDR Mt strains the prevalent point mutation was Ser531Leu (59%). Among strains resistant to isoniazid the mutations of katG gene were found in 91% (inha gene – 7% – and aphC gene -2%, respectively). The most frequent mutations in katG was Ser315Thr (91% of cases). The frequent mutations of gyrA gene were AprC94Gly and Ala90Val. Conclusion: In Kyrgyz Republic the main cases of Mt resistance to rifampicin is Ser531Leu mutation in rpoB gene, to isoniazid – Ser315Thr mutation of katG gene. The cause of resistance to fluoroquinolone are gyrA gene – AprC94Gly and Ala90Val.

273. Tuberculous and non-tuberculous mycobacterial infections: epidemiology I

High completion rates with directly observed preventive treatment (DOPT) of latent tuberculosis infection (LTBI) in Ethiopian immigrants (EI) to Israel
Hashem Bisbar, Liara Ore, Najat Arma, Daniel Weiler Ravel.
1Pulmonary Division and Tuberculosis Center, Nachazeth Hospital, Nazareth, Israel.
2School of Public Health, Faculty of Social Welfare and Health Science, University of Haifa, Haifa, Israel.
3Division of Respiratory Physiology and Chest Disease, Carmel Medical Center, Haifa, Israel.

Background: Previous studies show rates for completion of treatment of LTBI in immigrants from high TB burden countries between 22%-60%. In a study in southern Israel only 16.4% of EI completed their course of treatment. Since all EI in our catchment area were located in absorption centers, we applied DOPT to all. Each patient was examined by a physician once on evaluation and twice for follow up.

Objective: To evaluate the efficacy of a nurse-managed, active outreach DOPT program with minimal physician involvement, in a cohort of immigrants from a high TB burden country.

Methodology: A retrospective cohort analysis of 710 medical records of EI at absorption centers in Zefat who had started DOPT for LTBI and were followed up during 2005-2010.

Findings: Forty three individuals were excluded due to translocation during treatment and DOPT was stopped prematurely in 4 women who became pregnant. Of the 663 EIs included (359 males), 628 (94.7%) completed treatment. Of the 35 who failed to complete INH therapy, 23 went on to complete 4 months of Rifampin. Thus 98.0% completed LTBI therapy. Demographic factors did not predict treatment completion; however side effects were significantly (p <0.001) associated with non-completion.

Conclusions: High completion rates for LTBI were attained among EI in absorption centers, through outreach DOPT. Skilled and dedicated nursing made routine physician involvement redundant.

Sponsored by the Israel National Institute for Health Policy Research and by the Israel Lung and Tuberculosis Association.

Part of a Thesis submitted for MPH degree, School of Public Health, University of Haifa, Israel.
Results of a tuberculin skin test survey performed in a national representative sample of young Albanian students

Hassan Kadriu1, Zeki Kajtazi2, Arben Voskas3, Rosita Centa4, Giovanni Battista Migliori1, Liu D'Ambrosio4, Paolo Castiglioni4, Guvannit Sotro4,1, University Lung Diseases Hospital, Shqetër Ndriqë1, Tirana, Albania; 2 National Institute of Public Health, Tirana, Albania; 3 Centre for Respiratory Health & TB, Tirana, Albania; 4 World Health Organization Collaborating Centre for Tuberculosis and Lung Diseases, Fondazione S Maersk, Tuberculosis Institute, Trastevere, Italy; 5 Epidemiology and Medical Statistics Unit, Department of Biomedical Sciences, University of Sassari, Italy

Background: Tuberculosis (TB) epidemiology in Albania has significantly improved in the last decades owing to advanced TB control activities following financial support from different sources. In 2010, WHO estimated a TB incidence and mortality rate of 14 and 0.38 per 100,000 population, respectively.

Objective: To estimate the Albanian prevalence of latent TB infection (LTBI). Methods: A national Tuberculin Skin Test (TST) survey was carried out in 2010.

Results: Three districts (Dibra, Tirana-Kamez, Vlora) were selected based on representativeness criteria (location, incidence and migration patterns). The survey performed according to WHO recommendations enrolled 4,722 students (2,359, 49.9%, were males); proportions of educational level were: grade 5 (30%), grade 6 (33%) and grade 7 (37%). Results were evaluated in 98.5%. Induration size exceeds 15 mm in 16%, while in 56% of the cases ranged from 6 to 10 mm. Prevalence of LTBI was higher in Dibra District and Kamer (13.9% and 9.5% respectively, strictly related to TB incidence. 2,813/3,242 could answer an anonymous questionaire on TB. Students living in the district of Dibra showed the highest proportion of positive responses on TB items, probably explained by the high TB incidence and by the high frequency of information from television programmes.

Conclusion: Estimated LTBI prevalence is low in Albania, although a high geographical variability was described. Students’ knowledge on TB was deemed not satisfactory, despite 87% knew the presence of the disease.

Stigma associated with tuberculosis among Tajikistan labor migrants

Bekhruz Salikhov, Oktum Bobobodzhov, Phthisiopulmonology, Tajik State Medical University by Abdul Baev, Sino, Dushanbe, Tajikistan Republican Centre for Tuberculosis, Republican Centre for Tuberculosis, Dushanbe, Tajikistan

Problem statement: Stigma is the most significant barrier in prevention of TB transmission, provision of adequate care, support, treatment and decreasing negative impacts. Currently, TB issue and stigma associated with labor migrants have not been learned yet in republic of Tajikistan. Goal of the survey: The goal of the survey was deep understanding of stigma and low TB awareness among labor migrants. Majority of labor migrants do not apply for health care services because of wrong perceptions. National bodies and organizations would apply for health care services in case of symptoms related with TB.

Materials and methods: The survey was done through individual interviews at respondents houses. We used qualitative and detailed interviews for detection of labor migrants. Only 6 labor migrants (1,2%) noticed that they would not talk feel depression in case of TB diagnostics. Other widely spread reaction was fear of TB. 58 were TB positive. Out of these, 53 followed up. 9/53 (16.98%) had turned TST positive after 3 months. Duration of stay in the wards as well as number of TB patients in the ward during their hospital stay was found to have proportionately increased the risk of transmission (P <0.001). Out of 117 visitors, 98 were TST negative. Out of these, 61 followed up. 4/61 (6.56%) had turned TST positive after 3 months. This study indicates that there is a small but definite risk of nosocomial spread of TB. Isolating TB patients in a separate ward and restricting frequent visitors may help.

Prognostic factors in tuberculosis related mortalities in hospitalized patients

Ashok Kumag, Ghazal Haq, Fatima Safuddin, Shaiasta Ghazal, Nadeem Rizvi. Chest Medicine, Income Postgraduate Medical Centre, Karachi, Sindh, Pakistan

Introduction: Despite effective treatment regimes available, Tuberculosis (TB) stands among one of the leading causes of death in Pakistan. Objectives: To evaluate the factors concerned with in-hospital deaths in patients admitted with Tuberculosis at a tertiary care centre.

Methods: A retrospective case-control study was undertaken at the Pulmonology Department of the largest state-run tertiary care centre in Karachi, Pakistan. For patients hospitalised with TB, sixty of those who were discharged were compared with sixty of those who could not survive during hospitalisation. Radiological findings, clinical indicators and laboratory values were matched between the two groups to locate poor prognostic factors.

Results: Factors concerned with in-hospital mortality listed female sex (p<0.01), late sequelae of disease (p<0.01), not taking anti-tuberculosis therapy (ATT, p<0.01), smoking (p<0.01), longer duration of illness (p<0.01), and low haemoglobin levels (p<0.02). Extrapulmonary TB, dissemination of disease, bilateral radiological findings, co-morbidities and multi drug-resistance were not implicated in higher mortality. Most deaths occurred during the first week of admission indicating late referrals and late presentation as an important factor related to in-hospital fatalities.

Conclusions: Poor prognosis in TB patients was associated with non-compliance to therapy, anemic states, late presentation of disease, and development of complications. Patients not taking ATT and hence having longer duration of illness showed higher mortality and so a more radical and effective treatment regimen is required to eliminate TB early on during the onset of disease.

Influence of social adaptation of tuberculosis patients on the TB form and a chemotherapy outcomes

Mikhail Chernov1, Sergey Sterliekov2, Elena Bogorodskaya1, University Clinical Hospital of Phthisiopulmonology, First Sechenov Moscow State Medical University, Moscow, Russia; 2 Research Institute of Phthisiopulmonology, First Sechenov Moscow State Medical University, Moscow, Russian Federation; 3 Research Institute of Phthisiopulmonology, First Sechenov Moscow State Medical University, Moscow, Russian Federation

The problem of chemotherapy (CT) efficiency in pulmonary tuberculosis (PTB) patients is one of the most burning one at the organization of TB aid.
Aims and objectives: Connection between social adaptation and stages of PTB (presence of SS+ (sputum smear positive) and cavitary lesions) have been studied. The CE efficiency in the patients with SS+ (sputum smear negative) and without lung cavity decay, and in the patients with SS+ and lung cavitary lesions, receiving CT regimen I have been assessed.

Method: Data of 2663 newly detected PTB patients, registered in 2008, from regions of the Russian Federation have been studied. Patients with less severe TB forms (SS- and without lung decay) and with patients with extended TB forms (SS+, cavitary lesions) - in the group 1 (467 persons), and the patients with extended TB forms (SS+, cavitary lesions) - in the group 2 (25 persons).

Results: In group 1, there were 41.1%, [95% CI 36.6-45.6] of socially-adapted patients (SAP) (workers, employees, students) and 40.5%, [95% CI 36.0-44.9] of socially-vulnerable patients (SVP) (jobless). In group 2, there were 24.3% [95% CI 19.0-29.5] SAP and 53.3% [95% CI 47.1-59.4] SVP. CE efficiency in group 1 was 92.7% (95% CI 190.3-95.1), in group 2 - 69% (95% CI 63.3-74.7). In group 2, CE efficiency in SVP was 58.2% [95% CI 49.9-66.4], and in SAP - 78.7% [95% CI 68.4-88.9].

Conclusions: In SAP, detection of TB with SS- and without lung cavity decay and effective treatment are more frequent, than in SVP. Therefore PTB patient social support measures should be brought into all TB programs.

P3659
Extrapulmonary tuberculosis (TB): 40 years observations in Poland
Maria Korzeniewska-Kosela
TB Epidemiology and Control, National Tuberculosis and Lung Diseases Research Institute, Warszawa, Plocka26, Poland

Aim of the study: To describe changes in extrapulmonary TB epidemiology in Poland since 1970 (beginning of notification of different forms of extrapulmonary TB)

Methods: Retrospective analysis of data from National TB Register. Data presented in ten years intervals.

Results: Since 1970 the systematic decline of number of all TB cases (from 41536 to 7590) in 2010 with the shift to older age groups and decline of extrapulmonary TB cases (from 4848 to 716 in 2010) has been recorded in Poland without significant differences of fraction of extrapulmonary TB among all TB cases (11.6% in 1970; 11.2% in 1980; 9.0% in 1990, and 9.2% in 2010). Some differences in profile of extrapulmonary TB was noticed. The decrease in pleural tuberculosis occurred (5.8% of all TB and 50% of extrapulmonary TB in 1970; 5.8% of all TB and 27% in 1980; 5.6% in 1990; 9.0% and 9.0% in 2000; 9.0% and 9.2% in 2010) also in central nervous system TB (0.3% of all TB and 2.8% of extrapulmonary TB in 1970; 0.2% and 1.9% in 1980, 0.1% and 1.7% in 1990, 0.1% and 1.4% in 2000; 0.1% and 1.3% in 2010).

Conclusions: The demographic characteristics of TB patients changed in Poland in last 40 years with the shift to older age groups however the proportion of TB at extrapulmonary sites remained stable. It is interesting although unexplained finding.

P3660
Predictors of delayed smear conversion after 2 months of tuberculosis treatment
Hajer ben Abdeljalil, Eya Tangara, Leila Fekhti, Soraya Fenniche, Ines Akkari, Hassen Deraa, Helia Kumn, Nabila Boushehri
Department of General Medicine, City Hospital, Ariana, Tunisia

Late smear conversion after 2 months of tuberculosis (TB) treatment represents a major problem.

Objectives: Isolate the environmental, clinical, radiological, bacteriological and biological factors associated with a delayed smear conversion.

Methods: We analyzed records from 60 tuberculosis patients, from which 20 had a delayed smear conversion. Those patients were compared in terms of clinical presentation, radiological, bacteriological and biological results, environmental data and evolution under treatment.

Results: Smoking was significantly associated with delayed smear conversion (85% of patients with a late conversion were smokers versus 47.5% p = 0.05), as well as history of diabetes type II (25% with late smear conversion versus 4% of controls p=0.005). This correlation was established for a delayed consultation (2 months) p = 0.01. Radiological data showed that bilateral lesions and extended unilateral lesions were significantly associated with delayed smear conversion (p = 0.03, p = 0.003). Biologically, a frank increase in CRP was statistically predictive of late conversion. (p = 0.02). A positive association between the occurrence of adverse events that did not require discontinuation of treatment and delayed smear conversion was also found (p=0.02). A positive correlation has not been established for the geographical distance, the low economic level, for a body mass index below 18.5 kg/m². In terms of bacteriology, the load of bacilli was not significantly associated with delayed smear conversion.

Conclusion: Identifying predictors of late smear conversion may allow us to set up effective preventive measures to fight against the spread of the disease and limit its complications.

P2661
Screening for tuberculosis in patients with rheumatic diseases commencing anti-TNF-α treatment: A regional survey
Elena Karampini, Ramamurthy Sathyamurthy, General Medicine, City Hospital, Birmingham, United Kingdom

Introduction: The increase in active tuberculosis (TB) associated with anti-tumor necrosis factor α (anti-TNF-α) treatment has led to screening for active/latent TB before anti-TNF-α is given. Marked variation in TB incidence has been noted depending on patients' ethnicity, country of birth and, for those not born in the UK, the length of time since their first entry. We aimed to evaluate our risk assessment mechanism.

Method: Retrospective study of 227 patients (F: 65.2%, M: 34.8%, median age: 53 yrs) with rheumatic diseases receiving anti-TNF-α (infliximab, etanercept, adalimumab) in 2001-2009. This sample represents a particularly multiethnic patient population.

Results: 1 patient (0.44% of the total) underwent tuberculin skin testing (TST). All patients were on additional immunosuppressants interfering with the accuracy of TST. No patients underwent interferon-gamma assay testing for latent TB. 9 patients (4% of the total) received chemoprophylaxis prior to anti-TNF-α. 2 patients (0.88% of the total) who had not received chemoprophylaxis developed active TB. The first was on etanercept & adalimumab prior to developing miliary TB. The second was on adalimumab & infliximab prior to TB diagnosis. Both patients recovered with quadruple anti-TB therapy. Both patients were born in the Indian subcontinent and had been in the UK for over 5 years. The TB incidence rate was 196.8 per 100,000 patient-years.

Conclusion: TB screening prior to starting anti-TNF-α can be improved so as to facilitate appropriate chemoprophylaxis targeting. Interferon-gamma assays could be a useful tool in the diagnosis of latent TB when patients are already on immunosuppressants.

P2662
Childhood tuberculosis in Romania
Ramona Nedelcu1, Nicolina Ciocan2, Elmina Bruham3
1Department of Pneumology, INP Marius Nasta, Bucharest, Romania; 2Department of Pneumology, INP Marius Nasta, Bucharest, Romania; 3National TB Programme, INP Marius Nasta, Bucharest, Romania

Introduction: TB incidence rate in children sharply decreased in Romania in the last decade. TB etiology is difficult to confirm, as the sample for bacteriological examination is obtained in low proportion of cases. For this reason the diagnosis can often be overlooked.

Aim and objectives: To analyze the trend and the profile of TB epidemic in children in Romania.

Method: The trend of TB incidence rate in children has been observed in Romania in the last decade and all children with TB diagnosis notified in 2009 have been analyzed by gender, residence, age group, treatment history, site and extension of disease, bacteriological status and treatment outcome. Data have been extracted from National TB Register.

Results: TB incidence rate in children failed from 2001 (47.3‰) to 2010 (25.3‰). In the 965 children registered with TB in Romania in 2009, the male/female ratio was 1.1 and urb/rural ratio 0.87. By age group, 18% were less than 1 year, 33% were in 1-4 years age group and 58.9% (59.9%) in 5-14 years age group. From the total number of 965, new cases represented 98.7%, 14.9% had severe forms of the disease (30 meningitis, 8 miliaria and 106 with cazo-caviatory pulmonary lesions), 39.3% had pulmonary TB and of them smear and culture positivity rates were 14% and respectively 25%. Of 98 culture positive cases, only 34 (34.7%) had a DST and of them 2 (5.9%) had MDR-TB. Overall outcome was favorable in 96.4% of pulmonary cases, but 2 children deceased, 2 failed and 8 abandoned the treatment.

Conclusion: Despite the decrease in incidence rate in Romania, there are still many challenges in the control of TB epidemic in childhood, as early detection of cases, proper diagnostic with confirmation of the etiology and successful treatment.

P2663
Risk factors for Mycobacterium tuberculosis infection among contacts of pulmonary tuberculosis patients
Jae Suk Park, Do Hyung Kim, See Young Kang
Department of Internal Medicine, Dankook University College of Medicine, Cheonan, Chungnam, Republic of Korea

Background: Detection and treatment of tuberculosis(TB) infection with contact investigation is a key component of TB control program. We evaluated the risk factors for TB infection among contacts of recently diagnosed pulmonary TB patients in a tertiary hospital in Korea, an intermediate incidence country.

Methods: 206 contacts of 90 adult pulmonary TB patients underwent tuberculin skin test(TST) and chest radiography. The TST results were considered positive with induration of 10 mm or more, suggesting TB infection. A standardized questionnaire was used to assess risk factors associated with TB infection.

Results: TST was positive in 97 of 206 contacts of TB patients(47.1%) and TST positive rate increased with age. The risk of TB infection was significantly associated with close contact with TB patients(sleeping in the same room) (OR=4.94, 95% CI = 1.43-17.00).

490s
Conclusion: TB infection rate was higher in elderly, and risk of TB infection was significantly increased with close contact of TB patients.

P2664 Improvement of treatment adherence and success in homeles patients with tuberculosis

M. Amin Afridi1, Ziauddin Ansvari, Nazim Nathani, Bilal Chaudhari, Whirter4, Ioan Serban5, Traian Mihaescu1, Christoph Lange3,6.

Background: To assess the impact of a program for homeless patients with tuberculosis in Iasi, Romania, on treatment adherence and outcomes.

Methods: Adherence and treatment outcomes were analyzed in homeless patients with tuberculosis in Iasi, Romania, who participated in 2011 in a charity project that offered regular anti-tuberculosis treatment together with free food and clothes at a central shelter. WHO recommendations on tuberculosis case definition and treatment results were used. Adherence to treatment and treatment outcomes in these patients were compared with those in homeless tuberculosis patients registered in Iasi between 1998 and 2005 when incentives were not provided.

Results: In 2011, 17 homeless (11 male, 6 female, median age 45 years) with tuberculosis were included in the project following discharge from the hospital. Of 12/17 patients who had completed the treatment at the time of analysis, cumulative adherence to treatment was 128/1316 (97.4%) doses provided. Of 82 homeless patients with tuberculosis treated in the years 1998 to 2005 (72 male, 10 female, median age 43 years), cumulative adherence to treatment was 583/7062 (54.4%) doses provided (p=0.001). Treatment success in 2011 was 70.5% compared to 26.8% in 1995-2005 (p<0.001).

Conclusions: Adherence to anti-tuberculosis treatment and treatment success significantly improved when food and clothes were offered to homeless patients with tuberculosis on a regular basis at the treatment dispensary.

P2665 Tuberculosis in healthcare workers: 5-year, multi-institutional analysis of the northern region of Portugal

Ricardo Reis1, Ana Maria Correia2, Marta Gomes3,1, Raquel Duarte4,5,6.

Background: Strengthening health care systems is the first step to control tuberculosis. Portugal is a high TB incidence country 15 years ago and little is known about the impact of TB in its HCWs.

Aim: Study the incidence and occupational risk of TB in HCWs in the northern region of Portugal. Evaluate potential risk factors and compare HCWs characteristics with the regional population.

Methods: We reviewed all TB cases among HCWs from Jan06 to Dec10 in the region. TB incidence was calculated and compared with the regional rate to obtain occupational odds ratio. Correlation between incidence and both admittance and district incidence was analyzed. TB and individual characteristics were compared with a chi-square test.

Results: Ninety TB cases were notified from a total of 42731 HCWs, with an annual average incidence of 42.1/100000 and an occupational odds ratio of 1.27 (95%CI: 1.03-1.56). Five (27%) of the hospitals had rates above the annual average, from 111 to 45. 81% of cases worked in hospitals but incidence in primary HCWs was similar. TB incidence in hospital HCWs was correlated with TB admissions (p=0.026) but not with district TB incidence.

Conclusions: Our study showed that HCWs in the north of Portugal have a significant occupational risk for TB that seems related with TB admission rates. Most cases were in young female nurses with no individual risk factors.

P2666 Impact of social risk factor on treatment outcome in patients with culture positive pulmonary tuberculosis (CPPTB)

Izabela Siemion-Szczesniak1, Maria Korzeniewska-Kosela2, Jan Kus1, 1 Ist Department of Pulmonary Diseases, National TB and Pulmonary Diseases Research Institute, Warsaw, Poland; 2Department of Epidemiology, National TB and Pulmonary Diseases Research Institute, Warsaw, Poland.

Objectives: The aim of the study was to evaluate the impact of social risk factors on treatment outcome among culture-positive patients treated for active pulmonary tuberculosis (PTB).

Material and methods: We retrospectively reviewed all medical records of patients notified in 1995 and 2000 in three separate districts in Poland in years 1995 and 2000. The relation between both alcohol abuse and homelessness and poor treatment outcome was evaluated. Treatment outcome was categorized as: cured, treated, completed, treatment defaulted, treatment failure.

Results: 708 patients with culture positive PTB were included to the study (373 in 1995 and 335 in 2000). There were 85 patients with risk factors in 1995 and 101 patients in 2000. 80 of participants in 1995 and 69 in 2000 abused alcohol, 5 and 32 were homeless, respectively. Among alcohol abusers treatment success rate were 45.1% in 1995 and 53.6% in 2000. Among patients not abusing alcohol treatment success rates were 63.8% and 54.1%, respectively (p=0.005 in 1995 and p=0.0186 in 2000). In 1995-40% of homeless patients had succeeded treatment, while the rate of treatment success among non-homeless was 60%. The difference was not statistically significant (p=0.6532) probably because of small number of homeless patients. In 2000 treatment success rate among homeless patients was 25% and among non-homeless 57.1%, which was highly statistically significant (p=0.001).

Conclusions: Alcohol abuse and homelessness were associated with no success of treatment outcome among patients with PTB. Interventions to improve treatment adherence in patients considered to be at risk for default are necessary.

Patients diagnosed of TB in the Oreuren area in the last decade: A descriptive study
Hugo Gómez, Abel Rodriguez, Isaura Parente, Blanaco Nagore, Jose Abal. 
Pedro Velázquez. Servicio de Neonatología, Complejo Hospitalario Universitario de Oreuren, Oreuren, Spain

Objective: To assess the annual incidence TB and its epidemiology

Material and methods: Retrospective study on patients diagnosed of tuberculosis during the decade 1999-2009. Data collecting was possible thanks to the “Programa Galego de Prevención y Control de Tuberculosis”. The usual descriptive study was then performed based on these data; quantitative variables were expressed as mean ± SD, whereas the qualitative ones as absolute frequencies or percentages, using the x² test to assess associations among them.

Results: The whole series included a total of 1746 cases, with a greater incidence among males and those between 24 – 35 yr. Exposure to infected persons, smoking habit, alcoholism and immunosuppression were the main risk factors.

The most common site of infection was pulmonary (67.5%), followed by pleural (14%), lymphadenopathies (7.1%) and others (9.3%). With regard to microbiology, the best yield could be obtained from culture (positive in 80% of cases), whereas the detection of AFB was positive only in 41% of patients.

The chest X-ray was pathologic in 93.3%, even though cavitations were only present in 27.6% of cases.

The scheduled therapy was completed and microbiological cure was attained in 85.6%, which fares favourably compared to other published series.

The global death rate was 10.63%, but only 1.1% were attributable to TB.

Conclusions: The incidence of pulmonary TB has clearly decreased in the preceding years, although it still prevails in males and in the 24-35 yr-old group.

The “pathology: cavity with cavitation” was observed in 28% of cases.

85.6% completed the scheduled treatment.

The global death rate was 10.63%, but TB just accounted for 1.1%.

P2669
Analysis of risk factors of recurrent tuberculosis in Han and Tibetan populations in Southwest of China
Panwen Tian, Fujiang Wen. Department of Respiratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China

Background: Recurrent tuberculosis (TB) poses significant threats, including drug resistance, to TB control programs. However, the causes of TB recurrence, particularly in Southwest China, which is the high burden area, have not been well described.

Objectives: To investigate the risk factors of recurrent TB, and analyze the differences between Han and Tibetan populations with TB recurrence in Southwest China.

Methods: A population-based retrospective case-control study was carried out in Southwest China. All patients with culture-confirmed TB and drug susceptibility testing were included between 2000 and 2001 and followed until December 2010. Two category logistic regression was used in the statistical analysis.

Results: We found that, among 80 patients (40 Han patients and 40 Tibetan patients) with recurrent TB who completed adequate therapy for a first episode of TB, factors independently associated with a greater risk of recurrent TB were not receiving directly observed therapy (HR 5.867, 95% CI 2.557-13.461), diabetes (HR 3.288, 95% CI 1.301-8.312), smoking (HR 2.387, 95% CI 1.328-4.291) and malnutrition (HR 3.288, 95% CI 1.110-3. 285).

The independent risk factors (HR 3.288, 95% CI 1.301-8.312), smoking (HR 2.387, 95% CI 1.328-4.291) receiving directly observed therapy (HR 5.867, 95% CI 2.557-13.461), diabetes (HR 3.288, 95% CI 1.301-8.312), smoking (HR 2.387, 95% CI 1.328-4.291) and malnutrition.

Conclusions: Our results establish that not receiving directly observed therapy, diabetes, smoking and malnutrition are associated with recurrent TB in Southwest China. To reduce the relapse rate of TB, especially for Tibetan populations, pursuing high-quality DOTs is essential.

P2670
The trends of tuberculosis in Kosovo in the post war period, (2001-2010)
Bahir Tigani. GFATM Programme in Kosovo, Community Development Fund, Prishtina, Kosovo, Albania

Objective: To analyze the trends of Tuberculosis in Kosovo during the first decade of the post war period, (2001-2010).

Methods: The TB National Reports of the years 2001-2010 has been used and different TB indicators has been analyzed and measured.

Results: Number of TB cases for the period 2001-2010 decreased from 1674 (Year 2001) to 920 (Year 2010). TB Notification Rate/100 000 decreased from 78.2 in year 2001 to 920 (Year 2010). TB Notification Rate/100 000 decreased from 78.2 in year 2001 to 920 (Year 2010).

TB Notification Rate/100 000 decreased from 78.2 in year 2001 to 920 (Year 2010).

Extra pulmonary TB has increased from 19% (year 2001) to 33% (year 2010).

P2671
How much knowledge is healthy? Results of a KAP survey of TB patients in Republic of Macedonia
Dance Gudeve Nikovska, Stefan Tavelesky. Global Fund Funded Project for TB Control, Ministry of Health, Skopje, Macedonia, The Former Yugoslav Republic of

Operations research study to explore knowledge, attitudes, and practices (KAP) related to tuberculosis (TB) among new TB patients in Kosovo was conducted in Republic of Macedonia (KM), in the period April-December 2010.

Cross-sectional study was conducted in the period April – June, 2010; TB patients were interviewed with a standardized questionnaire.

45% agreed that TB is a very serious illness and 48.7% think that TB is serious problem in RM. 50% have correctly identified the signs and symptoms of TB, although significantly smaller proportion correctly identified airborne transmission of TB (14.1%). A sizable proportion did not correctly identify ways to avoid transmission, i.e. just over 30% agreed that one can avoid TB by not shaking hands with someone who has TB and 20% said that one can avoid transmission by TB covering the mouth and nose while coughing or sneezing. 78% believed that TB can be cured by any drug recommended by a pharmacist, and only two respondents reported having heard of drug resistant TB.

Given the low number of respondents who correctly identified how TB is transmitted, the National Tuberculosis Program (NTP) should consider strategies to improve knowledge among people with TB, such as training on client-provider communication skills, new TB patients should receive a standard set of written materials regarding diagnosis, treatment, and infection control with key messages and broader communication campaign aimed at the general population to reinforce the key messages.

P2672
Latent tuberculosis in patients submitted to anti-TNF therapy – a retrospective study at a Santarem chest clinic
Sonia Silva1, Ermelindo Tavares2, Maria Graça Evaristo1, José Miguel Carvalho1, 2Pulmonology, Santarem Hospital, Santarem, Portugal; 1Dermatology, Santarem Hospital, Santarem, Portugal

Introduction: TNF-α plays an important role in immune defense against Mycobacterium tuberculosis and, as such, the risk of reactivation of latent tuberculosis (LTB) increases with TNF-blocking agents.

Aims: To determine the prevalence of LTB in patients undergoing TNF-blocking agents, between 2006 and 2009. To assess the type of therapy established and its complications.

Materials and methods: Review of clinical records and registration of clinical and epidemiological data, risk factors for liver toxicity and adverse effects. The used screening tests were Tuberculin Skin Test (TST), chest x-ray (CXR) and, in special cases, the QuantiFERON®-TBGold.

Results: One hundred and twelve patients were included in this retrospective study 50 with Rheumatoid Arthritis; 45 with Psoriasis; 12 with Ankylosing Spondylitis; 4 with Crohn disease and one with Sjögren’s syndrome). TST and CXR were used in all and QuantiFERON® in 36 (32.1%). LTB was confirmed in 66 cases (58.9%), 38 females (57.6%). The therapeutic scheme proposed in all of them was isoniazid for nine months which was completed in 92.4% of patients. The transient elevation of liver transaminases occurred in 7.6%, however no patient developed moderate to severe hepatotoxicity. One patient developed pulmonary tuberculosis after a recent contact.

Conclusion: LTB was diagnosed in 58.9% of patients submitted to anti-TNF therapy. In 92.4% of cases the instimted treatment regimen was completed with no relevant complications. One patient developed tuberculosis after a recent contact.

A comparison of on-site versus remote physician follow up of directly observed preventive treatment (DOPT) for latent tuberculosis infection (LTBI) on completion rates
Hashem Bisheh1, Liaa Ore2, Najat Armaily1, Daniel Weiler Ravell3, 1Pulmonary Division and Tuberculosis Center, Nazareth Hospital, Nazareth, Israel; 2School of Public Health, Faculty of Social Welfare and Health Science, University of Haifa, Israel; 3Division of Respiratory Physiolog and Chest Disease, Carmel Medical Center, Haifa, Israel

Background: Ethiopian immigrants (EI) at absorption centers treated for LTBI Disease, Carmel Medical Center, Haifa, Israel.

Objective: To compare completion rates and cost of DOPT among EI when managed at their place of residence vs. management at a TBC. We aimed to enhance completion to therapy. This strategy could not be continued and between 2008-2010, patients were followed at a tuberculosis center (TBC) 60 Km. away, while DOPT was continued at the absorption center.

Methodology: A retrospective cohort analysis of 547 medical records for all EI at absorption centers in Zefat who had started DOPT for LTBI and were followed up at absorption centers (2005-2006, study group -SG), compared to patients followed up at a TBC (2008-2010, comparison group - CG). Free transportation to the TBC was provided for the CG.

Findings: Altogether 495 EI's were included (263 in the SG and 232 in the CG group). Both groups had high completion rates (SG: 96.2% vs. CG: 91.1%; p=0.14). While demographic factors did not predict treatment completion side effects were significantly associated with non-completion. Costs were the same for both groups.

Conclusion: The success and cost of DOPT was not dependent on on-site physian involvement. High completion rates could be due to the congregation of EI at the absorption centers leading to easy access to dedicated skilled TB nursing staff.

Sponsored by the Israel National Institute for Health Policy Research and the Israel Lung and Tuberculosis Associated Tumor.

Part of a Thesis submitted for MPH degree, School of Public Health, University of Haifa, Israel.

P2674
Differences in the management of latent tuberculosis infection in patients treated with anti-TNF-α in Turkey
Serzil Oral1, Nalan Demir2, Sebnem Ataman1, Ahmet Ugur Demir1, Nurben Sukdur1, Akin Kaya1, Oya Kayacan1. 1Department of Chest Diseases, Hacettepe University, Ankara, Turkey; 2Department of Chest Diseases, Ankara University, Ankara, Turkey.

Aim: Latent tuberculosis infection (LTBI) is commonly detected with the tuberculin skin test (TST) before anti-TNF-α. BCG vaccination modifies TST reaction. We use different approaches to evaluate LTBI. We aimed to evaluate different approaches to LTBI and results in our clinic.

Method: This report retrospectively evaluated data of patients treated with anti-TNF-α, including symptoms, size of TST reaction, used anti-TNF agent, treatment details and development of active tuberculosis disease. We used different approaches to evaluate LTBI and results in our clinic.

Results: The study identified 99 consecutive patients referred for the evaluation of LTBI before starting anti-TNF therapy (54 men, mean age±SD: 44±12). The diagnosis of ankylosing spondylitis was established in 56 patients, rheumatoid arthritis in 36 and other systemic inflammatory diseases in 7. Fifty four patients received infliximab, 36 adalimumab, 41 etanercept. The median follow up was 25 months (range 3-120). Of the 56 patients who underwent LTBI treatment, 29 took isoniazid for 6 months and 20 for 9 months, 7 did not complete a 6-month course of LTBI treatment. Two took isoniazid for 12 months and one for 24 months. Three patients who had a history of treatment of tuberculosis had received anti-TNF-α agent. Active tuberculosis developed in one of the two patients who had TST > 15 mm and refused LTBI treatment after 3 months of anti-TNF-α treatment.

Conclusion: Different LTBI approaches according to threshold size of TST reaction was observed even in the same center in our country. We need a multicenter study to determine the best TST threshold value to develop national guidelines.

P2675
Particular aspects of TB endemic in Bucharest after adoption DOTS strategy
Emilia Tabacu1, Elinira Baim, Cristian Didilescu. Pneumology, Institute of Pneumology “Maritis Iusta”, Bucharest, Romania, Pneumology, Institute of Pneumology “Maritis Iusta”, Bucharest, Romania, Pneumology, University of Medicine, Craiova, Romania

Bucharest, Romania’s capital, a great urban agglomeration with almost 2 000 000 inhabitants and a population density of 8 528 inhabitants/Km², was confronted with a rate, sometimes very high of tuberculosis cases for a long time period.

Objective: The study of the main indicators of the TB endemic in Bucharest between years 2001 and 2011.

Material and method: We used the information existing in the official documents of the information system within the National Program of Tuberculosis Control.

Results: In 1963 the tuberculosis incidence reached 223‰ inhabitants, after presenting a clear tendency of reduction till 1985 (65.9‰). After last year, an appreciable increase of the tuberculosis incidence installed, reaching 154,1‰ in 2001, after which a decrease occurred yearly, reaching 67,5‰ in 2011. The incidence for new cases decrease from 153,8‰ in 2001 to 56,9‰ in 2011 and the incidence for relapses decrease from 18,3‰ in 2001 to 10,7‰ in 2011. The tuberculosis incidence in the 0-14 year children population decrease from 60,8‰ in 2001 to 21,4‰ in 2011. The source density was reduced from 2‰ sources/km² in 2001 to 5 sources/km² in 2010. DOPT strategy implemented in Bucharest proved to be an important weapon for TB control, success rate increase yearly. The rate of the therapeutic success of the new source cases with pulmonary TB (M+) increased from 82.2% in the patient cohort from 2001 to 86% from 2009.

Conclusion: The strict monitoring of the treatment is the medical key in fighting the tuberculosis.

