Sunday, September 2nd 2012

160–167 48. Different ways to phenotype asthma ................................................................. 1s
168–175 49. Sarcoidosis ........................................................................................................... 3s
176–183 50. Chest wall, diaphragm and pleura ............................................................... 4s
184–191 51. Diagnostics in OSA: from polygraphy to genetics and cancer ................. 6s
192–199 52. Exacerbations of asthma and COPD: assessment, impact and novel treatments 8s
200–206 53. MDR- and XDR-TB: epidemiological and public health overview .......... 10s
P207–P224 54. COPD is not a pulmonary disease alone ...................................................... 12s
P225–P241 55. Asthma: risk factors and effect of anti-IgE .................................................... 16s
P242–P259 56. Pathophysiological mechanisms in disease: new insights ..................... 19s
P260–P277 57. Functional imaging in pulmonary oncology and COPD. Radiation dose in chest CT: survey and real life 23s
P278–P295 58. Ultrasound in pulmonary medicine: from inside and outside ............. 27s
P296–P313 59. Airway diseases: from invasive to noninvasive biomarkers .................... 31s
342–349 68. Late breaking results: Asthma from phenotyping to emerging new treatments 34s
350–357 69. Asthma and COPD at work: what are the effects of exposure and risk factors? 36s
358–365 70. Mechanisms of asthma ................................................................................. 38s
366–373 71. Pulmonary circulation: clinical databases and registries ........................... 40s
374–381 72. Functional imaging of the lung parenchyma, tumours and circulation .... 43s
382–389 73. Update on neutrophil and macrophage function in COPD ......................... 45s
390–396 74. How to use technology to provide better critical care ................................. 47s
P397–P414 75. Clinical management of lung diseases: from bronchi to pleura ............ 48s
P415–P431 76. Tuberculosis and immunologic assays ..................................................... 52s
P432–P449 77. CPAP: beneficial effects on different aspects of health ......................... 56s
P450–P467 78. Asthma and COPD: quality of life and comorbidities ......................... 60s
P468–P481 79. Gene–environment treatment and asthma ............................................. 64s
P482–P499 80. Physiotherapy and rehabilitative interventions applied to different populations with respiratory impairment ................................................................. 67s
P500–P519 81. Asthma: assessment and treatment ............................................................ 71s
P520–P539 82. COPD comorbidities I ............................................................................ 75s
P540–P559 83. COPD comorbidities II .......................................................................... 79s
P560–P579 84. Respiratory infections: a clinical point of view ......................................... 83s
P580–P599 85. Respiratory manifestations of systemic disease: a holistic approach .... 87s
P600–P619 86. The latest insights in chronic care ......................................................... 91s
P620–P639 87. The latest insights in integrated care .................................................... 96s
P640–P659 88. Standard of care, incidental findings, image acquisition ..................... 100s
P660–P679 89. From the laser through the stent to the valve: the broad spectrum of interventional pneumology ................................................................. 105s
P680–P699 90. Cystic lung diseases: lung granulomatosis ............................................. 109s
P700–P719 91. Diffuse parenchymal lung disease: clinical profiles and collagen vascular disease ................................................................. 113s
P720–P739 92. Diagnostic insights and decision making in primary care ..................... 117s
P740–P759 93. Effectiveness of therapeutic interventions in primary care .................. 122s
P760–P779 94. New results in molecular pathology and functional genomics of neoplastic and non-neoplastic lung disease ................................................................. 126s
P780–P799 95. Inflammatory mechanisms in COPD ....................................................... 130s
P800–P818 96. Cell biology and inflammatory gene expression in chronic lung disease 134s
P819–P838 97. The many roads to lung injury ................................................................. 138s
P839–P858 98. Exercise capacity: from elite athletes to severe impairment ................ 142s
P859–P878 99. New issues in pulmonary function ......................................................... 147s
P879–P898 100. Physiology, heart failure and respiration in relation to OSA .................. 151s
P899–P915 101. Technology, screening and questionnaires in OSA ............................. 155s
P916–P934 102. Pulmonary circulation: clinical aspects of PAH and associated PH .... 159s
P935–P954 103. Pulmonary circulation: clinical PAH, registries and treatments ......... 163s
P955–P974 104. Pulmonary circulation: clinical diagnosis, treatment, end-points and animal models ................................................................. 168s

Identification of aspirin-induced asthma (AIA) subphenotypes using a clustering approach

Krakow, Poland; 2Department of Epidemiology and Population Studies, Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, Poland; 3Department of Internal Medicine, Jagiellonian University Medical College, Krakow, Poland

Background: AIA is a distinct asthma phenotype which symptoms are exacerbated by aspirin and other NSAIDs. It is generally recognized as a severe disease to treat asthma accompanied by chronic rhinosinusitis, nasal polyps, blood eosinophilia, elevated levels of urinary LTE4 (uLTE4). It seems, however, that AIA phenotype is not homogeneous.

Aim: To identify distinct subphenotypes in a cohort of AIA patients by applying a clustering technique.

Methods: Clinical data from 201 AIA patients (134 women, mean age 49.4 yrs) were collected using unified questionnaire. Asthma severity and control were assessed using NAEPPI EPR3 guideline. Spirometry, skin tests, blood eosinophilia, uLTE4 were evaluated.

Results: Four clusters of AIA were identified. Cluster 1: severe uncontrolled atopic asthma with non-reversible or reversible airway dysfunction, high rates of health care visits (HCU) for asthma. Cluster 2: moderate uncontrolled/partially controlled non-atopic asthma with non-reversible or reversible airway dysfunction, high rates of HCU. Cluster 3: mild partially controlled atopic asthma with normal airway function, lower rates of HCU. Cluster 4: intermittent well controlled atopic asthma with normal airway function, lower rates of HCU. Upper airway symptoms were very common in all clusters. The groups did not differ with respect to blood eosinophilia and uLTE4.

Conclusions: From a clinical point of view AIA patients are not a homogeneous population. Only part of them have severe uncontrolled asthma. Despite of the presence of upper airway symptoms, some subjects have milder, better controlled disease. Asthma not blood eosinophilia and uLTE4 may discriminate patients assigned to different clusters.

Safety of long-acting β2-agonist (LABA) withdrawal in patients in two clinical asthma trials

Ronald A. Simon 1,2, David S. Pearlman 3, Yun Chon 4, Joseph H. Lin 5, Shao-Lee Lin 6

Background: LABAs are used with inhaled corticosteroids (ICS) for asthma treatment. Due to safety concerns, the US FDA has recommended stopping LABA therapy when asthma control is achieved. Little data exists on the effect of LABA withdrawal in patients on LABA/ICS therapy.

Methods: Patients receiving LABA/ICS therapy at enrollment in Amgen AMG 317 and AMG 835 clinical trials underwent LABA withdrawal at screening. Patients who received either ineffective treatment with study drug or placebo were analyzed. Clinical endpoints were change from screening in prebronchodilator forced expiratory volume in 1 second (FEV1), percentage of predicted prebronchodilator FEV1, Asthma Control Questionnaire (ACQ) score, daily rescue medication use, daily symptom eDiary, exacerbation incidence, and adverse events.

Results: A total of 366 patients were previously treated with ICS+LABA (underwent withdrawal), and 177 patients were treated with ICS only. Changes in prebronchodilator FEV1%, percentage of predicted prebronchodilator FEV1%, ACQ score, daily rescue medication use, symptoms, and exacerbation incidence were not significantly different between patients with previous LABA use and those with-out. Time to exacerbation did not differ between groups (log rank test P=0.412; Cox regression analysis P=0.9755, adjusted for screening characteristics). Adverse events were similar between groups. Similar patterns were observed in placebo patients.

Conclusions: Asthma symptoms, lung function, and exacerbations were not significantly affected by LABA withdrawal in these clinical trial patients.

Managing asthma in the outpatient clinic – Athletes with exercise-induced asthma

Asgar Sverrild, Celeste Porsbjerg, Lise Stensen, Birgitte Nybo, Vibeke Backer.

Dep. of Respiratory Medicine, University Hospital Bispebjerg, Copenhagen, Denmark

Background: In athletes with exercise-induced asthma, confirmation of the disease with an objective test is required as part of the Therapeutic Use Exemption (TUE) application. An objective test often requires multiple testing with bronchial provocations and lung function measurements. Currently no guidelines exist on a diagnostic strategy in this group of subjects.

Aim: To evaluate the use of diagnostic tests in newly referred athletes with possible exercise-induced asthma in a specialized outpatient clinic.

Methods: Medical records on all patients with a suspected diagnosis of asthma referred to the outpatient clinic at Bispebjerg Hospital, Copenhagen, Denmark in 2010 where reviewed. Data on reversibility to beta2-agonist and airway hyperresponsiveness (AHR) to inhaled mannitol, methacholine and eucapnic hyper- ventilation was collected. Subjects with exercise-induced symptoms that reported to spend at least 10 hours a week on their sports were defined as athletes and were included in the analysis.

Results: Of 221 subjects referred with possible asthma to the outpatient clinic, 51 (23%) were athletes with possible exercise-induced asthma. A total of 39% (72%) was concluded to have asthma, based on a specialist's assessment. Among these subjects the final diagnosis was confirmed by an objective test in 31/39 (80%). The number of tests required to confirm the presence of disease was one in 9 (29%) of the subjects, two in 15 (48%) subjects, three in 6 (19%) and four in 1 (3%) subject.

Conclusion: In more than eight out of ten athletes with exercise induced asthma, more than one test for AHR or reversibility was necessary as part of the diagnostic process.

A comparison of the frequency of cough with laughter in asthmatic and non asthmatic patients

Christopher Leahey, Bernard Leahey.

Respiratory Medicine, Trafford General Hospital, Manchester, United Kingdom

Cough is a frequent symptom in asthmatic patients. Cough may be induced by typical asthma triggers such as allergens, exertion or change in atmospheric temperature. This study investigates the symptom of cough with laughter as an asthmatic symptom.

Patients attending a general adult respiratory clinic were routinely asked if they experienced cough with laughter. Seventy four consecutive patients with a single respiratory diagnosis were included. The patients were divided into two groups: patients with asthma and those with another respiratory diagnosis.

The asthma group had forty three patients with a mean age of 57.7 years. Twenty seven were female and sixteen male.

The non asthma group had thirty three patients with a mean age of 63.9 years, sixteen were male and fifteen female. In this second group their diagnoses were chronic obstructive pulmonary disease in eleven, pulmonary fibrosis in eight, sarcoidosis in five, bronchiectasis in two, hyperventilation in two and one each of carcinoma of bronchus, tuberculosis and sleep apnoea.

In the asthma group forty two of the forty three patients had the symptom of cough with laughter.

In the non asthma group one of the thirty one patients had the symptom of cough with laughter.

The symptom of cough with laughter is highly significantly associated with a diagnosis of asthma compared to other respiratory diagnoses (p<0.0001) and has a 97.6% sensitivity and a 96.8% specificity as an asthma symptom in this study.

A retrospective analysis of methotrexate therapy as a steroid sparing agent within a UK severe asthma clinic

Leanne Jo Holmes, Helen C. Francis, Robert M. Niven. Manchester Severe Asthma Service, University Hospital of South Manchester, Manchester, Greater Manchester, United Kingdom Manchester Severe Asthma Service, University Hospital of South Manchester, Manchester, Greater Asthma Service, University of Manchester & Univ. Hosp of South Manchester, Manchester, United Kingdom

Background: Treatment with Methotrexate (MTX) immunosuppressive therapy in severe asthma is used in an effort to reduce corticosteroid dependency and associated side effects. This study aimed to evaluate the effectiveness of MTX within this patient population as an efficient aid to reduce corticosteroids.

Methods: A retrospective data collection was performed within the severe asthma service. Patients whom were established on or had started MTX within the last twelve months were included. Variables explored included mean daily corticosteroid dose, exacerbation frequency, acute admission episodes and blood eosinophil count twelve months prior to and twelve months post commencement of Methotrexate therapy.

Results: n=30, 9 patients stopped MTX due to side effects. Within the ongoing stable group, corticosteroid dose was significantly lower post MTX compared to previous treatment (mean dose 10.4mg daily post MTX compared with 16.8mg pre
MTX \( (p < 0.001) \). The exacerbation frequency following MTX commencement was significantly lower (2.7) than in the year prior to treatment (6.1) \( (p < 0.002) \). Reduced hospitalization following MTX therapy was also demonstrated (0.4 episodes post treatment compared to 1.5 episodes pre treatment \( (p < 0.0006) \). There was a trend for a reduction in eosinophil level post treatment compared with prior to treatment, but this did not reach statistical significance.

**Conclusion:** MTX (where tolerated within this severe asthma population) was found to significantly reduce the demand for corticosteroids. A reduction in exacerbation rate and hospitalization are also demonstrated when sufficiently monitored and supervised within a specialist setting.