P2676
Effectiveness of a tuberculosis screening program in rheumatic patients treated with immunosuppressants
Joana Pimentel1, Claudia Miguel1, Mónica Grafino1, Tiago Abrera1, Margarida Felizardo2, Ana Teixeira2, José Vaz-Pato2, Maria Conceição Gomes1, 1Pulmonology, Centro Hospitalar Lisboa Norte, Lisbon, Portugal; 2Rheumatology, Instituto Português de Reumatologia, Lisbon, Portugal; 3Pulmonology, Centro de Diagnóstico Pneumológico, Lisbon, Portugal

Background: Immunosuppressants, including new biological therapies, enhance the risk of developing active tuberculosis (TB). An effective screening program is essential.

Aim: To investigate the impact of a TB screening program on the development of active TB in rheumatoid patients treated with immunosuppressants.

Method: Retrospective analysis of patients followed at Portuguese Institute of Rheumatology, screened for latent or active TB in the Pulmonology Diagnostic Center, since February 2005. The evaluation included clinical history, tuberculin skin test, chest x-ray, interferon gamma release assay and chest CT according to protocol. If any of these was positive, 9 Hepatitis B and 9 tuberculin was prescribed. If all were negative, patients remained under biannual monitoring.

Results: The study had 641 patients with 471 females and mean age 52±13 years. The average length of follow-up was 2±1.4 years. Main rheumatological diagnoses were rheumatoid arthritis (n=394), ankylosing spondylitis (n=104) and psoriatic arthritis (n=70). 173 were candidates to biological therapy and 468 were proposed or already treated with classic immunosuppressants. 532 patients were prescribed INH, of whom 14 refused and 10 suspended for intolerance (9 hepatoxicity and 1 medullar aplasia). The remaining 109 were proposed only for clinical monitoring. No patient developed TB after the screening program.

Conclusion: In this population, 89% required chemoprophylaxis with INH and only 0.02% developed intolerance. The TB screening program was used effectively, with no cases of TB reported, however these results did not allow calculating its impact in reducing the risk of TB.

P2677
Impact of the global economic crisis on the possible increase TB incidence in Serbia

Introduction: Turbulence of the global economic crisis spilled over into Serbia. The economic factors, as a personal standard of individual and society development are factors influencing the incidence.

Method: We used economic indicators (number of non/employees, index movements in salaries, annual price index, the movement of income per capita) and the movement TB incidence in 1990-2010 in Vojvodina (northern Serbia- 25% of the total population).

Results: The incidence of TB decreased from 38.28 to 17.08, but had two tops - middle of 90s and the beginning of this millennium. Continuing decline in the number of employees by 2003. (234 per 1000 population) from 2004. g. there is a slight increase in employment. But, by 2009, again saw a drop, and continues to this day. Chain index of nominal net earnings showed the highest growth at a time when "inflation is raging" - mid 90s in Serbia.

The analysis of these parameters with the movement of TB in Vojvodina found low correlation between the rate of TB patients and the number of workers per 1000 population (r = 0.190). Correlation analysis revealed a strong correlation between rates of TB and the chain index of nominal net earnings (r = 0.513).

Conclusion: However, 100% implementation of DOTS strategy in Serbia hope that the economic crisis will not affect the eventual increase in TB incidence and the possibility of resistant forms of TB.
TB represents a major healthcare problem in Romania. The incidence of TB in children registered, in Iasi County, significant annual changes (47.4‰ in 2001 to 26‰ in 2010).

Aim: Analysis of TB characteristics in children in a high incidence TB County.

Method: Retrospective study of TB cases in persons 0-14 years old, registered and treated 2001-2010. WHO recommendations were used.

Demographic data, TB contact, site of TB, bacteriological status, co morbidities and treatment results were followed up.

Results: 763 children were notified in 10 years, males – 52%; 70.2% from rural area.

TB contact – 47.5%.

TB meningitis – 4.8% (37), disseminated TB – 0.9% (7).

HIV positive were 5.5%.

88.3% cases were extra pulmonary TB, 11.6% pulmonary TB.

TB contact – 47.5%.

TB meningitis – 4.8% (37), disseminated TB – 0.9% (7).

HIV positive were 5.5%.

88.3% cases were extra pulmonary TB, 11.6% pulmonary TB.

TB contact – 47.5%.

TB meningitis – 4.8% (37), disseminated TB – 0.9% (7).

HIV positive were 5.5%.

88.3% cases were extra pulmonary TB, 11.6% pulmonary TB.

TB contact – 47.5%.

TB meningitis – 4.8% (37), disseminated TB – 0.9% (7).

HIV positive were 5.5%.

88.3% cases were extra pulmonary TB, 11.6% pulmonary TB.

TB contact – 47.5%.

TB meningitis – 4.8% (37), disseminated TB – 0.9% (7).

HIV positive were 5.5%.

88.3% cases were extra pulmonary TB, 11.6% pulmonary TB.

TB contact – 47.5%.

TB meningitis – 4.8% (37), disseminated TB – 0.9% (7).

HIV positive were 5.5%.

88.3% cases were extra pulmonary TB, 11.6% pulmonary TB.

TB contact – 47.5%.

TB meningitis – 4.8% (37), disseminated TB – 0.9% (7).

HIV positive were 5.5%.

88.3% cases were extra pulmonary TB, 11.6% pulmonary TB.
MDR TB which is again discouraging & warrants to search the cause behind such high incidence of drug resistance.

P2684

Latent tuberculosis infection among close contacts of multidrugs-resistant tuberculosis patients in eastern Taiwan Chin-Bin Lin 1,2, Jen-Jyh Lee 1,2, Hou-Wen Chou 3. 1) Internal Medicine, Tzu Chi General Hospital, Hualien, Taiwan; 2) Internal Medicine, School of Medicine, Tzu Chi University, Hualien, Taiwan; 3) Graduate Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan

Tuberculin skin test (TST) and QuantiFERON-TB Gold in Tube test (QFT-GIT) are diagnostic tools for detection of Mycobacterium tuberculosis infection. These tests are used to study the rate of infection in contacts of multidrug-resistant tuberculosis (MDR-TB) patients.

We performed TST and QFT-GIT to close contacts of MDR-TB patient in eastern Taiwan to increase the awareness and the necessity of each test, and both negative in 173 (29%). People older than 50 and aborigines showed higher rates of QFT-GIT-positive than people younger than 30 (69.9% vs. 39.2%) and 60.5% vs. 30.6%). Both TST and QFT-GIT can be used to detect latent tuberculosis infection, and both tests should be used in conjunction with risk assessment, radiography and other diagnostic tools. High incidence of latent tuberculosis infection among close contacts of MDR-TB patients in eastern Taiwan were detected and close follow up and monitoring are mandatory for early detection of possible active MDR-TB cases.

P2685

Dynamics of MBT drug resistance in a specialized urban TB hospital (Saratov, Russia)

Lysmiilna Pankratov 1, Ekaterina Perselentsueva 2, Aleksandr Filipov 1. 1) Chair of Phthisiopulmonology, Saratov State Medical University, Saratov, Russian Federation; 2) Microbiology Lab, TB City Hospital, Saratov, Russian Federation

DR dynamics over 2006-2011 was studied in a Specialized Urban TB hospital. Sputum from 1962 was tested for MBT DR. During the years 2006-2009, both primary (from 36.3% to 68.0%) and secondary DR (82.1% to 90.8%) was found to be increasing. But in 2011 primary DR decreased to 54.8% (a 13.2% drop). Secondary DR keeps growing: 88.7% in 2010 and 91.5% (the absolute peak over the entire study period) in 2011. Similar tendencies have been found for monoresistance.

Over 2006, 2009, MDR in primary DR doubled – from 16.8% to 32.4% (p<0.001), and in secondary DR it increased from 53.8% to 64.0% (2010). However, the latter parameter is showing signs of slight improvement: in 2011, MDR was 25.8% (8.4% in primary DR and 50.3% in secondary DR). By specific drugs: primary DR to H decreased in 2009-2011 to 32.3% (-16.4%), to R to 29.0% (-7.8%), to E to 19.4% (-8.2%), to S to 28.7% (-19.2%). Regrettably, a similar tendency was not observed for secondary DR.

Dynamics analysis of MBT resistance to various H concentrations during treatment of 44 patients showed that 11.4% of them were and remained DR to H (10 mg/ml) 59.1% of them remained non-DR to H (10 mg/ml) 11.4% developed DR to this concentration during treatment, in 18.2% strains sensitive to H10 developed. At the start of treatment, 70.5% were H10 non-resistant; later on non-resistance was found in 77.3%. Non-resistance to low H concentration (1 mg/ml) was 20.5% at the onset and 15.9% at follow-up test.

Conclusion: A certain primary DR improvement has been observed. Issues of DR amplification require further study.

P2686

Multidrug-resistant tuberculosis in the western region of Algeria Assia Ouardi 1, Mourad Hadjadj 2, Yahia Berrahla 1. 1) ORAN, CHU, Ouan, Algeria; 2)LEMENC; CHU; Temcen, Algeria

Introduction: The MDR-TB is entirely man-made and is the result of a failure in effective implementation of anti-tuberculosis national plan (PNLT). What assessment do we have of curing it in the western region of Algeria?

Material and method: A longitudinal descriptive study involving 97 patients followed for MDR-TB from January 2005 to December 2009 and put in 2nd line regimen with a duration of at least 21 months and including 05 drugs (Ofloxacin, Ethionamide, Kanamycin, Cycloserine and Pyrazinamide).

Inclusion Criteria: Patient with MDR-TB documented to INH and Rifampicin at least. Patients who underwent at least 02 chemotherapy regimens including one eight-month regimen that always have positive smears.

Results: Average age: 29 years

Extreme age: 15 to 61 years

75% of patients aged between 25 and 34 years. Sex ratio 1.4:1

33% of patients from the wilaya of Mostaganem

07 familial cases observed

06 patients are diabetic, one patient with HIV co-infection.

96% of exclusive lung locations

92% of patients received at least 02 treatments before drug susceptibility test

Of the 97 patients, 59 are cured, 14 patients in failure, 15 died and 09 have given up treatment.

82.5% of patients have benefited from a drug susceptibility test, the resistance to INH and Rif is observed in 100% of cases, streptomycin in 50% of cases and Ethambutol in 23% of cases.

For patients who have finished their treatment, the cure rate is 61%.

Conclusion: MDR-TB represents a threat which we must face with determination, respecting and reviving the PNLT in order to prevent the emergence of multi-resistant bacilli.

P2687

Risk factors of time to sputum smear conversion in multi-drugs resistant tuberculosis patients in Iran Farzaneh Baghaei Shiva 1,2, Majid Marjani, Payam Tabarsi, Mohammad Reza Masjedi. Clinical Tuberculosis and Epidemiology Research Center, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran

Objectives: Treatment of multidrug resistant tuberculosis is difficult and expensive. Sputum conversion is a proper monitoring tool in treatment of these patients. Also, reducing the time of conversion is an important infection control measure. This study was performed to evaluate the time and predictors of sputum conversion in the pulmonary MDR-TB patients.

Methods: During 2003-2011, all patients with documented MDR-TB in referral center, Tehran, Iran, were recruited. All patients received standard treatment consisted of Ofloxacin, Prothionamide, Amikacin and Cycloserine. All demographic and characteristic factors were studied. Time of sputum conversion was evaluated to predictors by conducting survival analysis (using a Cox proportional hazards model).

Results: Of 298 recruited MDR-TB patients, 171 patients were male and 178 patients were Iranian. The median age was 41 years. 60% of patients had the history of TB treatment. The median time to sputum conversion was 51 days. Diabetes mellitus, co-disease, adverse drugs reaction and male sex delayed sputum conversion.

Conclusion: Most MDR-TB patients achieved sputum smear conversion within 51 days. DM, adverse effects, male gender and co-disease were predictors of delay conversion.

P2688

The effectiveness of MDR TB treatment in children and adolescents depending on its duration Gulbadan Bekembaoeva, Aike Alenova, Larisa Kastykpaeva. Department of Pediatrics of MDR TB, National Center for TB Problems, Almaty, Kazakhstan

Target: to study the effectiveness of treatment of TB with multiple drug resistance with drugs of second line depending on duration of intensive and continuation phases.

Materials and methods: Group 1 – 50 patients treated by short regimens (intensive phase from 2 to 4 months, continuation phase from 12 to 16 months) up to adoption of standardized schemas and terms of treatments with DSL, during 2001 to 2006. Group II – 50 children and adolescents treated with DSL according to terms of
The incidence of MDR-TB among patients who received category II treatment from 35.5%. Of these, the highest was in Category I failure at 45%, followed by Relapse 35.6% and RAD at 19.4%. We recommend that patients with category I failure should no longer receive category II treatment. Instead, MDR-TB screening should be done and standardized treatment for MDR-TB should be started. As for RAD, and Relapse, MDR-TB screening should also be done and we need to carefully re-evaluate the use of Category II treatment regimen.

P2602
Diagnostic role of fiberoptic bronchoscopy in suspected smear negative pulmonary tuberculosis
Mahler Beatrice, Tinatin Mamaladze, Marina Kikvidze, Lali Mikiashvili.

Background: Sputum smear-negative pulmonary tuberculosis is a common problem faced by clinicians. Bronchoscopy-related transmission of Mycobacterium tuberculosis is rarely reported.

Methods: The retrospective study evaluated 40 patients(26males, 14females; mean age 45±9.6-years; range 19-88years) who had respiratory symptoms and radiographic findings consistent with pulmonary TB, but who were unable to produce sputum spontaneously or had three samples of spontaneously produced sputum that was smear-negative for AFB. Induced sputum tests, bronchial washings and bronchoalveolar lavage were performed where indicated. The relevant specimens were sent for direct smear for acid fast bacilli by Ziel-Neelsen method and culture for M. tuberculosis in Lowenstein medium. Data obtained were analyzed using MS Excel 2007.

Results: Bronchoscopy confirmed or contributed to the diagnosis in 18 patients. In 8 patients(45.5%) upper lobe mucosal inflation with/without narrowing and scarring was detected. Sputum culture confirmed the diagnosis in 12(30%) cases: 7(17.5%) had culture positive specimens(<0.005), 4(10%) was culture positive on bronchoscopy and one(2.5%) on induced sputum. All patients had negative HIV test, 3(77.5%) new cases and 35(87.5%) with high erythrocyte sedimentation rate. Majority of radiological findings were infiltrative ulcerated and cavitation lesions. Treatment with drugs of the third line. Thus, patients with positive smear were by 2 times more (62.3%) in the Group I than in the Group II (30.0%). MDR: in 100% of both groups culturally only. Thus, analysis of outcomes and follow-up control showed that among patients with MDR-TB treated with drugs of the first line 5 (6.2%) patients of the Group II died, while among patients treated with DOL, one adolescent only died. Relapse emerged in 12.5% of children and adolescents of the Group II. This fact proves the necessity to administrate the therapy with DOL to the children and adolescents with MDR TB.

275. Tuberculosis: invasive diagnostic and therapeutic interventions

P2690
Development of multi-drug resistant tuberculosis among patients treated with category II regimen: A lung center of the Philippines experience
Sablan Augusto Jr1, Joven Gonong1, Lawrence Raymond1, Vivian Lofranco2.

Background: Sputum smear-negative pulmonary tuberculosis is a common problem faced by clinicians. Preventive approaches, early diagnosis and the development of effective and relatively inexpensive methods of case search should be emphasized.

Objective: To enroll all cases of MDR-TB in State of Paraiba and check territorial distribution.

Methods: Using tabulated data collected by the MDR-TB Epidemiologic Vigilance System, in the period January 2002 to December 2010, we enrolled cities of residence of each case and provided an territorial picture of MDR-TB, regarding space distribution and city population. Population data were collected from Brazilian Institute of Geography and Statistics - IBGE, June 2008.

Results: Paraiba is the 13th Brazilian State in order of population (3,769,977 inhabitants, 1.9% of Brazilian population). Total tuberculosis cases in Paraiba were 7332 (1.4% Brazilian cases). Absolute number of MDR-TB was 39 (1.3% of total Brazilian cases). The proportion of MDR-TB and total tuberculosis cases in Paraiba was 0.53%. In concerning to territory distribution, MDR-TB cases scattered over 19 of 223 cities of Paraiba. Although most inhabited cities presented more cases, it did not happen in a proportional fashion. Some important cities (50 to 100 thousand inhabitants) presented no case. More interesting, MDR-TB occurred also in small cities, with less than 3,000 inhabitants. More than one third of all cases occurred in cities with less than 50,000 inhabitants. Most cases occurred less than 20Km from capital (Joao Pessoa).

Conclusion: MDR-TB cases are scattered over 19 cities in Paraiba, including less inhabited cities. Preventive approaches, early diagnosis and the development of effective and relatively inexpensive methods of case search should be emphasized.
ative cases. Bronchial washing cytological study may be useful for early diagnosis of pulmonary tuberculosis (PTB) as macrophages can respond to a variety of cellular signals and response to local cues.

Aims: Assessment of possibility of involvement bronchial washing cytology in PTB diagnosis as one of the most valuable and rapid method in order to improve surveillance and care of TB-infection.

Methods: 53 sputum smear negative adult patients had undergone diagnostic investigations including CXR, bronchoscopy, bacteriological, immunological and cytological tests. Cytopathologically TB diagnosis was established when elements of TB-granuloma and multinuclear macrophages were found in the bronchial washing’s smears. All results were compared to bacteriological data ("gold standard").

Results: From patients, 25 were diagnosed cytopathologically as PTB. In 19 cases bronchoalveolar lavage's smears were obtained. All results were compared to bacteriological data. Histological and bronchial washing's smears were positive in 28 patients (54%). Collected one sample were negative for 3 patients.

Conclusions: Present study showed quite high specificity in PTB diagnosis. Main strategic focus was that bronchial washing’s samples were sensitive to multinuclear macrophages. and thus, it can be performed a powerful diagnostic tool. Though, further fundamental researches and envelopment of cytosome method in PTB diagnosis is needed.

Surgical treatment of first-found destructive pulmonary tuberculosis
Tulkun Kariev 1, Sunnatiila Abdikasimov, Sherzod Rahmatov

Thoracic Surgery, National Centre of Pulmonology and Pulmonology, Tashkent, Uzbekistan

Resection operations were performed in 261 patients (males – 155, females - 106) with first-found destructive tuberculosis after 3-6 month long ineffective chemotherapeutic treatment. The majority of patients (220 – 84.3%) were in young age – from 20 to 40 years old. After a course of chemotherapy, infiltrative tuberculosis with lysis was diagnosed in 12 patients (4.5%), tuberculosis – in 101 (38.7%), obrous-cavernous – in 148 (56.8%). Mycobacteria of tuberculosis in sputum were observed in 98 patients (37.5%). Segmental lung resection was performed in 112 patients (43.0%) excalcation of tuberculosis – in 13 (5.0%), lobectomy – in 100 (38.3%), combined resection – in 8 (3.0%), and pneumonectomy – in 27 (10.7%). After operation, bronchial fistula and pleural empyema developed in 8 patients (3.1%), early re-activation of the tubercular process – in 10 (3.8%), pneumonia of the operated lung – in 5 (1.9%). These complications in 5 patients were eliminated by the therapeutic treatment, in 9 – by repeated operation. A total of 3 patients died from re-activation of tuberculosis, bronchial fistula and pleural empyema. Conclusions: At first-found destructive pulmonary tuberculosis after ineffective chemotherapy course, sparing resection operations are the final stage of complex therapy with low frequency of post-operative complications and high effectiveness of surgical treatment (96.5%).

Pneumonecrosis in pulmonary tuberculosis. To do or not to do?
Ioan Matus 1, Alexander Bashenov, Elena Kildyusha, Thoracic Surgery, Urals Research Institute for Phthisiology and Pulmonology, Ekaterinburg, Russian Federation

Conclusions: Using minimal invasive procedure for cutting the access to the affected lung allow a good chance of healing for a poor status MDR patient allow a good cooperation from the patient and later an easy tolerated and accepted pneumonectomy with minimal surgical risk of postpneumonectomy bronchial fistula since the fistula is already cicatrised at the pneumonectomy etap. We present in first communication a minimal invasive transversal approach of the right main bronchus.

Methods: A randomized study of the bronchoscopic valve blockade of the affected part of the lung in the complex treatment of patients with cavity drug-resistant pulmonary tuberculosis
Sergey Sklyuev 1, Denis Krasnov 1, Nonoosibirski TB Research Institute, Nonoosibirski, Russian Federation

In accordance to the existing hypothesis application of the endobronchial valve will contribute to early closure of cavity and the right one supported perfect the postponed pneumonectomy. No operatory complications or incidents were observed.

Results: Using minimal invasive procedure for cutting the access to the affected lung allow a good chance of healing for a poor status MDR patient allow a good cooperation from the patient and later an easy tolerated and accepted pneumonectomy with minimal surgical risk of postpneumonectomy bronchial fistula since the fistula is already cicatrised at the pneumonectomy etap. We present in first communication a minimal invasive transversal approach of the right main bronchus.
database, with culture confirmed PTB between January 2008 and December 2011. Patients, who were SSN or non-productive of sputum (NPS) before bronchoscopy, were eligible.

Results: The inclusion criteria were met by 503 subjects. BA was performed in 369 cases, BW - 116 cases, BAL - 18 cases, PBS was available in 37 patients. Microbiological examination of BSS was the exclusive method for the microbiological confirmation of PTB in 344 (68.4%) cases. The overall diagnostic rate of BSS for smear positive PTB was 21% (98/466). Higher rate for diagnosis of smear positive PTB were proven for bronchial washing (30.3%) and bronchial aspirate (17.2%) which were superior to BAL (8.5%; p<0.01 and p<0.005, respectively).

The overall rate of MDR TB among smear positive cases was 27.6% (27/98).

Conclusions: Microbiological examinations of BSS give a higher rate of definitive diagnosis of PTB among SSN cases, with an earlier identification of contagious subjects with potential MDR TB. 

P2699
Long-term results after pneumonectomy and lobectomy for pulmonary tuberculosis: Quality of life and pulmonary function

Pulmonary Physiology, Research Institute of Phthisiopulmonology, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; Rehabilitation, Medical Center, Central Bank of Russian Federation, Moscow, Russian Federation; Pulmonary Rehabilitation, Pulmonology Research Institute, Moscow, Russia; Thoracic Surgery, Research Institute of Phthisiopulmonology, Moscow, Russian Federation

The diagnostic yield of ultrasound-guided cutting needle biopsy in the operations need more active treatment including pulmonary rehabilitation.

Methods: We investigated quality of life (QoL) and pulmonary function in 58 patients after pneumonectomy. Of these 58 patients, 36 underwent single lobectomy (group L) and 22 underwent pneumonectomy (group P). All postoperative examinations were performed more than one year after surgery. QoL, was studied by SF-36, SGRQ (St. George’s Respiratory Questionnaire) (SGRQ), and MOS. Shortness of Breath Questionnaire (SOBQ). Shortness of Breath Questionnaire (SOBQ). Pulmonary function was studied by spirometry and plethysmography.

Results: In patients in group P and group L, respectively, FVC was 58.7±15.2 and 103.3±15.3%; FEV1 - 47.1±13.9 and 84.8±16.7%; TLC - 66.0±11.2 and 98.5±12.8%; FRC - 81.1±26.1 and 110.1±28.0%; IC - 53.8±19.3 and 89.7±19.1% (p<0.01 for all cases). All SF-36 components did not differ between groups.Symptoms SGRQ scores were 45.8±26.2 and 32.3±22.3% (p>0.05). Activity SGRQ scores were 51.0±22.0 and 30.8±19.5% (p>0.05). Impact SGRQ scores were 31.5±18.8 and 17.8±15.9% (p>0.05). Total SGRQ scores were 39.9±18.9 and 28.4±16.26 and 16.4±15.3 points (p<0.05); group P and group L, respectively.

Conclusion: Pulmonary function and QoL were significantly worse in patients after pneumonectomy. SGRQ was more sensible then SF-36 in assessment of QoL.

In both groups QoL was worse than in healthy patients. So the patients after these operations need more active treatment including pulmonary rehabilitation. 

P2700
The diagnostic yield of ultrasound-guided cutting needle biopsy in the investigation of suspected pleural tuberculosis

Richard Turner, Omar Pirzada.

Department of Respiratory Medicine, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Introduction and Aim: Closed pleural biopsy for tuberculosis (TB) using the Abrams needle is long-established and gives yields > 75%.

Modern practice often employs smaller gauge cutting needles under guidance of ultrasound (US). Few studies have compared these smaller needles to established standard techniques. We undertook a large scale investigation to answer this important question.

Methods: We compared the Abrams needle to ultrasound guided biopsy. We recorded the number of patients who became smear-negative after biopsies, the percentage of patients who were smear-positive, and the number of biopsies required to diagnose TB.

Results: The Abrams needle diagnosed TB in 35% of cases. Ultrasound-guided biopsy diagnosed TB in 50% of cases. The Abrams needle had a sensitivity of 98%, specificity of 95%, and negative predictive value of 90%.

Conclusions: Ultrasound-guided biopsy is a safe and effective method for diagnosing TB. It is more sensitive than the Abrams needle and can be performed using smaller needles.

P2701
Safety aspects of endobronchial valve application in the complex treatment of patients with caviatory drug-resistant pulmonary tuberculosis

Sergey Sklyev, Denis Krasnov.

Clinical Department, Nовосибирск TB Research Institute, Novosibirsk, Russian Federation

Aims: To evaluate the safety of endobronchial valve application in TB patients.

Methods: In total, 68 patients with drug-resistant destructive pulmonary tuberculosi were taken into the study, they were randomly divided on two groups - one for 33 patients for endobronchial-valve installation (EBV) and another – for 35 to receive standard treatment (control group).

Results: On Day 2 of the study, 12 (36.7%) patients from EBV-group had developed severe, dry cough, in the control group - 2 (5.7%) patients (p = 0.019).

3 (9.1%) of patients from EBV-group were with worsening of COPD symptoms and required symptomatic treatment (p = 0.008).

All these manifestations had been happened within 2 weeks of treatment. During assessment of the bronchial tree after 8 months in patients from EBV-group we revealed proliferation of granulation tissue in the targeted bronchi in 100% of the cases, of whom 24 (72.7%) granulations were big (closing over 50% of the lumen of the bronchus).

After 10 months, during bronchoscopy in patients with EBV-group we found scars of the bronchus wall in 100% of the cases, in 17 (51.5%) - we revealed circular stenosis of the bronchi which reduced over 50% of the lumen of the bronchus, in 9 of these cases (27.3%) the lumen of the blocked bronchus was less than 1 mm in diameter. None of these changes were detected in the control group.

Conclusions: Endobronchial-valve treatment leads to the corrected without affecting the course of the disease complications in the first two weeks of treatment, and causes great severity of the targeted bronchus.

P2702
The treatment of a destructive lung tuberculosis by valuvlar lung volume reduction on early terms of therapy

Nikolay Yalkushenko, Irina Tabanakova, Marina Kondakova.

Endoscopy, Research Institute of Phthisiopulmonology, Saint-Petersburg, Russian Federation; Therapy Department, Research Institute of Phthisiopulmonology, Saint-Petersburg, Russian Federation

Lung tuberculosis (TB) can be complicated by cavity forming. Patients with destructions in the Russian Federation in 2010 have made 49.0% from first time revealed lung TB, closing of lung cavities was achieved in 63.0% of cases. The lethality of this patients reaches 14.0% and 36.0% in the control group (p = 0.008).

Objective: To increase the efficiency of treatment of a destructive lung tuberculosis by valvular lung volume reduction on early terms of therapy.

Material and methods: The work is the result of supervision over 40 patients with lung TB. 47.5% of patients were smear-positive, drug resistant MBT - in 25.0%. Destructions defined in the top shape of lungs in 72.3% of patients, in 27.7% - in the bottom shape (the sixth lung segment). Video-assisted thoracoscopic biopsy of lungs was performed from 1.0 cm. To 21 patient during a chemotherapy was installed a non-return endobronchial valve (1 gr.). The comparison group - 19 persons (II gr.) received only chemotherapy. Valvular installation was made with flexible bronchoscope. In all patients with lower lobe cavity localization therapy was supplemented with artificial pneumoperitoneum. Results: 70.0% of patients became smear-negative in a month, by 3 months - 100.0% of patients (33.3% and 77.8% in II gr). Destructions closed in 3 and 6 months in 38.0% and 90.5% in I gr., 15.8% and 57.9% in II gr. (p<0.05). Duration of lung volume reduction has made 128.9±10.9 day.

Conclusions: Valvular lung volume reduction is an effective non-drug technique in complex treatment of lung tuberculosis, raising efficiency of treatment in 1.7 times on closing of destruction cavities by 6 month.

P2703
A randomized study of bronchoscopic blockade of the affected part of a lung as a part the complex treatment of patients with drug-resistant pulmonary tuberculosis

Sergey Sklyev, Denis Krasnov.

Thoracic Surgery, Novosibirsk TB Research Institute, Novosibirsk, Russian Federation

At the present time in Russia, there are 60% of TB patients with unsatisfactory results of treatment by standard chemotherapy regimens with anti-TB drugs, and therefore there is permanent search for new treatment approaches to these patients. Scope and purpose: To assess and to analyze the impact of endobronchial-valve therapy on pulmonary function. According to the existing hypothesis, the implantation of an endobronchial valve and excision of the part of the total volume of the lung do not decrease pulmonary function indices.

Methods: We have compared the efficacy of endobronchial-valve therapy with a standard therapy. Changes in rates of FEV1 were the reference points for the selection of patients. Of 68 enrolled patients, 33 were randomly assigned to receive endobronchial valves (EBV group) and 35 to receive standard medical care (control group).

Analysis of 177 endobronchial tuberculosis cases in Serbia over 15-years period

Dragna Jevanovic1, Ljiljana Denic-Markovic2, Natalija Samardzic1, Sasoje Popovic1, Vesna Skodric-Trifunovic1, Marina Roksandi Milenkovic1, Ruza Stevic1, Marta Velinovic1, Jelena Stojilic1, Nada Vasic1, Milica Konic1, Dragana Maric.1 1University Hospital of Pulmonology, Clinical Center of Serbia, Belgrade, Serbia; 2Institute of Epidemiology, School of Medicine University of Belgrade, Serbia

Introduction: Tuberculosis still represents a significant health problem of population in Serbia, the incidence being for last few decades 32-36/100.000 inhabitants, up to last few years when it decreased to 24-26. Endobronchial tuberculosis (EBTB) is a chronic, progressive tuberculosis infection with often complicated clinical course and bronchostenosis formation.

Aim: The aim of the study was to determine common clinical features and diagnostic aspects of bronchoscopic biopsy proven EBTB in population of Serbia over 15 years period and compare with published data.

Method: Analysis and comparison of clinical features, radiologic, mycobacterial, bronchoscopic and histologic findings of 177 EBTB patients by SPSS ver. 15 for Windows, chi-square test, t-test and calculating Phi correlation coefficient.

Results: Male to female ratio was 1.2:1. Five patients (2.8%) were asymptomatic. None had normal chest radiograph finding; the most frequent localization of current pulmonary TB lesions was in the upper lobes. Two thirds of patients, 116 (65.5%) had cavernous lesions. Atypical TB was evident in 27% (15.3%). The most common endoscopic forms of EBTB were edematous hyperemic (40.1%) and non-specific bronchitis (35.6%) unlike majority of published data. Bacteriologic confirmation of TB had 117 patients (66.1%). Sputum cultures for AFB were positive in only 27.7%, bronchial washing culture in 10.1%. Sputum and bronchial washing culture both were positive in 28.2% patients. Correlation between bronchoscopic categories of EBTB and bacteriologic confirmation of TB diagnosis was analysed and discussed.

Conclusion: EBTB in Serbia has some distinctive and specific features in comparison with other published EBTB series.

P2705

Blocking of bronchoscopic endobronchial valve in the complex surgical treatment of patients with pulmonary tuberculosis

Denis Karavoy, Vladimir Krasnov, Nikolai Goloshechkov, Tymofei Boschetnyi, Dmytry Skvirschuk, Mikhail Reykhayd, Serhiy Skhusev. Clinical Department, Novosibirsk TB Research Institute, Novosibirsk, Russian Federation

A randomized study of osteoplastic thoracoplasty (OT), supplemented with bronchoscopic lung by blocking the affected part in the complex treatment of patients with pulmonary tuberculosis category CV + MBT + patients that OT was performed without installing an endobronchial valve. Effectiveness of the control points were CV and MBT. Estimated risk ratio. A total of 291 patients were involved, of whom 158 fulfilled OT after bronchoscopic block (main group), 133 continued treatment without having to install EBV (comparison group). EBV production company Medlung Inc., Barnaul, Russia.

Results: The proposed complex surgical treatment tactics can increase the effectiveness of remedial measures: the main group more frequently observed cessation of bacterial isolation (RR = 1.49, 95% CI = 1.33 - 1.52), the closure of decay cavities (RR = 1.49, 95% CI = 1.39 - 1.59).

Conclusions: Isolates of NTM were nearly twice as common as MTB. The significance of a mycobacterial isolate in a low tuberculosis prevalence setting

Guy Hagan, Andrew Fairfax. Department of Respiratory Medicine, Mid Staffordshire NHS Foundation Trust, Stafford, United Kingdom

Introduction: The incidence of tuberculosis in semi-rural Staffordshire is very low, around 2.8/100,000/year (1). We reviewed the significance of identifying mycobacteria in this population.

Methods: Retrospective analysis of patients from our institution with mycobacterium isolated from 1st Jan 2007 to 31st July 2011, with follow up until 1st Nov 2011. For patients with multiple isolates, the first species isolated was recorded.

Results: 67 patients were identified. Demographics of the M. tuberculosis(MTB) and non-tuberculous mycobacteria(NTM) patient groups are in Table 1. 22/43 (51%) of the NTM samples were considered significant and treated. Patients with NTM were older and more likely to die (p <0.001). Chronic lung disease was present in 11 (50%) of the treated NTM patients, and none of the MTB patients.

Skin biopsies and urine sample were +ve for NTM. Mycobacterial species isolated included 22 M. avium intracellulare, 6 gordonae, 4 chelonae, 3 kansassii, 3 malmoense, 2 xenopi and 1 each of shimoidai, maritumu and interjectum.

The burden of tuberculosis drug resistance in Eastern Europe: The Moldavian experience

Valeriu Crudu1, Liubana Domente2, Sofia Alexandru2, Elena Romancenco2, Vicel Soltan1, Andrei Mosneagag1. 1Center for Health Policies and Studies, Chisinau, Republic of Moldova

Aims: Surveillance the TB drug resistance on the national level and its impact upon public health in the Republic of Moldova;

The objective: to characterize the evolution of tuberculosis drug resistance in Moldova (2001-2011).

Methods: The study was retrospective, being based on the assessment results of M tuberculosis complex drugs resistance obtained in the reference laboratories from the country.

Results: Prevalence of MDR/TB among New TB cases increase from 6.3% in 2001 up to 26.4% in 2011. Trough previously treated patients (relapses, re-treatment after default, re-treatment after failure, chronic) prevalence of MDR TB was detected in 37.7% cases in 2001 and 64.3% cases in 2011. Extensively drug-resistant tuberculosis (XDR-TB) is present in some territories. The rate of XDR TB among the patients with MDR TB is 6.1% (2010). The prevalence of TB-HIV co-infection in country is 5.4%. The prevalence of MDR/TB among all TB-HIV is higher such from HIV negative patients (67.8%). Reasons of high level of TB resistance in Moldova: poor in infection control in TB hospitals -exogenous re-infection of TB patients; low compliance of treatment; the lack of a rigid control of TB patients, TB/HIV co-infection.

Conclusions: At the current stage MDR TB is a serious problem for National TB Program, bringing serious public health and economic consequences. It is a very alarming phenomenon, because the success of treatment (with first-line drugs) for this form of TB is less effective than for the susceptible tuberculosis and the accumulation of a greater number of resistant strains in society can lead to the infection of population and to an increase in the number of patients with MDRXDR TB.