**165 Small airways involvement is associated with bronchial hyperresponsiveness in asthma**

Eef Telenga1, Dirkje Postma1, Roland Riemersma2, Maarten van den Berge1, Nick ten Hacken1 (Dept. of Pulmonary Diseases, University Medical Center, Groningen, Netherlands; 2Dept. of General Practice, University Medical Center, Groningen, Netherlands)

**Background:** Bronchial hyperresponsiveness (BHR) is a hallmark of asthma. Although, the role of small airways involvement in asthma has been well established, little is known about the association between BHR and small airways obstruction. We hypothesize that small airways disease contributes to BHR.

**Methods:** A total of 119 patients with a doctor’s diagnosis of asthma were included. All subjects underwent spirometry and a BHR testing \( (PD_{20} \text{ histamine}) \). Small airways involvement was defined as an \( \text{MEF}_{50} \leq \text{LLN} \) and \( \text{MEF}_{30} \leq \text{LLN} \) respectively. Patients with small airways involvement showed a more severe BHR than patients without \( (PD_{20} \text{ histamine} 0.2 \text{ vs.} 1.1 \text{ mg}) \). In addition, \( \text{FEV}_1, \text{FEV}_3/\text{FVC} \) and reversibility were lower in patients with small airways involvement. Both a lower \( \text{MEF}_{30} \) and \( \text{FEV}_1 \) were independent predictors of more severe BHR in multivariate linear regression models.

**Results:** We found 36 patients with and 83 patients without small airways involvement \( (\text{MEF}_{50} \leq \text{LLN} \text{ and } \text{MEF}_{30} \leq \text{LLN} \text{ respectively}) \). Patients with small airways involvement showed a more severe BHR than patients without \( (PD_{20} \text{ histamine} 0.2 \text{ vs.} 1.1 \text{ mg}) \). In addition, \( \text{FEV}_1, \text{FEV}_3/\text{FVC} \) and reversibility were lower in patients with small airways involvement. Both a lower \( \text{MEF}_{30} \) and \( \text{FEV}_1 \) were independent predictors of more severe BHR in multivariate linear regression models.

| Table 1. Differences between asthmatics with and without small airways involvement (MEF50 ≤ LLN and MEF30 ≤ LLN respectively) |
|-----------------|-----------------|-----------------|
| **Age (years)** | 45 ± 35–52 | 47 ± 34–57 | 0.42 |
| **Gender (m,%)** | 29 ± 34.9 | 14 ± 38.9 | 0.68 |
| **Smoking (m,%)** | 43 ± 52.4 | 22 ± 61.1 | 0.58 |
| **ex-smoker** | 29 ± 34.9 | 12 ± 33.3 | |
| **occasional smoker** | 3 ± 3.7 | 0 | |
| **habitual smoker** | 7 ± 8.4 | 2 ± 5.6 | |
| **Packyears** | 7 ± 0.8–5.6 | 4.0 ± 7.0–7.0 | 0.10 |
| **Bectamethasone equivalent dose (μg/day)** | 600 ± 400–800 | 800 ± 400–800 | 0.14 |
| **BMT (kg/m²)** | 26 ± 24–29 | 26 ± 24–30 | 0.66 |
| **PD20 histamine (mg)** | 1.1 ± 0.9–0.9 | 0.2 ± 1.9–0.9 | <0.001 |
| **FEV₁/VC (%)** | 6.3 ± 2.9–4.3 | 2.6 ± 2.3–4.1 | <0.001 |
| **Reversibility (%)** | 4.0 ± 2.2–6.8 | 8.7 ± 5.9–11.1 | <0.001 |
| **FEV₁/FVC (%)** | 82.4 ± 79.5–85.5 | 68.5 ± 61.2–73.0 | <0.001 |
| **MEF₃₀ (L/s)** | 3.9 ± 2.4–6.6 | 2.1 ± 1.6–2.5 | <0.001 |
| **MEF₅₀/predicted** | 86.5 ± 88.6–102.5 | 46.9 ± 39.2–51.5 | <0.001 |

**Conclusion:** Small airways involvement is associated with more severe BHR in asthma. Since \( \text{FEV}_1 \) is used as a read-out in current BHR tests, we hypothesize that small airways disease contributes to BHR.

**167 Local coagulation activation following bronchial instillation of house dust mite allergens (HDM) and HDM/Lipopolysaccharide (LPS) in mild asthmatics**

Mariëke Berger1, Johannes D. de Boer2, Tom van der Pol2, Peter J. Sterk1, Tariq S. van der Zee1, 2, 3 Respiratory Diseases, Academic Medical Center, University of Amsterdam, Netherlands; 2Center for Experimental and Molecular Medicine, Academic Medical Center, University of Amsterdam, Netherlands

**Rationale:** Exposure to house dust, containing HDM and LPS, is associated with exacerbations of allergic asthma. In patients with asthma, the hemostatic balance in the lungs is often unstable. We hypothesized that adding LPS to bronchial provocation with HDM increases activation of coagulation and complement pathways in asthmatics while on maintenance treatment with inhalation corticosteroids (ICS).

**Aim:** To assess the activation of coagulation in bronchoalveolar lavage fluid (BALF) induced by provocation with HDM +/- LPS.

**Methods:** We included 32 mild asthmatic patients with HDM allergy. After 2 weeks run-in with fluticasone 100μg bid, subjects underwent bronchoscopy for segmental instillation of saline in one lung followed by instillation of HDM +/- LPS in the contralateral lung. Six hours later, BAL was performed. Statistical comparisons were made by univariate analysis.

**Results:** Additional instillation of LPS to HDM resulted in a significant increase in levels of thrombin-antithrombin complexes \( (\text{TATc}) \) \( (p=0.015) \) and complement 4b \( (p=0.007) \) in BALF.

**Conclusion:** Additional instillation of LPS to a provocation with HDM in mild asthma increases pulmonary activation of coagulation and activation of the comple-
49. Sarcoidosis

168 Methotrexate vs azathioprine in chronic sarcoidosis

Limburg, Hasselt, Belgium

Background: Although steroids remain the mainstay of therapy in sarcoidosis,
chronic use is associated with toxicity. Evidence is missing on which second
line therapy is most appropriate.

Aim: To compare the effect of methotrexate (MTX) and azathioprine (AZA) in second
line treatment of chronic sarcoidosis patients regarding steroid use, lung function
and side effects.

Methods: This is a retrospective cohort study, reviewing all patients who started
MTX or AZA in two Dutch/Belgian tertiary referral centres. Demographic data,
steroid use, lung function tests and side effects were noted from initiation until
2 years after or discontinuation. Treatment effect was calculated with a linear
mixed model with FEV1, VC, DLCO and prednisone dose changes over time as
endpoints. Differences in side effects were calculated with χ²-tests.

Results: 200 patients were included. 145 received MTX and 55 received AZA.
Prednisone daily dose decreased with 6.32 mg/year (p<0.0001) while on therapy,
with no difference between MTX and AZA. FEV1 showed a mean increase of
52 ml/year (p=0.0066) and VC of 95 ml/year (p=0.0001), with no difference be-
tween drugs for both. DLCO (% predicted) increased with a mean of 1.23%/year
(p=0.018). Mean DLCO was 5.12% lower in the AZA group (p=0.05), but this
difference was constant over time. There were significantly more patients with
infections on MTX (6.5% vs. 16.0%; p=0.01). No significant differences
were found regarding other side effects.

Conclusions: This is the first study comparing the effect of MTX and AZA in sarcoidosis
patients. Although more infections occurred in the AZA group,
this study shows both drugs were equally effective in terms of lung function
improvement and had a significant steroid sparing effect.

169 Concentration of sFas in bronchoalveolar lavage fluid of smoking patients
with sarcoidosis
Tomasz Urbanowski, Aleksandra Safianowska, Rafal Krenke,
Izabela Knyziak-Medrzycka, Joanna Domagala-Kulakw, Department of Internal
Medicine, Pneumonology and Allergology, Medical University of Warsaw, Poland

Sarcoidosis (SA) is a multifactor organ granulomatous disease of unknown etiology. SA is
more prevalent among non-smokers. The postulated protective role of smoking on
inflammation in SA remains enigmatic. Fas/FasL system is assumed to participate in
the regulation of immune response and granuloma formation in SA. Soluble Fas
(sFas) is known to inhibit Fas-induced apoptosis. In previous study we reported an
elevated number of Fas positive cells in the bronchoalveolar lavage fluid (BALF)
of smoking sarcoidosis patients.

The aim of this study was to find out whether sFas concentration in BALF differs
between ever smoking (S) and never smoking (NS) patients with sarcoidosis.
We investigated 57 patients with confirmed SA: 36 NS and 21 S. Total and
differential cell count in the BALF samples were performed according to standard
methods. The sFas concentration was measured by ELISA.

There were significant differences in BALF composition between NS and NS.
The total cell count and the percentage of macrophages were significantly higher
among S than among NS (11.3 vs. 6.5 x 10⁵, 62 vs. 50%, respectively), while the
percentage of lymphocytes was significantly lower among S than among NS (29
vs. 41%). The sFas concentration was lower in the BALF of S compared with NS
(median values 68.3 vs 95.5 pg/ml, p=0.01). Furthermore, the sFas concentration
among active smokers was significantly lower than among NS (65.6 vs 95.5 pg/ml,
p=0.01).

We found out that sFas concentration is reduced in the BALF of smoking sarco-
idosis patient. Lower sFas concentration may result in higher apoptosis rate of
inflammatory cells, thereby promoting granulomatous inflammation resolution.

170 Association study of ANXA1I-R230C with sarcoidosis
Fotini Banadaki1,2, Zoe Danil1, Katerina M. Antoniou1, Antigoni Mamara2,
Fotini Malil1, Konstantinos I. Gourgouliantis2, Anastasios E. Germenis2,
Mathaios Speletas3, 1Respiratory Medicine Department, University of Thessaly,
Larissa, Greece; 2Laboratory of Immunology and Histocompatibility, University of
Thessaly, Larissa, Greece; 3Respiratory Medicine Department, University of
Crete, Heraklion, Greece

Introduction: Recently, a genome wide association study demonstrates that the
polymorphism ANXA1I-R230C (rs1049550) is strongly associated with sarco-
idosis, a chronic granulomatous disease (GD) of unknown etiology.

Aim: Considering that also other diseases are accompanied by granulomas for-
mation, as observed in 10% of patients with common variable immunodeficiency
(CVID), the purpose of this study was to confirm the association of ANXA1I-R230C
with sarcoidosis and to examine its possible association with GD in CVID.

Methods: DNA was extracted from peripheral blood of 71 patients with sarco-
idosis (MF/24/47, mean age: 52.5 years, range-20-75), 101 normal individuals
(MF/35/66, mean age: 54.1 years, range-19-76), and 19 CVID patients (MF/7/12,
mean age: 28.1 years, range-2-60), two of which had granulomatous disease (one
with familial CVID history including a sister without GD). A PCR-RFLP protocol
was designed to detect ANXA1I-R230C and statistical analysis was performed using
the SPSS software (ver.-10.0).

Results: The difference in the allele frequency of ANXA1I-R230C between pa-
ients with sarcoidosis and healthy individuals was not marginally reached to be
significant (p=0.073). The allele frequency of ANXA1I-R230C in CVID patients
was 50.0% and no significant difference between patients with and without GD
was observed. However, in the family with CVID, the member with GD carried
only the R alleles, associated with granulomas formation, while her sister was
heterozygous.

Conclusions: The association of ANXA1I-R230C with sarcoidosis was not con-
firmed, while the emerged contribution of this polymorphism in the granulomas
formation in CVID needs to be further clarified.

171 HLA-DRB1 allele distributions in Danish sarcoidosis patients. Increased
prevalence of HLA-DRB1*15
Nils Milman1, Claus Bo Svendsen1,4, Thomas van Oeveren Hansen1,
Lars Ryder1, Klaus Richter Larsen1, 4Department of Rheumatology,
Rigshospitalet, University of Copenhagen, Copenhagen O, DK, Denmark;
2Center for Genomic Medicine, Rigshospitalet, University of Copenhagen,
Copenhagen O, DK, Denmark; 3Department of Clinical Immunology/Tissue
Typing Laboratory, Rigshospitalet, Copenhagen O, DK, Denmark; 4Department of
Microbiological Surveillance and Research, Statens Serum Institut, Copenhagen S, DK, Denmark;
5Department of Pulmonary Medicine, Bispebjerg Hospital, University of Copenhagen, Denmark

Background: The MHC class II region appears to play an important role in the
development and clinical picture of sarcoidosis, probably due to the influence on
the immune response against yet unknown antigen(s). A previous HLA-class II
study in Danes has shown that HLA-DR3 antigens is associated with a favorable
prognosis and HLA-DR6 with susceptibility to sarcoidosis (Hdum et al., Exp Clin
Immunogenet 1999;8:227-31).

Subjects and methods: HLA-DRB1 allele classification was performed by PCR
in ethnic Danish patients with biopsy-verified sarcoidosis (n=94). Danish blood
donors (n=10146) served as controls.

Results: The prevalence of DRB1*01 was lower and the prevalence of DRB1*15
was higher in sarcoidosis patients compared to controls.

Conclusions: There exist no specific biochemical markers of sarcoidosis. Diagno-
sis relies on histological examination of tissue biopsy specimens in combination
with the exclusion of infection with mycobacteria and other causes of the gran-
ulomatous response. Due to the paucity of prognostic markers, we suggest that
analysis of HLA-DRB1 (and BTNL2 genotype (Milman et al., Clin Respir J
2011;5:105-11) be incorporated in the evaluation of sarcoidosis patients.

SUNDAY, SEPTEMBER 2ND 2012
Whole-body magnetic resonance imaging in sarcoidosis to assess extrapulmonary organ involvement

Methods: 24 consecutive patients at the Clinic of Respiratory Medicine, University Hospital Basel, Switzerland, with histologically-confirmed sarcoidosis were prospectively included. All patients underwent whole-body MRI. Results: In total 52/4 (38%) patients showed findings of probable or possible sarcoidal origin. 52/4 (21%) showed skeletal lesions, 3/4 (13%) had muscular findings and 1/4 (4%) had enhancement of the cauda equina. EPOST score was significantly higher in those 9 patients with abnormal whole-body MRI-findings (17.3) than in those with normal images (10.6). FVC percentage predicted (FVC%, TLC, FRC) were significantly lower in those patients with abnormal skeletal enhancement compared to those without skeletal abnormalities.

Conclusions: Whole-body MRI depicted manifestations of extrapulmonary sarcoidosis in 38% of cases in an unselected patient sample. Abnormal whole-body MRI findings correlated with high EPOST scores, and might thus be a valid tool to assess extrapulmonary disease activity. Abnormal skeletal findings correlated with decreased lung volumes, and might therefore be a marker of total disease activity.

HLA-DPB1 and chronic sarcoidosis

Methods: HLA-DPB1 was determined in 98 patients with chronic sarcoidosis. 17 different DPB1 alleles were observed. The DPB1*04:02 allele was less frequent among the patients (10.2% vs 20.3%; p=0.003, OR=0.45) than controls. A haplotype with DPB1*04:01, one C4A gene and one C4B gene was increased among sarcoidosis patients (30.6% vs. 22.5%; p=0.036, OR=1.5). By studying polymorphic amino acid residues of DPB1, we did not detect an association of Glu226, but a DPB1*04:02 specific amino acid variant was detected at the position 178 (Met) suggesting a protective role for chronic sarcoidosis (p=0.004, OR=4.42).

Furthermore, preliminary SNP analyses of HLA class II and III region showed a significant protection to sarcoidosis was observed, confirming previous data in populations from different geographic regions, but only in those patients without EN.

Results: The frequency of ANXA11 rs1049550 (R230C) allele was significantly lower in sarcoidosis patients (33.1% vs. 46.2%, p<0.01, OR=0.58, 95%CI=0.38-0.86). An OR=0.44 and OR=0.4 for sarcoidosis was obtained respectively, in the carriers of one (genotype ANXA11 CT) and two (genotype ANXA11 TT) copies. There is no valid tool to ANXA11 rs1049550*T allele normalised to the CC wild type genotype (p<0.01). When patients with erythema nodosum (EN) were removed, this association persists only in the group without EN. There was no significant difference among radiological Scadding stages.

Conclusions: In this population an association between ANXA11 rs1049550*T SNP and protection to sarcoidosis was observed, confirming previous data in populations from different geographic regions, but only in those patients without EN.

50. Chest wall, diaphragm and pleura

Pectus excavatum, small lungs or small chest cavity?

Conclusion: After 16 weeks of treatment, bosentan therapy was associated with a significant improvement in pulmonary artery mean (PAM) and pulmonary vascular resistance (PVR) for those treated with 16 weeks (wks) of bosentan (BOS) versus no change in those treated with placebo (PLA).

Introduction: We reported significant improvement in pulmonary artery mean (PAM) and pulmonary vascular resistance (PVR) for those treated with 16 weeks (wks) of bosentan (BOS) versus no change in those treated with placebo (PLA) for sarcoidosis associated pulmonary arterial hypertension (SAPAH).

Purpose of the study: To determine whether patients with advanced parenchymal disease were less likely to respond to BOS.

Methods: Patients with SAPAH confirmed by right heart catheterization (RHC) were randomised 2:1 to receive either BOS or PLA. After 16 wks of therapy, patients underwent repeat RHC. Patients had forced vital capacity (FVC) and Scadding chest x-ray (CXR) stage.

Results: Of the 25 patients treated with BOS, 2 stopped study drug before wk 8. At 16 wks, 21 had repeated RHC. Patients were subgrouped into those with FVC% 70% predicted (FVC% ≥70% predicted (FVC% ≥70%) and those with CXR stage 4 versus stage 4 (CXR=4). The table demonstrates the changes in PAM and PVR. There was significant improvement in PAM and PVR for those with FVC 70% but was not for those with FVC ≥70%. No changes were seen for the PLA group.

Discussion: The preoperative TLC and VC were almost normal, but FRC and RV were significantly increased in the 27 patients. Central hemodynamic parameters were also within normal limits. Hence, the chest deformity is a secondary effect caused by this ‘Little Lung Syndrome’.

After surgery, all lung volumes and hemodynamic functions decreased.

Conclusion: It is probable that we need to change the surgical technique to not only correct the chest wall defect but also to reduce the intra-thoracic volume, so as not to stretch the lungs.

177 Evaluation of the effects of surgical correction of left mediastinal displacement in children with pectus excavatum on pulmonary perfusion, using minimal radiation exposure

Methods: We prospectively evaluated 34 consecutive patients with PE pre- and post-Nuss procedure using chest radiography (CXR), echocardiography (UCG), and PP scintigraphy. CXR was used to visualize the vertebral index (VI) and left displacement index (LDI, ratio between the distance from the left border of the mediastinum to the left border of the thorax and the transverse thoracic dimension on posteroanterior CXR). PP scintigraphy was visually interpreted and left-to-right shunting ratio (RL) was calculated. Pre-ejection period, acceleration time (AcT), and ejection time (ET) of the right pulmonary artery (RPA) and left pulmonary artery (LPA) were measured by pulse Doppler UCG.

Results: VI and LDI improved postoperatively (P < 0.001). Preoperatively, left PP was impaired. Postoperatively, Ls/Rs increased (P = 0.001) and AcT/ET changed (LPA: P < 0.001; RPA: P = 0.008). Evaluation of the usefulness of CXR showed that LDI correlated with Ls/Rs (R = 0.411, P < 0.001) and LPA-AcT/ET (R = 0.50, P < 0.001), and that VI did not correlate with Ls/Rs and correlated poorly with LPA-AcT/ET (R = 0.28, P = 0.05).

Conclusions: The imbalance of PP improves after the Nuss procedure. The degree of leftward displacement of the mediastinum correlates with decreased left PP. Follow-up can be achieved with minimal radiation exposure.

179 Stabilization of sternum using absorbable copolymer plate in the open surgery for pectus deformities

Methods: We reviewed the records of 31 patients who had undergone open surgery for pectus deformities using absorbable copolymer plates between November 2008 and January 2012. All patients were evaluated retrospectively according to the demographics, type and form of deformity, operation duration, perioperative and postoperative complications, and recurrence.

Results: Twelve patients were male and the median age was 19.5 (range: 14-31). Seven patients had pectus carinatum, 7 had pectus excavatum, and 4 had mixed deformity. The median operation duration was 120 minutes (40-210). One patient had severe complications in the postoperative period. No recurrence was seen. Absorbable copolymer plates can be used for the stabilization of sternum in open surgery for pectus deformities with low morbidity rates, as it is a safe, durable, and easy-to-use material.

180 Surgery for sternal tumors: Extent of resection, reconstruction and survival

Methods: We conducted a retrospective study of 74 patients from January 1999 to December 2008. The histological diagnosis was salivary gland malignances. The chest wall reconstruction depends on the size and site of the malignances. The chest wall reconstruction depends on the size and site of the malignances. The chest wall reconstruction depends on the size and site of the malignances. The chest wall reconstruction depends on the size and site of the malignances.

Results: The median operation duration was 120 minutes (40-210). One patient had severe complications in the postoperative period. No recurrence was seen. Absorbable copolymer plates can be used for the stabilization of sternum in open surgery for pectus deformities with low morbidity rates, as it is a safe, durable, and easy-to-use material.

181 Our experience in the surgery of the chest wall tumors

Introduction: The tumor pathology of the chest wall is extremely interesting and wide, and still it rises a great amount of problems related to the diagnosis and surgical treatment. That is why the purpose of this article is to share our department’s experience confronting this type of pathology.

58
Material and method: We analysed a series of 154 patients that underwent surgery in our department in ap 10 years period (2001 – 2011), with ages between 21 and 74 years old. 43 of the patients had benign pathology, the rest of 111 had primary, secondary or contiguous malignancies of the chest wall. The surgical procedures applied were chest wall resection followed by reconstruction with several types of synthetic materials such as Thoratex mesh, “Spider Web” suture or the use of methylmetacrylate and chest wall resection without stabulation. In 74.6% of the patients. The mean hospital stay was 8 days.

Results: In all the cases the perioperative mortality and morbidity was zero. The immediate postoperative outcome off the patients was good in 150 cases, 3 cases developed wound seroma that was managed with conservative treatment and one patient underwent a second surgery with muscular flap after stabulation with methylmetacrylate. Conclusions: The tumoral pathology of the chest wall still raises a series of problems of surgical treatment, some cases are indeed a challenge for the surgeon, but the continuous development of the surgical techniques and of the materials for reconstruction along with the development of experienced surgical teams lead to obtaining optimal results without complications that require further surgical attention.

182
Eventration surgery of the diaphragm via trans-thoracic approach
Haluk Sasmaz, Akin Yıldızhan, Nurettin Yiyit, Faith Candas, Baiju Gorur, Turgut Isıtmangil. Thoracic Surgery, GATA HEH, Uskudar, Istanbul, Turkey

Eventration of the diaphragm is a rare anomaly due to congenital or acquired etiology. Congenital eventration of the diaphragm is probably a true congenital defect acquired during the fetal period. Eventration of the diaphragm also occurs in adults is thought to be caused by an acquired or complete or in complete paralysis of the diaphragmatic leaf. Operative repair is indicated for older patient who has symptoms. A transthoracic approach and diaphragmatic plication is preferred. We performed 32 diaphragmatic plication at our institution between 2005-2011. Six of the cases on the right, 26 on the left. All operation performed under laterally decubitus position and one lung ventilation. The classical approach was a posterolateral thoracotomy through 7th intercostal space. The thinned diaphragmatic leaf was repaired with plication. We had no postoperative mortality or any other major complication. The eventration of the diaphragm need to surgically repair to take away symptoms and respiratory relieve.  

183
Neural networks analysis of spontaneous pneumothorax development
Luca Bertolaccini1, Lucia Boschetto2, Claudio Cassardo2, Andrea Viti2, Alberto Zerra2. Thoracic Surgery, S. Croce e Carle Hospital, Cuneo, Italy; 1General Physics “Amedeo Avogadro”, University of Turin, Italy

Spontaneous pneumothoraces (SP) tend to cluster. Correlations between SP and atmospheric variations were reported by previous studies. In our work SP correlation with meteor variables and air pollutants in Cuneo County was analyzed. 2004-2010, 451 SP patients were prospectively evaluated. For each day of an-alyzed period, meteo parameters and pollutants were recorded. Statistics on SP occurrence significantly increases in warm windy days with high atmospheric pressure and high NO2 concentration. These data don’t affect SP treatment; nevertheless, they add information on SP tendency to cluster.

51. Diagnostics in OSA: from polygraphy to genetics and cancer

184
The method for diagnosis matters in sleep apnea. A systematic analysis of polygraphy and polysomnography data in the European Sleep Apnea Database (ESADA)
Pierre Escourrou1, Fadia Jilwan1, 1Centre de Médecine du Sommeil, Hôpital Béclère ; AP-HP, Clamart, France; 2ESADA office, Center for Sleep and Vigilance Disorders, Sahlgrenska Academy, Gothenburg, Sweden

In the ESADA study, each of the 23 participating centers used its own routine clinical and diagnostic procedures for OSA detection. Altogether, data from 8228 patients with suspected OSA (M or F, 18–80 yrs) were analysed in order to compare results obtained by polygraphy (PG) (n = 5032) or polysomnography (PSG) (n=3196). The AASM 2007 criteria have been used for visual scoring of apnoea/hypopnoea and in addition in a PSG study, an event with ≤50% flow reduction, associated with arousal was also classified as hypopnoea (Eur Respir J 2011; 38: 633–642).