P2707

The significance of a mycobacterial isolate in a low tuberculosis prevalence setting

MONDAY, SEPTEMBER 3RD 2012
Clinical analysis of pulmonary Mycobacterium avium complex disease in Japan
Masaki Ikeda, Yoshihiro Koshashi, Keiji Mouri, Yasushi Obuse, Mikio Oka.
Division of Respiratory Diseases, Department of Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan

Objective: To analyze the clinical characteristics of patients who diagnosed pulmonary Mycobacterium complex (MAC) disease recently in the affiliated several hospitals.

Patients and methods: The subjects consisted of 150 patients who satisfied the diagnostic criteria of ATS between 2003 and 2010. We evaluated the backgrounds, diagnostic methods, microbiological findings, radiological findings, treatments, and prognosis.

Results: The average age of 150 patients with pulmonary MAC disease was 65.0 years old. The detection method was most frequently recognized by bronchoscopy (50%). The microscopic findings were smear positive for acid-fast bacilli in 98 patients (65%) and the sensitivity of isolated MAC for antituberculosis drugs was comparatively good for clarithromycin (CAM) and rifampicin (RFP). The clinical disease type of pulmonary MAC disease consisted of nodular/bronchiectatic type in 101 patients (67%), fibrocavitary type in 43 (29%) and solitary nodular type in 6 (4%), respectively. Concerning the treatment for pulmonary MAC disease, the combined chemotherapy including CAM was performed for 76 patients (51%). Sputum conversion rate was 76%, the sputum relapse rate was 31% and the clinical improvement including radiological findings and/or clinical symptoms was obtained in 49%.

Conclusions: We positively perform the bronchoscopy examination to obtain the diagnosis of pulmonary MAC disease. The diagnostic rate of pulmonary MAC disease has recently increased with the revise of diagnostic criteria reported in 2007 and we could obtain comparatively good clinical effect by the positive performance of combination chemotherapy including the increase dose of CAM.

Pharmacokinetics of drugs for non-tuberculous mycobacterial lung infections
Cecile Mass-Jacouyn1, Jacko van Ingen2, Rob Aarnouts3
1Pulmonary Diseases, University Medical Centre Nijmegen, UCCZ Dekkerswald, Groesbeek, Gelderland, Netherlands; 2Medical Microbiology, University Medical Centre, Nijmegen, Gelderland, Netherlands; 3Clinical Pharmacy, University Medical Centre, Nijmegen, Gelderland, Netherlands

Successful treatment for Non-Tuberculous Mycobacterial (NTM) infections is easily frustrated. Little is known about the pharmacokinetics (PK) and dynamics of treatment regimens in relation to treatment outcome. Drug concentrations may be an intermediate link. In NTM disease very few PK studies have been performed. We performed a prospective, descriptive pharmacokinetic (PK) study of the plasma pharmacokinetics (full PK curve) of rifampin (RFP), ethambutol, clarithromycin (CAM), azithromycin, isoniazid and moxifloxacin and their active metabolites in a Dutch series of patients with clinically relevant NTM lungdisease and we compared the results with two other series from the literature. The baseline characteristics are shown in table 1.

Results were generally consistent with the data published in the past by Wallace and Pelouin. Our data showed that rifampicin causes a reduction in clarithromycin and azithromycin serum concentrations. The current study has confirmed the significant PK interactions between rifampicin and clarithromycin and we feel this calls for a reevaluation of the dosing strategies in NTM lung disease as an inadequate response to treatment might be attributed to suboptimal drug exposure.

Recovery rate of nontuberculous mycobacteria over a 10-year period at a tertiary referral hospital in Korea
Boksoon Chang1, Kyeongmoon Jeon1, O. Jung Kwon1, Nam Young Lee2, Chang-Seok Kr, Won-Jung Koh3.
1Division of Pulmonary and Critical Care Medicine, Samsung Medical Center, Seoul, Republic of Korea; 3Laboratory Medicine & Genetics, Samsung Medical Center, Seoul, Republic of Korea

The incidence of nontuberculous mycobacteria (NTM) infection is increasing in Korea. The aim of this study was to evaluate the recovery rate of NTM from respiratory specimens over a 10-year period in a tertiary referral hospital in Korea with a intermediate tuberculosis burden.

Method: Twenty immune competent patients who were diagnosed with a lung NTM infection by positive cultures and 20 healthy controls were enrolled. Based on the preferential percentage of neutrophils and lymphocytes in BAL fluids, patients were divided into two groups: predominant neutrophil and a lymphocyte-dominant group. The HRC scores indicating the extent and severity of airway disease (modified method of Fowl et al. Eur Respir J 2007) was compared between the groups.

Results: The numbers of neutrophils and lymphocytes were significantly higher in patients with NTM (17.4±4.6 and 6.9±2.4 x 10^7/ml) than those in healthy controls (0.1±0.1 and 0.8±0.2 x 10^7/ml) (p<0.01, respectively). Among the NTM group, HRC scores of the lobe in which BAL was performed in the neutrophil-dominant group (8.0±0.7) were significantly higher than the lymphocyte-dominant group (1.7±0.4) (p<0.01).

Conclusion: Neutrophil-dominant inflammation due to pulmonary NTM infection was related to severity of HRC findings in patients with NTM infection. These results will help us in understanding the biological defense mechanism against NTM.

Detection of volatile organic compounds in cattle caturally infected with Mycobacterium bovis

Nir Peled1, Matthew Koslow1, Jack Ryan1, Hessam Haick2. 1 The Thoracic Cancer Research and Detection Center, Department of Pulmonary Medicine, Chaim Sheba Medical Center, Tel Aviv University, Tel Aviv, Israel; 2 The Department of Chemical Engineering and Russell Berrie Nanotechnology Institute, Technion- Israel Institute of Technology, Haifa, Israel; 3 The National Wildlife Research Center, U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Fort Collins, CO, United States

We report a novel method in detecting Mycobacterium bovis infection in cattle based on identifying unique VOC (volatile organic compounds) profiles in the breath of cattle. The study was conducted on breath samples collected from cattle on an M. bovis-infected dairy in southern Colorado, USA. All animals were skin test positives; the presence of disease was either confirmed or inferred after necropsy. Negative controls included breath samples from animals on two tuberculosis-free dairies in northern Colorado. Gas chromatography/mass-spectrometry analysis revealed significant differences between M. bovis-infected and non-infected animals in the concentrations of 15 VOCs, allowing for distinctly different VOC patterns. Based on these results, a nanotechnology-based array of sensors was tailored for detection of M. bovis-infected cattle via breath. The tailored system successfully identified all M. bovis-infected animals (8/8) while 21% (3/14) of non-infected animals were misclassified as M. bovis-infected. The method shows promise in identifying unique VOC patterns in cattle with bovine tuberculosis. Applicability in humans warrants further study.

Figure 1. (a) Predominant VOCs in animals’ breath samples. (b) Exclusive VOCs for bTB positive and bTB negative cattle.

Figure 2. DFA (Discriminant factor analysis) plot showing the discrimination between bTB-negative (circles, n=14) and bTB-positive (rhombs, n=8) exemplars. An insight of the bTB-negative animals from the different dairies shows the complete mixing of the exemplars from M. bovis-infected (green filled circles, n=4) and tuberculosis free (red open circles, n=10) dairies.

Conclusions: Increased symptoms incidence, advanced radiological changes, increased ESR and high fibrinogen levels are risk factors for pulmonary MAC-PD from other lung diseases.

Based on these results, a nanotechnology-based array of sensors was tailored for detection of M. bovis-infected cattle via breath. The tailored system successfully identified all M. bovis-infected animals (8/8) while 21% (3/14) of non-infected animals were misclassified as M. bovis-infected. The method shows promise in identifying unique VOC patterns in cattle with bovine tuberculosis. Applicability in humans warrants further study.

P2713

Detection of volatile organic compounds in cattle caturally infected with Mycobacterium bovis

Nir Peled1, Matthew Koslow1, Jack Ryan1, Hessam Haick2. 1 The Thoracic Cancer Research and Detection Center, Department of Pulmonary Medicine, Chaim Sheba Medical Center, Tel Aviv University, Tel Aviv, Israel; 2 The Department of Chemical Engineering and Russell Berrie Nanotechnology Institute, Technion- Israel Institute of Technology, Haifa, Israel; 3 The National Wildlife Research Center, U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Fort Collins, CO, United States

We report a novel method in detecting Mycobacterium bovis infection in cattle based on identifying unique VOC (volatile organic compounds) profiles in the breath of cattle. The study was conducted on breath samples collected from cattle on an M. bovis-infected dairy in southern Colorado, USA. All animals were skin test positives; the presence of disease was either confirmed or inferred after necropsy. Negative controls included breath samples from animals on two tuberculosis-free dairies in northern Colorado. Gas chromatography/mass-spectrometry analysis revealed significant differences between M. bovis-infected and non-infected animals in the concentrations of 15 VOCs, allowing for distinctly different VOC patterns. Based on these results, a nanotechnology-based array of sensors was tailored for detection of M. bovis-infected cattle via breath. The tailored system successfully identified all M. bovis-infected animals (8/8) while 21% (3/14) of non-infected animals were misclassified as M. bovis-infected. The method shows promise in identifying unique VOC patterns in cattle with bovine tuberculosis. Applicability in humans warrants further study.

P2714

Clinical evaluation of GPL core IgA antibodies for serodiagnosis of MAC pulmonary disease

Yoshihiro Kobashi, Masaki Ikeda, Keiji Mouri, Yasushi Obase, Mikio Oka. Division of Respiratory Diseases, Department of Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan

Objective: To evaluate the clinical usefulness of GPL core antibodies for diagnosing MAC-PD and distinguishing MAC-PD from other lung diseases.

Methods: GPL core antibody levels were measured in 57 patients with MAC-PD, 18 with clinically suspected MAC-PD but who did not satisfy the diagnostic criteria of MAC-PD proposed by ATS, 10 with MAC contamination, 18 with pulmonary tuberculosis (TB) and 9 with other nontuberculous mycobacterial (NTM) disease, 18 with other lung diseases.

Results: The positive response rate for MAC-PD was 77%, that for suspected MAC-PD was 39%, and that for MAC contamination was 10%, and that for pulmonary TB, other NTM diseases, and other lung diseases was 0%, respectively. GPL core antibody levels were significantly higher in patients with MAC-PD including patients with clinically suspected MAC-PD, than in those in the other groups (p<0.01). The sensitivity and specificity of the antibody for diagnosing MAC-PD were 77% and 100%, respectively. Although thirteen patients with MAC-PD showed false negative responses for the GPL core antibody, five patients had immunosuppressive conditions due to underlying diseases. No significant correlations between the antibody level and species of MAC, clinical disease types, and extent of the disease on chest computed tomography were found in patients with MAC-PD.

Conclusions: The EIA kit is a useful supportive method for the rapid and convenient diagnosis of MAC-PD using a small dose of serum, and for the differentiation of MAC-PD from other lung diseases.

P2715

Clinical evaluation of interferon-gamma release assay (IGRA) in patients with nontuberculous mycobacterial disease

Yoshihiro Kobashi, Masaki Ikeda, Keiji Mouri, Yasushi Obase, Mikio Oka. Division of Respiratory Diseases, Department of Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan

Objective: To evaluate the clinical usefulness of two IGRA (QuantiFERON-TB and T-SPOT.TB) in patients with nontuberculous mycobacterial (NTM) disease.

Materials and methods: The study consisted of 180 patients with NTM disease who satisfied the diagnostic criteria proposed by American Thoracic Society (ATS). Tuberculin skin test (TST) was also performed for these patients as much as possible.

Results: The causative microorganism was Mycobacterium avium in 76 patients, M. intracellulare in 60, M. kansasi in 22, M. avium in 7, M. marinum in 7, others in 7, respectively. While the positive response rate for M. kansasi, M. marinum, and M. szulgai (30 patients) which possess the ESAT-6 and CFP-10 (Mycobacterium tuberculosis (MTB)-specific antigens) was 60% for TST, 33% for QFT, and 40% for T-SPOT.TB, the indeterminate response rate was 7% for QFT and 0% for MAC-PD, respectively. On the other hand, the positive response rate for M. avium and M. intracellulare etc. (150 patients) was 58% for TST, 7% for QFT, and 11% for T-SPOT.TB, the indeterminate response rate was 7% for QFT and 2% for T-SPOT.TB, respectively.

Conclusions: Although IGRA may be a useful diagnostic method to differentiate TB disease and MAC disease, there are several problems to be resolved before it can be used as a diagnostic method for M. kansasi disease etc. We also would like to describe the results of QFT for M. kansasi disease in other hospitals in Japan.

P2716

Pharmacokinetics and drug susceptibility testing implied limited activity of current regimens for Mycobacterium avium complex disease

Jacco van Ingen, Marin Boeree, Charles Peloquin, Charles Daley. Medical Microbiology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands Pulmonary Diseases, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands Emerging Pathogens Institute, University of Florida, Gainesville, FL, United States Mycobacterial and Respiratory Infections, National Jewish Health, Denver, CO, United States

Background: Treatment outcome in Mycobacterium avium complex (MAC) lung
Conclusions: are given in Table 1. Simultaneous use of rifampicin significantly lowered serum mycobacteria. The poor outcomes of MAC disease treatment may partly explain the poor outcomes of MAC disease treatment.

Results: Isolates were identified as MAC by AccuProbe assays. MICs were determined by the BacTec460 modulifecation method; synergy between rifampicin and ethambutol was assessed. Results: Pharmacokinetic data, median MICs and pharmacodynamic calculations are given in Table 1. Simultaneous use of rifampicin significantly lowered serum concentrations of macrolides (30-60%) and moxifloxacin (10-15%).

Conclusions: Serum rifampicin, ethambutol and moxifloxacin concentrations attained effective levels in a minority of patients; rifampicin use exerts detrimental effects on pharmacokinetics of macrolides and moxifloxacin. This may partly explain the poor outcomes of MAC disease treatment.

P2717
PCR based method for accurate diagnosis of mycobacterial disease and description of clinical profile of disease caused by non tuberculous mycobacteria
Anoma Siribaddana1, R.B. Vasanathriksn2, S.B P. Ashnada3.

Methods: A comparison of employment and primary care registries at National Jewish Health, Denver, USA, in the January 2006-June 2010 period was retrieved from databases. Pharmacokinetic measurements were done by high performance liquid chromatography and gas chromatography. Isolates were identified as MAC by AccuProbe assays. MICs were determined by the BacTec460 modulifecation method; synergy between rifampicin and ethambutol was assessed.

Results: Pharmacokinetic data, median MICs and pharmacodynamic calculations are given in Table 1. Simultaneous use of rifampicin significantly lowered serum concentrations of macrolides (30-60%) and moxifloxacin (10-15%).

Conclusions: Serum rifampicin, ethambutol and moxifloxacin concentrations attained effective levels in a minority of patients; rifampicin use exerts detrimental effects on pharmacokinetics of macrolides and moxifloxacin. This may partly explain the poor outcomes of MAC disease treatment.

P2718
High incidence of the Beijing strains among multi drug resistant isolates of Mycobacterium tuberculosis from extra pulmonary tuberculosis cases in northern India
Anand Kumar Maurya1, Surya Kant2, Vijaya Lakshmi Nag3, Ram Awadh Singh Kushiwahia, Taparn N. Dholea2.

Objectives: The aim of the study presented here was to investigate incidence of Beijing genotypic among MDR-TB isolates from extra pulmonary tuberculosis cases (EPTB) in Northern India.

Methods: A total of 756 specimens from patients of EPTB cases with varied presentation were studied. A total of 164 M. tuberculosis complex (MTB) isolates recovered during the period Sept 2007-Dec 2010 were tested for drug susceptibility against S/HRE by radiometric BACTEC method. MDR-TB isolates were sequenced in spolig and katG genes for mutation analysis. All MDR-TB strains were processed by genotypic method. The proportional of Beijing strains was significantly higher among MDR-TB strains (72.7%, p < 0.05). Genotypic analysis of spolig and katG gene revealed significantly high mutation rate among Beijing vs non Beijing strains (50% vs 33.4%, p < 0.05). While mutation for katG gene was common among Beijing vs. non Beijing strains (68.2% vs. 50%, p < 0.05). Conclusion: We found high incidence of Beijing strains among MDR-TB strains from EPTB cases in Northern India.

P2719
Identification of new immigrants to the UK for latent tuberculosis screening: A comparison of employment and primary care registries
Rakesh Punjabi, Haldar Pranabanish, Wollman Gerri. Department of Respiratory, Medicine, Institute for Lung Health, Glenfield Hospital, Leicester, Leicestershire, United Kingdom

Introduction: Comprehensive screening for latent M tuberculosis infection (LTBI) in immigrants relies on effective strategies for identifying at-risk groups. The utility of national registries has been suggested but not formally evaluated for this purpose.

Objectives: To compare and characterise profiles of immigrant registration on the UK National Insurance Number (NINO) and Flag-4 GP registries.

Methods: Retrospective analysis was conducted of both registries for Leicester between 2002-2009. Comparison between registries was performed on immigrants stratified by age at UK entry (<18yrs, 18-34yrs and ≥35yrs).

Results: The total number of immigrants registering was similar for NINO (47,000) and Flag-4 (46,653). Differences existed between the registries stratified by age. Flag-4 identified immigrants across all age ranges including children. In contrast, NINO was comprised of a greater percentage of young adults. The total number of younger adults identified with NINO was greater with a trend to significance (p=0.08). This suggests a proportion of immigrants to the UK for employment do not immediately register with a GP.

NINo overseas & Flag-registrations: Leicester 2002-2009

Conclusion: The UK NINO and Flag-4 registries provide complementary immigrant data in children and young adults that is relevant for TB services planning new immigrant screening.

P2720
Misdiagnosed pulmonary TB: Influencing factors and diagnostic chances in TB hospital
Zhanna Lushchik, Pavel Filimonov. Pulmonary TB Department, Nosovitskhir Research TB Institute, Nosovitskhir, Russian Federation Pulmonary TB Department, Nosovitskhir Research TB Institute, Nosovitskhir, Russian Federation

Differential diagnosis of pulmonary TB is still difficult. We found the tendency to overdiagnosis of pulmonary TB in TB hospital.

Purpose: Purpose of the study was to analyze causes of diagnostic errors and improve the quality of in-hospital management of patients supposed to having of pulmonary TB.

Methods: Noncomparative retrospective study, subject of interest were medical records of 136 most difficult cases, in which previously established diagnosis of pulmonary TB was rejected. The chances for establishment of true diagnosis and influencing factors were estimated.

Results: 1. Diseases, most often initially misdiagnosed as tuberculosis, were pneumonia (52%), lung cancer (20%). 2. The period from the disease manifestation up to establishment of final diagnosis was 84±7.2 days (mean±SD) days. 3. Clinico-radiological signs in these cases were more characteristic for TB, than for other pulmonary diseases. 4. False positive diagnosis is: “limited pulmonary opacity” (OR 1.75, p=0.003), pulmonary dissemination

**Clinical characteristics and treatment outcomes of tuberculosis in the elderly**

Yeon Soo Kwon1, Su Young Chi1, Yu Il Kim1, Sung Chul Lim1, Yoo Duk Choo2

1Internal Medicine, Chonnam National University Hospital, Gwangju, Korea; 2Pathology, Chonnam National University Hospital, Gwangju, Korea

*Background:* The purpose of this study was to describe the differences clinical characteristics and treatment outcomes between elderly TB patients and young TB patients.

*Methods:* The medical records of 271 young (aged 20 to 64 at diagnosis) and 199 elderly (aged 65 and older) TB patients, who were newly diagnosed with and treated for TB from May 2008 to May 2010, were reviewed.

*Results:* Respiratory symptoms such as cough, sputum, and dyspnea and comorbid medical conditions such as cardiovascular disease, diabetes mellitus and chronic obstructive pulmonary disease were more frequent in elderly patients. In chest CT scan of pulmonary TB patients, findings of active TB such as nodules (< 30 mm in diameter), masses (> 30 mm in diameter), and cavities were less frequently found in elderly TB patients except consolidations. However in microbiological diagnosis, positive TB culture rates were higher in elderly TB patients. Of those with known results of drug sensitive test, 95% were found. However, 6% were more frequently found in younger TB patients. In adverse drug reactions, the incidences were not different between two groups except severe GI troubles which were more frequently developed in elderly TB patients. There were no significant differences in the rates of treatment success (97% vs. 93.7%, p=0.161), failure (0% vs. 0.7%, p=0.19), and deaths due to TB (0.5% vs. 1.1%, p=0.844) between two groups.

*Conclusions:* Elderly TB patients presented more frequent respiratory symptoms and showed less frequent active TB findings on chest CT scan. Treatment success rates of elderly TB patients were not inferior to those of younger TB patients without development of more frequent adverse drug reactions.

**Risk factors for extrapulmonary tuberculosis**

José Sanchez1, Aurora Carvalllos2, Raquel Duarte3,4,5

1Palomar Hospital, Centro Hospitalar e Universitário de Coimbra- Hospital Geral, Coimbra, Portugal; 2Palomar Hospital, Centro Hospitalar e Universitario de Coimbra EPE, Vila Nova de Gaia, Portugal; 3Palomar Hospital, Centro Hospitalar de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal; 4Department of Clinical Epidemiology, Predictive Medicine and Public Health University of Porto Medical School, Porto, Portugal

*Introduction:* Tuberculosis (TB) remains a major global public health problem and 20% of all cases are extrapolumonar. The purpose of this study was to identify risk factors associated with extrapulmonary tuberculosis.

*Methods:* We performed a transversal study involving all patients with extrapulmonary tuberculosis registered in a TB reference centre in northern Portugal, between January 2008 and January 2012. We evaluated demographic data, comorbidities, BCG vaccination status, previous treatment outcomes. Multivariable logistic regression was used to identify independent risk factors (p < 0.05).

*Results:* Among the 386 patients studied, 260 (67.4%) had pulmonary tuberculosis (PTB) and 126 (32.6%) had extrapulmonary TB (EPTB). Being older than 40 years old (OR=2.09, 95%CI: 1.29-3.38), female (OR=1.63, 95%CI=1.02-2.6) and HIV positive (OR=2.72, 95%CI=1.25-5.93) were independent risk factors for EPTB. Alcoholism (OR=0.30, 95%CI: 0.12-0.75) is associated with higher risk for TB. Previous liver disease (OR=22.36; 95%CI: 1.89-263.57) was an independent risk factor for peritoneal TB. HIV co-infection (OR=12.97; 95%CI: 1.71-48.42) and the presence of previous treatment (OR=7.62; 95%CI: 1.00-57.9) increase the risk of disseminated disease.

*Conclusion:* We identified independent risk factors for EPTB compared with TB. Recognizing risk factors associated with EPTB is essential to suspect of disease and may help to get an accurate diagnosis.

**P2722**

**Comparative performance of interferon gamma release assays in detection of latent tuberculosis infection among health-care professionals**

1Microbiology Research Center and Department of Medical Microbiology, Avicenna (Bu-Ali) Research Institute and Ghaem University Hospital, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran; 2Center for Communicable Diseases Control, Ministry of Health and Medical Education, Tehran, Islamic Republic of Iran; 3Department of Thoracic Surgery, Ghaem University Hospital, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran; 4Center for Communicable Diseases Control, Ministry of Health and Medical Education, Tehran, Islamic Republic of Iran; 5Department of Medical Microbiology, Faculty of Medicine, Kermanshah University of Medical Sciences, Kermanshah, Islamic Republic of Iran; 6Immunology Research Center; Bu-Ali Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran; 7Department of Medical Virology, Faculty of Medicine, Alzahri Jundishapur University of Medical Sciences, Ahvaz, Iran; 8Immunology Research Center; Bu-Ali Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran

*Background:* The primary aim of the study was to compare the performance of three interferon gamma release assays (IGRA) in detection of latent tuberculosis infection (LTBI) in health-care professionals (HCPs).

*Materials and Methods:* A total of 450 HCPs working in the hospital wards with the highest number of admissions for patients with PTB were evaluated. The mean age of participants was 33.6 years and the male/female ratio was 57/84 (58.4%). Out of 95 eligible HCPs working in a university hospital in northeastern Iran and in hospital wards with the highest number of admissions for patients with PTB were evaluated. The mean age of participants was 33.6 years and the female/male ratio was 57/84 (88.4%) were bacille Calmette-Guérin (BCG) vaccinated at birth. The 95 HCPs, 43.2% were positive by TST, and about 29% by each of the IGRA. Of 53 (55.6%) individuals with a positive test, 15 (28.3%) were positive to all six tests and 26 (49.1%) were simultaneously positive to at least two tests. The global agreements (k) between TST-IGIT and T-SOT-IGIT with TST, and between the two IGRA were 0.73, 0.684, and 0.779 respectively. The concordance in interpretation of results was 80.9% for TST and 80.9% for IGIT. When considering the results, we would recommend concordance application of at least two tests for LTBI.

*Conclusions:* The TST is the most appropriate test for LTBI screening, comparing with the tuberculin skin test (TST).

P2726 Does adding telemonitoring to optimised management of chronic obstructive pulmonary disease (COPD) reduce hospital admissions? Randomised controlled trial

Hilary Pinnock1, Lucia McCoughan2, Allison Todd3, Janet Hanley4, Stephanie Lewis5, Asthma Krishan6, William MacNe2l Claudia Pagni2, Aziz Sheikh1, Brian McKinstry7, Allergy & Respiratory Research Group, Centre for Population Health Sciences, The University of Edinburgh, Edinburgh, United Kingdom; 3Asthma Health Research Group, Centre for Population Health Sciences, The University of Edinburgh, Edinburgh, United Kingdom; 4Nursing Midwifery and Social Care, Edinburgh Napier University, Edinburgh, United Kingdom; 5Edinburgh Clinical Trials Unit, The University of Edinburgh, Edinburgh, United Kingdom; 6Edinburgh Lung and the Environment Group Initiative, The University of Edinburgh, Edinburgh, United Kingdom

Introduction: Previous trials of telemonitoring in COPD have been confounded by additional supportive clinical care in the intervention group. It is unclear if telemonitoring alone will improve clinical outcomes.

Aim: To determine if telephysically supported telemonitoring of COPD prevents hospital admissions when both groups received optimised care.

Trial design: Researcher-blind RCT.

Setting: UK primary care settings.

Methods: Patients with a COPD admission in the previous year were centrally randomised to telemonitoring or control. The primary outcome, assessed at 1 year, was time to first hospital admission with a COPD exacerbation. Other outcomes included number of days in hospital, death and health-related quality of life (St George’s Respiratory Questionnaire (SGRQ)).

Results: We randomised 256 patients (128 telemonitoring) to baseline characteristics and time in hospital to admission between the groups (adjusted hazard ratio for admission (reference=tele-group) 1.04 (95% CI 0.73 to 1.50). 61 patients in each group had an admission. There was no significant difference in the mean number of admissions (tele-group: 1.2 (SD1.9); bed days (tele-group: 9.4 (SD 19.1) vs usual 8.8 (SD 15.9)); deaths (tele-group: 16, control 21; p=0.38) or SGRQ at year (mean difference: 1.5 (-1.4 to 4.5))

Conclusion: When both groups received optimised care, telemonitoring did not reduce the time to a hospital admission or increase quality of life.

ISRCTN number: 96634935

P2727 Multicenter COPD registry for quality improvement and comparative effectiveness research

Jerry A. Krishnan1, David H. Au2, Shannon S. Carson3, Todd A. Lee1, Peter K. Linderman4, Mary Ann A. McBurny1, Richard A. Malarski5, Edward T. Naureckas6, William M. Volmern1, Medicine, University of Illinois, IL, United States; 2Medicine, University of Washington/VA Puget Sound Health Care System, Seattle, WA, United States; 3Medicine, University of North Carolina at Chapel Hill, NC, United States; 4Center for Care of Quality Care Research, Baystate Medical Center, Springfield, United States; 5Center for Health Research, Kaiser Permanente Northwest, Portland, United States; 6Medicine, University of Chicago, Chicago, United States

Rationale: Studies evaluating quality, safety, effectiveness, and costs of care using registries linking electronic health records from diverse healthcare settings are attracting increasing interest because they can provide information more applicable to ‘real-world’ patients and clinicians.

Methods: The COPD Outcomes-based Network for Clinical Effectiveness and Research Translation (CONCERT) developed a multicenter COPD registry (COPD DataHub) linking 8 U.S. academic healthcare institutions. Inclusion criteria were based on age (>=40 yrs), ICD-9 billing codes, problem lists, medications, or spirometry data. We reported on Medicare and Medicaid beneficiaries with chronic obstructive pulmonary disease (COPD) with a prevalence of >4%, based on the condition being the reason for being enrolled in Medicare, as of January 2010. The prevalence of Charlson comorbid conditions was estimated. An in-person study visit was used to collect additional information, including height, weight, smoking status, symptoms, and lung function. Preliminary findings are presented here.

Results: In 226,261 patients, the five most common co-morbid conditions (highest estimated) were diabetes (32 and 23%), heart failure (26 and 11%), renal disease (20 and 9%), malignancy (20 and 12%), and peripheral vascular disease (16 and 8%). In 1,216 patients who completed the study visit, 73% were overweight or obese, 84% were ever smokers, 44% smoked >40 pack-years, 34% had chronic bronchitis symptoms, and 54% had fixed airflow obstruction (post-BD FEV1/FVC<70%).

Conclusions: Quality improvement and comparative effectiveness research in COPD should 1) include lung function testing to confirm the diagnosis, and 2) address a range of comorbid conditions, including overweight or obese body habitus and smoking-related behaviors. Given the high levels of comorbidity, heterogeneous treatment effects appear likely.

P2729 Latin America asthma insight and management (LA AIM): A survey of asthma patients in 4 Latin American countries and Puerto Rico

Jorge Maspero1, Jose Jardim2, Alvaro Aranda3, C. Pablo Tassinar4, Allergy and Respiratory Research Unit, Fundacion CIDEA, Buenos Aires, Argentina; 2Respiratory Division, Federal University of Sao Paulo Medical School, Sao Paulo, Brazil; 3Respiratory, Hospital Auxilio Mutuo, San Juan, Puerto Rico; 4Institute of Immunology, Universidad Central de Venezuela, Caracas, Venezuela

Introduction: In 2011, we conducted a comprehensive asthma survey in Latin America. Asthma Insight and Management (LA AIM) survey was modeled on similar programs in the United States, Europe and Canada, and the Asia-Pacific region.

Aim: Face-to-face interviews lasting approximately 35min were conducted with respondents in a national probability sample. The survey was included 2000 patients (400 patients/location) in Latin America (Argentina, Brazil, Mexico, Venezuela) and Puerto Rico. Survey questions covered asthma burden, impact of asthma on patients; emotional burden; symptoms; seasonal influences on symptoms; triggers; most bothersome symptoms; and patient perceptions about current levels of control.

Results: More than 51,000 households were screened, and 2,169 respondents completed the LA AIM survey across the 5 locations. Respondents were predominantly female (67% for the region, proportion similar in each country). Mean age was 37y (for the region; 35-45y, range across countries). Mean age at diagnosis across locations was 15y; (Argentina:19y; Mexico and Puerto Rico:18y; Brazil:16y; Venezuela:11y). Dust was the most commonly reported trigger (61% overall), following by change in weather (41% overall).

Conclusions: The LA AIM survey provides a comprehensive view of the state of asthma across 5 distinct Latin American cultures. The survey reveals that asthma has a profound impact on patient health and quality of life, suggesting a continuing unmet need for asthma education in Latin America. Results were primarily similar across the region.

P2730 Cough, active smoking ever, smoking history of >10 packyears and wheezing/chest tightness should prompt COPD suspicion in cardiac patients who remain symptomatic despite adequate management

Maria Kolacznikova Plon1, Jaroslav Dvorak2, Marzena Zielinska3, Piette Kuna4, 1Allergy, Medicine, Asthma and Allergy, Medical University of Lodz, Lodz, Poland; 2Clinic of Internal Medicine, Asthma and Allergy, Medical University of Lodz, Lodz, Poland; 3Clinic of Cardiology, Medical University of Lodz, Lodz, Poland; 4Clinic of Intensive Cardiac Therapy, Medical University of Lodz, Lodz, Poland

Background: Coronary heart disease (CHD) and chronic obstructive pulmonary disease (COPD) share common risk factors and often coexist. Dyspnea, effort intolerance and chest tightness in CHD patients are readily attributed to cardiovascular disorder while COPD passes unnoticed. Proper COPD management optimizes patient’s outcome.

Aim: The aim of our study was to determine key features from history and physical examination that should raise COPD suspicion in persistently symptomatic cardiac patients.

Material and methods: Patients were recruited with respect to the following inclusion criteria: angiographically confirmed CHD, adequate cardiac management, ability to visit study site, expressed informed consent for study participation. Subjects were evaluated for: demographics, smoking, respiratory complaints (modified ECRHS questionnaire), airflow limitation (spirometry accompanied by reversibility test if applicable). COPD diagnosis was based on clinical presentation, history and post-bronchodilator FEV1/FVC<LLN.

Results: Among 206 subjects eligible for the study 33 (16%) were found to have COPD. COPD vs. non-COPD subjects did not differ in age, sex, BMI, waist circumference and tobacco exposure in general. Active smoking ever (OR 5.45, 95%CI 1.24-23.9), >10 packyears (OR 4.28, 95% CI 1.57-11.7), cough (OR 4.28, 95%CI 1.36-23.6) and wheezing/chest tightness (OR 3.38 95%CI 1.51-7.58) significantly increased COPD risk.

Conclusions: Longstanding history of active smoking ever, cough and wheezing/chest tightness in persistently symptomatic cardiac patients should raise the suspicion of concomitant COPD.

P2731 The predictive value of the COPD assessment test (CAT) for acute exacerbations in patients with chronic obstructive pulmonary disease (COPD)

Dimitar Sajkov,1 Ming-Shyan Huang2, Jian Kang1, Ching-Hsiung Lin1, Myung Jae Park1, Nanthem Kwon3, Sang-Do Lee3 1Australian Respiratory and Sleep Medicine Centre, Adelaide, Australia; 2Department of Internal Medicine, Kaohsiung Medical University Hospital, School of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; 3The Institute of Respiratory Diseases, The First Affiliated Hospital of China Medical University, Shenyang, China; 4Division of Chest Medicine, Department of Internal Medicine, Changhua Christian Hospital, Changhua, Taiwan; 5Division of Respiratory and Critical Care Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea; 6Asia Pacific Medical, GlassSmithKline, Singapore, Singapore. 1Division of Pulmonary and Critical Care Medicine, Asan Medical Centre, Seoul, Republic of Korea

Acute exacerbations significantly impair health-related quality of life (QoL) and productivity of patients with COPD. Predicting the probability of exacerbation may help in optimising COPD management. We evaluated whether the COPD Assessment Test (CAT) could predict the risk of future exacerbations of COPD. COPD patients with a history of exacerbation were recruited from 19 sites in four Asia Pacific countries. CAT score, Medical Research Council (MRC) dyspnea score, spirometry data, medical history, and exacerbation episodes were prospectively collected over six months. In 495 evaluable patients with a mean age of 69.4±8.8 years, 68% had at least one exacerbation over the study period. The baseline CAT score categorised into four severity groups showed a strong predictive value for time to first exacerbation (AUC=0.83). Time to first exacerbation was shorter with worsening category of CAT score (p<0.001; mean 19.9, 15.8, 10.4 and 4.5 weeks for CAT score categories of 0–9, 10–19, 20–29 and ≥30 respectively). The risk of future exacerbation was higher with worsening category of CAT score (p=0.04; adjusted relative risks: 1.0, 1.26, 1.33 and 1.45 respectively). The un categorised CAT scores, used as a continuous variable, found predictions of similar magnitude. In outpatients with COPD, the baseline CAT score showed a strong predictive value for time to first exacerbation. It also provided modest prediction of exacerbations in the following six months.