AHI was higher by PG (29.9±26.2 hr-1) than by PSG (22.3±23 hr-1) (p<0.001). 66% of the patients had an AHI>15 by PG whereas only 50% of patients were above this limit by PG (p<0.001). Although analyzed time (7±4±0.9 hr) by PG was higher than total sleep time (6.4±1.3 hr) by PSG (p<0.001), oxygen desaturation index (ODI) (≥4%) was only marginally different: 21±24 hr-1 by PG and 19±22 hr-1 by PG. Furthermore the difference between the AHI and ODI scores was higher by PG (8.6±1.7) than by PG (1.1±1.0) (p<0.001). The average number of events per recording was similar by PG (186±183) and by PSG (184±189) (NS) which rules out a significant time dilation effect to explain the higher AHI by PG compared with PG.

In summary, the AHI is underestimated by PG leading to a lower rate of patients suffering from significant OSA than by PG. This discrepancy is likely to relate to the scoring of hypopnea by arousal rather than the result of the time dilation effect. Supported by enabling grants from RESMEDI and PHILIPS RESPRONICS.
Conclusion: Real-time attended HPSG through telematic data transmission is feasible and could be an interesting perspective to decrease the failure rate of home sleep studies even if some technical aspects need to be improved.

186 Contribution of APO E alleles and ACE I/D polymorphism in the development of hypoxia in sleep apnoea/hypopnoea syndrome

María González1, Félix del Campo1, Julio de Frutos1, Ainhoa Arroyo2, Mercedes Díaz-Álvarez3, María Jesús Alonso1,3, Servicio de Neumología, Hospital Río Hortega, Valladolid, Spain; 2Instituto Biología y Genética Molecular, Universidad de Valladolid, Spain

Sleep apnea/hypopnea syndrome (SAHS) is a common condition affecting approximately 0.3–4% of the middle-aged population and is defined on the basis of symptoms of daytime sleepiness and objective measures of disordered breathing during sleep. Several studies have identified SAHS as a risk factor for hypertension, but a direct etiologic link between these disorders has not been established definitively. Aim: To evaluate the influence of polymorphisms on the APO E gene and the I/D polymorphism on ACE in the presence of hypoxia (HT) in Sleep Apnea – Hypopnoea Syndrome patients.

Methods: APOE and ACE I/D genotypes were obtained from 99 controls and 114 patients with a diagnosis of sleep apnea/hypopnea syndrome after polysomnography in the Sleep unit of the Rio Hortega Hospital.

Results: There were not any difference in the APOE alleles frequency between patients and controls, but SAHS patients carrying the APO E ε4 allele showed an increased frequency of HT 3.145 higher than ε3 homozygous and ε2 carriers (CI 1.29-7.79). These findings keep significant even after correction for sex. The ACE I/D genotypes were in Hardy-Weinberg equilibrium (< 0.05) and they seem don’t have any influence on the development of HT in these patients (DD OR 0.478 (CI 0.21-1.08)

Conclusions: Our results demonstrate that the presence of the ε4 allele increases the probability to develop HT in Sleep Apnea patients. We suggested that this allele could be useful as a biological marker for identification of a subgroup of SAHS patients who are more likely to have HT.

187 Independent impact of obstructive sleep apnea severity on glycated haemoglobin in adults without diabetes

Pascaleine Pein1, Marc Le Vaillant2, Nicole Meslier1, Sylvaine Chollet3, Pascaline Priou1, M. Pierre Humeau1, Thierry Pigeon1,4, Acyn De Bie5, Dominique Gagnadoux1,6, 1Department of Respiratory Diseases, University Hospital, Angers, France; 2CERMES, CNRS UMR2211- INSERM U988, EHESS, Villejuif, France; 3Department of Respiratory Diseases, University Hospital, Nancy, France; 4Department of Respiratory Diseases, Hospital, Cholet, France; 5Department of Respiratory Diseases, Nouvelles Cliniques Nantesiennes, Nantes, France; 6Department of Respiratory Diseases, Pôle Santé des Olonnes, Olonnes Sur Mer, France; 7Department of Respiratory Diseases, Hospital, La Roche-Sur-Yon, France; 8Department of Respiratory Diseases, Hospital, Le Mans, France

Hypothesis: There may be an independent association between obstructive sleep apnea (OSA) severity and glycated hemoglobin (HbA1c) in adults without known diabetes.

Methods: HbA1c was measured in 1,728 patients with no history of diabetes undergoing nocturnal recording for suspected OSA.

Results: A dose-response relationship was observed between apnoea-hypopnoea index (AHI) and percentage of patients with HbA1c >6.0% that increased from 13.8% for AHI<5 to 42.6% for AHI>50. After adjustment for age, gender, smoking habits, body mass index (BMI), waist circumference (WC), cardiovascular morbidity, daytime sleepiness, depression, insomnia and sleep duration, odds ratios (95% confidence intervals) for HbA1c >6.0% increased from 1.43 (0.88 to 2.33), 1.74 (1.08 to 2.81), 1.94 (1.23 to 3.09) and 2.89 (1.79 to 4.67) for AHI values <5, 5 to <15, 15 to <30 and >30 respectively. Increasing hypoxemia during sleep was also independently associated with the odds of HbA1c >6.0%.

Conclusions: Among adults without known diabetes, increasing OSA severity is independently associated with impaired glucose metabolism that may expose to higher risks of diabetes and cardiovascular disease.

Odds ratio (95% confidence intervals) for HbA1c >6% according to AHI (AHI<5(reference) after adjustment for age, gender, smoking habits, BMI, WC, cardiovascular morbidity, daytime sleepiness, depression, insomnia and total sleep time.

188 Prediction modeling and temporal validation of sleep disordered breathing from large community samples

Neil M. Skovd1, Ronald S. Platt2, Sagatech Electronics, Calgary, AB, Canada

Aim: Common sleep apnea prediction tools (e.g. the STOP-BANG score) were derived using laboratory-based polysomnography in academic centers. In contrast, we assessed and temporally validated the sleep apnea risk factors in patients undergoing ambulatory screening and testing in community practice.

Methods: Two consecutive sets of 2000 ambulatory sleep monitor recordings referred for interpretation by community physicians and CPAP vendors were used for modeling and validation. With each study the patient’s age, gender, mass, height, neck circumference, use of dental appliances, reported excessive snoring and Epworth sleepiness score were reported. An estimated respiratory disturbance index (RDI) was derived from each study’s signals. Modeling of the predicted RDI was done using linear regression and induced error pruning tree methods on the first sample with temporal validation testing on the second sample (WEKA, v. 3.7.5).

Results: Linear regression modeling showed all risk factors significantly associated with RDI, however, the model’s correlation coefficient was poor in both the training (0.3953) and validation (0.4604) samples. Tree modeling showed sequential cutoffs for neck circumference < 44 cm, Epworth score < 18.5 and mass < 107 kg best modeled the estimated RDI. The tree model’s training (0.3755) and validation (0.3015) correlation coefficients were, like the regression model values, also poor.

Conclusions: Common sleep apnea risk factors have poor statistical validity for predicting sleep disordered breathing in patients undergoing ambulatory screening and testing.

189 Association between sleep apnoea and cancer incidence. Longitudinal study of a large multicenter Spanish cohort

Francisco Campos-Rodríguez1, Miguel A. Martínez-García2, Montserrat Martínez-Alonso3, José M. Marin4, Joaquín Durán-Cantolla1, Mónica de la Peña5, Mónica González6, Inmaculada Gallego7, María J. Maseda6, Félix del Campo10, Ferran Barbé11, Ramón Farré11, José M. Montserrat12, 1Pneumology, Valme Hospital, Sevilla, Spain; 2Pneumology, La Fe University and Polytechnic Hospital, Valencia, Spain; 3Pneumology, IRB Lleida, Spain; 4Pneumology, Miguel Servet Hospital, Zaragoza, Spain; 5Research Department, Hospital, Valladolid, Spain; 6Pneumology, Alava University Hospital, Alava, Spain; 7Pneumology, Son Dureta Hospital, Palma de Mallorca, Spain; 8Pneumology, Marques de Valdecilla Hospital, Santander, Spain; 9Pneumology, Vallme Hospital, Sevilla, Spain; 10Pneumology, Parc Taulí Hospital, Barcelona, Spain; 11Pneumology, Rio Hortega Hospital, Valladolid, Spain; 12Facultad de Medicina, Barcelona University, IDIBAPS, Barcelona, Spain; 13Pneumology, Clinic Hospital, Barcelona, Spain; 14Pneumology, IRB Lleida, Spain

Background: The role of Sleep Apnoea (SA) in the development of cancer in humans has not yet been assessed.

Objective: To investigate whether SA is associated with increased cancer incidence.

Methods: We performed a multicenter, clinical cohort study, analyzing 8,961 patients referred to 8 Spanish Sleep Clinics for suspected SA. Subjects with an apnoea-hypopnoea index (AHI) ≥ 10 comprised the control group. SA was diagnosed when the AHI was ≥10. We used the log-rank test to compare cancer incidence between groups, and the Cox proportional hazards model to calculate both unadjusted and adjusted HR and 95%CI for incident cancer.

Results: 8,542 (93.3%) patients were finally analyzed. The median follow-up of the cohort was 5.1 years (interquartile range 4.0 to 7.1). SA was associated with increased incidence of cancer in unadjusted analyses (HR 1.27, 95%CI 1.04-1.56). The cancer incidence density rate was also significantly higher in patients with SA compared to the control group (14.99 vs. 11.71 per 1,000 person-years; incidence density rate 1.28 [95%CI 1.04-1.57]). Further adjustments for body mass index, smoking or alcohol intake did not modify these results. Cancer incidence was not associated with either mild-moderate SA (HR 1.02; 95%CI 0.81 to 1.28), or severe SA (HR 0.85; 95%CI 0.68 to 1.00) in the adjusted models.

Conclusions: Sleep Apnoea was associated with increased cancer incidence, but this association disappeared when the results were adjusted for confounders.
Intermittent hypoxia increases melanoma metastasis to the lung in a mouse model of sleep apnea

Isaac Almendros1, Josep M.Montserrat1, Marta Torres1, Mireia Dalmau1, Josep Ramirez2, Francisco Campos-Rodriguez3, Daniel Navajas3, Ramon Farré3, 1Laboratori de la Son, Pneumologia, CIBERES - Hospital Clinic Barcelona, Barcelona, Spain; 2Anatomia Patològica, Hospital Clinic Barcelona, Spain; 3Servicio de Neumología, Hospital de Valme, Sevilla, Spain; 4Unitat de Biofisica i Bioenginyeria, CIBERES - Universitat de Barcelona - IBE, Barcelona, Spain; 5Unitat de Biofisica i Bioenginyeria, CIBERES - Universitat de Barcelona - IDIBAPS, Barcelona, Spain

Background: Obstructive sleep apnea (OSA) is associated with an increased risk of cancer mortality in humans (Nieto et al., ATS Congress, 2012). Experimental data in mice have recently shown that a pattern of intermittent hypoxia mimicking OSA: 20 s 5% O2 followed by 40 s room air, for 6 h/day. The other 15 animals were breathing room air (controls). After 30 days the mice were sacrificed, their lungs were excised and hematoxilin-eosin preparations were analyzed by a pathologist to quantify the number of metastases.

Methods: The number of lung metastases in each mouse was significantly greater in the animals subjected to intermittent hypoxia (5.5±3.2) (mean ± SE) than in control mice (1.0±0.6) (p=0.028).

Conclusion: The data from this animal study strongly suggest that intermittent hypoxia enhances metastasis to the lung from a subcutaneous melanoma.

Aim: To test the hypothesis that intermittent hypoxia enhances metastasis to the lung from a subcutaneous melanoma.

Methods: 28 male C57BL/6J mice were investigated. To induce a melanoma tumor in each mouse, one million of B16F10 cells were subcutaneously injected in the left flank region of the animal. Thirteen of these animals were then subjected to breathe intermittently hypoxic air with a pattern mimicking OSA: 20 s 5% O2 followed by 40 s room air, for 6 h/day. The other 15 animals were breathing room air (controls). After 30 days the mice were sacrificed, their lungs were excised and hematoxilin-eosin preparations were analyzed by a pathologist to quantify the number of metastases.

Results: The number of lung metastases in each mouse was significantly greater in the animals subjected to intermittent hypoxia (5.5±3.2) (mean ± SE) than in control mice (1.0±0.6) (p=0.028).

Conclusion: The data from this animal study strongly suggest that cancer metastasis could be enhanced in patients with OSA.

Mortality and morbidity after sleep disorders in Europe

Pool Jennum1, Rikke Ibsen, Jakob Kjellberg1, 1Department of Clinical Neurophysiology, Center for Healthy Ageing, Faculty of Health Sciences, University of Copenhagen, Glostrup Hospital, Glostrup, Denmark; 2Trucks, Trucks, Aarhus, Denmark; 3Institute for Health Services Research, Copenhagen, Denmark

The long-term prognosis of obstructive sleep apnea (OSA) and obesity hyperventilation syndrome (OHS), as compared to age, gender and social controls, are incompletely described.