P2732 Sleep-related breathing disorders in patients with schistosomal cor-pulmonale

Yehia Khalil, Emad Ibrahim, Rasha Daabis, Engy El-Nahas. Chest Department, Alexandria Faculty of Medicine, Alexandria, Egypt

Schistosomiasis has long been an endemic disease in Egypt and an important cause of pulmonary hypertension. Objectives: We aimed to investigate the clinical and polysomnographic features of sleep-related breathing disorders (SRBD) in patients with schistosomal cor pulmonale and to evaluate their effects on pulmonary hemodynamics. Patients and methods: We studied 10 stable patients with schistosomal pulmonary hypertension (mean age was 43.7) and 10 healthy volunteers matched. All underwent overnight polysomnography. Results: The mean AHI in patients group was 20/h while in the control group it was 2.3/h. 80% of the patients were found to have an AHI >10/h and 60% had moderate to severe sleep apnea (AHI >15/h). In addition, the majority of the patients (80%) spent ≥30% of the night with an arterial oxygen saturation <90%. SRBD were not correlated with anthropometric measures, spirometry nor with the typical symptoms of SA such as excessive sleepiness as assessed by ESS. More SRBD were not correlated with anthropometric measures, spirometry nor with the severity of PAH. The predictive value of the COPD assessment test (CAT) for acute exacerbations of COPD (COPD) could predict the risk of future exacerbations of COPD. COPD patients with a history of exacerbation were recruited from 19 sites in four Asia Pacific countries. CAT score, Medical Research Council (MRC) dyspnea score, spirometry data, medical history, and exacerbation episodes were prospectively collected over six months. In 495 evaluable patients with a mean age of 69.4±8.8 years, 68% had at least one exacerbation over the study period. The baseline CAT score categorised into four severity groups showed a strong predictive value for time to first exacerbation (AUC=0.83). Time to first exacerbation was shorter with worsening category of CAT score (p<0.001; mean 19.9, 15.8, 10.4 and 4.5 weeks for CAT score categories of 0–9, 10–19, 20–29 and ≥30 respectively). The risk of future exacerbation was higher with worsening category of CAT score (p=0.04; adjusted relative risks: 1.0, 1.26, 1.33 and 1.45 respectively). The un categorised CAT scores, used as a continuous variable, found predictions of similar magnitude. In outpatients with COPD, the baseline CAT score showed a strong predictive value for time to first exacerbation. It also provided modest prediction of exacerbations in the following six months.

P2733 SIIDS and idiopathic ALTE: Genetic similarities

I. Nosetti1, L. Filomini2, C. Magnani, V. Mongardi3, C. Bocchi1, V. Milan1, L. Negri1, F. Nonnis4, Mazzano2 1Pediatric Clinic, University of Insubria, Varese, Italy; 2Biocybernetics, University of Insubria, Varese, Italy; 3Biocybernetics, University of Parma, Italy

Background: Recent advances in molecular genetics have opened new perspectives in the definition of pathogenic mechanisms of SIIDS. Several studies, during the past decade, identified polymorphisms in the serotonin transporter (5HTT) (5-HTLPR, hydroxytryptamin transporter-linked polymorphic region, and S11T, intron 2 VNTR), the promoter region of MAOA (monoamine oxidase A), and DAT in an Italian SIIDS population. ALTE patients, IALTE (idiopathic ALTE) and controls. Methods: We enrolled 76 infants with an history of Apparent Life Threatening Event, distinguished in Idiopathic ALTE (IALTE) and Non Idiopathic ALTE (ALTE) by clinical, diagnostic and therapeutic data (12 channels polysomnography E Series Compumedics). Genotypes and allelic frequencies of DAT, MAOA and 5HTT were determined in ALTE and IALTE infants compared with data obtained from 150 healthy controls.

Results: No association was found between DAT polymorphism and ALTE/IALTE groups either in the genotype (p=0.25; p=0.112) nor in the allelic frequency (p=0.94; p=0.88). The comparison of MAOA genotypes and allelic frequency between ALTE and control group was not significant, on the opposite the comparison between IALTE and control group was statistically significant for the genotypes (P=0.09) and a tendency for allele (p=0.036). Analysis of 5HTT polymorphisms in IALTE remarked the pathogenetic role of L/L genotype (P<0.00001) and L allele (P<0.00001) as previously demonstrated in SIIDS.

Discussion: The CS decrease with breath hold time correlates with in vitro data showing CS decrease with RBC deoxygenation. To our knowledge, this is the first demonstration in humans of the effect of RBC oxygenation on the CS of dissolved 129Xe. Localisation of this technique may provide insight into regional RBC oxygen non invasively.

P2734 Measuring red blood cell oxygenation in vivo using hyperpolarized 129Xe MRI

Guoqing Lei, Guang Nonquay, Juan Parra-Robles, Jim Wild. Royal Hallamshire Hospital, Sheffield, Great Britain, United Kingdom

Introduction: Red blood cell (RBC) oxygenation plays an important role in cell survival. However, measuring this parameter in deep tissues is difficult. We report a method of detecting RBC oxygenation in vivo using MRI chemical shift (CS) of hyperpolarized (HP) 129Xe dissolved in RBCs explored previously in vitro (Mag Res Med 43;4(491) 2000).

Methods: 400mL of HP 129Xe mixed with 600mL N₂ was delivered to 3 healthy volunteers who inhaled the gas and held their breath. Spectroscopy was performed on a 3T Philips Intera every 3 seconds for the length of the breath hold. CS was extracted from fits to the spectra. Surrogate oxygenation was measured using an SpO₂ monitor.

Results: Example spectra from one volunteer early(red) and at end of breath hold(blue) are shown in Fig 1(left). The CS change between the tissue/plasma and the RBC peak are plotted as a function of time(green) in the panel right along with measured SpO₂ (blue). A decrease in the separation between these two peaks is seen over the course of the breath hold corresponding with a measured decrease in SpO₂. Similar trends are seen in data from all subjects.

Development of an intervention algorithm in telemetrically supervised adaptation of positive airway pressure therapy for OSAS

O. J. Schoch, Florent Bury, Jolanda Neidermann, Jochen J. Rüdiger, Martin H. Brune, Fachbereich Pneumologie, Schlafmedizin und Heimbeatmung, St. Gallen, Switzerland

Introduction: The acceptance of positive airway pressure therapy (PAP) is a major clue to successful OSAS therapy. Telemedicine is a novel tool to supervise PAP use at the patient’s home. We report on treatment results with an intervention scheme developed to guide patients during the first month of telemetrically supervised PAP adaptation.

Methods: After mask adaptation and explanation of the PAP devices (ResMed Inc, Australia), newly diagnosed OSAS patients were equipped with telemedicine (ResTraxx from ResMed, Munich, Germany). The automatically downloaded 4h in 55% of patients. A total of 174 calls were analyzed by antibody radioimmunoassay. PAH patients had elevated PIIINP, CITP, MMP-9 and TIMP-1 levels measured by ELISAs. PHIP was measured by antibody radioimmunoassay. PAH patients had elevated PHIP, CITP, MMP-9 and TIMP-1 levels suggesting active collagen metabolism (Table 1). PHIP levels were higher in WHO FC-IV as compared to WHO FC-I/II PAH patients (p<0.01). PHIP levels negatively correlated with six-month distance (R=-0.3, P=0.008), and positively correlated with right atrial pressure (R=0.35, P=0.002) and BNP levels (R=0.25, P=0.02).

Circulating procollagen markers may provide a novel non-invasive method of documenting active collagen synthesis reflective of severe disease in PAH.

Circulating procollagen markers may provide a novel non-invasive method of documenting active collagen synthesis reflective of severe disease in PAH.

Prevention of RSV infection in infants from the high-risk groups in Moscow: The first season’s results
Dmitry Evginyan1, Irina Krsheminskaya1, Elena Detygureva2. 1Medical Faculty, People’s Friendship University of Russia, Moscow, Russian Federation; 2IMER Group, Moscow, Russian Federation

Aim: Analysis of efficacy and safety of immunization with palivizumab of infants from the high-risk groups of severe respiratory syncytial viral (RSV) infection carried out during 2012 infection season in Moscow.

Methods and materials: Immunization against RSV infection with palivizumab was conducted for the first time in six Moscow hospitals from January to May 2012. The total number of infants immunized was 156 aged from 15 days to 1 year 11 months. Patients received from 1 to 4 shots with treatment-free interval 30±5 days: 1 infant was immunized four times, 139 – three times, 9 children – twice, 7 children – once. The reasons for discontinuation of immunization after 1 and 2 shots were not connected to medical conditions. 139 (89.1%) of all infants were premature, including 42 (26.92%) with extremely low birth weight, 83 (53.21%) with bronchopulmonary disease, 19 (12.18%) with congenital heart diseases.

Efficacy of immunization was estimated on a basis of the average monthly frequency of lower respiratory tract infections and hospitalization within three months ahead and three months during prophylaxis. A frequency of adverse events was used for safety analysis.

Results: Immunization with palivizumab led to decrease of the average monthly frequency of lower respiratory tract infections (from 0.064 to 0.014) and hospitalization (from 0.048 to 0.031). The following adverse events were reported: short-term, low-grade fever, anxiety, rhinitis, upper respiratory tract infection, frequency of lower respiratory tract infections and hospitalization within three months ahead and three months during prophylaxis. A frequency of adverse events was used for safety analysis.

Conclusion: Immunization against RSV infection with palivizumab conducted during the 2012 infection season was safe and effective.

P2741
Association of airway bacterial load with inhaled corticosteroid dosage in stable COPD
Davinder Garcha1, Sarah Thurston1, Anant Patel1, Alexander Mackay1. 1Academic Unit of Respiratory Medicine, University College, London, United Kingdom; 2Centre for Medical Microbiology, Royal Free and University College Medical School, London, United Kingdom

Inhaled corticosteroids (ICS) are commonly used in COPD, either alone or in combination with bronchodilators to reduce exacerbation frequency, but may also increase risk of pneumonia (Calverley et al, NEJM, 2007; Wedzicha et al, JRCCM, 2008) which is not well understood. Lower airway bacterial colonisation is often present in stable COPD and may predispose to pneumonia. We investigated the relationship between airway bacterial load and ICS dose in stable COPD patients.

We quantified typical bacterial load using a validated PCR (for H. influenzae, S. pneumoniae, M. catarrhalis) from the sputum of 47 stable COPD patients positive for at least one of these species. Patient characteristics: Mean(SD) age 71(±8.0) years; Male gender 64%; Current smoker 34%; FEV1 49(±18.4%) predicted. Median (IQR) beclomethasone-equivalent dosage was 2000 (400-2000) g g daily. Higher airway bacterial load was correlated to higher ICS dosage (corrected for smoking status and FEV1 % predicted (p=0.022).

For the first time we have shown that the use of high ICS dose is associated with higher airway bacterial load and may therefore play a part in increasing susceptibility to pneumonia in COPD.

P2742
Pleural irrigation trial (PIT): Standard care versus pleural irrigation, a randomised controlled trial in patients with pleural infection
Claire Hooper1, Antony Edey1, Adam Wallis1, Amelia Clive1, Anna Morley1, Mike Darby2, Natalie Zahan3, Andrew Medford1, Nick Maskell3. 1Academic Respiratory Unit, School of Clinical Sciences, University of Bristol, Bristol, United Kingdom; 2Department of Radiology, Southmead Hospital, North Bristol NHS Trust, Bristol, United Kingdom; 3Pleural Clinical Trials Unit, Southmead Hospital, North Bristol NHS Trust, Bristol, United Kingdom

Background: Pleural infection remains common with an increasing incidence and high mortality. Despite chest tube drainage and antibiotic therapy up to 30% of patients will die or require surgery. Case reports suggest that irrigation of the pleural space with saline may be beneficial but this has never been tested in the form of a randomised controlled trial.

Method: Randomised controlled pilot study comparing standard care plus saline irrigation, with best standard care alone, in patients with pleural infection requiring chest tube drainage, who had a residual pleural collection on baseline CT thorax. Primary outcome was percentage change in CT pleural volume from day 0 to day 3. Secondary outcomes included referral for surgery, hospital stay & adverse events.

Results: 65 patients approached, 38 randomised, 3 excluded. Saline irrigation resulted in significant reduction in CT pleural collection volume compared to standard care – Irrigation group 29.2% reduction (95% CI 16.2- 62) vs Standard care 13.9% (95% CI 4.1 - 26.3) p<0.04. There was also a significant reduction in the need for thoracic surgery in the irrigation group 2/18 vs 9/17 p=0.01 (OR 0.03, 95% CI 1.6-51.9). No differences were seen in length of hospital stay or fall in inflammatory markers (CPR, WCC and procalcitonin). Safety profile of saline irrigation was good with no serious complications and similar adverse events between groups.

Conclusion: Saline irrigation improves fluid drainage in pleural infection, leading to reduction in referral for surgery. This study now needs to be repeated as a large multicentre RCT using the hard endpoints of mortality and length of hospital stay.

306. New drug targets and pre-clinical models for respiratory diseases

Late asthmatic response is modulated by TRPA1 antagonists in ovalbumin-induced bronchoconstriction in anaesthetized guinea pigs
Thierry Bouyssou, Zoe Noakes, Silke Hobbie, Martin Fleck, Andreas Schnapp, Florian Gnant. Respiratory Diseases Research, Boehringer-Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Baden Württemberg, Germany Respiratory Diseases Research, Boehringer-Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Baden Württemberg, Germany Respiratory Diseases Research, Boehringer-Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Baden Württemberg, Germany Respiratory Diseases Research, Boehringer-Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Baden Württemberg, Germany

In animal models of asthma, ovalbumin (OVA) aerosol results in bronchoconstriction characterized by a histamine-related early asthmatic response (EAR) followed by a neuropeptide-related late asthmatic response (LAR) which can be modulated by transient receptor potential (TRP) channel A1 antagonists (Thorax. 2012. 67, 19-25).

The aim of the study was to assess the potential of two TRPA1 antagonists on the EAR and LAR in OVA-induced bronchoconstriction in anaesthetized guinea pigs.

Bronchoconstriction was induced by intra-tracheal administration of a single dose of OVA (50 μg/kg) and lung resistance recorded for 30 minutes. The animals were pre-treated with pyrilamine (2 mg/kg i.v.) or its vehicle (saline) 10 min before OVA. The TRPA1 antagonists HC-030301 and A-967079 or their vehicle (0.5% m-cellobiulose) were administered i. h before OVA. Without pyrilamine pre-treatment, OVA induced a fast increase in lung resistance (max. 60±13 ml overlap after 1 min) which was not reduced by the TRPA1 antagonists. Under pyrilamine pre-treatment, OVA induced a slow increase in lung resistance (max. 33±10 ml overlap at the end of the recording). HC-030301 (1 μg/kg – 1 mg/kg) dose-dependently inhibited the non-histamine-related OVA-induced bronchoconstriction (ED50 = 0.01 mg/kg) with a maximum bronchoprotection of 76% at 0.03 mg/kg (p<0.05). A-967079 (1 μg/kg – 1 mg/kg) displayed the same profile as HC-030301 (ED50 = 0.01 mg/kg) with a maximum bronchoprotection of 78% at 0.03 mg/kg (p<0.05).

This study shows that the EAR is histamine related, while the LAR is modulated by the TRPA1 channel in OVA-induced bronchoconstriction in anaesthetized guinea pigs.
2804
Effect of nilotinib on airway smooth muscle thickening in a murine model of chronic asthma
Youngkyu Yoon, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, St. Mary's Hospital, Seoul, Republic of Korea
Background: Asthma is characterized by airway inflammation and remodeling. The tyrosine kinase inhibitor nilotinib was developed to inhibit BCR-ABL kinase activity; however, it also has potent inhibitory activity against the c-Kit and platelet-derived growth factor receptor (PDGFR). The present study was aimed to determine whether nilotinib suppresses airway smooth muscle (ASM) remodeling and whether its effect is associated with c-Kit and PDGFR pathways.
Methods: We developed a mouse model of airway remodeling, which includes smooth muscle thickening, in which ovalbumin (OVA)-sensitized mice were repeatedly exposed to intranasal OVA administration twice a week for 3 months. Mice were treated with nilotinib during the OVA challenge.
Results: Mice chronically exposed to OVA developed sustained eosinophilic airway inflammation compared with control mice. In addition, the mice chronically exposed to OVA developed features of airway remodeling, including thickening of the peribronchovascular and perivascular muscle layer. Administration of nilotinib significantly inhibited eosinophilic inflammation and ASM remodeling in mice chronically exposed to OVA. Nilotinib treatment significantly reduced the expression of p-c-Kit, p-PDGFR, and p-ERK1/2. The expression levels of genes encoding c-Kit and PDGFR were also reduced by nilotinib treatment.
Conclusions: These results suggest that nilotinib administration can prevent not only airway inflammation, but also airway remodeling associated with chronic allergic challenge. Nilotinib may provide a clinically attractive therapy for chronic severe asthma.

2805
A comparison of anti-inflammatory compounds in a steroid-insensitive mouse model of chronic asthma
Vincent Russell, Paul Woodman, Andrew Connolly, Dianne Spicer, Alan Young, Pharmacology, Argenza, Stoke Court, Slough, United Kingdom
The effects of PDE4 and p38 inhibitors were compared to steroids in a robust model of lung inflammation induced by 4 days of exposure to tobacco smoke (TS). Methods: Mice were exposed to either air or TS for 4d and were killed 24h after the last exposure, the lungs lavaged and cells counted. Compounds were given at maximal efficacy doses as defined in a mouse LPS model. Steroids were dosed orally (Dexamethasone, 300 μg/kg 1hr pre- and 6hr post-TS); or intra-nasally (Flunisolide propionate (FP), budesonide (BUD) 300 μg/kg 1hr pre-TS). Rosmarinast (ROF) reduced TS-induced inflammation (p<0.05). The p38 inhibitor (BIRB-796) was orally (1mg/kg) dosed 1hr pre- and 6hr post-TS.
Results: Mice caused cellular infiltration into the lung which was reproducible across multiple studies. Oral or i.n. dosed steroids did not inhibit the inflammation (p<0.05 total cell and neutrophil (neut) count). Body weight significantly decreased over the 4d (FP 6%, BUD 11%, DEX 11%; all p<0.05) confirming steroid availability and efficacy. ROF reduced TS-induced inflammation when given i.n. (totals -50%, neuts -60%; both p < 0.05) or orally (totals -50%, neuts -60%; both p < 0.05). The p38 inhibitors were effective dosed orally (BIRB-796 -40% i.n. -55%) or i.n. (PF totals -50%, neuts -45%; all p < 0.05).
Conclusions: TS-exposure for 4'd induced a steroid-insensitive lung inflammation which was reproducibly inhibited by PDE4 and P38 inhibitors; although neither caused a total inhibition of the inflammation, suggesting that there is scope to investigate more efficacious mechanisms and combinations within this model.

2806
Synbiotics reduce airway inflammation and improve airway function in a mouse model for COPD
Gillana Bezemer1, Mara Diks1, Paul Vos2, Johan Garssen1,2, Paul Henricx1, Aletta Kraneveld1, Gert Folkerts1, 1Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands; 2Dantone Research, Centre for Specialised Nutrition, Wageningen, Netherlands
Background: Good gut health plays an important role in maintaining immunity in and beyond the gastrointestinal tract. Respiratory disorders can be influenced by gut microbiota. Chronic obstructive pulmonary disease (COPD) is a major health problem worldwide. The disease is characterized by a progressive airflow limitation caused by an abnormal inflammatory response. Aim of this study is to investigate the effectiveness of specific dietary fibers and lactic acid producing bacteria in a mouse model for COPD.
Methods: Male BALB/c mice were instilled intra nasally (i.n.) with lipopolysaccharide (LPS, 10μg) or with LPS (1g/kg) 3 times per week for 16 days. Mice were treated 5x per week by intra-gastric supplementation with: 1) Prebiotic fiber mixture of short-chain fructooligosaccharides and long-chain fructooligosaccharides (GOS/FOS), 2) Probiotic Bifidobacterium or 3) Synthetic combination of GOS/FOS and Bifidobacterium. Broncho alveolar lavage (BAL) samples were analyzed for airflow inflammation. Airway function was measured by plethysmography in anesthetized mechanically ventilated mice.
Results: LPS treatment significantly induced inflammatory cell influx in the bronchoalveolar lavage (BAL) fluid. Treatment with either GOS/FOS or GOS/FOS
combined with Bifidobacterium was able to reduce the influx of macrophages and neutrophils into BAL fluid. Only treatment with synbiotics was able to attenuate the LPS induced reduction in airway function.
Conclusion: These findings suggest that a combination of Bifidobacterium and GOS/FOS might be beneficial as nutritional intervention in patients suffering from COPD.

2807
Mice with immortelle cilia spontaneously cough due to mechanical stimuli of postnasal drip
Toshikazu Iwai1, Isao Ito1, Aki Niimi2, Koji Isegami1, Satoshi Marumo1, Naoya Tanabe1, Hitoshi Nakaj1, Hisako Matsumoto1, Tetsuo Oguma1, Haeki Inoue1, Tomoko Tajiri1, Tadafuji Nagasaki2, Yoshihiro Kanemitsu1, Junro Kamei3, Mitsutoshi Setou2, Michiaki Mishima3, 1Respiratory Medicine, Graduate School of Medicine Kyoto University, Kyoto, Japan; 2Medical Oncology and Immunology, Nagoya City University School of Medical Sciences, Nagoya, Japan; 3Cell Biology and Anatomy, Hamamatsu University School of Medicine, Hamamatsu, Japan, 4Pathobiology and Therapeutics, Hoshi University, Tokyo, Japan
Background: The underlying mechanisms of cough in patients with rhinosinusitis are poorly understood. We reported that tubulin tyrosine ligase-like family member 1 gene (Ttll1) knockout (KO) mice showed disorders of ciliary motility resulting in rhinosinusitis together with cough reflex. Aim: To examine mechanisms of cough in Ttll1-KO mice.
Methods and results: We pathologically searched for the causes of cough and examined structural changes of the airway in KO mice. We observed that Ttll1-KO mice was reproducibly inhibited by rapidly adapting receptor (RAR), decreased cough, while capsaicin, an antagonist of the transient receptor potential vanilloid subfamily 1, did not. Tolfudoxacin, a fluoroquinolone antibiotic, improved nasal inflammation but accumulation of mucus and cough remained. To prove that mucus stimuli evoke cough, artificial PND were made to evoke cough in WT mice. WT mice distinctly coughed due to artificial PND. Blue dye and contrast material were administered to study nasal clearance and movement of mucus. We confirmed that nasal ciliary clearance was decreased in KO mice. Further, blocking nasal discharge from flowing to the larynx completely inhibited cough of KO mice. Conclusions: Mechanical stimulation to larynx due to PND was transduced to the central nervous system via RAR and evoked cough in Ttll1-KO mice. Ttll1-KO mice may serve to reveal the mechanisms of cough in patients with PND and to develop new antitussive drugs.

2808
Intratracheal administration of dry powdered low-molecular-weight chitosan/siRNA complexes suppressed gene expression in the airway and metastatic tumors in murine lung
Makoto Hattori1, Noboru Hatton2, Hirokazu Okamoto2, Nobuo Kohn3, 1Department of Molecular with Clinical Medicine, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan; 2Faculty of Pharmacy, Meijo University, Nagoya, Japan
Introduction: There is an increasing number of efforts to deliver small interfering RNA (siRNA) to lung. Although many different formulations with siRNA have been optimized in vitro studies, only a few have been reported successful in vivo.
Objectives: As a carrier of siRNA, we chose low-molecular-weight chitosan (LMWC) and succeeded in producing dry powder of LMWC/siRNA complexes. In the present study, we tried to determine whether intratracheal administration of dry powdered LMWC/siRNA complexes suppressed gene expression in murine lung.
Methods: Dry powdered LMWC/siRNA targeting green fluorescent protein (GFP)-siRNA and Lewis lung carcinoma cells stably expressing GFP (LLC-GFP) were prepared. Dry powder of LMWC/GFP-siRNA complexes was intratracheally administered to GFP transgenic mice and the C57BL/6 mice injected with LLC-GFP cells through tail vein. The fluorescence in the lung tissue sections was analyzed with a BIOREVO fluorescence microscope (BZ-9000; KEYENCE, Japan).
Results: Intratracheal administration of LMWC/GFP-siRNA complexes was found to suppress the fluorescence level of bronchial epithelium in the lung of GFP transgenic mice. It was also effective at reducing the fluorescence level in metastatic lung tumors consisting of LLC-GFP cells.
Conclusion: The results of the present study suggest that LMWC is an effective carrier for siRNA delivery to the lung, and powdered LMWC/siRNA complexes may become a promising tool to knock-down a specific gene expression in lung diseases such as bronchial asthma, COPD, and metastatic lung tumors.
Background: Protease inhibition has been shown to prevent development of fibrosis in several organs. Effects of protease inhibitors (PI) on lung fibrosis are controversial and cytoxic side effects of the inhibition of proteasomal degradation in the cell cannot be excluded.

Hypothesis: Administration of PI allows efficient drug delivery to the lung and prevents development of pulmonary fibrosis without systemic toxicity.

Methods and results: ONX0912 (ONX), a new irreversible PI was evaluated in comparison to bortezomib, the only FDA-approved PI, with regard to cytotoxicity and proteasomal inhibition in the cell line A549. Primary lung fibroblasts were isolated from proteasome reporter mice (ODD-luc) and characterized using MITT survival, and proteasome activity assays. The ODD-luc reporter accumulates upon proteasome inhibition and can be quantified by bioluminescence reflecting the actual degree of proteasome inhibition in the cell.

While bortezomib had strong cytoxic effects, ONX only partially inhibited the proteasome at low doses but efficiently blocked fibroblast function without affecting cell viability of fibroblasts or epithelia cells. An optimal nontoxic dose of ONX was obtained after intratracheal instillation into ODD-luc mice. This dose then was applied locally into the lung of ODD-luc mice with bleomycin induced fibrosis and therapeutic effects were investigated by histological analysis of the lungs.

Conclusion: ONX provides antifibrotic effects in murine lung fibroblasts in a non-toxic dose range. Local administration of ONX into the lungs partially inhibits the proteasome without toxic side effects and can be regarded as a promising approach to inhibit pulmonary fibrosis.

2810 Benefits of dual bronchodilution with QVA149 once daily versus placebo, indacaterol, NVA237 and tiotropium in patients with COPD: The SHINE study

Eric Bateeman 1, Gary T. Ferguson2, Neil Barnes 3, Nicola Gallagher 4, Yulia Green4, Rachael Horton 4, Michelle Henley4, Donald Banerji5.
1 Department of Medicine, University of Cape Town, South Africa; 2 Pulmonary Department, Pulmonary Research Institute of Southeast Michigan, Livonia, MI, United States; 3 London Chest Hospital, Barts Health NHS Trust, London, United Kingdom; 4 Respiratory Department, Novartis Research Centre, Horsham, United Kingdom; 5 Respiratory Department, Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

Background: QVA149 is a novel once-daily dual bronchodilator combining the LABA indacaterol and the LAMA NVA237 (glycopyronium) in development for COPD.

Methods: In a double-blind study, 2141 patients with moderate-to-severe COPD were randomized (2:2:2:1) to receive QVA149 110/50μg, indacaterol (IND) 150μg, NVA237 5μg (NVA), open-label tiotropium (TIO) 18μg or placebo (PBO), for 26 weeks. The primary endpoint was trough FEV1 with QVA149 vs IND, NVA and TIO at week 26.

Results: 89% patients completed the study. Trough FEV1 at Week 26 was significantly greater with QVA149 vs PBO, IND, NVA, TIO and mean difference (200, 70, 90 and 80mL, respectively; p<0.001). Significant improvement was also seen with QVA149 in other outcome measures evaluating lung function, dyspnea, health status and rescue medication use (table).

2811 Multidimensional approach to non-cystic fibrosis bronchiectasis. The FACED score

Miguel Angel Martinez-Garcia 1, Javier De Gracia-Roldán 2, Montserrat Vendrell-Relat 3, Rosa Girón 4, Luis Maiz 5, David de la Rosa 6, Casilda Olivera 7, 1 Pneumology Service, La Fe University Hospital, Valencia, Spain; 2 Pneumology Service, Vall Hebron University Hospital, Barcelona, Spain; 3 Pneumology Service, Josep Trueta University Hospital, Girona, Spain; 4 Pneumology Service, La Princesa University Hospital, Madrid, Spain; 5 Pneumology Service, Ramón y Cajal University Hospital, Madrid, Spain; 6 University Hospital of Bremen, Germany; 7 Pneumology Service, Carlos Haya University Hospital, Málaga, Spain

Background: The severity of non-cystic fibrosis (NCF) bronchiectasis cannot be adequately quantified by analyzing one single variable.

Objective: To develop and validate an easy-to-use multidimensional score that classifies the severity of bronchiectasis according to its prognosis.

Methods: Multicenter study in an initial cohort of 819 patients diagnosed with NCF bronchiectasis by HRCT scan. 397 subjects were selected at random (construction cohort) and 422 were the validation cohort. Outcome: 5-year all-cause mortality after diagnosis. From an initial set of 30 variables, those included in the final score were selected using a logistic regression analysis and dichotomized to facilitate the score’s interpretation.

Results: Mean age: 58.7 yrs (56% women).154 deaths during follow-up. The final 7-point calculated score (FACED score) incorporated 5 dichotomized variables (OR[95%IC]: FEV1; predicted % (F, cut-off point 50%; OR:5.2 [2.8-9.8]; maximum value:2 points); age (A, cut-off point: 70 yrs; OR: 4.9 [2.7-9.3]; maximum value:2); chronic colonization by P. aeruginosa (C, OR: 2.4 [1.3-4.6]; maximum value:1); radiological extension (E,n number of lobes affected; cut-off point at 2 lobes; OR:1.9 [1.3-3.5]; maximum value:1) and dyspnea (D, cut-off point at grade II on the MRC scale; OR:2.8 [1.5-5.2]; maximum value:1).No differences were found between the ABC-ROC (prognostic value) of the construction cohort: 0.87 [0.82-0.91] and validation cohort 0.83 [0.78-0.89]. All centers had an ABC-ROC>0.8.

Conclusions: This easy-to-use multidimensional grading system proved capable of accurately classifying the severity of bronchiectasis according to its prognosis.

2812 Clostridium difficile infection (CDI): Are junior doctors aware of risk factors and markers of severity?

Clara Addison, Tony Jordan. Respiratory Medicine, University Hospital North Staffordshire, Stoke-on-Trent, Staffordshire, United Kingdom

Introduction: There are approximately 20 000 cases of CDI in England per annum. Lower Respiratory Tract Infections are the main indication for antibiotic prescription. In order to reduce CDI, it is essential that doctors are able to identify patients at risk of CDI to facilitate appropriate antibiotic prescribing. 2 Trust’s clinical guidance on CDI informs on markers of severity but not risk factors. We sought to determine the level of knowledge of both among doctors based on a Respiratory ward including clinical guidelines as a conduit of knowledge.

Methods and results: Using a questionnaire 19 doctors and 5 fourth and fifth year medical students were asked to identify risk factors and markers of severity for CDI. 1st year doctors identified 36% of risk factors, 28% of severity markers; senior house officers 38% and 24%; registrars 47% and 21%; medical students 41% and 21%.

Conclusions: Knowledge of risk factors and severity markers for CDI amongst doctors and medical students on the Respiratory ward is poor. Clinical guidance is not a reliable conduit of knowledge. To raise awareness, information should be relayed more directly e.g. at induction.

2813 The respiratory microbiome in chronic obstructive pulmonary disease (COPD) exacerbations: Relationships with clinical characteristics

Bethan Barker, Mona Bafadhel, Koirobi Haldar, Ian Pavord, Mike Bater, Chris Braggitt. Institute for Lung Health, Department of Infection, Immunity and Inflammation, The University of Leicester, United Kingdom

Background: There has been recent interest in the significance of the respiratory microbiome in COPD.

Methods: Within an observational COPD study, spontaneous and/or induced sputum samples were collected from 283 patients at baseline and at exacerbation assessment. 16sRNA sequencing was performed on samples from the first exacerbation of 172 patients. The COPD exacerbation sample was compared to the baseline sample from each individual.

Conclusions: This study is the first to comprehensively profile the respiratory microbiome in the context of COPD exacerbation.
Admission glucose levels predict an adverse outcome in CAP in patients without known diabetes. Hence, acute hyperglycemia may identify patients particularly in need of intensified care to reduce mortality in CAP.

**Conclusion:** Long-term use of ICS in patients who develop CAP is associated with lower incidence and less severity of parapneumonic effusion regardless of the baseline chronic respiratory condition.

**Pulmonary immunostimulation with macrophage-activating lipopeptide-2 in influenza-A-virus infected mice increased survival of subsequent pneumococcal pneumonia.**

Karin Repp1, Peter Radinicz1, Thomas Tschernig1, Thorsten Wolf1, Achim Gruber4, Norbert Suttorp5, Martin Witzenrath1. 1Department of Infectious and Respiratory Diseases, Charité Berlin, Berlin, Germany; 2Institute of Anatomy and Cell Biology, Medical Faculty of the Saarland University, Homburg/Saar, Germany; 3Department of Infectious Diseases, Robert Koch Institute, Berlin, Germany; 4Institute of Veterinary Pathology, Freie Universität Berlin, Germany; 5Department of Respiratory Medicine, Maastricht University Medical Center, Maastricht, Netherlands

**Rationale:** Secondary bacterial infections in the course of seasonal influenza virus epidemics are associated with high morbidity and mortality, and Streptococcus pneumoniae is the most prevalent causal pathogen. Local immunosuppression due to pulmonary influenza virus infection has been discussed as major cause in the pathogenesis of secondary bacterial lung infection. Thus, specific local stimulation of the pulmonary innate immune system might improve host defense against secondary bacterial pathogens.

**Methods:** Influenza-AH1N1/PR/09/04-virus infected female C57BL/6 mice received the TLR-2 ligand macrophage-activating lipopeptide-2 (MALP-2) intra-tracheally 24h prior to transnasal infection with S. pneumoniae.

**Results:** Intratracheal application of MALP-2 increased pro-inflammatory cytokine and chemokine release and enhanced recruitment of leukocytes, mainly neutrophils in the alveolar space of influenza virus infected mice. After secondary pneumococcal infection, Influenza-A-virus infected mice pretreated with MALP-2 showed increased survival rates compared with untreated influenza infected mice. Notably, levels of pro-inflammatory cytokines and leukocytes were comparable in bronchoalveolar lavages of virus infected mice treated with MALP-2 and untreated infected controls. Further, MALP-2 significantly reduced bacterial numbers in the lung tissue without changing pulmonary viral load.

**Conclusion:** Local immunostimulation with MALP-2 in influenza virus infected mice improved pulmonary bacterial elimination and increased survival in secondary pneumococcal pneumonia.

**Safety and pharmacokinetics of two dose strengths of ciprofloxacin dry powder for inhalation (DPI) in patients with moderate to severe COPD.**

Heiko Stass1, Johannes Nagelschmidt2, Henrik Watz2, Anne Marie Karsten1. 1Clinical Pharmacology, Ruhr University, Bochum, Germany; 2Pulmonary Research Institute (PRI), Hospital Grosshansdorf, Germany

**Introduction:** Ciprofloxacin dry powder for inhalation (DPI), formulated using Novartis' PulmoSphere™ technology for pulmonary delivery via a T-326 inhaler, is under investigation in various respiratory tract disorders.

**Aim:** To compare the safety and PK of two dose strengths of ciprofloxacin DPI in patients with COPD.

**Methods:** In a randomized, phase I, double-blind, crossover study, 12 (8m/4f) adults with GOLD stage II or III COPD received a single dose of 32.5 mg and 48.75 mg ciprofloxacin DPI (corresponding to 50 mg and 75 mg dry powder, respectively). The washout period was 7–14 days between doses.

**Results:** There were no severe or serious AEs nor clinically relevant differences in incidence or severity of AEs between the doses, most being mild. Drug related AEs (bitter taste) occurred in 7 and 6 patients after 32.5 mg and 48.75 mg ciprofloxacin DPI, respectively. The PK (Table) was similar to previous studies, showing high and variable lung exposure at low systemic exposure.

*a Geometric means/SCV. AUC(0–∞)-Cmax t1/2 tmax, h, median.