Using data from the Danish National Patient Registry (NPR) (1998-2010), 30278 individuals with a diagnosis of OSA (23208 men and 7070 women) and 1562 with a diagnosis OHS (1092 men and 470 women) were identified. For every patient, four ages-, sex- and social matched citizens were randomly selected from the Danish Civil Registration System, a total of 120506 OSA and 6241 HS controls.

The 10 year survival of treated and untreated OSA patients was 90.7% compared to 92.4% (controls) and of OHS patients 63.9% compared to 85.5% (controls) (both: p<0.0001).

Commonly significant (p<0.01) observed morbidities in OSA patients were related to respiratory (1.9 (1.82-2.0), ventilator duration, 1.65 (1.55-1.75), endocrine, metabolic, nutritional (1.35 (1.34-1.75), ENF1.39 (1.30-1.49), circulatory: 1.20 (1.16-1.29), musculoskeletale: 1.25 (1.20-1.30), digestive illnesses (1.09 (1.03-1.14), and injuries 1.12 (10.8-1.16). Mental disease and neoplasm showed a lower occurrence: 0.90 (0.81-0.99) and 0.85 (0.80-0.95), respectively.

OHS showed higher morbidities to respiratory: 4.03 (3.21-5.07), renal: 3.17 (2.43-4.15), endocrine, metabolic, nutritional (4.65 (3.67-5.90), ENF1.39 (1.30-1.49), circulatory: 1.84 (1.50-2.6), musculoskeletale: 1.25 (1.20-1.30) and digestive illnesses (1.09 (1.03-1.14), and injuries 1.12 (10.8-1.16). Neoplasm occurred less often: 0.70 (0.50-0.97).

OHS and especially OHS present significant mortality. The morbidity includes a wide range of medical disorders besides cardiovascular complications.

52. Exacerbations of asthma and COPD: assessment, impact and novel treatments

Once-daily QVA149 significantly improves lung function and symptoms compared to twice-daily fluticasone/salmeterol in COPD patients: The ILLUMINATE study

Claas Vogelmeier1, Eric Bateman2, John Pallante3, Hannah Bryant4, Vijay Alagappan5, Peter D’Andrea6, Eilee He7, Donald Banerji8, 1Department for Respiratory Diseases, University of Marburg, Marburg, Germany; 2Department of Medicine, University of Cape Town, South Africa; 3Respiratory Department, Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, United States; 4Respiratory Department, Novartis Horham Research Centre, Horham, United Kingdom

Background: QVA149 is a novel dual bronchodilator combination of the LABA indacaterol and the LAMA NVA237 (glycopyrronium), in development for the treatment of COPD. QVA149 once daily (QD) vs salmeterol/fluticasone (SFC) twice daily (BID) was evaluated in moderate-to-severe COPD patients with no history of exacerbations in the previous year.

Methods: In a double-blind, double-dummy, parallel-group study, 523 patients (QVA=258, SFC=264) were randomized to receive QVA149 110/50 μg QD (via the Breezhaler device®) or SFC 500/50 μg BID (via the Accuhaler device®) for 26 weeks.

Results: Mean age was 63 years; mean post-bronchodilator FEV1: 60% predicted. Mean FEV1, AUC0-12h at Day 1 and Weeks 12 and 26 (primary endpoint) was significantly higher with QVA149 vs SFC (p<0.001 for all comparisons; table).

* p<0.001.

Serial spirometry showed significantly higher and clinically meaningful improvements in FEV1 with QVA149 vs SFC at all timepoints from 5 min to 12 h at Day 1 and Weeks 12 and 26 (p<0.001). QVA149 significantly improved the Transition Dyspnea Index score vs SFC (treatment mean: 2.16 vs 1.41, respectively; p<0.003), reduced rescue medication use (~0.39 puff/day; p<0.019) and improved other lung function measures (table) over 26 weeks. The safety profile of QVA149 was similar to that of SFC.

Conclusion: QVA149 QD provided significant, sustained and clinically meaningful improvements in lung function vs SFC BID over 26 weeks, with significant symptomatic benefits.

193 Accuracy in assessment of acute asthma needs improved to avoid potential adverse outcomes

Selina Tump1, Lorraine Bridges, Grace Murphy, Peter Kewin. Respiratory Medicine, Southern General Hospital, Glasgow, United Kingdom

Introduction: Despite comprehensive BTS Asthma Guidelines (2011 revision), there are up to 1200 deaths annually in the UK, 90% due to identifiable and preventable disease, management and psychosocial factors. We retrospectively compared management of acute asthma admissions in a city centre hospital for 1 year (2010) with BTS guidelines to identify key areas for service improvement.

Results: Data was obtained for 72/106 admissions. The majority of admissions were female (70.8%), during winter months (63.9%), and outside normal working hours (63.9%; fig 1A). Initial peak expiratory flow rate (PEFR) and severity guide management decisions. While 79.2% had a best previous PEFR documented, pre-and post treatment PEFR were recorded in only 65.3% and 36.1% respectively. No severity was recorded in 68.1% and there was a tendency to underestimate it (fig 1B). In spite of this 91.7% of admissions were appropriate according to BTS criteria (fig 1C) and there were no subsequent deteriorations resulting in emergency treatment.

Impact of a single chronic obstructive pulmonary disease (COPD) exacerbation on lung function decline: Analysis of UPLIFT

David Halpin, Mark Decramer, Bart Celli, Antonio Martin, Inge Leimer, Norbert Metzdorf, Donald Tashkin.

Aims and objectives: To examine the effect of a single COPD exacerbation on rate of decline in lung function, using data from a 4-year randomized, double-blind, placebo-controlled trial of tiotropium in moderate-to-severe COPD (UPLIFT).

Methods: Retrospective analysis of annual rate of decline in pre- and postbronchodilator (BD) forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC). Before and after first COPD exacerbation (increase in onset of respiratory symptom lasting ≥3 days and treated with antibiotics/ systemic corticosteroids). Eligible patients (pts) had ≥3 pulmonary function tests (PFTs) before exacerbation.

Results: 462 pts were eligible (mean age 64 y, 76% male, mean baseline FEV1 1.19 L and FVC/FVC 0.44). Mean annual rate of decline in pre- and post-BD FEV1 and pre-BD FVC significantly increased (Table).

Conclusion: A single exacerbation can lead to a significantly larger rate of decline in lung function in COPD pts 1-2 years post exacerbation.

195 Aclidinium bromide reduces COPD exacerbations as defined by healthcare resource utilisation and EXACT: Results from ATTAIN

Paul W. Miller, David Singh, Alvar Agusti, Eric D. Bateman, Rosa Lamarca, Gonzalez de Miquel, Cynthia Caracta, Esther Garcia Gil, St George’s, University of London, United Kingdom; 2Medicines Evaluation Unit Ltd, Manchester, United Kingdom; 3Thorax Institute, Hospital Clinic, Barcelona, and CIBER Enfermedades Respiratorias and Fundación Caibet-Cibernet, Barcelona, Spain; 4University of Cape Town, South Africa; 5Almirall S.A, Barcelona, Spain; 6Forest Research Institute, NJ, United States

Introduction: COPD exacerbations can lead to considerable morbidity and mortality. ATTAIN investigated the effect of twice-daily (BD) aclidinium bromide, a long-acting muscarinic antagonist, on exacerbations in patients with moderate to severe COPD.

Methods: In this 24-week, randomised, double-blind trial, 819 patients (mean -SD FEV1, 56.8±12.8% predicted) received aclidinium (200 μg or 400 μg) BD or placebo. Prior exacerbation history was not an inclusion criterion. Exacerbations were assessed by healthcare resource utilisation (HCRU); increased symptoms on ≥2 consecutive days requiring a change in treatment and the EXacerbations of Chronic pulmonary disease Tool (EXACT); persistent increase in total score of ≥9 points for ≥12 points for ≥2 days).

Results: EXACT captured more exacerbations per patient per year than HCRU (EXACT: 1.0, 0.98 and 1.39 for aclidinium 200 μg, 400 μg and placebo, respectively; HCRU: 0.43, 0.40 and 0.66, respectively). Exacerbation rates were significantly lower for both aclidinium doses compared with placebo and ratio rate differences were: EXACT 200 μg 0.72 [p=0.017] and 400 μg 0.71 [p=0.012]; HCRU: 200 μg 0.72 [p=0.043] and 400 μg 0.67 [p=0.020]; corresponding to a rate reduction of about 28% with aclidinium using each method.

Conclusions: More than twice as many events were recorded using EXACT compared with HCRU. Aclidinium 200 μg and 400 μg BD reduced exacerbations compared with placebo as assessed by HCRU and EXACT. The proportional reduction in exacerbations demonstrated in the non-prespecified secondary outcome confirms the efficacy of aclidinium 200 μg, which was sufficient to reach statistical significance in both the primary and non-prespecified secondary outcomes.

196 Increased rate of mortality in COPD patients using tiotropium respimat vs tiotropium Handihaler

Katia Verhamme, Ana Afonso, Silvana Romio, Bruno Stricker, Guy Bruesselle, Miriam Sunkenboom, Medical Informatics, ErasmusMC, Rotterdam, Netherlands; 2Clinical Epidemiology, ErasmusMC, Rotterdam, Netherlands; 3Respiratory Diseases, University of Ghent, Belgium

Background: Tiotropium is a long-acting, once daily anticholinergic drug that is delivered via Handihaler (dry powder inhaler) or via Respimat (soft mist inhaler). Data from RCTs suggest that use of tiotropium Respimat is associated with an increased risk of mortality.

Objectives: To explore the risk of mortality in users of either tiotropium Handihaler or tiotropium Respimat.

Methods: Within the IPCI database, a Dutch GP database, we defined a source population of patients ≥ 40 years with at least 1 year of follow-up. The study ran from 2008 to 2011. Patients were followed from start of the study until the patient died or end of follow-up date. Date and cause of death were verified for all patients. From the source population, we defined a cohort of tiotropium users (Handihaler and/or Respimat) and created episodes of use. To assess the risk of dying, we considered a 30-day carry-over effect. The risk of mortality was calculated using a Cox proportional hazard regression analysis. Crude and adjusted HRs were calculated with corresponding 95% CI.

Results: From the source population, we defined a tiotropium cohort of 11,287 patients providing 24,540 episodes of use. 496 patients died while being exposed to either Handihaler or Respimat. Use of Respimat was associated with an increased risk of dying (HRadj 1.52, 95% CI 1.24-1.87) and this association remained upon adjustment (HRadj 1.33, 95% CI 1.07-1.65). The association was strongest for incident users and cardiovascular death, but due to low numbers not longer statistically significant (HRadj 1.87, 95% CI 0.74-4.73).

Conclusions: Use of tiotropium Respimat vs tiotropium Handihaler is associated with a 30% increase of mortality.
The anti-IL-17A-antibody secukinumab does not attenuate ozone induced acute airway neutrophilia in healthy volunteers

Anne Kirsten 1, Henrik Watz 2, Franke Pedersen 1, Olaf Holz 2,3, Rachel Smith 2,4, David Denning 1,2, North West Lung Centre, University Hospital of South Manchester, Manchester, United Kingdom; 2Respiratory Research Group, Manchester Academic Health Science Centre, University of South Manchester, Manchester, United Kingdom.

Background: Interleukin-17 (IL-17) or IL-17A is linked to neutrophilic airway inflammation.

Aim and Objective: To evaluate the effect of a novel anti-IL-17A antibody secukinumab (AIN457) on ozone-induced airway neutrophilia in healthy volunteers.

Methods: 24 healthy volunteers with normal neutrophil levels in sputum and a proven inflammatory response to ozone 24 and 48 hours after the baseline ozone challenge (3 hours intermittent exercise with inhalation of 250 ppb ozone during the challenge) were randomized to secukinumab (10mg/kg bodyweight) or placebo or an open label prednisolone (50mg) arm in the ratio 2:1:1. Secukinumab or placebo was administered as an infusion whereas prednisolone was administered as an oral tablet. Sputum analyses were performed 24 and 48 hours following ozone challenges during the treatment phase at various time-points. Safety and pharmacokinetics were also assessed.

Results: Administration of secukinumab was safe and well tolerated. Compared to placebo, secukinumab did not attenuate ozone-induced sputum neutrophilia 24 and 48 hours after ozone challenge. Prednisolone treatment resulted in an increase of neutrophils in sputum and in peripheral blood. No immunogenicity with secukinumab was observed. Mean half life of secukinumab was 29.8 days.

Conclusions: Neutralizing IL-17A by secukinumab did not attenuate acute ozone-induced airway neutrophilia in healthy subjects. Study of the effects of anti-IL17A treatment on chronic neutrophilic airway diseases may be warranted in patients with disorders characterized by airway neutrophilia.

The Abstract was funded by Novartis Institutes for BioMedical Research, Switzerland.