**Conclusions:** Ciprofloxacin DPI was well tolerated in patients with moderate chemistry and microbiological variables. Patients were classified whether they received prior long term ICS treatment or not.

**Results:** 659 patients (18%) were treated with ICS before diagnosis of CAP (ECOPD: 56%). Long-term use of ICS was significantly associated with less incidence of parapneumonic effusion compared to those without prior ICS treatment 5% vs. 12%, p<0.001. Multivariate analysis adjusted by sex, age, comorbidities and CAP severity showed a significant association between ICS treatment and lower incidence of pleural effusion (OR 0.42 (95% CL 0.28-0.64, p<0.001). Prior treatment with ICS was significantly associated with lower incidence of empyema compared to those without treatment (5% vs 16%, p<0.001).

**Conclusions:** Long-term use of ICS in patients who develop CAP is associated with lower incidence and less severity of parapneumonic effusion regardless of the baseline chronic respiratory condition.

*a Geometric means/SCV. AUC(0–∞)-Cmax t1/2 tmax, h, median.

**Conclusions:** Ciprofloxacin DPI was well tolerated in patients with moderate
to severe COPD with no clinically relevant differences between the two dose strengths. Increased systemic exposure from the 48.75 mg dose was not matched by increased lung exposure. PK data indicate that the lower dose produced similar drug concentrations in the lung, with less powder inhaled.

T cells in peripheral blood during viral acute exacerbation of COPD

Maria Inés Vargas-Rojas1, Alejandra Ramírez-Venegas1, Leonardo Linomi-Camacho2, Oliver Pérez-Bautista1, Helena Solleiro-Villavicencio1, Raúl H. Samores1. 1Department of Research in Smoking and COPD, Instituto Nacional de Enfermedades Respiratorias “Ismael Cosío Villagrán”, Mexico, D.F, Mexico; 2Rheumatology, Hospital Central Norte PEMEX, México, D.F, Mexico

Introduction: Exacerbations in COPD patients increase premature mortality. The main cause of AECOPD are viral infections however, the type of predominant cellular immune response is unknown. Objective: To quantify the T cell subpopulations in peripheral blood of patients with viral AECOPD and compare them with patients in a stable disease (COPD) and healthy controls (HC).

Methods: We included 82 patients from the cohort of COPD Clinic, between May 2009 and December 2011. 49 of them were exacerbated and we included 19 HC. Viral diagnosis was performed by using real-time PCR and we used flow cytometry to determine T-cell subpopulations. Differences between groups were evaluated by Kruskal-Wallis and we performed a post-hoc U-Mann-Whitney test.

Results: 26 patients (53%) had a viral exacerbation (Influenza A 54%, Coronavirsus 14%, Influenza B 7%, RSV 7%, H1N1 7%, MPV 4%). In these patients predominated the Th1 response 8.6 (6.2-11) versus COPD 2.5 (1.3-4.29) and HC 1.2 (0.8-1.4) p<0.0001. The TCR8 response has a predominance of Th1 AECOPD 11.2 (7.1-13), COPD 2.8 (1.9-4.2) and HC 1.0 (0.5-2.2) p<0.0001 and Tc1 AECOPD 7.6 (4.1-10), COPD 1.7 (1.1-2.8), HC 1.1 (0.8-1.2) p<0.0001.

Conclusions: Our data show a polarization Th1, Tc1, Tc2 and Tc17 in AECOPD patients suggesting the involvement of these populations in the cellular immune response during viral infections. We did not find a higher prevalence of H1N1 infections in patients in the cohort.

308. Idiopathic pulmonary fibrosis

2819

Phase 2 trial of FG-3019, anti-CTGF monoclonal antibody, in idiopathic pulmonary fibrosis (IPF): Preliminary safety and efficacy results

Ganesh Raghu1, Mary Beth Scholand2, Joao de Andrade3, Lisa Lancaster4, Jonathan Goldin5, Seth Porter6, Thomas Neff6, Frank Valone6, John Stauffer6. 1Department of Medicine, Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, WA, United States; 2Department of Medicine, Pulmonary Division, University of Utah, Salt Lake City, UT, United States; 3Department of Medicine, Division of Pulmonary, Allergy and Critical Care Medicine, University of Alabama at Birmingham, AL, United States; 4Department of Medicine, Division of Allergy, Pulmonary, and Critical Care Medicine, Vanderbilt University, Nashville, TN, United States; 5Department of Radiology, Duke University School of Medicine, Durham, NC, United States; 6Department of Medicine, Medical University of South Carolina, Charleston, SC, United States; 7Department of Medicine, Assistance Publique-Hôpitaux, Paris, France; 8Department of Medicine, Imperial College, London, United Kingdom

Introduction: FG-3019 is a novel anti-fibrotic agent, is well tolerated by subjects with IPF. No drug-related SAEs have been reported to date. Promising results of measurement of quantified lung fibrosis scores and FVC warrant pursuing the clinical trial with a higher dose of FG-3019 to further assess safety and efficacy in subjects with IPF.

Methods: A randomised, double-blind, placebo-controlled, Phase 2 prospective, open label study of FG-3019 (15 mg/kg IV every 3 weeks for 45 weeks) in subjects with well-defined IPF (duration ≥5 years, evidence of disease progression during the preceding year, FVC ≥50% predicted, DLCO ≥30% predicted, and 10–50% parenchymal fibrosis by HRCT). Treatment response was assessed by changes in extent of parenchymal disease (HRCT and FVC).

Results: 54 subjects (males 83%, mean age 67 years, median FVC % predicted 63.2%) were enrolled. Quantified HRCT scores of whole lung fibrosis (QLF) and all abnormal interstitial lung disease (QILD) at week 24 showed decreases from baseline greater than analytical variability (2.2%) in 6 (24%) and 8 (32%) of 25 subjects, respectively. Changes in both QLF and QILD score were significantly correlated with changes in FVC % predicted (for QILD, r=0.55, p<0.004). Mean decreases in FVC % predicted were less than in historical controls. Safety findings to date include 13 SAEs (none drug-related), 1 acute exacerbation, 9 respiratory-related hospitalizations, and 3 deaths (all related to IPF).

Conclusions: FG-3019, a novel anti-fibrotic agent, is well tolerated by subjects with IPF. No drug-related SAEs have been reported to date. Promising results of measurement of quantified lung fibrosis scores and FVC warrant pursuing the clinical trial with a higher dose of FG-3019 to further assess safety and efficacy in subjects with IPF.

2820

Analysis of lung function and survival in RECAP: An open-label extension study of pirfenidone (PFD) in patients with idiopathic pulmonary fibrosis

Ulrich Costabel1, Carlo Albera2, Williamson Bradford3, Phil Hormel3, Talmadge King4, Paul Noble5, Steven Sahn6, Dominique Valeyre7, Roland du Bois4. 1Pneumologie/Allogre, Ruhlandlink, Essen, Germany; 2Clinical and Biological Sciences, University of Turin, Italy; 3Clinical Research, InterMune Inc., Brisbane, CA, United States; 4Department of Medicine, University of California San Francisco, CA, United States; 5Department of Medicine, Duke University School of Medicine, Durham, NC, United States; 6Department of Medicine, Medical University of South Carolina, Charleston, SC, United States; 7Department of Medicine, Assistance Publique-Hôpitaux, Paris, France; 8Department of Medicine, Imperial College, London, United Kingdom

Introduction: RECAP is an open-label extension study evaluating long-term treatment with PFD in IPF patients who completed one of the CAPACITY (CAP) trials.

Objective: Further examine the effect of PFD on lung function and survival in patients with IPF.

Methods: PFD 2403 mg/dL was administered orally in 3 equally divided doses. Forced vital capacity (FVC) was measured at baseline and Wks 12, 36, and 60. To facilitate comparison with CAP outcomes, analyses were based on patients newly-treated with PFD in RECAP who had baseline FVC and DLco values that met CAP entry criteria.

Results: A total of 178 patients were newly-treated with PFD in RECAP and had baseline values that met CAP entry criteria. The mean change from baseline to Wk 60 in %FVC was ~5.8%, median survival was ~7.0% in the PFD group (N=345) and ~9.4% in the placebo group (N=347). The percentage of patients with an FVC decline ≥10% was 16.6% in RECAP, compared with 16.8% and 24.8%, respectively, in the PFD and placebo groups in CAP. Overall survival in newly-treated patients in RECAP was similar to that of PFD patients in CAP (Figure 1).

Conclusions: FVC and survival outcomes in IPF patients newly treated with PFD in RECAP were similar to those in PFD-treated patients in CAP. These data provide further evidence to support the use of PFD in patients with IPF.

2821

Combined pulmonary fibrosis and emphysema: A distinct entity?

Dong Kyun Oh1, Jinn Woo Song1, Kyung-Hyun Do2, Sung Min Lee2, Dong Soon Kim1. 1Department of Pulmonary and Critical Care of Medicine, Asan Medical Center, University of Ulsan, College of Medicine, Seoul, Korea; 2Department of Radiology, Asan Medical Center, University of Ulsan, College of Medicine, Seoul, Korea

Introduction: Although combined pulmonary fibrosis and emphysema (CPFE) syndrome has been proposed as a distinct entity, it is controversial.

Figure 1. Kaplan-Meier estimates of overall survival.

Conclusions: FVC and survival outcomes in IPF patients newly treated with PFD in RECAP were similar to those in PFD-treated patients in CAP. These data provide further evidence to support the use of PFD in patients with IPF.
2822

Extent of fibrosis by high-resolution computed tomography does not improve prediction of mortality in idiopathic pulmonary fibrosis when added to a simple clinical prediction model

Breit Lect 1, Erci Vittinghoff 2, Brett M. Elicker 3, Thomas E. Hartmann 4, Talmadge E. King Jr. 5, Harold R. Collard 1, 6, Medicine, University of California, San Francisco, CA, United States; 2Epidemiology and Biostatistics, University of California, San Francisco, CA, United States; 3Radiology, Mayo Clinic, Rochester, MN, United States; 4Medicine, Mayo Clinic, Rochester, MN, United States; 5Pathology, University of California, San Francisco, CA, United States

Background: We previously reported a simple clinical prediction model for mor-
tality (the GAP model) in idiopathic pulmonary fibrosis (IPF). Gender, age and Physiology (forced vital capacity and diffusion capacity for carbon monoxide) were used to assess reliability. Models were based on competing-risks regression for mortality, transplanting as a competing risk. Predictive performance of the GAP model and GAP + fibrosis score (GAP-FS) model was compared by the C-index, net reclassification improvement (NRI), and clinical NRI (cNRI).

Results: We included two of three cohorts used to develop the GAP model (n=354). All patients had HRCTs available within 1 year of baseline. Two radiologists (JH, B.E.) scored fibrosis on HRCCT using the modified Proposal for the International Multidisciplinary Classification of IPF. A score of 0 to 3 was assigned in 25 cases. Both radiologists had 85% agreement for fibrosis score. A higher fibrosis score was associated with shorter survival on unadjusted analysis (HR=0.96, 95% confidence interval [CI] 0.94 to 0.97). However, in both groups, diffusion capacity for carbon monoxide was a sole determinant of survival. We evaluated the additive predictive value of fibrosis score to the GAP model for IPF. Methods: We included two of three cohorts used to develop the GAP model (n=354). All patients had HRCTs available within 1 year of baseline. Two radiologists (JH, B.E.) scored fibrosis on HRCCT using the modified Proposal for the International Multidisciplinary Classification of IPF. A score of 0 to 3 was assigned in 25 cases. Both radiologists had 85% agreement for fibrosis score. A higher fibrosis score was associated with shorter survival on unadjusted analysis (HR=0.96, 95% confidence interval [CI] 0.94 to 0.97). However, in both groups, diffusion capacity for carbon monoxide was a sole determinant of survival. We evaluated the additive predictive value of fibrosis score to the GAP model for IPF. Results: C-index, net reclassification improvement (NRI), and clinical NRI (cNRI) were used to assess reliability. Models were based on competing-risks regression for mortality, transplanting as a competing risk. Predictive performance of the GAP model and GAP + fibrosis score (GAP-FS) model was compared by the C-index, net reclassification improvement (NRI), and clinical NRI (cNRI).

Conclusion: When added to a simple clinical prediction model, extent of fibrosis from HRCCT does not improve prediction of mortality in IPF.

2823

Recombinant thrombomodulin improves survival in acute exacerbation of idiopathic pulmonary fibrosis

Hiroshi Taniuchi 1, Yasuhiro Kondoh 2, Tomoki Kimura 2, Kensuke Kataoka 2, Dept. of Respiratory Medicine and Allergy, Tosei General Hospital, Seto, Aichi, Japan

Background: Acute exacerbations of idiopathic pulmonary fibrosis (AE-IPF) are episodes of acute respiratory worsening caused by unknown etiology with high short-term mortality. The presence of disordered coagulation and endothelial dam-
age in AE-IPF has been reported. Recombinant human soluble thrombomodulin (rTM) binds to thrombin to inactivate coagulation, and the thrombin-rTM com-
plex activates protein C to produce activated protein C. The purpose of this study is to examine the efficacy of rTM for treating patients with AE-IPF.

Methods: Patients with AE-IPF in our hospital from 2006 to 2011 were enrolled. AE-IPF was defined using the revised Japanese criteria for AE-IPF (Eur Respir J. 2010;35[4]:821-9). All patients received corticosteroid pulse therapy and immunosuppressant (cyclosporine 3mg/kg/day, p.o). NPPV was the first line intervention. AE-IPF was defined using the revised Japanese criteria for AE-IPF (Eur Respir J. 2010;35[4]:821-9). All patients received corticosteroid pulse therapy and immunosuppressant (cyclosporine 3mg/kg/day, p.o). NPPV was the first line intervention. AE-IPF was defined using the revised Japanese criteria for AE-IPF (Eur Respir J. 2010;35[4]:821-9). All patients received corticosteroid pulse therapy and immunosuppressant (cyclosporine 3mg/kg/day, p.o). NPPV was the first line intervention. AE-IPF was defined using the revised Japanese criteria for AE-IPF (Eur Respir J. 2010;35[4]:821-9). All patients received corticosteroid pulse therapy and immunosuppressant (cyclosporine 3mg/kg/day, p.o). NPPV was the first line intervention.

Conclusion: In this prospective study the use of the TLC may allow to identify a pathological pattern in patients with clinical and radiographic features compatible with fibrosing DPLD and/or chronic Idiopathic Interstitial Pneumonia (IPF).

Results: Biopsies obtained from 40 patient s were evaluated. Adequate cryobiop-
sies have been shown to be useful for obtaining more large biopsy samples of lung parenchyma bronchoscopically in patients with DPLD. Objective: The purpose of this prospective study was to identify the pathological pattern by transbronchial lung cryobiopsy (TLC) using flexible cryoprobes in patients with clinical and radiographic features compatible with fibrosing DPLD and/or chronic Idiopathic Interstitial Pneumonia (IPF).

Background: Specimens from transbronchial lung biopsies lack sufficient quality due to crush artifact and are generally too small to identify any pathological pat-
tern for diagnosis of fibrosing diffuse parenchymal lung disease (DPLD). Flexible cryoprobes have been shown to be useful for obtaining more large biopsy samples of lung parenchyma bronchoscopically in patients with DPLD.

Objective: The purpose of this prospective study was to identify the pathological pattern by transbronchial lung cryobiopsy (TLC) using flexible cryoprobes in patients with clinical and radiographic features compatible with fibrosing DPLD and/or chronic Idiopathic Interstitial Pneumonia (IPF).

Results: Biopsies obtained from 40 patients were evaluated. Adequate cryobiop-
sies were available in 39 of 40 patients. The average size of cryobiopsy was 6.0 x 4.2 mm. Crush artifacts were not seen. In 34 cases (85%) TLC identified a pathological pattern and contained features to suggest a Usual Interstitial Pneu-
monia pattern (ie. at least 2 of three pathologic features of UIP present, ie. patchy interstitial fibrosis, fibroblast foci and/or honeycomb changes) in 21 cases; Non-
specific Interstitial Pneumonia pattern in 8 cases; Organizing Pneumonia pattern in 2 cases; Desquamative Interstitial Pneumonia pattern in 1 case; Eosinophilic Pneumonia pattern in 1 case; bronchiolitis pattern in 1 case. In 6 cases (15%) a pathological pattern was not identified.

Conclusions: In this prospective study the use of the TLC may allow to identify a pathological pattern in patients with clinical and radiographic features compatible with fibrosing DPLD and/or chronic IPF.

2826

Late stage of experimental pulmonary fibrosis is modulated by collagen V

Alexandre Todorovic Fabro 1, Nazar Malinak 2,3,4,5, Marco Sucina 6,7,8,9, José Antonio Maclaren 7,8,9, Amilcar Romagnoli 7,8,9, Claudio Ravaglia 1,2, Carla Gurioli 1,2, Vittorio Pietrangeli 1,2,3, Eberardo Coimbra 2,3,4,5,6,7,8,9, Christopher J. Ryerson 5,6,7, Jay H. Ruddy 5,6,7, Joyce S. Lee 5,6,7, Kirk D. Jones 7,8,9, Talmadge E. King Jr. 5, Harold R. Collard 1, 6, Medicine, University of California, San Francisco, CA, United States; 2Epidemiology and Biostatistics, University of California, San Francisco, CA, United States; 3Radiology, Mayo Clinic, Rochester, MN, United States; 4Medicine, Mayo Clinic, Rochester, MN, United States; 5Pathology, University of California, San Francisco, CA, United States

Objectives: To investigate whether the combined pulmonary fibrosis and emphy-
sema has different prognosis and prognostic factors from pure idiopathic pulmonary fibrosis.

Methods: Clinical data and high resolution computed tomography images of 300 patients with idiopathic pulmonary fibrosis were retrospectively reviewed. The extent of emphysema and fibrosis were scored and the patients with moderate to severe emphysema (grade 2) were categorized as combined disease group.

Results: Seventy five (25.0%) patients had combined disease and the survival period was not significantly different from isolated idiopathic pulmonary fibrosis (n=200). In both groups, survival period was significantly correlated with fibrosis score, but not with emphysema score. In isolated idiopathic pulmonary fibrosis group and also all patient group, forced vital capacity and fibrosis score were predictors for mortality on multivariate analysis. In combined disease group, pulmonary hypertension was more frequent and an independent prognostic factor. However, in both groups, diffusion capacity for carbon monoxide was a sole determinant of pulmonary hypertension, suggesting the combined effect of both fibrosis and emphysema in the development of pulmonary hypertension (ICCI).

Conclusions: The combined pulmonary fibrosis and emphysema seems to be co-morbidity with similar survival period rather than a distinct disease entity.

Introduction: A subset of patients with IPF present with abnormal auto-antibodies (AA) without clinical features sufficient to diagnose connective tissue disease (CTD). CTD-associated ILD is generally associated with a better prognosis than IPF.

Aims: To study the prevalence and significance of abnormal AAs in IPF.

Methods: Consecutively presenting patients with suspected IPF between 1/1/02 and 12/31/12 were prospectively recruited to a database. All IPF diagnoses required exclusion of overt CTD and an HRCT appearance of UIP with ≥ 70% probability. Patients with HRCT scans with ≥ 95% probability of UIP, or a confirmatory surgical lung biopsy were defined as definite IPF. The remainder were defined as probable IPF. Abnormal AA profile was defined as the presence of at least one of: RHF ≥ 40, ANA >1/640 and/or positive specific ENA screen. Patients were followed-up until Dec 2011 (median [IQR] among survivors 45 [25-63] months). Of 233 patients recruited, 25 did not have AAs performed within 12 months of presentation and were excluded. Of the 208 patients reported, 95 had definite IPF: AAs were abnormal in 18% of patients. Definite v probable IPF, gender, age, smoking and baseline lung function were similar for normal and abnormal AA groups. Only 3 patients developed overt CTD and all had abnormal AAs. Median survival was lower in those with abnormal AAs (30 v 69 months); unadjusted HR 1.57 [0.97 to 2.53] p=0.07; adjusted for age, sex, baseline VC, smoking and definite/probable IPF: HR 1.69 [1.03 to 2.78] p=0.04.

Conclusions: Only 1% of all IPF patients developed overt CTD. Abnormal AA serology was associated with a poorer survival.
these models tend to go for the resolution of the fibrosis, but in different degrees of intensity depending on the strain. Thus these mechanisms in certain strains may participate in the progression of PF.

**Methods:** We used the models of Bleomycin-Balb/c (BLM), Paracut-Balb/c, Bleomycin-C57BL/6 and BLM-IL17RA-KO-C57BL/6. We analyzed the amounts of total collagen (TC) and collagen V (Col5) through the morphometric evaluation by the picrosirius and IF. These data were validated by RT-PCR of Col5.

**Results:** The peribronchiolar TC by PPM did not differ between the treated groups, but the peripheral interstitial TC was higher in the C57BL/6, independent of the absence of IL-17RA. The protein expression of Col5 was higher in IL-17RA-KO (75.8±9% X 52.7±13%; p<0.01) and lower in BLM-Balb/c (68.9±3.4% X 53.3±14.3%; p<0.05). Likewise, the gene expression of Col5 was also higher in the IL17RA-KO (p<0.0485) and lower in the BLM-Balb/c (p<0.0037) (Figure 1).

**Conclusion:** The perpetuation of PF in fibrosis-susceptible mice is related to the IL17RA-KO (p<0.0485) and lower in the BLM-Balb/c (p<0.0037) (Figure 1).

**2827**

Right atrial enlargement and prognosis in the hemodinamically stable pulmonary embolism

**Introduction:** The Right-Atrium (RA) is easily accessible from the apical 4-chamber view (4Cv) and its enlargement is easily verifiable.

**Aims:** To study if RA enlargement is associated with increased short-term mortality in patients with acute symptomatic hemodynamically stable PE.

**Methods:** The RIBETE Registry is international registry of patients with symptomatic acute VTE. Patients diagnosed of hemodynamically stable PE were included in the current study. RA enlargement was considered if the RA End-Systolic (ES) area in the apical 4Cv was greater than the Left Atrium ES area. Right Ventricle/Left Ventricle (RV/LV) ED ratio and RV dyskinesia were also determined.

**Conclusion:** The presence of RA enlargement is significantly associated with mortality from all causes during the first month after diagnosis. This association is particularly strong with mortality caused by PE itself. Compared to patients with normal RA, the risk of dying from PE during the first month is 4 times higher in patients with RA dilatation.

A novel echo-score for evaluating the pre-test probability of pre-capillary versus post-capillary pulmonary hypertension

Michele D’Alto, Emanuele Romeo, Paola Argiento, Anna Corerra, Berardo Sarubbi, Maria Pignatello, Antonietta Caronna, Nicola Grimaldi, Raffaele Calabrò, Maria Giovanna Russo. Cardiology, Second University of Naples, Monaldi Hospital, Naples, Italy

**Aims:** To provide an echo-score for evaluating the pre-test probability of pre-capillary (pre-PH) vs post-capillary (post-PH) pulmonary hypertension (PH).

**Methods:** One hundred thirty-five consecutive patients underwent Doppler echocardiography (DE) within 1 hour of a clinically indicated right heart catheterization (RHC). The DE was scored on the basis of features suggesting pre-PH: right atrium (RA) > left atrium (LA), right ventricle (RV) > left ventricle (LV), apex forming RV, LV eccentricity index (EI) <0.9, pericardial effusion (PE), systolic notch at right ventricular outflow tract (RVOT), dilated and fixed inferior cava vein (ICV) (yes = 1, no = 0), or post-PH: LV ejection fraction (EF) <40%, moderate/severe aortic and/or mitral disease (yes = 1, no = 0). Patients were divided in 3 groups: low score (-2 to 0), medium score (1 to 2) and high score (3 to 7).

**Results:** Twelve/135 patients did not have PH at RHC; 84 showed pre-capillary PH (54 group 1) and 39 post-capillary PH (group 2). The probability of pre-PH was 37% in presence of low, 86% in presence of medium and 95% in presence of high echo-score. LV-EF <40% had 100% specificity for post-PH. The majority of echo features showed an high specificity but a low sensitivity for pre-PH.

**Conclusion:** RHC remains the gold standard for the diagnosis of PH. Nevertheless, a novel easy and integrated echo-score provides a good pre-test probability of having a pre-capillary rather than post-capillary PH.
Methods and results: We monitored steady flow parameters (pulmonary vascular resistance (PVR), steady flow parameters (PVG) and pulmonary vascular pressure gradient (PVG) in dependent PH patients). Pulmonary vascular pressure gradient (PVG) is a dependent PH-specific treatment.

Conclusions: ADMA correlates with the hemodynamic benefit of PH-specific treatment in patients with PH of various etiologies. ADMA can serve as a biomarker for the effect of PH-specific treatments.

2832 Respiratory event hospitalizations are reduced in heart failure patients with comorbid chronic obstructive pulmonary disease using a wireless implanted pulmonary artery pressure monitoring system

Introduction: Respiratory event hospitalizations (REH) from COPD exacerbations, bronchitis, pneumonia, and other respiratory events frequently occur in patients with heart failure (HF). Pulmonary artery pressure (PAP) monitoring and treatment has been shown to reduce heart failure hospitalizations.

Methods: The CHAMPION trial enrolled 550 patients with NYHA class III HF who were followed for an average of 15 months. In all patients PAP data were monitored using a novel, implantable hemodynamic system. In the treatment group, patients received PAP data to guide therapy decisions in addition to standard of care versus standard of care alone in the control group.

Results: REH rates were higher in the COPD subgroup compared to the entire CHAMPION cohort. In the COPD subgroup (91 treatment vs. 96 control), treatment experienced a 62% reduction in REH rates (0.12 vs. 0.31, HR 0.38, 95% CI 0.21-0.71, p=0.0023, Anderson-Gill). In the CHAMPION cohort (270 treatment vs. 280 control), treatment experienced a 49% reduction in REH rates (0.07 vs. 0.14, HR 0.51, 95% CI 0.44-0.81, p=0.0009).

Conclusions: Treating HF patients with an implantable hemodynamic monitoring system significantly reduced REH in all patients with even greater benefit in COPD patients. Further investigations that analyze the relationship between PAP, COPD, and REH in chronic HF patients and its implication towards new treatment strategies are warranted.

2833 Pulmonary vascular gradient: A predictor of prognosis in pulmonary hypertension due to left heart disease

Christiane Greger1, Mario Greger1, Marie Lang1, Harald Heinz2, Yuhui Zhang2, 3, Peter Probst1, Gerald Maurer1, Irene Lang1. 1Internal Medicine II, Division of Cardiology, Medical University of Vienna, Austria; 2Cardiology, University of Alabama at Birmingham, AL, United States; 3Cardiology, Allegheny General Hospital, Pittsburgh, PA, United States; 4Cardiology, Ohio State University, Columbus, OH, United States; 5Cardiology, Oklahoma Heart Institute, Oklahoma City, OK, United States; 6Clinical Research, CardioMEMS, Inc., Atlanta, GA, United States; 7Pulmonary and Critical Care Medicine, Temple University Health System, Philadelphia, PA, United States

Purpose: Pulmonary hypertension (PH) is defined by a mean pulmonary artery pressure (mPAP) ≥25mmHg. The disease can be further classified into pre-capillary pulmonary wedge pressure, PCWP ≤15mmHg) and post-capillary PH (PCWP >15mmHg). The driving pressure across the pulmonary circulation is often referred to as the transpulmonary gradient (TPG). In the current guidelines post-capillary PH with a TPG >12mmHg is labeled as “out-of-proportion” PH, as opposed to what is labeled as “passive” PH, i.e. PH as the consequence of elevated left ventricular filling pressures. The TPG can be determined non-invasively using Doppler echocardiography. The TPG is a strong and independent predictor of mortality and morbidity in PH.

Methods: The CHAMPION trial enrolled 550 patients with NYHA class III HF who were followed for an average of 15 months. In all patients PAP data were monitored using a novel, implantable hemodynamic system. In the treatment group, patients received PAP data to guide therapy decisions in addition to standard of care versus standard of care alone in the control group.

Results: REH rates were higher in the COPD subgroup compared to the entire CHAMPION cohort. In the COPD subgroup (91 treatment vs. 96 control), treatment experienced a 62% reduction in REH rates (0.12 vs. 0.31, HR 0.38, 95% CI 0.21-0.71, p=0.0023, Anderson-Gill). In the CHAMPION cohort (270 treatment vs. 280 control), treatment experienced a 49% reduction in REH rates (0.07 vs. 0.14, HR 0.51, 95% CI 0.44-0.81, p=0.0009).

Conclusions: Treating HF patients with an implantable hemodynamic monitoring system significantly reduced REH in all patients with even greater benefit in COPD patients. Further investigations that analyze the relationship between PAP, COPD, and REH in chronic HF patients and its implication towards new treatment strategies are warranted.

2831 Asymmetric dimethylarginine, a biomarker for the effects of drug therapy in pulmonary hypertension

Nika Skore-Sagi1, 2, Stefan Aschauer3, Michael Wolter1, Irene Lang1. 1Department of Internal Medicine II, Division of Cardiology, Vienna General Hospital, 2Medical Statistics, 3Clinical Pharmacology, Vienna General Hospital, Medical University of Vienna, Austria

Rationale: Asymmetric dimethylarginine (ADMA), a potent endogenous nitric oxide synthase inhibitor, is increased in pulmonary hypertension (PH), and associated with unfavorable outcome. We hypothesized that plasma ADMA may serve as a biomarker to monitor disease progression under PH-specific treatment.

Methods: ADMA was measured at baseline and at least after 24 weeks of treatment in consecutive patients (pts) under advanced PH-targeted treatments. Treatment responders were defined by decrease of pulmonary vascular resistance (PVR) of at least 200% at time point of 5-6 walking distance > 300m, and improvement of WHO at follow-up and were compared with non-responders.

Results: 51 consecutive patients (44 pts with pulmonary arterial hypertension and 7 patients with PH due to lung disease) were enrolled in this study. According to our definition, there were 16 non-responders, and 23 responders to treatments. 11 patients showed no change. ADMA plasma levels did not change significantly under treatment in the whole group. There was a significant drop of ADMA in responder group (p <0.0001). Furthermore, ADMA change in responders and nonresponders was significantly different (p=0.003).

The decrease of ADMA correlated with the decrease of PVR (p=0.56, p<0.0001), with the decrease of mean pulmonary arterial pressure (p=0.44, p=0.001). Furthermore, the difference of ADMA correlated with the increase of cardiac index (r=0.38, p=0.005) and improved venous saturation (r=0.37, p=0.03).

Conclusions: ADMA parallels the hemodynamic benefit of PH-specific treatment in patients with PH of various etiologies. ADMA can serve as a biomarker for the effect of PH-specific treatments.

2830 Hemodynamic assessment of pulmonary hypertension in grown-up congenital heart disease

Mario Greger, Christian Greger, Marie Lang, Irene Lang. Internal Medicine II, Division of Cardiology, Medical University of Vienna, Austria

Purpose: Pulmonary arterial hypertension (PAH) associated with congenital heart disease (CHD) is included in group I of the pulmonary hypertension (PH) clinical classification system. The persistent exposure of the pulmonary vasculature to increased blood flow due to systemic-to-pulmonary shunts as well as increased pressure may result in a typical pulmonary arteriopathy that leads to an increase in invasively measured mean pulmonary arterial pressure (mPAP) ≥25mmHg at rest.

Methods: 3107 right and left heart catheterizations were analyzed. Diagnoses were validated on the grounds of patient histories, imaging, clinical data and patho-anatomic evidence (2369 complete datasets). 257 data sets were from patients with CHD.

Conclusions: Steady flow parameters (PVR, SCA and PVG) assessed immediately (immediate) after PEA in 110 consecutive patients, who were followed for 34.5 (11.9, 78.3) months. The quantity of extracted vascular obstructions were expressed as the total number and total length of small-vessel thrombus appendages, and correlated inversely with immediate postoperative PVR (p <0.0001, p =0.566; p<0.0001, r=−0.58). Cox regression analysis revealed only steady flow parameters (PVR, SCA and PVG) predicted of long-term survival/freedom of lung transplantation (p<0.0001, p=0.02, p=0.04).

Patients with immediate PVR <59 dynes·s·cm−5 or SCA <26.5mmHg or PVG <21.5mmHg had a better long-term outcome (Logrank tests: p<0.0001, p=0.0006, p<0.0001).

Conclusion: The data demonstrate that a significant proportion (almost 50%) of patients with PH in grown-up congenital heart disease suffer from post-capillary pulmonary hypertension.
Effects of exercise training and neuromuscular electrical stimulation on symptoms, muscle strength, exercise capacity, activities of daily living, and quality of life in COPD
Filipe Tasdemir1, Deniz Inal-Ince2, Pinar Ergun1, Dicle Kayzam1, Nese Demir1, Ebru Demir1, Nurcan Ergoç1, 1Division of Pulmonaries Rehabilitation and Home Care, Atatürk Chest Diseases and Thoracic Surgery Training and Research Hospital, Ankara, Turkey; 2Department of Physiotherapy and Rehabilitation, Hacettepe University, Faculty of Health Sciences, Ankara, Turkey
Purpose: Chronic obstructive pulmonary disease (COPD) have systemic consequences affecting exercise capacity and quality of life. The purpose of this randomized controlled study was to evaluate effects of neuromuscular electrical stimulation (NMES) on symptoms and function in COPD patients undergoing exercise training.
Materials and methods: Twenty-seven clinically stable COPD patients (62.6±7.5 years, FEV1 40.0±16.4%) were included. The NMES group (n=13) underwent endurance and quadriiceps resistance training plus NMES, 2 days/week for 10 weeks. Control group (n=14) was applied the same exercise regimen plus placebo NMES. Increased ISWT distance in the control group was significantly more than that of NMES group (62.8±33.6 m vs. 38.46±14.80 m, p<0.05). There were no significant differences in any of the other parameters (p>0.05). Conclusion: Increase in exercise capacity was more evident when endurance and quadriiceps resistance training was applied without NMES. Inclusion of NMES have no additional effects beyond exercise training on muscle strength, symptoms, activities daily living, and quality of life in stable COPD.

310. Exercise and physical activity: towards evidence-based benefits in different populations

Exercising training is beneficial in patients with non-cystic fibrosis bronchiectasis – A multi-centre, randomised controlled trial
Annamarie Lee1,2,3, Catherine Hill1,4, Nola Ceca5,6,7,8,7 Sue Jenkins1,6,8
Christine McDonald1,5, Angela Burge1, Linda Raunkla1, Robert Stratling2, Philip Thompson9,10, Anne Holland9,11, 1Physiotherapy, Alfred Health, Melbourne, VIC, Australia; 2Clinic for Breathing and Sleep, Austin Health, Melbourne, VIC, Australia; 3Institute for Breathing and Sleep, Austin Health, Melbourne, VIC, Australia; 4Physiotherapy, Sir Charles Gardiner Hospital, Perth, WA, Australia; 5Physiotherapy, Curtin University, Perth, WA, Australia; 6Lung Institute of Western Australia, University of Western Australia, Perth, WA, Australia; 7Physiotherapy, La Trobe University, Melbourne, VIC, Australia; 8Allergy, Immunology and Respiratory Medicine, Alfred Health, Melbourne, VIC, Australia; 9Respiratory and Sleep Medicine, Austin Health, Melbourne, VIC, Australia; 8Allergy, Immunology and Respiratory Medicine, Alfred Health, Melbourne, VIC, Australia; 7Lung Institute of Western Australia, University of Western Australia, Perth, WA, Australia; 11Physiotherapy, La Trobe University, Melbourne, VIC, Australia
Background: Non-cystic fibrosis (CF) bronchiectasis is characterised by chronic cough and sputum production, exercise limitation and reduced quality of life (QOL), but the role of exercise training in this patient group is unclear. The aim of this study was to determine the effects of exercise training on cough-related symptoms, quality of life, exercise capacity, and respiratory and peripheral muscle force. Responders were those who increased TPA >mod after the protocol.
Methods: Participants with non-CF bronchiectasis with a modified Medical Research Council dyspnoea score ≥2 were randomised to receive eight weeks of twice-weekly supervised exercise training or twice-weekly telephone support. The incremental shuttle walk distance (ISWD), 6-minute walk distance (6MWD), the Chronic Respiratory Disease Questionnaire, Leicester Cough Questionnaire and Hospital Anxiety and Depression Scale were measured by a blinded assessor at baseline and following intervention.
Results: Eighty-five participants, aged (mean [SD]) 64 (13) years, FEV1 74 (22)% predicted and median modified Medical Research Council score of 1(IQR 3) were included. Of those in the exercise training group (n=42), 35 (83%) completed the program. There was a greater magnitude of change in the ISWD (mean difference 62m, 95% CI 24 to 101m) and the 6MWD (mean difference 41m, 95% CI 19 to 63m) in the exercise training group compared to the control group. Exercise training significantly reduced dyspnoea <0.01 and fatigue (p < 0.01) but there was no difference in cough-related QOL or mood between groups.
Conclusions: Exercise training in non-CF bronchiectasis improves exercise capacity and symptoms of sputum and fatigue. Ongoing follow up will assess changes in these effects over time.