198 Reducing exacerbations in omalizumab in a real-world setting

Gert-Jan Braunstahl, PhD, Andreas Georgiou 2, Robert Niven 2, David Denning 1,2, North West Lung Centre, University Hospital of South Manchester, Manchester, United Kingdom; 2Respiratory Research Group, Manchester Academic Health Science Centre, University of South Manchester, Manchester, United Kingdom.

Asthma exacerbations are a major cause of morbidity and mortality. Omalizumab (OMA) reduced exacerbations in clinical trials. The 2-year, global, observational eXpeRience registry was initiated to collect data from OMA-treated allergic (IgE-mediated) asthma patients (pts), and to assess whether results from clinical trials apply in real-life practice. The intent-to-treat population included 916 pts (734 and 643 evaluable pts at Month 12 and 24, respectively). In the 12 months prior to inclusion in the registry, only 11.8% of pts were exacerbation free; at months 12 and 24, 54.9% and 65.8% of pts, respectively, were exacerbation free over the prior year.

Compared with the 12-month pre-treatment period, clinically significant and severe clinically significant asthma exacerbations decreased over time following OMA initiation (Table).

<table>

</table>

These real-world data and safety profile are consistent with results from clinical trials. OMA reduces clinically significant and severely clinically significant exacerbations in pts with uncontrolled persistent allergic asthma.

Rationale and Objectives: There is growing evidence linking asthma severity with fungal allergy. We assessed the effect of voriconazole or posaconazole therapy on asthma control and severity (GINA criteria) among patients with SAFS and ABPA.

Methods: We conducted a retrospective review of adult asthmatic patients with either ABPA or SAFS receiving voriconazole or posaconazole. Clinical, radiological and immunological evaluation was used to assess response. Voriconazole (500-600 mg/day) or posaconazole (800 mg/day) (adjusted by plasma level monitoring) was given for at least 6 months, if tolerated.

Results: There were 26 patients, ABPA (n=21, severe=17) or SAFS (n=5), 11 males, median age 59 yrs. Eighteen of 24 (75%) discontinued oral corticosteroids, 12 of them within 3 months of therapy. Asthma severity was downgraded from severe to moderate (n=8) and moderate to mild (n=1) in 9 of 24 (38%) patients. There was a marked reduction in OCS and SABA use, health care utilization due to asthma and improvement in overall health status. Furthermore, there was a statistically significant reduction in immunological markers appearing at 9 months (p=0.008) for total IgE and at 12 months for RAST IgE Aspergillus fumigatus (p=0.0056). Six of 23 (26%) patients on voriconazole had AEs requiring discontinuation before 6 months compared to none on posaconazole (p=0.15). Four relapsed (57%), one at 3 months and 3 at 12 months after discontinuation.

Conclusion: Both voriconazole and posaconazole are effective treatment options which can improve asthma control and severity, though larger prospective studies are required.

53. MDR- and XDR-TB: epidemiological and public health overview

200 Time trends in multidrug-resistant tuberculosis

Matteo Zignol, Dennis Falzon, STOP TB Department, World Health Organization, Geneva, Switzerland

Background: To investigate time trends in multidrug-resistant tuberculosis (MDR-TB) in different geographical settings worldwide we used data collected by the World Health Organization over the period 1994-2010.

Methods: Time trends in MDR-TB rates from 45 countries or territories were calculated by multiplying the new TB case notification rates by the frequency of MDR-TB in new TB cases in the same year. The number of available country-year data points differed between countries. The annual percentage change in MDR-TB rates was plotted against the annual percentage change in TB notification rates, placing all countries or territories in one of six groupings according to whether MDR-TB rates and TB notification rates were increasing or decreasing.

Results: In countries like Japan, Japan, Poland, Singapore and the US, the incidence of MDR-TB has been falling quicker than the incidence of TB. Countries with a high proportion of MDR-TB among TB cases (Georgia, Russian Federation: Tomsk Oblast), with a majority of TB cases of foreign origin (Sweden, United Kingdom) and with high HIV prevalence (Botswana, South Africa: Mpuanalago Province, Swaziland) show net increments in both TB and MDR-TB incidence, with the latter increasing faster than the former.

Conclusions: While global trends in MDR-TB may not be inferred directly from
the national data currently available, MDR-TB incidence is increasing in countries with disparate epidemiological and geographical settings.

201 Determinants of multidrug-resistant tuberculosis (MDR-TB) in Belarus
Alena Skrahina1, Henza Huereux2, Aksana Saluntskaya2, Andrei Avchupoko1, Sven Hofnife1, Valiantas Rusovich1, Andrei Dadu2, Pierpaolo de Colomn3, Masoud Dara4, Wayne Van Gemer5, Matteo Zignol5
1Clinical Department, Republican Scientific and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus; 2Laboratory Department, Republican Scientific and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus; 3Laboratory Department, Republican Scientific and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus; 4Department of Preparedness, Swedish Institute for Communicable Disease Control, Stockholm, Sweden; 5Communicable Diseases, WHO Country Office in Belarus, Minsk, Belarus; 6Tuberculosis and M/XDR-TB Programme, WHO Regional Office for Europe, Copenhagen, Denmark

Introduction: A nationwide survey to investigate risk factors for multidrug-resistant tuberculosis (MDR-TB) was conducted in Belarus in 2010-2011. A total of 1,344 TB patients were enrolled.

Results: MDR-TB was found in 32.3% (95% CI: 29.7-35.0) and 75.6% (95% CI: 72.1-78.9) of new and previously treated patients, respectively. History of previous treatment for TB was the strongest independent risk factor for MDR-TB (Odds Ratios [OR] 6.1, 95%CI: 4.8-7.71) followed by HIV infection (OR 2.2, 95%CI: 1.4-3.5). Other independent risk factors were young age (<35 years) (OR 1.4, 95%CI: 1.0-1.8), history of imprisonment (OR 1.5, 95%CI: 1.1-2.0), disability in such a way as to be unable to work (OR 1.9, 95%CI: 1.2-3.0), alcohol abuse (OR 1.3, 95%CI: 1.0-1.8), and smoking (OR 1.5, 95%CI: 1.1-2.0).

Discussion: MDR-TB is a widespread problem in Belarus, with very high levels documented nationwide. The convergence of the MDR-TB and HIV epidemics and association between MDR-TB and numerous risk factors calls for stronger collaboration between TB and HIV control programmes and a more targeted approach to high-risk groups. Adherence to TB treatment could be improved by integrating treatment for alcohol use disorders into TB services and enhancing patient incentives and enablers.

202 Survival and risk factors of mortality among defaulters from treatment of pulmonary tuberculosis
Alan Altraja1,2,3, Piet Vlietkamp2, Lea Pehme1
1Department of Pulmonary Medicine, University of Tartu, Estonia; 2National Institute for Health Development, Estonian Tuberculosis Registry, Tallinn, Estonia; 3Tartu University Hospital, Tartu, Estonia

Defaulters from treatment of pulmonary tuberculosis (PTB) convey a significant transmission risk that is particularly dangerous during increasing prevalence of MDR-TB and TB/HIV co-infection. We estimated 1- and 5-year survival, assessed infectiousness and identified risk factors of mortality of PTB patients after treatment default. We observed all patients with PTB registered in the Estonian Tuberculosis Registry as defaulters during 2004-2006 (n=160) in a cohort study until 12.12.2011 and used multivariate Cox regression analysis to identify risk factors of mortality. Median follow-up time was 5.94 (IQR: 3.21-6.68) years after default. One-year and 5-year survivals were 90.5% and 86%, respectively. Among the 50 patients (31.3%) who died, median survival time was 1.86 (IQR: 0.88-3.04) years; 24 deaths (48.0%) occurred due to TB and 26 (52.0%) due to other reasons. At 1 and 5 years after default, 22.8% and 12.2% of surviving patients, respectively, were smear/culture positive. Smear-positivity (HR 2.86, 95% CI 1.05-7.80), previous TB (HR 2.99 95% CI 1.27-7.04) and offtreatment resistance (HR 5.77, 95% CI 1.74-19.18) increased risk of TB-related mortality. Disabled (HR 7.97, 95% CI 1.01-62.63), retired (HR 17.10, 95% CI 1.71-171.41), homeless (HR 2.36, 95% CI 1.61-4.78) and imprisoned people (HR 34.01, 95% CI 2.92-398.11) were at increased risk of all-cause mortality, whereas targeted case detection by medical personnel lowered this risk (HR 0.19, 95% CI 0.56-0.61).

Among defaulters, TB-related mortality is not associated with demographic factors, which influence all-cause mortality instead. Infectiousness of defaulters remains high, though decreases with time. Funded by ESF grant No. 8188.

203 Is multidrug-resistant TB more common in children? An analysis of surveillance data
Matteo Zignol1,2, Dennis Falzon3, Dara Masoud2,3
1STOP TB Department, World Health Organization, Geneva, Switzerland; 2Regional Office for Europe, World Health Organization, Copenhagen, Denmark; 3STOP TB Department, World Health Organization, Geneva, Switzerland

Background: Despite the limited availability of data and the possible bias from selective diagnostic testing, results indicate that MDR-TB in children is no less frequent than in adults in many settings. Of particular concern is the link between children and MDR-TB in southern African countries with high HIV prevalence.

Results: In all 5 countries a significant positive association between MDR-TB and HIV was documented (range OR: 1.5-2.6, p value <0.05 for all). Overall, combining data from all countries (6,455 TB cases tested for HIV and MDR-TB) the odds of having MDR-TB among HIV-positive patients were 110% higher than among HIV-negative patients (pooled OR: 2.1, 95%CI: 1.2-3.3), OR consistent across countries (P=19.2%) and the difference was statistically significant.

Conclusions: The association between HIV and MDR-TB epidemics found in these countries is alarming. Patients with dual HIV/MDR-TB infection require complex treatment with anti-retrovirals and toxic, expensive anti-TB drugs. The likelihood of successful outcome is low and transmission of MDR-TB to others is high. Urgent measures should be implemented to strengthen HIV prevention and treatment, contain the spreading of MDR-TB, and improve collaboration between HIV and TB control activities, particularly for individuals at high risk of dual infection such as people who inject drugs and those in congregate settings. Further operational research to identify the determinants and conditions leading to MDR-TB in people living with HIV is needed.
Rational use of tuberculosis drugs to prevent the development of drug resistance

Emma Huitema1, Marieke J. van der Werf2, Miranda W. Langendam3, Marieke J. van der Werf2, Miranda W. Langendam3, Liad D’Ambrosio4, Rosella Centis4, Francesco Blasi5, G.B. Migliori5, Davide Maniselli6, Office of the Chief Scientist, European Centre for Disease Prevention and Control (ECDC), Stockholm, Sweden; 2Unit Knowledge Management, Research, and Policy Development, KNCV Tuberculosis Foundation, The Hague, Netherlands; 3Dutch Cochrane Centre, AMC, University of Amsterdam, Netherlands; 4WHO Collaborating Centre for TB and Lung Diseases, Fondazione S. Maugeri, Care and Research Institute, Tradate, Italy; 5Respiratory Medicine Section, Dipartimento Torasco-Polmonare e Cardio-circolatorio, University of Milan, IHECS Fondazione Cà Grande, Milan, Italy

The tuberculosis (TB) drug pipeline has finally thickened and several new agents are under clinical development. We assessed risks related to the introduction of new drugs and the development of drug-resistance with the aim to support stakeholders when introducing new drugs and regimens in TB Programs. Using standardised Cochrane and PRISMA Guidelines systematic reviews were done to identify inappropriate TB regimens; the knowledge of healthcare workers (HCW) on TB regimens; and the risk of developing multi-drug resistant TB (MDR-TB) when an inappropriate regimen is used. These studies provide evidence that TB drugs are prescribed in inadequate regimens and that inadequate regimens, or the use of fluoroquinolone (FQ) for community acquired pneumonia (CAP), present an increased risk of developing MDR-TB or XDR-TB after treatment for CAP was assessed.

Background: Systemic inflammation is a potential determinant for the excess cardiovascular mortality in COPD. Endothelial dysfunction, a marker of subclinical atherosclerosis correlates with circulating inflammatory markers in stable COPD. Acute exacerbations of COPD are characterized by a transient aggravation of systemic inflammation and might be accompanied by deteriorated endothelial function.

Aim: We aim to assess endothelial dysfunction and systemic inflammation during acute exacerbations of COPD and after clinical restitution.

Methods: We enrolled patients admitted to our hospital due to an acute exacerbation of COPD. Study related procedures comprised spirometry, measurement of systemic inflammatory markers (i.e. C-reactive protein [CRP] and leukocyte count) and endothelial dysfunction by means of the flow-mediated dilatation technique.

Results: We recruited 28 patients (female: n=20) during acute exacerbation. Baseline characteristics were as follows: age: 64.8±5.9 years, BMI: 24.6±3.9 kg/m²; FEV1: 36.5±12.1, %pred. During the acute exacerbations patients showed a median CRP of 7.0 (2.0-26.0) mg/l, leukocytes of 9.7±4.3 G/l and a FMD of 6.8±3.6% indicating severe endothelial dysfunction. After confirmed clinical stability we observed a decrease of systemic inflammation (CRP: 4.0 (2.0-7.0) mg/l; leukocytes: 8.2±2.9 G/l) and a simultaneous improvement in FMD (10.6±3.4%).