3285
Effects of exercise training and neuromuscular electrical stimulation on symptoms, muscle strength, exercise capacity, activities of daily living, and quality of life in COPD

3286
Physical activity in daily life in COPD after exercise training: Are there responders, and who are they?
Nalda A. Hernandez1,2, Thais Sant’Anna1, Carlos A. Camillo1, Vanessa S. Probst1,2, Fabio Pitta1, 1Laboratório de Pesquisa em Fisioterapia Pulmonar (LFIP), Departamento de Fisioterapia, Universidade Estadual de Londrina (UEL), Londrina, Brazil; 2Centro de Pesquisa em Ciências da Saúde (CPCs), Centro de Ciências Biológicas e da Saúde, Universidade Norte do Paraná (UNOPAR), Londrina, Brazil
Background: Previous studies have shown that patients with chronic obstructive pulmonary disease (COPD) generally do not increase their level of physical activity in daily life (PADL) after short-lasting exercise programs. However, as PADL is influenced by several factors, there are individual patients who respond positively becoming more active in daily life.
Aims: To study the proportion and profile of patients with COPD who become more active in daily life after a 12-week exercise training program (responders). Methods: 23 patients (15 men, 66±8 yrs, FEV1 42±16% pred) completed an exercise training protocol (endurance and strength exercises, 3×/week, 12 weeks). PADL was assessed by an activity monitor (Sensewear2, BodyMedia) which registered the time spent in physical activities at least moderate intensity (TPA >mod). Other assessments were socio-economic and functional status, quality of life, exercise capacity, respiratory and peripheral muscle force. Responders were those who increased TPA >mod after the protocol.
Results: 12 patients (52%) were responders (TPA >mod 10 [3–28] min/day pre vs. 32 [10–38] min/day post; p=0.002; median [IQR]). The proportion of physiologically active patients (i.e. TPA >mod ≥30 min/day) increased after the protocol (26% vs. 39%; p=0.01). Although responders and nonresponders had similar physical and functional capacity, responders tended to present exertional desaturation (p=0.076), lower age (p=0.052) and live alone (p=0.089).
Conclusions: These preliminary findings suggest that around half of patients with COPD increase their level of PADL after a 12-week exercise training program. Responders tend to be younger, live alone and desaturate during exertion.

3287
Symptom experience in patients with COPD and their level of physical activity. Is there a good association?
Helen Demeyer1, Juliana Maria de Sousa Pinto1, Mick Hornikx1, Laurence Vrancken2, Marc Decramer2, Wim Janssens2, Thierry Troosters3
1Rehabilitation Sciences and Physiotherapy, KULeuven, Belgium; 2Respiratory Rehabilitation, UZ Leuven, Belgium; 3Department of Personality, Evaluation and Psychological Treatment, University of Salamanca, Spain
Rationale: Several instruments including physical activity monitors and questionnaires are used to assess the functional status in patients with COPD. The relation between objectively measured physical activity (PA) and questionnaires assessing functional status and symptoms is poorly studied.
Methods: 54 patients with COPD (age 66±7, FEV1 62±22% pred) were included. PA was assessed during 2 periods of 14 consecutive days in 6 weeks, by the dy-naport movemonitor and actigraph. The amount of steps per day and movement intensity during walking (MI) were used for this analysis. Symptom experience was measured by the MRC scale for dyspnea (MRC), COPD Assessment Test CAT, functionality subscale of the CCQ (CCQ-f) and the dyspnea subscale of the CRQ (CRQ-d), every 2 weeks. The correlations with PA were measured, both with and without inclusion of the weekends.
Results: The univariate correlations are shown in table 1. All questionnaires were significantly correlated with both the steps per day and the MI. Excluding week-ends did not increase the correlation between ‘functional status’ and steps per day and slightly enhanced the correlations with MI.

Conclusion: The symptoms experienced by the patients and functional status are mostly related to the amount and intensity of PA. Interventions that improve symptoms may therefore not automatically sin off in enhanced physical activity levels.
Conclusion: Comparison of two strategies using pedometers to counteract physical activity deficit likely to improve physical fitness and HRQoL after a pulmonary rehabilitation program. Twenty-eight patients (65.1%) were considered HRQoL responders and worst baseline HRQoL score, increased free-days asthma symptoms and lower depression score were significant predictors to HRQoL improvement (accuracy 81%, p < 0.001).

Results: Twenty-eight patients (65.1%) were considered responders in exercise capacity and baseline depression symptoms, ventilatory reserve (VE/VVFM) and FEV1 were significant predictors to HRQoL improvement (accuracy 81%, p < 0.001). Twenty-one patients (48.8%) were considered responders in both parameters, with baseline depression as a significant predictor (accuracy 79%, p < 0.001).

Conclusion: Asthmatic patients with impaired HRQoL, better clinical control, fewer depression symptoms and lower ventilatory limitation are significantly more likely to improve physical fitness and HRQoL after a pulmonary rehabilitation program.

Aim: A comparison of two different 5-month protocols using pedometers and informative booklets to increase physical activity in daily life (PADL) in smokers who reach or not 10000 steps/day in daily life.

Methods: PADL was re-assessed (A2), and the interventions were crossed over for 1 month, following an early intervention including lung expansion + expiratory muscle training (Active) or lung expansion + sham training (Control). Training has been set with incremental resistive load over the study period. At present, 39 patients (out of the 54 programmed) completed the study, 19 and 20 in Active and Control respectively, with one patient dropped in each group. Anthropometrics and general characteristics, type of surgery, and functional variables at baseline were similar. Training has been set with incremental resistive load over the study period.

Results: The physically active subgroup of GP+B significantly increased steps/day at A2 and maintained this increase until A4. The physically inactive subgroup of GP+B initially increased to a lesser extent, reaching borderline statistical significance at A2 and A3 (p=0.06) and statistically significant increase only at A4 (p=0.02).

Conclusions: Both strategies were effective in increasing the number of steps/day in physically inactive smokers after 5 months, although the increase was more quickly obtained in smokers who used pedometers as the first intervention.

Physical training for asthma: Which patients obtain most clinical benefits? F. Felipe Mendes1, Andreza Pinto2, Beatriz Saravia-Romanholo1, Rafael Stefanch1, Alberto Cukier1, Pedro Giavina-Bianchi2, Milton Martins3, Celso Carvalho2. 1Physical Therapy, School of Medicine, University of Sao Paulo, Sao Paulo, SP, Brazil; 2Clinical Immunology and Allergology Division, School of Medicine, University of Sao Paulo, SP, Brazil; 3Clinical Medicine, School of Medicine, University of Sao Paulo, SP, Brazil; 4InCor-Pulmonary Division, School of Medicine, University of Sao Paulo, SP, Brazil

Background: Recent studies have shown that exercise training improves exercise capacity, health related quality of life (HRQoL) and clinical control in asthma; however, not all obtain clinical relevant benefits and can be considered responders.

Objective: To investigate baseline characteristics that determines the improvement after an exercise training program in asthmatics patients.

Methods: Forty-three adults with moderate or severe asthma performed an aerobic training (35min/twice a week/3 months). It was considered exercise responders those patients that increased ≥10% in maximal aerobic capacity (VO2peak) and HRQoL responders those patients that improved ≥20% in a specific-asthma HRQoL questionnaire. Discriminant analysis was used to distinguish responders from non-responders based on patient’s baseline data.

Results: Twenty-eight patients (65.1%) were considered responders in exercise capacity and baseline depression symptoms, ventilatory reserve (VE/VVFM) and FEV1, were significant predictors to training response (accuracy 86%, p < 0.001).

Conclusion: Muscle mass and strength in pts with thoracic cancer is thought to result from loss of muscle mass and functional impairment. The latter is thought to result from loss of muscle mass and strength.

Aim: To investigate the effect of radical treatment and post-treatment rehabilitation on muscle mass and strength in pts with thoracic cancer.

Methods: Muscle mass was estimated with the fat free mass (FFM) by bioelectrical impedance and the cross-sectional area (CSA) of skeletal muscle on a single 16-mm CT-scan slice. Muscle strength was estimated by the quadriceps force (QF). All variables were measured pre-treatment (M1), after radical treatment (M2) and after either 12w of rehabilitation (RA) or control (CON) (M3). Data are presented as medians with 95% CI.

Results: Of 29 consecutive pts, 18 were allocated to RA and 11 to CON. Both groups have comparable M1 characteristics. At M2, all pts showed a significant decrease in muscle mass and strength. At M3, only RA-patients improved significantly their muscle mass. There is a good correlation between muscle CSA and FFM (r = 0.70; p < 0.001).

Conclusion: Muscle mass and strength significantly decrease with radical treatment in pts with lung cancer and mesothelioma. Muscle mass increases with rehabilitation. CT scan can substitute bioelectrical impedance for measuring muscle mass. Mature data will be presented at the meeting.

311. Paediatric respiratory epidemiology: something for everyone!

314. Expiratory muscle training in patients recovering open thoracic and cardiac surgery

Enitesto Critsulfi1, Massimo Cerulli2, Elena Venturelli3, Fabio Florini4, Nicoletta Kidomax1, Assunta De Biase1, Vittoria Firuno1, Enrico M. Clini1,2, Respiratory Medicine, Ospedale Villa Pineta, Privada srl Modena, Italy; 3Oncology Haematology Respiratory Diseases, University of Modena, Italy

Respiratory muscle training has been so far demonstrated to be effective as a rehabilitation technique in COPD patients. However, it is still not clear whether it may similarly be useful when used in patients receiving open thoracic and cardiac surgery.

We therefore undertaken a randomised 14-day trial in these patients to evaluate changes in maximal expiratory (MEP, as the primary outcome) and inspiratory (MIP) pressures, lung volumes (FEV1, FVC, CV, CI, VR), oxygenation index (PaO2/FiO2), perceived symptoms (VAS), and generic quality of life (SF36) following an early intervention including lung expansion + expiratory muscle training (Active) or lung expansion + sham training (Control). Training has been set with incremental resistive load over the study period. At present, 39 patients (out of the 54 programmed) completed the study, 19 and 20 in Active and Control respectively, with one patient dropped in each group. Anthropometrics and general characteristics, type of surgery, and functional variables at baseline were similar. Training has been set with incremental resistive load over the study period.

Results: The physically active subgroup of GP+B significantly increased steps/day at A2 and maintained this increase until A4. The physically inactive subgroup of GP+B initially increased to a lesser extent, reaching borderline statistical significance at A2 and A3 (p=0.06) and statistically significant increase only at A4 (p=0.02).

Conclusions: Both strategies were effective in increasing the number of steps/day in physically inactive smokers after 5 months, although the increase was more quickly obtained in smokers who used pedometers as the first intervention.

The effect of radical treatment and pulmonary rehabilitation on muscle mass as measured by CT-scan: A randomised trial in patients (pts) with lung cancer and mesothelioma

Bhavya Sali1, Gilles Thyebeaut1, Thomas L. Malafa1, Karim Vermaelen1, Veerle F. Saimont2, Wouter Hueysse2, Georges Van Maelle3, Jan P. van Meerbeeck1, Eric Dromel1. 1Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; 2Radiology, Ghent University Hospital, Ghent, Belgium; 3Medical Informatics and Statistics, Ghent University Hospital, Ghent, Belgium

Introduction: Cancer and its treatment are known to contribute to fatigue and functional impairment. The latter is thought to result from loss of muscle mass and strength.

Methods: Forty-three adults with moderate or severe asthma performed an aerobic training (35min/twice a week/3 months). It was considered exercise responders those patients that increased ≥10% in maximal aerobic capacity (VO2peak) and HRQoL responders those patients that improved ≥20% in a specific-asthma HRQoL questionnaire. Discriminant analysis was used to distinguish responders from non-responders based on patient’s baseline data.

Results: Twenty-eight patients (65.1%) were considered responders in exercise capacity and baseline depression symptoms, ventilatory reserve (VE/VVFM) and FEV1, were significant predictors to training response (accuracy 86%, p < 0.001).

Conclusion: Muscle mass and strength significantly decrease with radical treatment in pts with lung cancer and mesothelioma. Muscle mass increases with rehabilitation. CT scan can substitute bioelectrical impedance for measuring muscle mass. Mature data will be presented at the meeting.

311. Paediatric respiratory epidemiology: something for everyone!

314. Expiratory muscle training in patients recovering open thoracic and cardiac surgery

Enitesto Critsulfi1, Massimo Cerulli2, Elena Venturelli3, Fabio Florini4, Nicoletta Kidomax1, Assunta De Biase1, Vittoria Firuno1, Enrico M. Clini1,2, Respiratory Medicine, Ospedale Villa Pineta, Privada srl Modena, Italy; 3Oncology Haematology Respiratory Diseases, University of Modena, Italy

Respiratory muscle training has been so far demonstrated to be effective as a rehabilitation technique in COPD patients. However, it is still not clear whether it may similarly be useful when used in patients receiving open thoracic and cardiac surgery.

We therefore undertaken a randomised 14-day trial in these patients to evaluate changes in maximal expiratory (MEP, as the primary outcome) and inspiratory (MIP) pressures, lung volumes (FEV1, FVC, CV, CI, VR), oxygenation index (PaO2/FiO2), perceived symptoms (VAS), and generic quality of life (SF36) following an early intervention including lung expansion + expiratory muscle training (Active) or lung expansion + sham training (Control). Training has been set with incremental resistive load over the study period. At present, 39 patients (out of the 54 programmed) completed the study, 19 and 20 in Active and Control respectively, with one patient dropped in each group. Anthropometrics and general characteristics, type of surgery, and functional variables at baseline were similar. Training has been set with incremental resistive load over the study period.

Results: The physically active subgroup of GP+B significantly increased steps/day at A2 and maintained this increase until A4. The physically inactive subgroup of GP+B initially increased to a lesser extent, reaching borderline statistical significance at A2 and A3 (p=0.06) and statistically significant increase only at A4 (p=0.02).

Conclusions: Both strategies were effective in increasing the number of steps/day in physically inactive smokers after 5 months, although the increase was more quickly obtained in smokers who used pedometers as the first intervention.
difficulty with using reported alcohol intake to measure exposure is that under-
comes at 7 years of age. Carriers of the minor A allele drink less in pregnancy and
reporting is common and associations are likely to be confounded. In contrast, a
with asthma and hayfever than mothers who reported never drinking (OR 0.81
week or more in the last two months of pregnancy were less likely to have children
(95% CI: 0.33 to 0.75), P=0.001, N=6,701). There were no significant associations
Results: Maternal ADH1B genotype was strongly associated with childhood
asthma and atopic diseases in childhood
Foetal exposure to maternal stressful events increases the risk of having
intake are likely to be confounded.

Aim: To test whether the children of mothers who had experienced SLE during pregnancy are at an increased risk for asthma, atopic eczema and allergic rhinitis.

Methods: The association between maternal SLE (at least one among: depressive disorders, anxiety, substance abuse, or suicide attempt) and childhood asthma and atopic diseases in childhood was studied in a population (n=3854) of children, aged 0-14 years, living in Northern Italy. The parents filled in a standardized questionnaire about the children’s health and the events occurred to their mothers during pregnancy.

Results: 337 (9%) of the mothers experienced at least one SLE during pregnancy. After adjusting for potential confounders (including risk factors of the children and their families, birth complications or drug use during pregnancy and children’s characteristics at birth), the foetal exposure to SLE was positively associated with wheezing (OR: 1.45, 95%CI: 1.07-1.97), asthma (OR: 1.69, 95%CI: 1.02-2.77), allergic rhinitis (OR: 1.69, 95%CI: 1.06-2.68) and atopic eczema (OR: 1.47, 95%CI: 1.08-2.00).

Conclusion: The children of mothers who had experienced SLE during pregnancy were at a moderately increased risk of having wheezing, asthma, eczema and allergic rhinitis during their childhood. Maternal stress during pregnancy may enhance the expression of asthma and atopic phenotypes in children, strengthening the hypothesis that promness to atopy begins in utero.

2844
Clinical index to evaluate the risk of primary ciliary dyskinesia in children
Jana Djakov1, Ewa Rozezhalova1, Magdalena Havlisova1, Tamara Svobodova1, Petra Pichova1

Introduction: Primary ciliary dyskinesia (PCD) is a rare genetic disorder causing a variety of symptoms. The diagnostics of PCD is challenging as the clinical presentation can differ in particular patients. Also the methods (as high-speed videomicroscopy or electron microscopy) to diagnose PCD are usually available only in specialized centres.

Aim & objective: To find out if a simple clinical index can be used to differentiate the patients with high risk of PCD.

Methods: All patients with PCD diagnosed in our clinic (n=31) and all patients sent to the diagnostic centre as suspected of PCD in 2009-2011 (n=352) were included into the study. We randomly divided the study group into 2 subgroups. The analysis subgroup was used for model preparation and hold-out group was used for subsequent cross-validation of the model. We measured quality of the test (model) by computing area under ROC curve (AUC) and discriminant validity by computing total scores for group with or without PCD diagnosis.

Results: The clinical index included 7 yes/no questions concerning the history and clinical symptoms. One point was assigned to each yes answer. AUC for analysis sample was 0.94, AUC for hold-out subsample 0.89. Discriminant validity was measured in whole study group by non-parametric Mann-Whitney U-test: U(555,5, Z=0.08, p<0.0001).

Conclusions: A simple clinical 7-item questionnaire can be used to evaluate the risk of PCD and to discriminate the patients that should be referred to diagnostic centre.

2845
PCD with normal ultrastructure is not rare
Mikee Boon1, Anne Smits1, Mark Jongse1, Lieven Dupont1, Francois Vermeulen1, Anjela M. Pescatore2, Erol E. Gaillard1, John Henderson2, Francois Vermeulen1, Anjela M. Pescatore2, Erol E. Gaillard1, John Henderson2, Claudia E. Kuzem1

1School of Social and Community Medicine, University of Bristol, United Kingdom; 2Institute of Social and Preventive Medicine, University of Bern, Switzerland; 3Division of Pulmonary, Department of Infection, Immunity and Inflammation, University of Leicester, United Kingdom

Aim: In young children with wheeze it is common to distinguish between those who wheeze only during respiratory tract infections (episodic viral wheeze, EVW) and those who also wheeze due to other factors (multiple trigger wheeze, MTW). The stability of this classification has recently been questioned. In two population based cohort studies, we compared the prevalence and stability of these phenotypes in early childhood.

Background: Very low birth weight (VLBW) infants (<1500g) with bronchopulmon-
ary dysplasia (BPD) may suffer lung damage through mechanical ventilation and the presence of incomplete recovery of respiratory function, which can lead to respiratory and airway resistance, functional residual capacity (FRC), maximal expiratory flow at FRC and blood gas values. Tidal volume, minute ventilation, respiratory compliance and FRC determined by SF6 multiple breath washout were significantly lower in BPD infants compared to controls, but the differences vanished after normalization to body weight.

Conclusions: While somatic growth and some lung function parameter were de-
layed in BPD infants, their lung function appeared to develop along trajectories of non-BPD infants when actual body weight is being considered. Longitudinal LFT of preterm infants after discharge may help to identify BPD infants at risk of incomplete recovery of respiratory function, which can lead to respiratory problems later on.

2846
Development of postnatal lung function in very low birth weight infants with
or without BPD
Charles Roelig1, Silke Wolitzki, Hans Proesacker, Christian Bührer, Gerit Schmädlisch. Neonatology, Charité Medical Centre, Berlin, Germany

Background: Neonates born at ≤1500 g were included and divided into two groups (BPD and non-BPD). The BPD group included children with bronchopulmonary dysplasia (BPD) who had mean gestational age (GA) <30 weeks and birth weight <1500 g and had received ventilation for at least 7 days or until death. The non-BPD group included children with GA ≥30 weeks and birth weight ≥1500 g and had no or only short-term respiratory support. All infants were ventilated with conventional ventilation and received surfactant at 36 weeks GA.

Methods: All infants born at ≤1500 g were included and divided into two groups (BPD and non-BPD). The BPD group included children with bronchopulmonary dysplasia (BPD) who had mean gestational age (GA) <30 weeks and birth weight <1500 g and had received ventilation for at least 7 days or until death. The non-BPD group included children with GA ≥30 weeks and birth weight ≥1500 g and had no or only short-term respiratory support. All infants were ventilated with conventional ventilation and received surfactant at 36 weeks GA.

Results: The analysis subgroup was used for model preparation and hold-out group was used for subsequent cross-validation of the model. We measured quality of the test (model) by computing area under ROC curve (AUC) and discriminant validity by computing total scores for group with or without PCD diagnosis.

Results: The clinical index included 7 yes/no questions concerning the history and clinical symptoms. One point was assigned to each yes answer. AUC for analysis sample was 0.94, AUC for hold-out subsample 0.89. Discriminant validity was measured in whole study group by non-parametric Mann-Whitney U-test: U(555,5, Z=0.08, p<0.0001).

Conclusions: A simple clinical 7-item questionnaire can be used to evaluate the risk of PCD and to discriminate the patients that should be referred to diagnostic centre.

2847
Multiple trigger and episodic viral wheeze in early childhood: Are these
phenotypes stable over time?
Ben D. Spycher1, 2, Jonathan A. C. Sterne1, Raquel Granell1, Michael Silverman1, Ana M. Pescatore2, Erol E. Gaillard1, John Henderson2, Claudia E. Kuzem1

1Institute of Social and Preventive Medicine, University of Bern, Switzerland; 2Division of Pulmonary, Department of Infection, Immunity and Inflammation, University of Leicester, United Kingdom

Aim: In young children with wheeze it is common to distinguish between those who wheeze only during respiratory tract infections (episodic viral wheeze, EVW) and those who also wheeze due to other factors (multiple trigger wheeze, MTW). The stability of this classification has recently been questioned. In two population based cohort studies, we compared the prevalence and stability of these phenotypes in early childhood.
Methods: We included 14062 children from the Avon Longitudinal Study of Parents and Children (ALSPAC) and 4300 from the Leicester Respiratory Cohorts (LRC). Mothers received postal questionnaires including questions on wheeze and triggers of episodes in past 12 months when children were aged 2, 4 and 6 yrs.

Results: Between ages 2 and 6 yrs, prevalence of current wheeze decreased from 18 to 10% in ALSPAC and from 23 to 10% in LRC. Among children with wheeze the proportion of those with MTW as opposed to EVW increased from 55% (both cohorts) to 70% (ALSPAC) and 74% (LRC). Among children with EVW who wheezed again 2yrs later, a considerable proportion were reclassified as MTW in both cohorts (Tables). There was less reclassification from MTW to EVW.

Conclusion: The phenotypes EVW and MTW show limited stability through early childhood suggesting that triggers of wheeze alone are not sufficient to distinguish underlying disease processes, or that the disease processes change in some children throughout this period.

Funding: BIDS is recipient of a ERS/Marie Curie Joint Research Fellowship (MC 1614-2010).

2848 Increased risk of preschool wheeze both with higher BMI in infancy and at age 4 years
Emma Gokal1, Bernt Alm1, Rolf Pettersons2, Per Möllborg1, Ilaslo Erdes1, Nina Ahlbom1, Department of Environmental Medicine, Gothenburg, Sweden; 2Central Infant Welfare Unit, Pediatric Outpatient Clinic, Mölndal, Sweden; 3Pediatric Outpatient Clinic, Pediatric Outpatient Clinic, Skene, Sweden

Background: Overweight has been associated with wheezing and asthma both in children and adults. It is debated whether overweight early in life predisposes for later wheeze or if the association is due to asthmatic children being less active. The aim of this study was to explore the relationship between body mass index, BMI, and recurrent wheeze (≥3 episodes during the last 12 months) at preschool age.

Methods: Data were obtained from a prospective, longitudinal study of a cohort of children born in Western Sweden in 2003. 8176 families (50% of the birth cohort) were randomly selected. The parents answered questionnaires at 6 and 12 months and at 4.5 years of age. The response rate at 4.5 years was 4496, i.e. 83% of the 5398 questionnaires distributed at 4.5 years. Odds ratios were calculated with BMI as a continuous variable.

Results: In multivariate analysis, the risk of recurrent wheeze at preschool age was increased both by a higher BMI at 12 months (OR 1.2, 95% CI 1.03-1.4) and by a higher BMI at age 4 years (OR 1.2, 1.04-1.4). Adjusting for recurrent wheeze during infancy or excluding children with recurrent wheeze during infancy had no major influence on the ORs. In addition, recurrent wheeze in infancy did not increase the risk of overweight at 4 years.

The analyses controlled for preterm birth, smoking during pregnancy, family history of atopies, other allergic diseases in infancy, parental education, small for gestational age, gender and maternal overweight before pregnancy.

Conclusion: A higher BMI at 12 months or at 4 years both increased the risk of recurrent wheeze at preschool age. Wheezing during infancy did not explain the associations seen.

2849 Interactions between exposure to cigarette smoke and variations in the GSTM genotype for asthma quality of life
Steve Turner1, Roger Tavendale2, Somnath Mukhopadhyay1, Anil Mehta1, Colin Palmer3, Jon Ayres1, 1Child Health, University of Aberdeen, United Kingdom; 2Population Pharmacogenetics Group, University of Dundee, United Kingdom; 3Division of Maternal & Child Health Sciences, University of Dundee, United Kingdom; 4Child Health, Brighton and Sussex Medical School, Brighton, United Kingdom; 5Occupational and Environmental Medicine, University of Birmingham, United Kingdom

Background: Asthma is a heterogeneous condition and our hypothesis is that gene environment interactions explain some of the variation within the asthmatic population. Here we report on an interaction between exposure to second hand smoke (SHS, an oxidant stress) and variation in the gene coding for antioxidant protein GST-M for asthma outcomes.

Methods: Children with asthma were recruited from primary and secondary care across Scotland. A respiratory questionnaire and the Pardissia Asthma Quality of Life Questionnaire (PAQLQ) were completed and DNA collected. A subset underwent an assessment including spirometry and exhaled nitric oxide. Saliva was collected for cotinine analysis.

Results: From 894 children recruited, PAQLQ and DNA were obtained in 499 (56%). There were 88 children exposed to SHS. Compared to children null for GSTM who were not exposed to SHS, the overall PAQLQ score for exposed children null for GSTM was reduced (meaning worse quality of life) by a mean of -0.7 [95% CI -0.1, -1.3] p=0.020. Similar associations were present for domains of symptoms (mean difference -0.7 [-0.1, -1.3]) and emotions (mean difference -0.7 [-0.1, -1.2]) but not activities (mean difference -0.3 [95% CI -0.9, -0.3]). There were no differences in spirometry or exhaled nitric oxide between GSTM null children who were and were not exposed to SHS.

Conclusion: Our findings support the hypothesis that gene environment interactions are important to some of the heterogeneity of asthma. Whilst all children with asthma should avoid SHS exposure, parents of children null for GSTM (50% of all asthmatics) might be considered for specific intervention.

312. Recent technical developments in long-term noninvasive ventilation

2880 Pulse transit time allows a reliable non-invasive measurement of respiratory effort under non-invasive ventilation
Göran Östergard1, Claudio Carnevale2, Jean-Christian Borel3,4, AbdelKebir Sabil2,3, Renaud Tamisier2,3, Patrick Levy2,3, Jean-Paul Janssens1, Jean-Louis Pepin2,3, 1Division of Pulmonary Diseases, Geneva University Hospitals, Geneva, Switzerland; 2HP 2 Laboratory (Hypoxia: Pathophysiology), INSERM U 1042, Joseph Fourier University, La Tronche, France; 3ECFR and Sleep Laboratory, Locomotion, Rehabilitation and Physiology Department, Grenoble University Hospital, Grenoble Cedex 09, France; 4Research and Development Department, AGIR à Dom, Meylan, France

Rationale: Among respiratory events which may occur during nocturnal non-invasive ventilation (NIV), differentiating between central and obstructive events requires appropriate indicators of respiratory effort.

Objective: To assess pulse transit time (PTT) as an indicator of respiratory effort under NIV in comparison with esophageal pressure (Pes).

Methods: 1: During wake period, PTT was compared to Pes during spontaneous breathing and under NIV with or without induced leaks in 11 healthy individuals. 2: To evaluate the contribution of PTT vs Pes for differentiating central from obstructive respiratory events occurring under NIV during sleep in 10 patients with obesity hypventilation syndrome (OHS).

Results: 1: From spontaneous breathing to NIV without leaks, respiratory effort decreased significantly and with increasing level of leaks, there was a significant increase in respiratory effort. In both situations changes in PTT accurately reflected changes in Pes.

2: In the OHS patients during nocturnal NIV, intraclass correlation coefficients between Pes and PTT were 0.970 for total number of events and 0.970 for percentage of central events.

Conclusions: PTT accurately reflects the unloading of respiratory muscles induced by NIV and the increase in respiratory effort during NIV. PTT during sleep is also useful to differentiate central from obstructive respiratory events occurring under NIV.

Clinical trial registration number: NCT00983411.

2881 Validation of a method for non-invasive assessment of transdiaphragmatic pressure during support ventilation
Kristel Lopez-Navas1,2, Sebastian Brandt1, Merle Strutz1, Hartmut Gehring1, Ulrich Wenkembach1, 1Laboratory of Medical Systems, University of Applied Sciences, Lübeck, Germany; 2Department of Anaesthesiology, University Medical Center Schleswig-Holstein, Campus Lübeck, Germany

Especially during long term support ventilation continuous assessment of the patient’s work of breathing can be helpful to improve the quality of the assistance. We designed the Oeselon-Delta (O+D) method to estimate non-invasively transdiaphragmatic pressure (Pdi) and started validation in a study with volunteers.

Methods: Respiratory flow and airway pressure were recorded from 11 healthy men (21 to 68 years old) during quiet spontaneous breathing, increased effort and supported by a ventilator in ASB mode. Pdi was measured for control using a double-balloon catheter. Each 3 to 5 cycles our method was applied getting an estimation of respiratory resistance R and compliance C used to reproduce the Pdi of the coming cycles, which was compared to the measured Pdi by their respiratory pressure time products (PTT).
Results: The short occlusions required by O+D did not disturb the volunteers and produced the expected signals. The obtained R (3.2 to 7.1 cmH2O/l/s) and C (58.7 to 97.7 ml/cmH2O) remained in the usual range for healthy adults. Regression and correlation analysis revealed high agreement between methods (PTP0 = 1.00*PTPv+0.02, r=0.92, R2=0.86). The overall differences (n=2420 (220 per volunteer)) were 0.01±10.3 cmH2O/s (mean±2SD).

Conclusions: The results obtained demonstrate great potential in the developed method. A study with 30 volunteers is being carried out to complete validation.

2852
Initiation of nocturnal ventilation using an intelligent autotitrating non-invasive ventilator: Impact on ventilatory efficiency, sleep and adherence
Jay Jays, Julia Kelly, Rachel Pickerill, Michelle Chawin, Mary Morrill, Anita Simonds.
Sleep and Ventilation Department, NIHR Respiratory Disease Biomedical Research Unit at the Royal Brompton and Harefield NHS Foundation Trust and Imperial College London, London, United Kingdom

Intro: A novel intelligent non invasive ventilator allows automated set-up & delivery of volume assured ventilation within preset pressure support boundaries adjusting to patient requirements (iVAPS). iVAPS controls nocturnal hypoventilation (NH) comparably to standard non invasive pressure support ventilation (PS) in established NIV users. We hypothesise iVAPS is as effective as PS in naive patients for controlling NH.

Methods: 18 patients with chronic obstructive or restrictive disorders & newly diagnosed NH, (mean±SD) age 51(17) yrs, mean day PaO2 9.2(1.2) kPa, PaCO2 6.4(0.7)kPa completed a randomised crossover study of iVAPS vs PS (ResMed Ltd). Baseline FEV1/FVC & respiratory muscle strength (RMS) were repeated at 1 month treatment, plus polysomnography.

Results: iVAPS used less PS for the same ventilatory outcome; 7.7(2.9) v 10.2(2.9) cmH2O (p=0.03*).

Conclusion: No differences were seen for FEV1/FVC, RMS or sleep quality; arousal index 16.9(9.2) v 18.1(12.0) (p=0.65), O2 desaturation index 7.2(6.6) v 6.4(6.9) (p=0.59).

Adherence was superior with iVAPS: 5.6(2.1) v 4.6(2.3) hrs/day (p=0.002). Patients expressed an iVAPS preference.

Conclusion: iVAPS is as effective as PS initiated by a skilled healthcare professional in controlling NH. It may facilitate NIV use without extensive prior team experience & may encourage compliance/adherence to therapy for patients newly adjusting to NIV.

2853
Impact of long-term target-volume noninvasive positive pressure ventilation on sleep quality
Jan Hendrik Stroes1, Elena Matrosovich2, Emelie Ekkernkamp2, Claudia Schmoeer3, Wolfram Windisch1. 1 Pneumologie (Lungenklinik), Cologne-Merheim Hospital, Kliniken der Stadt Köln GmbH, Witten/Herdecke University Hospital, Cologne, Germany. 2 Pneumologie, University Hospital, Freiburg, Germany. 3 Clinical Trials Center, University Hospital, Freiburg, Germany

Objective: Target-volume noninvasive positive pressure ventilation (TV-NPPV) was introduced to combine the advantages of volume- and pressure-preset NPPV. However, diverging results have been reported regarding a deterioration of sleep quality due to pressure variation.

Methods: 12 COPD-patients on long-term high-intensity NPPV (HI-NPPV) were switched to TV-NPPV for 10 weeks. Sleep quality and overnight gas exchange were analyzed at run-in during HI-NPPV and after 10 weeks of TV-NPPV. Two TV-NPPV-settings were tested overnight in a randomized order: 8ml/kg ideal body weight (TV1) versus 110% of individual tidal volume analyzed during follow-up HI-NPPV (TV2). Inspiratory pressures were set to -5cmH2O up to 35cmH2O. TV-NPPV-settings reflecting the lower overnight transcutaneous PCO2-values (PtcCO2) were chosen for long-term TV-NPPV.

Results: 10 patients completed the study, 2 patients refused to complete the trial using TV2-NPPV at home. Mean overnight PtcCO2 was similar during HI-NPPV and TV-NPPV (both 45±5mmHg), p=0.75. In addition, no difference was found comparing sleep quality by polysomnography regarding sleep efficiency, sleep stages, total sleep time, arousal index, apnoe-hypopnoea index or oxygen saturation.

Conclusion: After 10 weeks of TV-NPPV at home no differences regarding sleep quality or overnight PtcCO2 were observable compared to conventional HI-NPPV.

2854
Home polysomnography in the management of noninvasive ventilation in neuromuscular patients
Grazia Crescimanno, Francesca Greco, Oreste Marrone. Institute of Biomedicine and Molecular Immunology, Italian National Research Council, Palermo, Sicily, Italy

Objective: PSG in the management of NIV in NMD patients are lacking.

Design: To compare feasibility and patients’ acceptance of PSG during NIV performed either in hospital or at home.

Methods: Fifty-two consecutive NMD patients on long-term NIV were assigned to home or to unassisted hospital PSG during NIV application. A 7 item self-questionnaire was administered after PSG to explore perceived sleep efficiency, sleep quality, awakenings, and acceptance of the polysomnographic procedure. Sleep was scored according to AASM rules.