Conclusions: Our results indicate endothelial dysfunction in COPD patients. Furthermore, acute exacerbations deteriorate endothelial function in COPD, probably via aggravation of systemic inflammation.
Bone radio density (BRD) was lower in COPD patients than smokers or non-smoker controls (163.4±48.6 vs 185.1±89.8 vs 213.8±50.2 HU, p<0.001). In the COPD group, BRD correlated with age (r=0.256, p<0.001), FEV1% predicted (r=0.367, p<0.001), FEV1/FVC (r=0.31, p=0.002), BMI (r=0.231, p<0.001), mMRC (r=0.089, p=0.006), BODE (r=0.116, p<0.001), exacerbation rate (r=0.088, p=0.006), dyspnea (r=0.126, p<0.001). Agatston score (r=0.252, p<0.001) and MESA score (r=0.197, p<0.001). However, BRD in COPD patients did not correlate with pack years smoked (p=0.398) or decline in FEV1 (p=0.546). Comorbid heart failure in COPD patients was associated with lower BRD (0.1±1.5 vs 165.1±48.5 HU, p=0.025).

We show in a COPD cohort that low bone radio density is associated with adverse clinical features and with high CACS.

P210

Coronary artery calcification in COPD is associated with adverse functional assessment and mortality

Michelle Williams1, Lisa Edwards2, Ruth Tal-Singer2, Bruce Miller2

John Marcheson3, Edwin van Beek3, David Newby3, William MacNee4, 1Centre for Cardiovascular Science, University of Edinburgh, United Kingdom; 2Respiratory CEDD Discovery Medicine, GlaxoSmithKline, Philadelphia, PA, United States; 3Department of Radiology, Royal Infirmary of Edinburgh, United Kingdom; 4Clinical Research Imaging Centre, University of Edinburgh, United Kingdom; 5MRC Centre for Inflammation Research, University of Edinburgh, United Kingdom

COPD is associated with coronary artery disease (CAD). Coronary artery calcium score (CACS) can identify and stratify risk in CAD. We evaluated CACS and its relationship with clinical outcomes using non-gated chest CT in a well-characterised cohort of COPD patients (ECLIPSE study).

CACS (Agatston score) was assessed in 946 patients (COPD n=476, FEV1% predicted 48.7±14.1, age 63.4±2.4 yrs; Smokers controls: n=199, FEV1% predicted 110.0±11.0 yrs; Non-smokers controls: n=71, FEV1% predicted 114.4±13.8, age 54.7±7.0 yrs). CACS was higher in COPD patients than smokers or non-smoker controls (415.6±89 vs 141.7±39.6 yrs vs 66.6±22.8 yrs, p<0.001). When corrected for pack years, the calcium score percentile based on age, sex and smoking was greater in the COPD group (56.4±16 vs 40.5±22 vs 30.5±15, p<0.001). CACS in the COPD group correlated with age (r=0.40, p<0.001), pack years (r=0.20, p<0.001), function (6 minute walking distance (r=0.13, p<0.001) and mMRC dyspnoea score (r=0.196, p<0.001) and some biomarkers (Interleukin 13 vs 0.18, p<0.001; Clara Cell secretory protein16 R=0.18, p<0.001; Surfactant Protein-D vs 0.11, p=0.006) but not with emphysema (% low attenuation areas), FEV1% predicted, exacerbation frequency or decline in FEV1. CACS and calcium percentile corrected for pack years were higher in those who died during 3 years follow up (65.3±SD23 vs 39.6±60, p<0.003 and 68.4±46 vs 57.2±15, p=0.027) and a significant association between high CACS and mortality was confirmed by a Cox Proportional Hazard model. Thus in a cohort of COPD patients higher CACS was associated with poor function and increased mortality.

Supported by GlaxoSmithKline (SCO104960, NCT0292552).

Clinical impact of anaemia in patients with chronic obstructive pulmonary disease: Results from ECLIPSE study

Mina Lamsch1,2, Lisa Edwards3, Stefan Anker2, Courtney Crim5

Stephen Fernando4, Emil Wouters3, William MacNee1 | 1Division of Cardiology, University University of Pulmonary and Allergic Diseases, Golkın, Slovenia; 2Applied Causexis Research, Churite Universiutmedizin Berlin, Berlin, Germany; 3Respiratory CEDD Discovery Medicine, GlaxoSmithKline, Philadelphia, PA, United States; 4Pulmonary and Critical Care Medicine, University of Nebraska Medical Center, Omaha, United States; 5Department of Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands; 6MRC Centre for Inflammation Research, University of Edinburgh, United Kingdom

Anaemia is common in chronic diseases, associated with poor outcomes. In COPD, data on the effects of anaemia are scarce and inconclusive. We assessed the prevalence, incidence, clinical impact of anaemia in the ECLIPSE study,a large well characterised COPD cohort.

Methods: We included patients with haemoglobin (Hb) value at baseline and at least one measurement during 3-years follow-up. Analyses were performed. The study population was divided into three groups, smokers, never smokers and non-smokers smokers, and current or former smokers.

Results: In 2997 COPD patients (63.7% men, 65% current or former smokers, and 168 current or former smokers, 162 never smokers, 162 former smokers, 162 never smokers). Individuals with diabetes were excluded from this study. The CML and sRAGE levels in COPD patients were measured by using a sandwich enzyme-linked immunosorbent assay (ELISA) in 146 subjects, aged ≥ 65 years, divided into five groups: 58 with CHF, 23 with COPD, 29 with CHF and COPD and 36 controls (18 current or former smokers, and 18 never smokers). In the control group, the CML and sRAGE levels were higher in CHF patients than in controls [CML: 1.9 (1.5-2.4) vs 1.6 (1.4-2.0) ng/mL; sRAGE: 0.51 (0.3-0.8) vs 0.41 (0.3-0.5) ng/mL; p<0.01]. By contrast, both CML and sRAGE were not different between the group with COPD and that with CHF/COPD were compared with controls (p<0.05). CML and sRAGE positively correlated with N-terminal proBNP (N-Pro BNP) in the three patient groups: CHF (r=0.43, p<0.001), COPD (r=0.77, p<0.001) and in CHF/COPD (r=0.60, p<0.01).

In conclusion, subjects with CHF have high plasma levels of CML and sRAGE. The binding of the receptor for advanced glycation end products (RAGE) with its ligands begins a cellular activation and an inflammatory signal amplification in different diseases. We determined the plasma levels of Neopterin-cobalamin/iron (CML) and soluble RAGE (sRAGE) in chronic heart failure (CHF) patients, in cases with chronic obstructive pulmonary disease (COPD) and in healthy controls. We also investigated the associations between these biomarkers and the clinical and functional characteristics of the study populations. The CML and sRAGE plasma levels were measured by using a sandwich enzyme-linked immunosorbent assay (ELISA) in 146 subjects, aged ≥ 65 years, divided into five groups: 58 with CHF, 23 with COPD, 29 with CHF and COPD and 36 controls (18 current or former smokers, and 18 never smokers). The CML and sRAGE plasma levels were measured by using a sandwich enzyme-linked immunosorbent assay (ELISA) in 146 subjects, aged ≥ 65 years, divided into five groups: 58 with CHF, 23 with COPD, 29 with CHF and COPD and 36 controls (18 current or former smokers, and 18 never smokers). Individuals with diabetes were excluded from this study. Investigation of neuromuscular transmission in patients with chronic obstructive pulmonary disease: A preliminary report
Yuksel Kaplan1, Gazi Gulbas2, Hilal Ermis3, Ozden Kamisli3, Suat Kamisli1, Cemal Orzan1, 2, Neurology, Inonu University, Malatya, Turkey; 3Pulmonary Medicine, Inonu University, Malatya, Turkey

Introduction: Chronic Obstructive Pulmonary Disease (COPD) is accepted as a pulmonary disease that affects all systems of the body. There is growing awareness about systemic inflammation and cardiovascular, neurologic, psychiatric, and endocrine comorbidities associated with COPD. Various studies of patients with COPD affecting both the central and peripheral nervous system, either sequentially or simultaneously, have been reported by electrophysiologic studies. Single-tiber electromyography (SFEMG) is an electrophysiological technique of great value in the assessment of neuromuscular disorders. The aim of study was to delineate any dysfunction of NMT by SFEMG in COPD patients.

Methods: Sixteen COPD patients without evident clinical signs of muscle involvement and 16 healthy controls underwent SFEMG. Ten to 20 different potential pairs were recorded and individual jitter values calculated. The results obtained from patients were compared with those from the controls.

Results: Of 201 individual jitter values of the patients, 15 (7.4%) were abnormally high, whereas only 1/65 (0.6%) jitter values from normal subjects were abnormal. Abnormal NMT was found in 6/16 (37.5%) patients, but in none of the control subjects.

Conclusion: Our study demonstrates that subclinical NMT abnormality is present in COPD patients. To our knowledge, this is the first study to explore NMT abnormality in patients with COPD, and we believe that further comprehensive studies are needed to clarify whether patients with NMT abnormality have different clinical/laboratory characteristics and prognosis than patients with normal NMT.

P215
The impact of bacterial colonisation on airway inflammation in stable COPD
Rica Singh1, Davinder Garcha1, Anant Patel1, Alexander Mackay1
1Academic Department of Respiratory Medicine, UCL Medical School, London, United Kingdom

Culture-independent approaches are increasingly used for diagnostic microbiology. Quantitative PCR (qPCR) enables accurate assessment of bacterial load in sputum. We hypothesised that the degree of airway inflammation relates to bacterial load in colonised stable COPD patients and may increase over time. Sputa prospectively collected from stable patients in the London COPD Cohort were analysed using qPCR, to detect H. influenzae, M. catarrhalis and P. aeruginosa. The samples were cultured and qPCR was done for the above three pathogens. The results were normalised and expressed as maximum bacterial load (MBL) per sample.

Mean age was 71.1 years (SD 8.0), FEV1 1.3L (0.5), FEV1 predicted 51.0% (17.5).

There was no change in bacterial load or airway inflammation over time (table 1). Bacterial load and airway inflammation are stable over time in successive samples. Increasing bacterial load, identified by qPCR, is associated with airway inflammation in stable COPD, suggesting the importance of airway infection in COPD pathogenesis.

Table 1. Changes in bacterial load and airway inflammation over time

The evaluation of sensory gating with P50 paradigm in chronic obstructive pulmonary disease
Ozden Kamisli1, 2, Hidal Ermis3, Suat Kamisli1, Gazi Gulbas2, Cemal Orzan1
1Department of Neurology, Inonu University School of Medicine, Malatya, Turkey; 2Department of Chest Diseases, Inonu University School of Medicine, Malatya, Turkey

Objective: Chronic obstructive pulmonary disease (COPD) is a common preventable and treatable disease characterized by persistant airflow limitation in the airway. It is major cause of morbidity and mortality throughout the world. It is well known that COPD is associated with significant systemic abnormalities. Numerous neurologic involvement like cerebrovascular diseases, motor neuron diseases and cognitive impairment has been reported in COPD. Cognitive dysfunction is usually associated with hypoxia or hypercarbia in these patients. We aimed to investigate the relationship between arterial blood gas analysis and sensory gating test parameters with P50 sensory gating in COPD patients.

Methods: 25 male (mean age 65.16±9.95 years) patients with COPD and 17 healthy male controls (61.52±6.33 years) were included into the study. The diagnosis of COPD was defined according to GOLD guidelines. N100 measurements were taken, the suppression percentage of P50 and N100 was calculated.

Results: COPD patients showed significantly less P50 and N100 suppression when compared to healthy controls. P50 suppression percentage mean was 43.82±30.23 in COPD patients, and 65.21±15.77 in controls (p=0.012). N100 suppression percentage was 35.56±8.28% in COPD patients and 55.63±31.66 in controls (p=0.042).

Conclusion: We found reduced P50 and N100 suppression in COPD patients. This impairment is more clear in hypoxic COPD patients. Hypoxia leads to a decrease in cerebral perfusion and an impairment of some cognitive abilities. P50 sensory gating may be considered as a marker for cognitive decline in COPD patients. To our knowledge, this is the first P50 sensory gating study in COPD.

P217
Oxidative stress, inflammation and endothelial function in patients with combined flow of chronic obstructive pulmonary disease and arterial hypertension
Vitalii Kryvenko1, Therapy and Family Medicine, Zaporiжzhya State Medical University, Zaporiжzhya, Ukraine

Objective: To study oxidative stress, inflammation and endothelial function in patients with combined flow of chronic obstructive pulmonary disease (COPD) and arterial hypertension (AH).