Results: One home and 1 hospital PSG were not reliable due, respectively, to insufficient sleep or to signal loss. Four hospital and three home recordings showed minor technical problems that did not affect their reliability. The remaining 43 recordings were technically excellent both as regards neurological and respiratory signals. Subjective (382.80±114.28 vs 347.94±77.3 minutes, respectively) and objective total sleep time and sleep efficiency (68.80±19.40 vs 72.03±15.86%), that were correlated to each other, were similar in the two groups. Acceptance of home PSG (8.28±1.99 on a scale from 0 to 10) was higher than for hospital PSG (6.84±2.42, p=0.02).

Conclusion: In ventilated NMD patients, feasibility and reliability of PSG, as well as subjective and objective sleep quality, do not differ if it is performed in hospital or at home. Acceptance of the procedure in the home environment is higher.

2855
Is volume assured ventilation always able to compensate volume loss in presence of leaks?
Anna Schreiber1, Annalisa Carlucci1, Piero Ceriana1, Alessio Mattei1, Cesare Greco2, 1 Respiratory Intensive Care Unit, IRCCS Fondazione S. Maugeri, Pavia, Italy; 2Intensive Care and Emergency Department, CTO - M Adelaide, Torino, Italy; 2 Cardiotoracico Department, San Giovanni Battista Hospital- Molinette, Torino, Italy

Background: Volume assured (VTG) ventilation is a pressure targeted mode aimed to guarantee a target tidal volume (Vt) by varying the inspiratory pressure between two preset pressure values. VTG ventilation has been used to correct sleep-related periodic hypoventilations during noninvasive ventilation (NIV). However, in this setting the likelihood of non-intentional leaks (NIL) may be high.

Aim and methods: In a bench study we wanted to assess the VTG NIL compensation algorithm in three turbine driven ventilators designed to set a VTG either with an EVC or with an ILC (Vivo50, Breas; PB560, Covidien; Ventimotion, Weimann). All ventilators were tested in random order using a lung simulator (Ingmar, ASL5000) in VTG Pressure Control mode with both the ILC and the EVC.
at three level of leaks (15, 27 and 37 l/min) and at three different conditions of respiratory mechanics: normal, obstructive and restrictive.

Results: All the ventilators in the ILC configuration were able to maintain the Vtg in all simulated conditions; conversely, during all simulated leak conditions when the EVC was used a significant fall both in Vt and inspiratory pressure compared to the baseline value was observed.

Conclusions: All single circuit ventilators tested in ILC configuration were able to compensate the volume loss and to ensure the preset Vtg in all leak conditions but failed to ensure the Vtg when the EVC was used.

2856
Effectiveness of the use of heliox on nebulizer associated with noninvasive ventilation in chronic obstructive pulmonary disease patients: A randomized controlled trial
Vittoria Lima, Ceyda Reinaux, Luciana Alcoforado, Shirley Campos, Catarina Rattes, Simone Brandão, Valdecir Galindo Filho, Armêla Dornelas de Andrade, Physiotherapy, Federal University of Pernambuco, Recife, Brazil Saúde Materno-Infantil, Instituto de Medicina Integral Prof. Fernando Figueira, Recife, Brazil

Objective: To evaluate the efficacy of nebulized bronchodilators carried by heliox associated with NIV in the pulmonary deposition of radioaerosol in patients with COPD.

Methods: A randomized controlled trial involving 37 patients divided into four groups: heliox NIV, oxygen NIV, heliox and oxygen. For scintigraphy pulmonary inhalation dose was administered a dose of diethanolaminomonoacetate labeled with technetium (99mTc-DTPA). 25 mcU combined with fenoterol brome (0.12 mg) and ipratropium bromide (0.25 mg) delivered through a bi-level noninvasive ventilation system using a face mask with two unidirectional valves and connected to the nebulizer for radioisotopes (IPAP = 10 cm H2O and EPAP=8 cm H2O). Images were acquired immediately after the intervention using a Gama camera and Regions of interest was determined.

Results: There was a higher radioaerosol pulmonary deposition in the lower third in the heliox NIV and oxygen NIV groups compared to oxygen (p=0.03 and p=0.02, respectively). We observed a higher deposition in the middle third (p=0.008) in heliox NIV group when compared to O2. Thus, there was a positive correlation gain in inspiratory capacity(IC) and the total area of the right lung (p=0.04, r=0.71) in the heliox NIV group.

Conclusions: Our results suggest that coupling heliox or oxygen with bi-level NIV reached a higher lung radioaerosol deposition in the lower third for both lungs. The association between heliox and NIV seem to be more effective to promote a higher radioaerosol peripheral deposition considering the gain of the IC. Supported by: CAPES, CNPq, FACEPE.

Conclusions: Externally measured VT is only reliable when mask leakage is minimal. Since measurement is based on airflow inside the sensor, other derived parameters are also affected. The corrected VT from the internal sensor of the NIV device is much less susceptible to leakage but tends to overestimate the actual VT in the setup we used. When exact measurements are crucial, beforehand assessment of results under controlled conditions is advisable.

313. Tuberculosis: epidemiological and public health features

P2858 Agreement between Quantiferon-TB-Gold In Tube, T-SPOT.TB and tuberculin skin testing for diagnosing latent tuberculosis infection in a contact tracing study
Neus Altet1, Irene Latorre 1, Malí De Souza2, M. Angeles Jimenez 2, Célia Milà2, J. Solsona3, E. Lura2, Marta Dolores Ferrer3, Joan Caylà3, Jose Antonio Dominguez Benitez4, 5Servirs de Microbiologia, Institucio d’Investigacion en Ciencies de l’Adsalada, Badalona, Barcelona, Spain; 6Unitat de Prevenció i Control de la Tuberculosis de Barcelona, Institut Catala de la Salut, Barcelona, Spain; 7Agències de Salut Pública de Barcelona, Agència de Salut Pública de Barcelona, Barcelona, Spain

Aim: To determine the agreement between Quantiferon-TB Gold In Tube (QFN), T-SPOT-TB and TST in diagnosing LTBI in a contact study.

Methods: 753 individuals from contact tracing studies were included in the study. In all cases QFN and TST were performed, and in 141 patients the T-SPOT was also performed. TST was negative when the induration was less than 5 mm.

Results: The QFN and TST obtained concordant result in 478 cases from the 753 patients (the overall agreement was 63%), being both tests negative in 145 cases, and positive in 333 cases. From the 275 discordant results, in only one case the TST was negative and the QFN positive (corresponds with a high degree of exposure to the index case), and in 274 cases the TST was positive and the QFN negative, corresponding in 239 cases to BCG-vaccinated patients, and without significant difference between time of exposure to the index case.

With regards to the 141 patients tested with T-SPOT both in vitro tests were concordant in 120 cases (85.1%), being in 61 cases both tests negative, and in 59 cases positive. From the 21 discordant results, in 5 cases the QFN was positive and the T-SPOT negative, and in 16 cases the QFN was negative but the T-SPOT positive, being in 15 of them the time of exposure significantly higher.

Conclusions: QFN and T-SPOT-TB have a high concordance in the diagnosis of LTBI. T-SPOT-TB shows a higher number of positive results than QFN. The main discordant results between TST and QFN should be attributed to the BCG vaccination. Both tests seem useful for the diagnosis of LTBI in the contact studies. The study was supported by a grant from FIS (08/1738).

P2859 Tuberculosis in health care staff in Romania, 2006-2010
Nicoleta Cigan1, Horia Coci1, Elimara Bream. Central Coordination Unit of Romanian National Tuberculosis Program, “Marius Nasta” Institute of Pulmonology, Bucharest, Romania

Introduction: Health care staff represents a well recognized high risk group for TB.

Objective: To analyze characteristics of TB cases out of health care facilities in Romania during 2006-2010 by demographic, clinical, bacteriological parameters and treatment outcomes.

Methods: Retrospective descriptive study of TB cases notified among health care staff in Romania from 2006 to 2010. Data and information used was obtained from the National TB Register.

Results: Total number of TB cases reported in health care workers in Romania from 2006 to 2010 was 843, declining from 224 in 2006 to 139 in 2009 and slightly increasing (to 150) in 2010. Most of them were aged from 25 to 39 years. Conversely to the general population, female gender was predominant (over 70%).
as the residence in urban area (over 70% as well). Even the staff in TB network varied between 2006 and 2008 from 12.9% to 7.7% of all medical staff. TB incidence rate in this group was 114.5‰, versus 51.3‰ in other medical staff, in 2010. Pulmonary cases were from 74.0% to 85.9% in 2008. New cases and relapses represented over 96% of all cases (96.8% in 2006 and 99.3% in 2010). In the five years have been reported 18 MDR-TB cases – from in 2008 (6.9%) and positive pulmonary cases) to 3 in 2010 (respectively 3.8%) and none in 2007. Overall success rate was 98.3% in 2007 and 89.3% in 2006.

Conclusions: TB incidence rate in health care staff in TB facilities is 2.2 times higher than in the personnel in other health care facilities. New pulmonary cases were predominant, with a few MDR-TB cases and a therapeutic success rate over 89%.

P2860 Pattern of tuberculosis (TB) notifications among health care workers (HCW) attending a revised national TB control programme (RNTCP) unit in Kottayam Medical College (Kerala India)
Paul Davis, Aneshath Cherakulam. Pulmonary Medicine, Medical College, Kottayam, Kerala, India

Background: There is paucity of data with regard to pattern of TB in HCW

Aim: To study the pattern of TB among HCW.

Study setting: RNTCP unit of a Medical College in Kerala, India from October 2009-March 2011.

Methods: Clinical profile of patients referred to RNTCP unit with a proven diagnosis or with a clinical and radiologic diagnosis made by a specialist medical teacher were gathered by a preset oral questionnaire and clinical examination.

Result: Out of 1222 TB patients 5.72% (n=70) were HCW-90% of HCW (n=63) were nurses or nursing students, 10% (n=7) were paramedics or doctors and medical students registered in control programme for treatment. 68.6% (n=48) had extra pulmonary TB & 31.4% (n=22) pulmonary TB (OD 2.725). 63.6% (14/22) of pulmonary TB was smear positive. Occurrence of TB lymphadenitis (n=24) and extra pulmonary TB (n=5) were more common among HCW compared to general category patients (p value of <0.05). 92.8% were newly diagnosed (n=65), 4.2% (n=3) retreatment & 2.8% (n=2) MDR. None had brain or meningcal TB. 92.8% were BCG vaccinated.

Conclusion: TB lymphadenitis was more common among HCW compared to general category patients. Majority of HCW coming for treatment in RNTCP were nurses or nursing students. No doctors registered for treatment in control programme.

P2863 Risk of latent tuberculosis infection among healthcare trainees
Anja Schablon1, Gema Diner2, Ute Anskे2, Felix Ringshausen2, Albert Nienhaus1,3. *Vaccination Competence Centre for Epidemiology and Health Service Research in Nursing, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany; 2Occupational Safety and Health, Vivantes, Berlin, Germany; 3Pneumology, University Medical Centre, Hannover, Germany

Objective: The prevalence of latent tuberculosis infection (LTBI) and the risk of tuberculosis infection in nursing students in Germany are unknown. Therefore trainings were followed over a three-year period for the prevalence and risk of LTBI.

Method: In a prospective cohort study, all trainees (n=194) who began training as a nurse or carer at the Vivantes Healthcare Training Institute in Berlin on 1 October 2008, and 1 April 2009, were IGRA-tested at three different times. IGRA results were performed at the start of training and at the end of the first and third years of training. Socio-demographic data and possible risk factors were recorded.

Results: The cohort consisted of 154 IGRA-negative trainees (n=154) who began their training) of a total of 194 trainees. 70% were female. The average age was 23. The LTBI prevalence was 2.1% (4/194). 40 trainees quit before completing their training. In the first follow-up test, 2 out of 154 tested IGRA-negative. The prevalence of LTBI was 1.3%.

Conclusion: The prevalence rate of LTBI was 2.1% in this cohort. The LTBI prevalence rate was lower than expected. Therefore IGRA testing in this low risk group is feasible. However, screening should focus on trainees with personal risk factors for TB. All others should only be tested after they have been in close contact with a TB index patient.

P2864 The effect of the introduction of IGRA in screening French healthcare workers for tuberculosis
Dominique Tripodi1, Benedicte Courtois1, Albert Nienhaus1,3. *Occupational Health and Safety, University Medical Centre, Nanterre, France; 3Vaccination Competence Centre for Epidemiology and Health Service Research in Nursing, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany

Introduction: In France pre-employment screening for tuberculosis (TB) is performed for healthcare workers (HCW). Screening is repeated, when exposure to TB patients or infectious material occurs. The results of the TB screenings were analysed in a retrospective analysis.

Method: TB screenings were performed with Tuberculin Skin Test (TST) and Interferon-Gamma Release Assays (Quantiferon Gold in tube QFT). If TST was >5mm or TST increased by >10 mm, X-ray and pneumology consultation regarding preventive treatment of latent TB infection was performed. The screening results of 637 HCWs on whom QFT was performed were extracted from the files of the University Hospital of Nanterre.

Results: In 3 (0.5%) HCWs the QFT was indeterminate. In 22.2% the QFT was positive. A second QFT was performed in 118 HCWs. Reversion rate was 42% (5 out of 17). Conversion rate was 6% (6 out of 98). TST was performed in 466 (73.5%) of the HCWs. TST >10mm results were 77.4%. In those with TST <10mm, QFT was positive in 14% and in those with TST >10mm, QFT was positive in 26.7%. When based on QFT results, X-ray and pneumology consultation could have been reduced to 28.6% of those selected by TST.

Conclusion: TST overestimated the prevalence of LTBI in this cohort. The de-
cision on X-ray and consultation regarding preventive treatment should be based on QFT rather than TST results. The high reversion rate should be taken into consideration when consulting HCWs regarding preventive treatment.

P2865
Contact screening in tuberculosis. Can we identify those with higher risk?

Maria Aurora Mendes1, Ana Rita Gaio1, Ricardo Reis2, Fernando Calvário3, Manuel Mário Sousa4, Aurora Carvalho5,6, Raquel Duarte4,5,7,8, University of Porto, Medical School, University of Porto, Pulmonology Diagnosis Centre of Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 2Centre of Mathematics of University of Porto, Centre of Mathematics of University of Porto, Porto, Portugal; 3Mathematics Department, University of Porto, Sciences School, Porto, Portugal; 4Centre of Mathematics of University of Porto, Centre of Mathematics of University of Porto, Porto, Portugal; 5Pulmonology Department, Hospital Centre of Frás-os-Montes and Alto Douro, Vila Real, Portugal; 6Pulmonology Department, Pulmonology Diagnosis Centre of Vila Nova de Gaia, Vila Nova de Gaia, Portugal; 7Pulmonology Department, Hospital Centre of Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal; 8Public Health Department of the North Regional Health Administration, Public Health Department of the North Regional Health Administration, Porto, Portugal; 9Clinical Epidemiology, Predictive Medicine and Public Health, University of Porto, Medical School, Porto, Portugal

Introduction: Contact tracing is part of the tuberculosis (TB) elimination strategy. It is important to know which risk factors are associated with a positive screening.

Objectives: To identify risk factors associated with a positive screening.

Material and methods: During 2011, contacts of patients with pulmonary TB (sputum or broncho-alveolar lavage smear or culture positive), followed for screening in a TB reference centre, were questioned about their exposure to the index case. Positive screening was defined as active TB or latent infection. Contacts with incomplete characterization of exposure, unfinished screening or a past history of TB were excluded. A binary logistic model was used to analyze the variables.

Results: We observed 509 contacts of which 359 (153 men, median age: 32 years) were included in the analysis. 76 had a positive screening. Positive screening was associated with a positive sputum analysis of the index case (OR=2.62, 95%Ci=1.33-5.14) and with coinhabitation (OR=3.42, 95%Ci=1.66-7.07). Each additional year in age of the contact implied an increase in the odds for infection of 3% (OR=1.03, 95%CI=1.02-1.05) and each additional day of symptoms by the index case, previous to treatment, implied an increase in the odds for infection of 3% (OR=1.03, 95%CI=1.02-1.05). No significant differences were found regarding size and ventilation of the exposure site.

Conclusions: This study shows that there is a significant increase in the risk of TB transmission to contacts for every day that the diagnosis of the index case is delayed. Increased risk was also shown for coinhabitants, contacts of older age and the presence of positive sputum smear or culture of the index case.

P2866
Approaching tuberculosis in a vulnerable group

Elmira Ibraim1, Nicoleta Cioran1, Nicoleta Popescu2, Florentina Liguia Pârămucă1, NTPI, Marius Năstase Institute of Pulmonology, Bucharest, Romania; 2Medical Department, Samusocial, Bucharest, Romania; 3Public Health and Management, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania

Introduction: The homeless represents a high risk group for TB, with poor access to health care services. TB prevalence among the around 5,000 homeless estimated to live in Bucharest is not known.

Aims and objectives: To detect active TB cases in homeless population in Bucharest.

Methods: A screening program was developed based on partnership between the National TB Programme and Samusocial Romania (NGO providing medical, psychological and social support to homeless people). Persons coming to the surgery service of Samusocial have been screened for TB in TB facilities. Any homeless giving a positive informed consent has been included and only exclusion criterion was having another chest X-ray in the previous 6 months.

Results: In the 248 cases registered from January to June 2011, 83.9% were males, mean age was 43.9 years (from 18 to 73 years old), 30.2% didn't have any ID document and half were at first medical consultation. TB has been suspected in 44.4% by clinical criteria, but from eligible persons only 48% were screened by chest X-ray, 14.1% refused and 35.5% didn't come back for screening. Active TB has been found in 8 cases (6.7% from the screened persons, 2 of them negative to clinical examination. None was previously examined even though they have free access to TB services. All cases were admitted in long-stay hospitals for treatment and monitoring.

Conclusions: In this project the prevalence of active TB was found very high in the homeless population (6,700/1000). Providing free access to TB services is not sufficient to detect TB cases in this high risk group and active screening programs are necessary.

P2867
Tuberculosis and migration: Predictors of epidemiological trends

Anna Guldberg1, Viacheslav Zhuravlev2, Natalya Skrynnik3, 1Admiralty District, TB Dispensary, St. Petersburg, Russian Federation; 2The Molecular Genetics laboratory, The Research institute of Phthisiopulmonology, St. Petersburg, Russian Federation

Last years economic migration to the big cities of Russian Federation (RF) from other regions of RF and former Soviet republics has considerably increased. Since 2011 free diagnosis of tuberculosis (TB) and free TB-treatment are not available for foreigners in St. Petersburg, RF.

Objective: To determine the impact of health care changes on the incidence of TB.

Methods: The study was conducted in the district of St. Petersburg. The population of this district was 178,000. From 01.01.2008 an office for migrants has opened at the TB dispensary. All persons including migrants who addressed the TB dispensary during 2008-2011 were examined. The causes for examination were symptoms of tuberculosis or casual radiological findings. Examinations and treatment were free for all patients. Until 2008, there was no systematic recording of TB in migrants.

Results: During 2008-2010 the number of new TB cases in local population decreased, the number of infectious TB has decreased in local population and in migrants. The number of new cases of TB in children (local population and migrants) has decreased. In 2011, the trend reversed.

Conclusions: To ensure effective control of tuberculosis free access to health care is required for all TB patients, including migrants.

P2868
New-entrant screening for tuberculosis at port of entry in the U.K.: Is it time to change policy?

Vikas Panaminty1, Henke Kunst, Martin Dedicoat, Joy Troko. Department of Respiratory Medicine & Physiology, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom

Background: It is shown that 20% of tuberculosis (TB) cases are diagnosed in persons entering UK within 2 years & in 45% within 5 years of arrival. Therefore the first 2.5 years of arrival in UK presents a period of high risk of reactivation of new-entrants with LTBI. This clearly indicates the importance of early screening & reducing the risk of active TB by giving chemoprophylaxis to patients with LTBI.

UK policy at the moment advocates identification of active TB by chest x-ray for all new arrivals intending to stay for > 6 months from countries with a TB incidence 40/100,000; however, screening is very arbitrary & not standardised. The results are forwarded to local NHS TB services where new entrants intend to settle for complete screening.

Methods: A retrospective review was conducted of all new-entrants who were referred to our institution during a 2 year period, from January 2010, with supposed abnormal chest x-ray at port of entry. All new-entrants were screened for active & latent TB by TST or IGRA

Results: 103 patients, 51 females & 52 males were referred, however only 42 patients (40.7%) were referred to our institution during a 2 year period, from January 2010, with supposed abnormal chest x-ray at port of entry. All new-entrants were screened for active & latent TB by TST or IGRA

Conclusions: Screening new-entrants at port of entry is inadequate. New-entrants often do not attend clinic appointments since they have moved elsewhere or do not understand the necessity of being screened for latent or active TB.

P2869
Impaired pulmonary function and the risk of tuberculosis – A population based cohort study

Malin Inghammar1, Claes-Göran Lothdahl2, Nicais Winquist3, Gunnar Engström3, Arne Eggesten2. 1Section for Infection Medicine, Department of Clinical Sciences, Lund University, Lund, Sweden; 2Respiratory Medicine & Allergology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden; 3Cardiovascular Epidemiology Research Group, Department of Clinical Sciences Malmö, Lund University, Lund, Sweden; 4Infectious Disease Research Unit, Department of Clinical Sciences Malmö, Lund University, Lund, Sweden

Background: Even though COPD is a frequent co-morbid condition in elderly with active tuberculosis relatively little is known to what extent impaired lung

5225
function increases the incidence of active tuberculosis in excess of the direct effect

Introduction:

P2870

Incidence of tuberculosis: The application of capture-recapture method to compare two sources of information

Francisco Muñiz1, María López2, Nellieta Carracedo3, Sara Raposo2,
Piedro Rivero1, Silvia García1, Jose Guerra2, 1Respiratory Department, University Hospital, León, Spain; 2Internal Medicine, University Hospital, León, Spain

Objectives:

Methods:

The true incidence of tuberculosis is higher than that in national and international records. Underreporting is estimated to vary between 7% and 27% according to studies.

Conclusion:

The SIVE data on the incidence of tuberculosis in the study area underestimate the true incidence rate. The source of information that involves recording cases of tuberculosis in the community is underused. The capture-recapture method, the annual incidence for 2008 was 48.14 (95% CI 37.85 - 56.44) and for 2009 of 34.17 (95% CI 30.19-38.17). In each of the years studied the number of cases obtained from the pharmacy register was higher.

Conclusions:

The incidence obtained in 2008 using the SIVE data was 18.80 x100000 and the rate using the pharmacy register was 26.77. In 2009, the SIVE data gave an estimate of 18.23 and the pharmacy register 22.50. When applied the capture-recapture method, the annual incidence for 2008 was 44.14 (95% CI 37.85 - 56.44) and for 2009 of 34.17 (95% CI 30.19-38.17). In each of the years studied the number of cases obtained from the pharmacy register was higher.

Conclusions:

P2872

Efficiency of molecular methods for epidemiological investigation in tuberculosis (TB)

Grzegorz Fussak-Standa2, Mariusz Dupłaga3, Zofia Zwolska2,
Ewa Nizankowska-Mogilnicka1, 1Department of Pulmonology, Jagiellonian University Medical College, Krakow, Poland; 2Department of Microbiology, The Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; 3Referential Tuberculosis Laboratory, John Paul Hospital, Cracow, Poland

Introduction:

High prevalence of tuberculosis in Poland may related to active transmission.

Objectives:

Methods:

Results:

Adverse drug reactions (ADRs) can lead to a patient interrupting tuberculosis (TB) treatment before completion, and contribute to avoidable morbidity, treatment failure, loss in quality of life, or death. While many national TB control programmes have a long tradition of monitoring patient care, the surveillance of drug-related problems, or pharmacovigilance, has not been systematic. The increasing worldwide use of more extensive regimens for drug-resistant TB, the concomitant use of antiretroviral therapy in patients with HIV-associated TB, and the imminent release on the market of new classes of medicines to treat TB make the case for pharmacovigilance even stronger.

WHO produced guidance this year on pharmacovigilance for TB through the financial support of the European Commission Seventh Framework Programme. The manual discusses how pharmacovigilance can be effectively implemented in a programme through key stakeholders, and provides a step-by-step approach on how to identify signals, assess relationships between an event and a drug, determine causality, and communicate findings. It presents three methodologies of pharmacovigilance which can be applied for the detection, assessment, understanding and prevention of adverse events or any other drug-related problem under field situations. The first two - spontaneous and targeted spontaneous reporting - can be built into national programmes of routine pharmacovigilance and/or tuberculosis control. The third type, cohort event monitoring (CEM), is an active form of surveillance, similar in design and management to an epidemiological cohort study. CEM would be particularly well suited to the post-marketing surveillance of new drugs.

Administration of BCG vaccination: Survey of practice in the Mersey region, UK

Sean Mackin1, Syed M.H. Kazmi2, Nick Coombes1, Mohammed Hussain2,
Clifford Biscase3, Peter Davies2, 1School of Medicine, University of Liverpool, United Kingdom; 2Respiratory Medicine, Liverpool Heart and Chest Hospital, Liverpool, United Kingdom; 3TB Centre, Liverpool Community Health, Liverpool, United Kingdom

Introduction:

Method:

Amongst 1853 patients who received a patient history and 183 patients were included in the questionnaire survey. The blood pressure was measured with an automated blood pressure monitor.

Conclusions:

P2875

Reducing patient safety: New WHO guidance on pharmacovigilance in tuberculosis care

Shanthi N. Pal2; Christian Lienhardt1, Sten Olsson3, Dennis Falzon1, 1STOP TB Department, World Health Organization, Geneva, Switzerland; 2Department of Essential Medicines and Pharmaceutical Policies, World Health Organization, Geneva, Switzerland; 3The Uppsala Monitoring Centre, (UMC), Uppsala, Sweden

Results:

Questions Guidelines Compliance (%)

Administration of BCG at sites other than upper arm

Prior assessment of HIV status

Prior evaluation of anaphylaxis risk

Availability of resuscitation equipment

Formal training of staff in paediatric resuscitation

* The other sites used were right upper arm or upper thigh. Reasons included patient preference or confusing scar.

There were no recorded episodes of anaphylaxis in the past 12 months. All centres referred patients with severe adverse local reactions appropriately.

Our survey demonstrates that NICE recommendations and their implementation were essential in elucidating areas of uncertainty in the administration of BCG vaccination and subsequently the practice is now uniform across the Mersey region. We intend to extend this survey to national level.
314. Trials in COPD: novel treatments and insights

**P2876**

**Quantification and treatment patterns of real-world patients classified by the GOLD 2011 strategy**

Mark Small, Sarah Broomfield, Victoria Higgins. Respiratory DSP, Adelphi Real World, Maclesfield, Cheshire, United Kingdom

**Objectives:** The Global Initiative for Chronic Obstructive Lung Disease (GOLD) 2011 Strategy classifies COPD patients into 4 categories: A: low risk, low symptoms; B: low risk, more symptoms; C: high risk, low symptoms; D: high risk, more symptoms. Based on risk (FEV1 < 20%, 50% predicted and/or exacerbation history < or ≥ 2 per year) and symptoms (COPD Assessment test [CAT] score < or ≥10 or ≥15), 1007 medical research centers (mRC) dyspnea scale < or ≥2.

We examined the proportion of patients in each category when evaluated by CAT or mMRC, and corresponding pharmacological treatment (CAT classification).

**Methods:** GOLD 2011 criteria were applied to a real-world international COPD population sampled from the Adelphi Respiratory Disease Specific Programme undertaken June to September 2011. Physicians and patients completed matched questionnaires.

**Results:** 2392 patients completed a questionnaire, of which 1508 with all 4 GOLD classification parameters were analyzed. The proportion of patients in categories A, B, C, and D were using a long-acting β2-agonist (LABA) alone (8, 6, 0, and 1%), long-acting muscarinic antagonist (LAMA) alone (37, 25, 8, and 5%), inhaled corticosteroid plus LABA (ICS/LABA) alone (22, 18, 8, and 8%), and ICS/LABA plus LAMA only (11, 20, 46, 43%).

**Conclusion:** CAT assessment increased the number of patients in the more symptomatic categories (B and D), compared with mMRC. Contrary to the GOLD 2011 recommendations, by CAT assessment, a high proportion of low-risk patients (A and B) were using ICS/LABA.

**P2877**

**Differential dropout may affect exacerbation risk estimates differently in moderate-to-severe COPD**

Peter Calverley1, Gørøn Eriksson2,3, Dirkje Postma4, Christine Jenkins5,6, Mark Pauwels7,8, Claus Vogelmeier6.

1Pulmonary and Rehabilitation Research Group, University of Groningen, Netherlands; 2Woolcock Institute of Medical Research, University of Sydney, Sydney, Australia; 3Department of Respiratory Medicine and Allergology, University Medical Center Groningen, GRIAC Research Institute, University of Groningen, Netherlands; 4Woodcock Institute of Medical Research, University of Sydney, Sydney, Australia; 5Department of Pulmonology, University of Texas Health Sciences Center, San Antonio, TX, United States; 6Department of Pulmonary, Critical Care Medicine, Netherlands; 7Division of Pulmonary Sciences and Critical Care Medicine, National Jewish Health, University of Colorado, Denver, CO, United States; 8Research and Development, AstraZeneca, Lund, Sweden; 9Division of Pulmonary Diseases and Thoracic Surgery, Hospital Grosshansdorf, Germany; 10Wolfgang Koch, Boehringer Ingelheim, Ingelheim, Germany; 11Department of Oncology, Haematology and Respiratory Diseases, University of Modena & Reggio Emilia, Modena, Italy; 12Division for Pulmonary Diseases, Hospital of the Universities of Giessen and Marburg, Marburg, Germany.

**Background:** Differential withdrawal of patients from clinical trials (dropout) complicates interpretation of the effect of intervention on the exacerbation frequency in COPD studies. We examined the impact of differential dropout on exacerbations in moderate-to-severe COPD (GOLD grades 2–4).

**Methods:** Patients in 3 pooled COPD studies were randomised to budesonide/formoterol (B/F 320/μg bid) or placebo (P) via Turbuhaler®. Exacerbations, dropouts and a composite of the two outcomes were examined over the first 3 months of treatment.

**Results:** 1583 COPD patients were studied (24% moderate; 61% severe, 14% very severe). B/F improved time to first exacerbation in moderate and severe but not very severe COPD (HRβ/FP: 0.43 [95% CI 0.25–0.72], 0.45 [0.33–0.63] and 0.58 [0.32–0.95]) vs. P. Time to dropout was improved by B/F vs. P, the differences being larger with increasing COPD severity (HRβ/FP: 0.62 [0.34–1.11], 0.56 [0.39–0.81] and 0.38 [0.18–0.80]). A composite measure of time to first exacerbation or dropout showed a significant effect of B/F in all severities.

**Conclusions:** Differential study dropout (greater with P than B/F) increased as the severity of COPD worsened. This should be considered when interpreting clinical COPD trial data.

**A randomized, crossover study to examine the pharmacodynamics and safety of a new antimuscarinic (TD-4208) in COPD**

Peter Poppelreuter1, Alan Hopkins1, Phillip Lau2, Dean Quin3, Craig Amburgey1, Edmund Moran4, 1Research and Development, Theravance Inc., South San Francisco, CA, United States; 2Wellington Research Unit, P3 Research, Wellington, New Zealand.

**Background:** TD-4208 is a potent and selective inhaled muscarinic antagonist with functional lung selectivity and long duration in preclinical models of bronchodilator.

**Aims:** To investigate the bronchodilatory profile, safety and tolerability of nebulized TD-4208 in patients with COPD and when evaluated by CAT assessment, a high proportion of low-risk patients (A and B) were using ICS/LABA.

**Methods:** Thirty-two patients aged 45-75 years with moderate or severe COPD were randomized in a double blind, complete 4-way crossover study. Single doses of 350 μg or 700 μg TD-4208, ipratropium (500 μg) or placebo were administered using a PARLC® Plus nebulizer in each period. Baseline and serial post-dose spirometry assessments (0-25 hrs) were performed. Safety evaluation included AEIs, vital signs, ECGs, and clinical lab results.

**Results:** A statistically significant improvement in peak FEV1 versus placebo of 174 mL (95% CI: 112, 235) was observed (p<0.001 for each comparison). Similar to ipratropium, onset of action on TD-4208 was rapid and bronchodilation was sustained over the 25-hr monitoring period. FEV1 difference from placebo at 12 hrs was 112.5 mL, 123.4 mL, and 15.3 mL; p <0.001, <0.001 and 0.669, and at 24 hrs was 102.8 mL, 136.6 mL, and -24.2 mL; p <0.001 and 0.327, for TD-4208 350 μg, 700 μg, and ipratropium, respectively. AEIs were generally mild and occurred with similar frequencies in all groups, with the most common being headache and dyspnea. No SAEs occurred.

**Conclusions:** TD-4208 was well tolerated and demonstrated significant peak bronchodilation with rapid onset that was sustained over 24 hrs suggesting a once daily dosing regimen.

**P2879**

**Association of β2-adrenoceptor genotypes with prevention of COPD exacerbations by tiotropium or salmeterol in the POET-COPD® trial**

Harald Koegler1, Klaus F. Rabe1, Kai M. Bech2, Thomas Glab3, Hendrik Schmidt1, Leonardo M. Fabbi1, Claus Vogelmeier1,2, Medical Affairs Germany, Boehringer Ingelheim, Ingelheim, Germany; 3Center of Pulmonary Diseases and Thoracic Surgery, Hospital Grosshadern, Germany; 4Insauf, Respiratory Research Institute, Wiesbaden, Germany; 5Biometrics and Data Management, Boehringer Ingelheim, Ingelheim, Germany; 6Department of Oncology, Haematology and Respiratory Diseases, University of Modena & Reggio Emilia, Modena, Italy; 7Division for Pulmonary Diseases, Hospital of the Universities of Giessen and Marburg, Marburg, Germany.

**Background:** β2-adrenoceptor (ADRB2) polymorphisms are found at positions B16 (G16R) and B27 (Q27E). The POET-COPD® trial allowed assessing the effects of these polymorphisms on exacerbations in patients treated with tiotropium (Tio) or salmeterol (Sal).

**Methods:** RCT comparing Tio 18 μg qd vs Sal pMDI 50 μg bid over 1 y. 7376 COPD patients aged ≥40 y, with a smoking history ≥10 pack-y, postBD FEV1 <70% pred., FEV1/FVC ratio <0.7, ≥1 exacerbation in past year.

**Results:** Genotype distribution and baseline characteristics of 5125 patients (89.5%) (Tio 2564; Sal 2561) who consented to genotyping were balanced between groups. Exacerbations in the Tio group were unaffected by B16 or B27 genotypes. While B27 did not affect Sal outcomes, B16 significantly modified the efficacy of Sal. The fraction of patients with ≥1 exacerbation was 32.3% in R16R, 39.8% in G16R, and 42.1% in G16G carriers (log rank P-values vs R16R: 0.0130 and 0.0018, respectively). Among R16R carriers, exacerbation risk was lower between groups, while for G16G and G16R, Tio was more effective than Sal.

**Conclusions:** In R16R carriers (16.5% of patients), Sal prevented exacerbations as effectively as Tio. In the majority of patients (83.5%), Tio was superior to the...

**Effects of high dose N-acetylcysteine in COPD patients**

Wilfried De Backer¹, Cedric Van Holsbeke¹, Anna Sadowska², Jan De Backer¹, Rita Claes², Wim Vos², ³

**Aim:** Studies suggest that NAC can reduce inflammation and hyperinflation in COPD patients, but little data is published about effects of high dose NAC (3x500mg daily) on airway remodeling. Since hNAC may induce high levels of GSH, this study focuses on the effect of hNAC on airway structure/function in relation to GSH.

**Method:** A double blind randomized placebo-controlled 2way crossover pilot study in 12 GOLDII patients was performed. Patients were treated twice for 3m with either hNAC or placebo (provided by Zambon S.p.A.) on top of their usual medication according to GOLD guidelines. Respiratory functional imaging (RFI) was used to assess airway volume (iVaw) and resistance (iRaw) (De Backer et al. Radiol. 2010;257(3):854-862). Data was collected at baseline and after both treatment periods.

**Result:** A clear drop in iRaw is seen in patients with a higher anti-oxidant reserve (i.e. low baseline GPx) despite lack of overall improvement in the entire population. This drop in iRaw is observed in patients that were already treated according to GOLD criteria.

**Conclusion:** For the first time reduction in iRaw caused by anti-oxidant mucolytic drug is shown using highly sensitive RFI methods. It would be interesting to study in a larger population whether this indicates recovery of the β₂-receptor sensitivity subject to oxidative impairment. The results demonstrate the potential of using RFI to assess anti-inflammatory characteristics of existing and newly developed compounds.

**Acute effect of erdosteine on preventing recurrence of exacerbation in COPD patients after hospital discharge**

Maurizio Moretti¹, Maria Ballabio², ³

**Introduction:** Acute exacerbations of chronic obstructive pulmonary disease (AE-COPD) are frequent cause of hospital admission and associated to high risk of recurrence. Preventing exacerbations is a key treatment goal.

**Objectives:** To evaluate the effect of erdosteine, an anti-oxidant mucolytic agent, given on acute setting during hospitalization for severe AE-COPD to prevent subsequent recurrence of exacerbations.

**Methods:** 15 COPD patients hospitalized for severe AE-COPD randomly received erdosteine 900mg daily or placebo for 10 days in combination with standard treatment. Recurrence of exacerbations after hospital discharge was assessed at 30 and 60 days. Data were correlated to pulmonary function indices and serum C-reactive protein (CRP) measured at 10 and 30 days after hospitalization.

**Results:** Table 1. The mean exacerbation recurrence was significantly higher (p < 0.05) in the placebo group. The recurrence of exacerbation was inversely correlated to FEF25-75% value at 10d (p < 0.05), 30d (p < 0.05) and positively correlated to serum CRP marker of systemic inflammation at 10d (p < 0.05) and 30d (p < 0.05).

</tbody>
</table>

Data are mean values. *p < 0.05 vs. placebo.

**Conclusions:** Treatment with erdosteine plus standard therapy in severe AE-COPD reduced their early recurrence after hospital discharge. These results were related to improvement in small airway obstruction and decrease of serum CRP at recovery from AECOPD. Mucolytic agents with relevant antioxidant activity may improve clinical outcome after AECOPD by reducing the burst of airway inflammation.

**Dose-finding study for tiotropium and olodaterol when administered in combination via the Respimat® inhaler in patients with COPD**

René Aalbers¹, M. Reza Maleki-Yazdi², Alan Hamilton¹, Stella Wauter-Wijker³, Anna Poooravorda, Olaf Schmidt³, Leif Björner³.

**Background:** Dual administration may provide improved bronchodilation with conventional once-daily dosing.

**Objective:** To determine the optimum once-daily combination of T+O delivered via the Respimat® inhaler in patients with COPD.

**Methods:** In a randomised, double-blind, 4-period, incomplete crossover study, patients with post-bronchodilator forced expiratory volume (FEV1) of ≥30% and <80% of predicted normal received combinations of T and O, with both agents delivered via separate Respimat® inhalers, as well as O monotherapy.
once daily for 4 weeks (NCT 01040403). The primary end point was trough FEV1 response (L) at the end of week 4.
Results: In total, 232 COPD patients (133 male; 99 female) received treatment. FEV1 responses (tong and up to 6 h post-dose) for O 5 and 10 μg monotherapy were similar. For all doses of T, FEV1 responses were significantly increased when added to O 5 and 10 μg. Dosing order for T when added to O was evident. No safety or tolerability concerns were identified.
Conclusions: Addition of T to O resulted in significant improvements in FEV1 versus O alone. These data support further investigation of T 2.5 and 5 μg combined with O 5 μg in the Phase III T+O clinical trial programme.

P2885
Once-daily NVA237 reduces exacerbations and improves symptoms in COPD patients: A pooled analysis of the GLOW1 and GLOW2 studies.
Donald Banerji1, Vijay Alagappan2, Carmen Martinez1, Ellie He1, Hungta Chen1, Tim Overend2,1.1 Primary Care, Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, United States; 1Primary Care, Novartis Horsham Research Centre, Horsham, West Sussex, United Kingdom; 1Integrated Information Sciences (Respiratory), Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States
Introduction: NVA237 (glycopyrronium bromide) is a safe and once-daily (QD) inhaled long-acting muscarinic antagonist for the maintenance treatment of COPD.
Methods: This is a pooled analysis of the GLGlycopyrronium bromide in COPD airways clinical studies (GLOW1 and 2) which assessed the efficacy of NVA237 50 μg QD vs placebo (PBO) and open-label tiotropium 18 μg QD (TIO) over 26 to 52 wks in COPD patients. Results include exacerbations, symptoms (transition dyspnea index [TDI]) and Health Status (St George’s Respiratory Questionnaire [SGRQ]).
Results: 1854 patients were analyzed (NVA237=1059, TIO=267, PBO=528). NVA237 statistically significantly prolonged the time to first moderate/severe exacerbation vs PBO (WK 26: hazard ratio [HR] 0.64; WK 52: HR 0.67, both p<0.001), which was comparable to TIO (WK 26: HR 0.70, p=0.026; WK 52: HR 0.61; both p<0.001). NVA237 had a statistically significantly lower rate of moderate/severe exacerbations vs PBO (WK 26: rate ratio [RR] 0.66; WK 52: RR 0.66; both p<0.05), while TIO was not significantly different from PBO (WK 26; RR 0.74, p=0.085 and WK 52; RR 0.80, p=0.179). Treatment difference in TDI total score was significant for NVA237 (WK 26: 0.93 and WK 52: 0.57) and TIO (WK 26: 1.05 and WK 52: 0.66) vs PBO, all p<0.05. SGRQ score (LS Mean [SE]) at Wk 52: -3.32 [1.04], p<0.001 and TIO (WK 26: -2.43 [1.01] and WK 52: -2.84 [1.15], p<0.05) vs PBO.
Conclusion: NVA237 once daily significantly reduced COPD exacerbations and improved symptoms vs PBO over 52 wks. Overall, the effects of NVA237 were similar to tiotropium.
Results: In 35 patients analyzed, bronchodilation did not significantly increase 
tar retention (-4.5%, p=0.20), or nicotine retention (-2.6%, p=0.11).
Bronchodilation did not significantly affect our secondary outcomes. Secondary
analysis revealed potentially less retention due to bronchodilation: tar retention
-3.8% (p=0.13), and nicotine retention -3.4% (p=0.01).

Conclusions: Our results do not support the hypothesis that bronchodilation in-
creases cigarette tar and nicotine retention in COPD patients. Instead, we observed
a possibility for less retention.

P2887
Lung function effects and safety of fluticasone furoate (FF)/vilanterol (VI) in
patients with COPD: Mid-high dose assessment
Fernando Martinez1, Joseph Bosca2, Gregory Feldman3, Catherine Scott-Wilson4, Sally Kilbride4, Leonardo Fabbrini5, Peter
M.A. Calverley6, Courtney Crim7, 1Department of Medicine, University of
Michigan, Ann Arbor, United States; 2Clinical Research, CU Pharmaceutical
Research, Union, United States; 3Clinical Research, S. Carolina Pharmaceutical
Research, Spartanburg, United States; 4Respiratory Medicine Development
Center, GlaxoSmithKline, Research Triangle Park, United Kingdom; 5Department
of Oncology Haematology and Respiratory Diseases, University of Modena &
Reggio Emilia, Modena, Italy; 6Clinical Science Centre, University Hospital
Aintree, Liverpool, United Kingdom

Rationale: FF/VI is a novel once-daily (OD) inhaled corticosteroid/long-acting
beta2 agonist in development as combination therapy for COPD.

Objective: To evaluate the efficacy and safety of FFVI (2000 and 1000/25) vs
placebo (PBO), FF (200 and 100mcg) and VI (25mcg), given OD via novel dry
powder inhaler in moderate-severe COPD patients for 168 days.

Methods: A multicentre, randomised, PBO-controlled, double-blind, parallel-
group study (N=1224 (ITT)). Co-primary endpoints: weighted mean (wm) FEV1
(0–4h). Addition of FF to VI provided numerical improvements only
in trough FEV1 (0-4h). Additional endpoints to assess the contribution of VI, and
trough FEV1 (Day 169) to assess the contribution of FF and 24h duration of VI. Additional
endpoints included CRQ-SAS dyspnoea, and safety.

Results: Co-primary endpoints, see Figure. Treatment differences from PBO for
dyspnoea scores were -0.12, -0.01, 0.07, 0.24 and 0.10 for FF 100, 200, VI 25,
FFVI 100/25, 200/25, respectively. On-treatment AEs were similar between active
treatment groups (38-47%) and PBO (47%). No treatment effects on 24h urinary
cortisol, laboratory values, or cardiac monitoring parameters were seen.

Conclusions: Addition of FF to VI reduced the annual rate of MSE and time to
onset of 1st MSE, with evidence of a consistent effect of the 100/25mcg strength
in individual studies and the pooled analysis. Lung function improved at all strengths
of FF/VI vs VI in pooled analysis. The safety of the combination is reported
separately.

Funded by GSK: HZC102871: NCT01009463, HZC102970: NCT01107952.

P2889
Efficacy of combination fluticasone furoate/vilanterol (FF/VI) and
salmeterol/fluticasone propionate (SFC) over 12 weeks in patients with COPD
Alvar Aguisti1, Wilfried De Backer2, Luis de Teresa1, Michael Zvirch3,
Nick Locantore4, Neil Barnes5, Jean Bourbeau2, Courtney Crim1, 1Thorax
Institute, Hospital Clinic, University of Barcelona, Spain; 2Respiratory Medicine,
University of Antwerp, Wilrijk, Belgium; 3Internal Medicine, Clínica Mediterránea
de Neurociencias, Alicante, Spain; 4Respiratory Medicine Development
Center, GlaxoSmithKline Inc, Research Triangle Park, NC, United States;
5Respiratory Medicine, Barts and the London NHS Trust, London, United
Kingdom; 6Medicine, McGill University Health Centre, Montreal, QC, Canada

Introduction: The novel combination of FF, an inhaled corticosteroid and VI, a
long-acting beta2 agonist, is under development as a once-daily (OD) therapy for
COPD and asthma.

Objectives: To compare the efficacy of OD FF/VI and twice-daily (BD) SFC in
moderate-to-severe COPD.

Methods: In a randomised, double-blind, double-dummy, parallel-group study,
COPD patients (mean post-bronchodilator predicted FEV1, = 48%) received
FF/VI 100/25mcg OD AM (N=266) via a novel dry powder inhaler or SFC 50/500mcg
BD (N=262) via DISKU™. Primary efficacy: change from baseline in 0–24h weighed mean (wm) FEV1. Secondary endpoints included time to
100mL improvement on baseline on Day 1 (speed of onsets), SGRQ-C,
safety endpoints included adverse events (AEs).

Results: There were non-significant trends favouring FF/VI (130mL) versus SFC
(100mL) for wmFEV1 (22mL, [95%CI: –18.63, p=0.282) and speed of onset;
FF/VI=161mL, SFC=281mL (p=0.280). A clinically meaningful improvement (≥4.8)
in SGRQ-C score was seen with FF/VI, but not SFC (-3.3), though the
difference (-1.5 [95%CI: –3.9, 0.9]) was not statistically significant (p=0.215).
Both treatments were well tolerated. 13 (4%) and 6 (2%) patients in the FF/VI
and SFC arms experienced serious AEs; the same numbers withdrew as a result of
on-treatment AEs. Safety profiles, including pulse rate, were similar.

Conclusions: OD FF/VI and BD SFC improved lung function in patients with
moderate-to-severe COPD without substantial safety concerns. Primary and sec-

Research Group, Manchester Academic Health Sciences Centre, Manchester,

Arbor, United States; 3Department of Internal Medicine, University of
Michigan, Ann Arbor, United States; 4Respiratory Medicine Development
Center, GlaxoSmithKline, Research Triangle Park, United States; 5Quantitative
Sciences Division, GlaxoSmithKline, Uxbridge, United Kingdom

Introduction: FF/VI is in development as once-daily (OD) combination therapy
for COPD.

Objectives: Assess effect of FF/VI on exacerbation rates in COPD compared
to VI. Safety is described separately.

Methods: In two replicate 1 year studies (HZC871:N=1622, HZC970:N=1633),
after a 28 day run-in with ADVAIR DISKUS® 250/500mcg subjects received FF/VI
50/25, 100/25, 200/25mcg or VI 25mcg OD. Primary endpoint was the annual rate
of moderate/severe exacerbations (MSE). Secondary efficacy endpoints included
time to first 1st MSE and trough FEV1.

Results: Rate ratios (95%CI) for MSE with FF/VI vs VI (by-study & pooled
data) are shown (Figure). There was a reduction in risk in time to 1st MSE vs
VI (p<0.036) for FF/VI 200/25 (HZC970 & pooled) and 100/25mcg (all). Trough
FEV1 vs VI at week 52 was greater (p<0.011) for all FF/VI strengths in HZC871
(50/25=41mL, 100/25=58mL, 200/25=64mL) and pooled data (50/25=38mL,
100/25=42mL, 200/25=46mL) but for 50/25 only (34 mL, p=0.034) in HZC970.

Effects of twice-daily aclidinium bromide in COPD patients: A long-term extension of ACCORD-COPD I
Anthony D’Urzo1, Edward Kerwin2, James Donohoue3, Stephen Rennard4, Arun Gopalakrishnan5, Tasan Lakkrit6, Esther Garcia Gil6, Cynthia Caracta6, 
1Department of Family & Community Medicine, University of Toronto, Canada; 2Clinical Research Institute, Medford, United States; 3Department of Medicine, University of North Carolina, Chapel Hill, United States; 4Department of Internal Medicine, University of Nebraska Medical Center, Omaha, United States; 5Southern California Clinical Trials, Lakewood, United States; 6Biostatistics, Forest Research Institute, Jersey City, United States; 7R&D Centre, Almirall, S.A., Barcelona, Spain; 8Clinical Development, Forest Research Institute, Jersey City, United States

Introduction: The long-term effects of twice-daily (BID) aclidinium 200 μg and 400 μg were assessed in patients with moderate-to-severe COPD.

Methods: In this 52-week, double-blind, extension study, COPD patients on aclidinium 200 μg or 400 μg BID during the 12-week lead-in continued the same treatment while patients in the placebo group were re-randomized (1:1) to aclidinium 200 μg or 400 μg BID. Baseline was prespecified as Visit 2 of the lead-in study. Spirometry, SGRO, and adverse events (AEs) were assessed.

Results: A total of 467 patients completed the lead-in study and 291 patients volunteered for the extension study. At study end, placebo patients re-randomized to aclidinium 400 μg and those on either dose of continuous aclidinium treatment showed improvements from baseline in trough FEV1. All groups showed improvements from baseline in SGRO Total score (range, 4.85-7.92 point improvement).

The percentages of patients with an AE were similar for both doses. Incidence of anticholinergic AEs was low and similar for both groups; dry mouth occurred in 1 patient (400 μg). The incidence of cardiac AEs was low across treatments (<5%, any event) and did not occur in a dose-related manner. The incidence of serious AEs (SAE) was comparable in the 200 μg (14.6%) and 400 μg (13.2%) groups; the one SAE reported in the placebo group was COPD exacerbation. One patient from each treatment group died during the study and both deaths were deemed unrelated to treatment.

Conclusions: Patients continuing long-term treatment with aclidinium 200 μg or 400 μg BID maintained improvements in lung function and health status compared to baseline. Aclidinium was well tolerated throughout this 1-year extension study.

P2091
Pooled analysis of twice-daily aclidinium bromide in COPD patients: Dyspnea and health status in the ACCORD-COPD I and ATTAIN trials
Paul Jones1, Edward Kerwin2, Eric Bateman3, Rosa Lamarca4, Cynthia Caracta6, Esther Garcia Gil6, 
1Division of Pulmonary & Critical Care Medicine, David Geffen School of Medicine at UCLA, Los Angeles, United States; 2Department of Clinical Sciences, St. George’s University, London, United Kingdom; 3Clinical Research Institute, Medford, United States; 4Respiratory Medicine, University of Cape Town Lung Institute, Cape Town, South Africa; 5Clinical Statistics, Almirall, S.A., Barcelona, Spain; 6Clinical Development, Forest Research Institute, Jersey City, United States; 7R&D Centre, Almirall, S.A., Barcelona, Spain

Introduction: Aclidinium is a novel, long-acting muscarinic antagonist in development for COPD treatment. Pooled analyses of dyspnea and health status data from the ACCORD and ATTAIN trials are shown here.

Methods: Patients (N=1389) were randomized (1:1) to aclidinium 200 μg, 400 μg or pbo BID for 12- and 24-weeks for the ACCORD and ATTAIN, respectively. Endpoints included change from baseline in FEV1 over 3h postdose on Day 1 as well as trough and peak FEV1 at Week 12.

Results: Mean (SD) baseline and % predicted FEV1 were 1.45 (0.525) and 85 (14.3), respectively. Significant improvements in lung function were seen following the first dose, as measured by change from baseline in FEV1 at 0.5h postdose (first time point assessed) on Day 1 (200 μg, 99 mL; 400 μg, 128 mL; both p<0.0001 vs pbo). The long-term effects of twice-daily (BID) aclidinium 200 μg and 400 μg were sustained throughout the study. Both doses resulted in statistically significant improvements from baseline to Week 12 in trough FEV1; a greater improvement and a clinically significant effect in trough FEV1 was seen with the higher dose (200 μg, 80 mL; 400 μg, 112 mL; both p<0.0001 vs pbo). Mean change from baseline to Week 12 in peak FEV1 was 167 mL and 191 mL for 200 μg and 400 μg, respectively (both p<0.0001 vs pbo), with numerically greater improvements following treatment with the 400 μg vs 200 μg dose at all measured time points from 0.5h to 3h postdose.

Conclusions: Both doses of aclidinium produced significant improvements in lung function in COPD patients, with the 400 μg dose being consistently more effective. Maximal improvements in lung function were seen at Day 1 and were maintained over 12 weeks.

P2092
Twice-daily aclidinium bromide in COPD patients: A pooled analysis of lung function in the ACCORD-COPD I and ATTAIN trials
Edward Kerwin1, Paul Jones2, Anthony D’Urzo3, Ludmila Rekeda4, 
1Clinical Research Institute, Medford, United States; 2Division of Clinical Sciences, St. George’s University, London, United Kingdom; 3Family & Community Medicine, University of Toronto, Canada; 4Biostatistics, Forest Research Institute, Jersey City, United States; 5R&D Centre, Almirall, S.A., Barcelona, United States; 6Clinical Development, Forest Research Institute, Jersey City, United States

Introduction: Aclidinium is a novel, long-acting muscarinic antagonist being investigated for maintenance treatment of COPD. Pooled analyses of lung function data from the ACCORD and ATTAIN trials are presented here.

Methods: Patients (N=1389) were randomized to aclidinium 200 μg, 400 μg, or pbo BID for 12- and 24-weeks for ACCORD and ATTAIN, respectively. Endpoints included change from baseline in FEV1 over 3h postdose on Day 1 as well as trough and peak FEV1 at Week 12.

Results: Mean (SD) baseline and % predicted FEV1 were 1.45 (0.525) and 85 (14.3), respectively. Significant improvements in lung function were seen following the first dose, as measured by change from baseline in FEV1 at 0.5h postdose (first time point assessed) on Day 1 (200 μg, 99 mL; 400 μg, 128 mL; both p<0.0001 vs pbo). The long-term effects of twice-daily (BID) aclidinium 200 μg and 400 μg were sustained throughout the study. Both doses resulted in statistically significant improvements from baseline to Week 12 in trough FEV1; a greater improvement and a clinically significant effect in trough FEV1 was seen with the higher dose (200 μg, 80 mL; 400 μg, 112 mL; both p<0.0001 vs pbo). Mean change from baseline to Week 12 in peak FEV1 was 167 mL and 191 mL for 200 μg and 400 μg, respectively (both p<0.0001 vs pbo), with numerically greater improvements following treatment with the 400 μg vs 200 μg dose at all measured time points from 0.5h to 3h postdose.

Conclusions: Both doses of aclidinium produced significant improvements in lung function in COPD patients, with the 400 μg dose being consistently more effective. Maximal improvements in lung function were seen at Day 1 and were maintained over 12 weeks.

ized FEV1,AUC0−3, and change from baseline to Week 52 in SGRQ and EuroQol scores.

Results: A total of 605 patients were randomized to this study. Both aclidinium 200 μg and 400 μg BID resulted in improvements from baseline to Week 52 in trough and peak FEV1 (Table), with numerically larger increases seen with the 400 μg dose. At study end, change from baseline in normalized AUC0−3 FEV1 was also improved for both groups, with greater improvements seen with the higher aclidinium dose (Table). Both treatment groups showed clinically significant improvements in SGRQ Total score and improvements in EuroQol, parameters from baseline to Week 52 (Table).

Conclusions: Treatment with aclidinium 200 μg or 400 μg BID results in benefits in lung function and health status in COPD patients over 1 year.

P2894

Effect of inhalation of tobramycin on reduction of hospitalisation rate in severe COPD

Peter Hasl1 Pneumonology II, Fachkrankenhaus Kloster Grafshaft, Schmallenberg, Germany

Introduction: Exacerbation in severe COPD often requires hospital treatment and has a negative impact on patients prognosis. An important cause of frequent exacerbations is lower airway bacterial colonisation in stable disease. In addition moderate bronchectasis are present in up to 50% in severe COPD. The study investigated the effect of daily inhalation of tobramycin on hospitalisation rate in severe COPD.

Methods: At six centers we randomly assigned 44 patients (30 males) with severe COPD (FEV1 of predicted value 42.8±7.1 Tobra and 33.5±10.3 placebo) and a minimum of two hospitalisations in the year before inclusion. Patients inhaled twice daily for 12 months 80 mg tobramycin (GERNEBRICIN®) or isotonic saline ( placebo) with a jet nebulizer (Puri Boy SX). Primary endpoint was hospitalisation rate in the period of study, secondary endpoints time to first hospitalisation and 6 MWD.

ITT = number of patients which took study medication for at least 28 days.

Conclusion: Inhalation with 160 mg tobramycin by means of a nebulizer over a 12 month period didn’t reduce the hospitalisation rate for patients with severe COPD and a minimum of two hospitalisations compared to placebo. The statistical relevance is reduced by a high drop-out rate specifically in the tobramycin-group unrelated to side effects during inhalation of tobramycin. However, the underlying reason remains unexplained.

Discharge coordinator intervention prevents hospitalisations in patients with COPD: A randomized controlled trial

Mirja Launs1, Sasa Kadrev1, Mitja Kosnik1, Barbara Benedik2, Marjana Bratkov2, Tatjana Jakhel1, Robert Marcun2, Petra Mikloša2, Barbara Štak1, Jurema Farkas2, Division of Cardiology, University Clinic, Golnik, Slovenia; 2Division of Pneumology, University Clinic, Golnik, Slovenia; 3Chair of Public Health, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background: Discharge planning is key element in the healthcare continuum that seeks to bridge the gap between hospital and patient home environment. As limited data is available for COPD, we conceived this study to determine the effectiveness of discharge coordinator intervention in reducing the risk for COPD hospitalisation.

Methods: This was a randomized, controlled trial that compared discharge coordinator intervention with usual care. Patients were enrolled within 48 hours following admission due to COPD exacerbation. Discharge coordinator intervention included educational and self-management sessions with patients and caregivers and liaison with health and social care providers in patient home environment. Patients in control group received standard management.

Results: Of the 253 eligible patients (71.49 years, 72% men, 87% GOLD III/IV), 118 were assigned to intervention and 135 to usual care group. During follow-up of 180 days, fewer patients receiving intervention were hospitalized due to COPD (14% vs 31%; p=0.002). In time to event analysis, intervention was associated with lower rates of COPD hospitalisations (p=0.001). Cox model of proportional hazards adjusted for sex, age, GOLD stage, heart failure, cancer, and long term oxygen treatment demonstrated that intervention reduced risk of COPD hospitalisation (hazard ratio 0.43, 95% confidence interval 0.24-0.77, p=0.002).

Conclusions: Among patients hospitalized for COPD exacerbation, discharge coordinator intervention reduced COPD hospitalisations. Hospital management programs should consider discharge planning to improve outcome in patients with COPD.

P2896

QVA149 administered once daily provides significant improvements in lung function over 1 year in patients with COPD: The ENLIGHTEN study

Ronald Dahl1, Kenneth Chapman2, Michael Rudolf2, Rajendra Mehta3, Pearl Kho2, Vijay Alagappan4, Indriana Bethane5, Hungta Chen6, Donald Banerji7, Department of Respiratory Diseases, Aarhus University Hospital, Aarhus, Denmark; 2Airway and Asthma Care, University Health Network, Toronto Western Hospital, Toronto, Canada; 3Dept of Respiratory Medicine, Ealing Hospital NHS Trust and Imperial College, London, United Kingdom; 4Allergy and Asthma Care, Allergy and Asthma Care and Research Centre, Indore, India; 5Novartis Horsham Research Centre, Novartis, Horsham, United Kingdom; 6Novartis Pharmaceuticals Corporation, Novartis, East Hanover, NJ, United States

Background: QVA149 is a once-daily, fixed-dose combination of the long-acting β2-agonist indacaterol and the long-acting muscarinic antagonist NVA237 (glycopyrronium bromide) in development for the treatment of COPD. This study evaluated the long-term effect of QVA149 on lung function in patients with COPD.

Methods: In a multicenter, double-blind, placebo-controlled study, patients with moderate-to-severe COPD were randomized (2:1) to receive QVA149 (110/50 μg) or placebo (PBO) via a single-dose dry powder inhaler (Breatherhaler®) for 52 weeks. Treatment was taken in the morning at the same time of day. Lung function was measured as forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC) at 30 and 60 min post-dose at clinic visits over 52 weeks. Missing values were not imputed.

Results: 338 pts (77% male, mean age 63 years; mean post-salbutamol FEV1 57%; predicted, FEV1/FVC 54%) were randomized to receive QVA149 (n=225) or PBO (n=113); 86% and 79% of patients respectively completed treatment. QVA149 significantly increased FEV1 and FVC vs PBO at all assessment points (Table). QVA149 vs PBO differences in FEV1 and FVC (mL) (all p<0.001):

<table>
<thead>

Conclusion: QVA149 once daily provided rapid and clinically meaningful bronchodilation compared with PBO. No tachyphylaxis was observed and the bronchodilator effect was sustained over the 52-week treatment period.

P2897

Pneumonia in COPD patients treated with fixed ICS/LABA combinations

Kjell Larsson1, Kjell Larsson1, Karin Lisper1, Björn Ställberg2, Georgios Stratelis4, Gunilla Telg4, Leif Jörgensen4, Gunnar Johansson1.

1Department of Medical Scinces, Respiratory Medicine, Uppsala University, Uppsala, Sweden; 2Unit of Lung and Allergy Research, National Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; 3Deposed Department of Public Health and Caring Sciences, Family Medicine and Preventive Medicine, Uppsala University, Uppsala, Sweden; 4Department of Asthma, Northern Region, Sweden; 5Department of Public Health and Caring Sciences, Family Medicine and Preventive Medicine, Uppsala University, Uppsala, Sweden

Background: Inhaled corticosteroids (ICS) in combination with long-acting β2-agonists (LABA) improve quality of life and reduce exacerbations in chronic obstructive pulmonary disease (COPD). Increased prevalence of pneumonia has been identified during treatment with fluticasone but not with budesonide, but no direct comparions have been performed.

Objectives: To investigate occurrence of pneumonia in a COPD population treated with fixed ICS/LABA combination; budesonide/formoterol (BfF) or fluticasone/salmeterol (SfS) (NCT01146392).

Methods: Medical records’ data from primary care patients ≥ 18 years was linked to Swedish hospital and drug register data for 1999 – 2009. Index date was first prescription of a fixed ICS/LABA combination post COPD diagnosis. Propensity score matching was done at index date.

Results: The total sample covered 9,893 patients. Matching gave two equivalent populations (2,734 patients/group) using either BfF or SfS at index. Mean prescribed daily steroid dose was 562 μg budesonide and 786 μg fluticasone. In all, 15,353 pneumonia diagnoses were seen. 44% of all patients had experienced
pneumonia within 8 years post COPD diagnosis. Yearly rate of pneumonia for B/F was significantly lower, 0.062 compared to 0.11 for F/S; 44% difference (p<0.0001). Yearly rate of hospitalisations due to pneumonia was 0.041 vs 0.074 (+45%), days at hospital/year 0.34 vs 0.63 (+86%) for B/F vs F/S, respectively. Time to first diagnosis of pneumonia showed a hazard ratio of 0.794 (95% CI 0.706, 0.892) in favor of B/F.

**Conclusion:** In this observational register study, COPD patients treated with budesonide/formoterol experienced fewer pneumonias than patients treated with fluticasone/salmeterol.

**Study sponsor:** AstraZeneca.

Estimates of demand and use for home oxygen for COPD in England and Wales

Gavin Danahill1, Jadwiga Wedzicha1, Hamza Jamil1, Kevin Holton1, Sue Hill2,3, Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom; 2Department of Health, Medical Directorate, London, United Kingdom

**Introduction:** There are an estimated 60,080 patients (40% of GOLD IV) who require home oxygen in England and Wales. It is unknown whether this need is met, or whether assessment and/or review of all home oxygen users would be beneficial.

**Methods and results:** To estimate the prevalence of COPD among home oxygen users, a survey of 2,845 patients was undertaken with patients asked about the single condition for which they were prescribed oxygen. It is calculated that they received it for COPD and 15% gave a reply of “Not Known” or “Not Stated” or ticked two conditions. Thus 68%, from 58%/11.0.15), of all home oxygen were estimated as having COPD. This equates to 5825 patients. It suggests that either supply is matching demand, or that some COPD users may be being inappropriately prescribed home oxygen, and that there are others with an unmet need.

Further data was obtained on oxygen concentrator electricity consumption and cylinder deliveries to 71,078 patients (with varied diagnoses) over a 6-month period from three oxygen providers. A total of 16,657 or 24% patients with a home oxygen prescription used no oxygen, 16,524 used less than 20% prescribed and 5,124 between 20% – 40% prescribed. In addition, 2,664 patients were prescribed Short-Burst Oxygen Therapy (SBOT) without clinical trial evidence that SBOT is effective and for many patients, in addition to their oxygen concentrator.

**Discussion:** These data suggest the importance of research to the home oxygen user in England and Wales and inclusion of clinical assessment and review (HOS_AR) schemes to improve the accuracy of prescription, patient adherence and by withdrawing unnecessary home oxygen, particularly SBOT, ensure that supply matches demand.

Target lobar volume reduction and COPD outcome measures after endobronchial one-way valve therapy

Archanaj Vajirapalan1, Felix J.F. Herth2, Gerard J. Criner3, Jean Michel Vergeon4, Jonathan Goldin5, Frank Sciruba6, Armin Ernst7, 1Department of Respiratory and Critical Care Medicine, Ludwig-Boltzmann Institute for COPD and Respiratory Epidemiology, Ott-Wagner Hospital, Vienna, Austria; 2Pneumology and Critical Care Medicine, Thoraxklinik, Heidelberg, Germany; 3Temple Lung and Critical Care Medicine, Thoraxklinik, Heidelberg, Germany; 4Center for Computer Vision and Imaging Biomarkers, Department of Radiological Sciences, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States; 5School of Medicine, University of Pittsburgh, PA, United States.

**Introduction:** Clinical effectiveness of endobronchial one-way valve therapy in patients with emphysema appears to be related to the extent of lobar volume reduction.

**Methods:** Data derived from a multicentre study from 416 patients with severe emphysema (62% male, age 63.4±7.7, FEV1 30±8%), who were randomized to valve therapy (n = 284) or conservative treatment (n = 132), were analyzed. Pulmonary function, exercise capacity, dyspnea scores, and CT analysis of target lobar volume reduction (TLVR) were assessed before and after 6 months of valve therapy.

**Results:** Of patients randomized to the treatment group, 49 (17%) showed >50% target lobar volume reduction, 57 (20%) demonstrated TLVR between 20% and 50%, and 178 patients (56%) > 20% TLVR at 6 months post intervention (p < 0.001). Patients with TLVR > 50% demonstrated greater improvements in lung function parameters, exercise capacity (6-MWT), quality of life (SGRO) and dyspnea score (mMRC) compared with the other groups. Consequently, BODE index was significantly improved by 1.4±1.1, 0.2±1.3, and 0.1±1.3 points in patients with TLVR > 50%, < 50% TLVR > 20%, and TLVR < 20%, respectively, whereas it worsened by 0.3±1.2 points in controls after 6 months (p < 0.001 for inter-group differences). Logistic regression analysis identified target lobar volume reduction as the strongest independent predictor of improved BODE index scores from baseline to 6 months.

**Conclusions:** The extent of lobar volume reduction predicts improvement in BODE index and health outcomes associated with bronchoscopic lung volume reduction using one-way valves.
P2902
Hospital admitted COPD patients treated at home using teledermatology — A randomised, multi-centre trial
Anna Svarn Jakobsen, Lars Christian Laursen, Birte Østergaard, Susan Rydahl-Hansen, Christina Emme, Lone Schou, Klaus Viengpheth Phanareth. Telemedicine Research Unit, Frederiksborg University Hospital, Frederiksborg, Denmark; Medical Department 6, Herlev University Hospital, Herlev, Denmark Research Unit of Nursing, Institute of Clinical Research, University of Southern Denmark, Odense, Denmark Research Unit of Clinical Nursing, Bispebjerg University Hospital and Frederiksberg University Hospital, Bispebjerg, Denmark Telemedicine Research Unit, Frederiksborg University Hospital, Frederiksberg, Denmark Telemedicine Research Unit, Frederiksberg University Hospital, Frederiksberg, Denmark

Background: COPD Patients with acute exacerbations are frequently admitted to emergency wards causing the patients to feel anxiety, loss of control and stress, and also causing considerable healthcare costs for the society.

Aim: We investigated whether patients with COPD exacerbations admitted to a hospital following discharge can be future-safe and safely be treated at home by means of teledermatology technology (TT).

Methods: Fifty-seven patients with severe COPD, who fulfilled the inclusion criteria and consented to participate within 24 hours of a hospital admission, were randomised to receive either standard treatment at the hospital or standard treatment at home using TT. The equipment consisted of a video conference system and a webcam, measuring equipment (spirometer, thermometer, and pulsoximeter), 24 hour online web-service, access to oxygen, nebulizer and medical therapy. Two university hospitals participated. Readmission within 30 days after discharge was selected as primary outcome.

Results: Twenty-nine patients were allocated to the TT group and 28 patients received usual care in the hospital. There were 10 readmissions in each group involving eight patients in the TT group and six patients in the control group. Readmission rate was 27.6% (95% CI 11.3 to 43.9) in the TT group and 21.4% (95% CI 6.2 to 36.6) in the conventional group. No statistically significant differences between groups in readmission rate, use of antibiotics or systemic steroids were seen. No deaths occurred during the study period.

Conclusion: We propose that a considerable segment of patients with COPD exacerbations admitted to hospital can be safely treated at home using the TT solution.

P2903
COPD self management: The impact of implementing self management plans & rescue medications across 3 hospitals
Hasamin Khachi, Matthew Hodson, Robert Hudson, Michael Parker. Respiratory Pharmacy Department, Bart’s and the London NHS Trust, London, United Kingdom Respiratory Department, Homerton University Hospital NHS Foundation Trust, London, United Kingdom Health Innovation & Education Cluster, Health Innovation & Education Cluster, London, United Kingdom Postgraduate Medical Institute, Anglia Ruskin University, Essex, United Kingdom

Introduction: Guidelines for COPD suggests that patients should be given self-management advice and rescue medication.

Aims & Objectives: Assess if a unified self management strategy, consisting of a self management plan, education and rescue medications, reduces hospital readmissions at 30 and 90 days.