Design and methods: 106 patients with COPD and combined flow of COPD and AH were examined. The first group was formed by patients with combined flow of COPD and AH (n=61), the second by patients with COPD (n=45). All patients underwent clinical examination, measurement of C-reactive protein (CRP), ultrasound estimation of endothelium-independent vasodilation (EINVD). As oxidative and proinflammatory stress markers – the levels of spontaneous and iron induced aldehydehydrolephinehydrazine’s (SAPH and ISAPH) and carboxyhydrolephinehydrazine’s (SCPH and ICPH) were measured.

Results: Patients with COPD and AH had higher levels of CRP (7,1 mg/l; CI 95% 5,21 -9,22) while comparing with COPD group - CRP (5,1 mg/l; CI 95% 2,79-7,56; p=0,03). The patients with combined flow had impaired EINVD (7,5%; CI 95% 4,19-10,99) than COPD only (15.7%; CI 95% 11,79-19,63; p=0,001). The levels of SAPH (0,062 units/g; CI 95% 0,044-0,079) and SCPH (0,041 u/g; CI 95% 0,027-0,055) in COPD and AH group were also greater than COPD only - SAPH (0,042 u/g; CI 95% 0,022-0,051; p=0,009) and SCPH (0,032 u/g; CI 95% 0,019-0,042; p=0,025). The patients with combined flow had higher levels of ISAPH (0,212 u/g; CI 95% 0,187-0,242) and ICPH (0,124 u/g; CI 95% 0,014-0,148) comparing with COPD patients - ISAPH (0,143 u/g; CI 95% 0,118-0,168; p=0,001) and ICPH (0,07 u/g; CI 95% 0,075-0,112; p=0,001). The impairments found in EINVD may lie in the increase of oxidative stress and systemic inflammation.
P219
The absolute risk of osteoporotic fractures according to the program of FRAX patients with chronic obstructive pulmonary disease
Ekaterina Kostyukova, Court of Internal Medicine, Petrozavodsk State University, Petrozavodsk, Karelia, Russian Federation

Bone loss may be asymptomatic, and the first sign of osteoporosis are bone fractures. Assessment of absolute risk of osteoporotic fractures by using FRAX method in patients with COPD using the FRAX computer program is of great practical interest.

Objective: To examine the absolute risk of osteoporotic fractures by using FRAX method in patients with COPD.

Methods and materials: We examined 108 patients with COPD. The study group comprised men with long smoking history. Mean age 60.2±5.5 years. The study of bone mineral density (BMD) of lumbar spine and proximal femur was performed by X-ray absorptiometry at the densitometer “Lunar DPX-NT”. Evaluation of ten osteoporotic fracture risk was calculated using the computer program FRAX. To calculate the Risk methodology used FRAX T-score femoral neck index (RN) of the digital volume pulse in response to salbutamol (RISALB) and serum endotelin-1 (ET-1) were used to assess ED.

Results: The assessment of absolute risk (AR) of all hip fracture patients were divided into 3 groups (AR <1, AR 1-3 and AR> 3). The maximum number of patients with high risk of hip fracture observed among patients with COPD stage 4 - 84.6% (p <0.05). In evaluating the 10-year probability of any major osteoporotic fracture patients were divided into 3 groups (AR <10, AR 10-20 and AR> 20). AR 10-20 major fractures in the stages of COPD was observed in 15.68%, of patients with stage 4 COPD in 30.8%. These figures are significantly higher than the corresponding figures in patients with COPD stage 2 (p <0.05).

Conclusion: Assessment of absolute risk of fractures provides useful information to forecast the fracture in patients with COPD.

P220
Arterial stiffness and endothelial dysfunction in stable COPD patients
Marina Makarova, Sergey Avdeev, Alexander Chuchalnin. Clinical Department, Pulmonology Research Institute, Moscow, Russian Federation

Cardiovascular disease is common in COPD patients and is associated with poorer prognosis. Arterial stiffness (AS) is a validated measure of cardiovascular risk. Aim: to assess AS and endothelial dysfunction (ED) in COPD patients, to determine their association with other clinical and cardiologicalpulmonary functional parameters.

Methods: We enrolled 41 COPD patients (64.5±7.6 yrs, FEV1 37.7±14.1% and 34 normal control subjects (CS). Lung function, blood gases, six-minute walking distance (6MWD), nocturnal pulseoximetry, serum C-reactive protein (CRP) were measured. Assessment of AS was performed by use of digital plethysmography (Pulse Trace PCA 2 Medical). Change in reflection index (RI) of the abdominal obesity measured as an increased WC is associated with COPD. The abdominal obesity measured as an increased WC is associated with COPD. The abdominal obesity measured as an increased WC is associated with COPD.

Results: In COPD patients stiffness index (SI) was higher than in CS: 11.3±3.3 vs 6.9±4.0 mmHg, p<0.05. There were significant correlations of SI with FEV1 (r=0.40), BMI (r=0.53), 6MWD (r=0.53), pulse during sleep (r=0.50), CRP (r=0.47). RISALB was lower in COPD patients than in CS (1,15±0-10% vs 11,50±6-19%, p<0,05) and decreased according to COPD stages: GOLD II 5,85±15-13%; GOLD III 1,65±7,1-10,35%; GOLD IV 0.0-2%; p<0.05. The ET-1 levels were elevated in COPD patients and correlated with RISALB (r=0.46, p=0.03). RISALB was significantly associated with mean nocturnal SpO2 (r=0.38), DLCO (r=0.45).

Conclusion: AS and ED are significantly impaired in COPD patients. Decreased FEV1, 6MWD and systemic inflammation were associated with AS and ED. Hypoxemia, elevated ET-1 level and decreased DLCO have an association with both AS and ED.

P221
Evaluation of carotid intima media thickness in COPD patients
Fahil Halil Besic1, Leyla Yilmaz Aydin1, Omer Yargan1, Talha Demir2, Melih Engin Erkan1, Elif Ozer1, Hulya Coskun1, 1Radiology, Ducce University, Ducce, Turkey; 2Chest Disease, Ducce University, Ducce, Turkey; 3 Nuclear Medicine, Ducce University, Ducce, Turkey; 4 Internal Medicine, Ducce University, Ducce, Turkey

Background: Chronic obstructive pulmonary disease (COPD) and atherosclerosis may occur due to similar risk factors and have a significant cause of morbidity and mortality. In this study we assess the relationship between COPD and atherosclerosis; carotid intima media thickness (CIMT) of COPD patients and healthy individuals with normal BMI and metabolic parameters compared.

Methods: 2230 participants aged between 18 - 96 years diagnosed with COPD according to clinical features and pulmonary function tests study the test, 47 healthy controls while 1124 exclusion criteria were associated with COPD. The pulsed Doppler ultrasound was performed for the assessment of CIMT to all participants.

Results: Mean CIMT in COPD group and control group were 0.79±0.16 mm and 0.67±0.1 mm, respectively (p <0.001). In logistic regression analysis that made to determine the parameters affecting atherosclerotic, it was found that CIMT was related to age with direct proportion (p = 0.004) and to FEV1% with inversely proportion (p = 0.029).

Conclusion: Persistent low-grade systemic inflammation in COPD and atherosclerotic disease may possibly have been reported a factor in both pathologies. Early atherosclerosis and cardiovascular risks in adults with COPD increases independent of other risk factors. CIMT which shows direct proportion with age and inverse proportion with FEV1% is a non-invasive, easily applicable and cheap method that can be used in determining the risk of atherosclerosis.

Myocardial injuries in patients with chronic obstructive pulmonary disease
Mikhail Kinjuk1, Galina Sukhanova2, Olga Kurapetsdiani3. 1Chair of Hospital Therapeutics, Vladivostok State Medical University, Vladivostok, Primorsky Region, Russian Federation

The purpose of this study is to determine a value of computer electrocardiography (CECTG) in myocardial injuries revealing in patients with obstructive pulmonary disease (COPD) and to determine hypoxemia role in its developing.

Methods: We examined 62 male patients with COPD (15 – moderate, 28 – severe, 19 – very severe stages). CECTG method has been in addition to common physical examination. This technique allows to evaluate condition of all heart’s portions using multielectrode belt consisted of 65 unipolar leads, which makes it possible to consecutively applied to the frontal and right side of the chest, abdomen and the backside of the chest. Therefore, amount of monopolar leads increases to 260 electrocardiographs. That allows estimating panoramic view of electrical field of the heart. 10 myocardial regions were detected with estimating terminal part of QRS complexes. Patients have been divided into 2 groups by PaO2 level: first group (n=29) with PaO2<80 mmHg, second group (n=33) had PaO2>79 mmHg.

Results: CECTG method revealed significant generalization of the myocardial injuries in right ventricle as well as in the left one in patients with COPD (79.6%). Myocardial injuries were detected mostly in right ventricle area and posterioro- atragmatic area of left ventricle. In compare with standard ECG CECTG revealed myocardial injuries in 1.6 times often. Myocardial injuries in right ventricle area in patients with COPD has been detected significant more often (p<0.01) than in patient without hypoxemia.

Conclusion: CECTG method revealed myocardial injuries in right and left ventricle in 79.8% patients with COPD. Hypoxemia takes a definite role in injuries forming.

P223
The metabolic syndrome (MetS) in patients with chronic obstructive pulmonary disease (COPD) and its association with airway obstruction
Vejin Stratiev1, John Perez2, Sonya Galcheva1, Marinka Peneva1. 1 Clinic of Pulmonology and Allergology, UMBH "St. Marina", Varna, Bulgaria; 2 Dept. of Internal Diseases, Military Medical Academy - Naval Hospital, Varna, Bulgaria; 3 Dept. of Paediatrics, UMBH "St. Marina", Varna, Bulgaria

Background: The metabolic syndrome (MetS) is common in patients with COPD and shows part of the so called chronic systemic inflammatory syndrome. Aim: to investigate the presence of MetS in patients with COPD and healthy subjects and to assess the association of its components with airway obstruction.

Methods: We performed a cross-sectional study with 244 participants (mean age 60.5±9.5 years) divided into 2 groups: 141 subjects with COPD and COPD and 103 healthy matched controls. We measured the characteristics of the syndrome as stated by the IDF definition. Anthropometry and biochemical tests were performed, as well as spirometry to define the stage and severity of the disease.

Results: 41.8% of the COPD patients presented 3 or more features of the MetS versus 39% in the control group. Using multiple linear regression analysis we defined that the main predictor of MetS was the increased waist circumference (WC) (p=0.263, p=0.022). Among the MetS subjects, COPD patients had significantly higher WC compared to the controls (111.0±17.8 vs 104.0±12.4 cm, p=0.032). In COPD subjects with the syndrome BMI, WC, SHP DHP, fasting blood glucose and triglycerides were significantly higher compared to those without MetS (p<0.01 for all), while HDL-cholesterol was significantly lower (p=0.017). In patients presenting MetS we also found a significant negative correlation between WC and FVC and FEV1% predicted (r=-0.291, p=0.011 for FVC and r=-0.327, p=0.004 for FEV1, respectively).

Conclusion: The present study suggests that the MetS is frequent among patients with COPD. The abdominal obesity measured as an increased WC is associated with the airway obstruction.

P224
Increased sympathetic nerve activity in COPD associated with elevated morbidity and mortality
Helge Haerrmann1, Stefan Klanner1, Tobias Raupach1, Stefan Andreas1,2, 1Cardiology and Pneumology, University Medical Center, Goettingen, Germany; 2Pneumology, Lung Hospital Immenhausen, Immenhausen, Germany

Chronic obstructive lung disease (COPD) is characterized by systemic effects. Studies using microneurographic recordings and heart rate variability proved an increase in sympathetic nerve activity in COPD, which possibly contributes to progression and severity of the disease. Aim of this study was to investigate in a follow-up survey if increased sympathetic nerve activity is associated with elevated morbidity and mortality in patients with COPD.

Methods: Evaluations of the sympathetic nerve activity via microneurographic recordings were performed in two studiesa in 1998/99 and 2005/06 at the Univer-
sity Medical Center Göttingen, including an overall of 20 patients with COPD (as published in AJRCCM 2001;164:597 and ERJ 2008;32:387). The study participants or their relatives were contacted via a telephone survey in the year 2010/11 and asked for the number of hospitalizations or date of decease of the participant. The results of the survey were correlated with the collected data of the past two studies.

**Results:** COPD patients who were hospitalized or deceased (n=12) compared to live patients without hospitalizations (n=8) show a significant increase in muscular sympathetic nerve activity (MSNA) in bursts/min (60.3 to 40.5, p=0.022), furthermore lower values in FEV1 (% pred) (39 to 54, p=0.035) and lower pO2 (69.12 to 78.04, p<0.025).

**Conclusion:** As well as other characteristics of COPD (decrease in FEV1, pO2) the increase in sympathetic nerve activity is likely to be associated with elevated morbidity and mortality in patients with COPD.

Assessment of long-term omalizumab treatment in severe allergic asthma

Eylem Sozan Ozar, Cengiz Örge, Ahmet İvan, Sibel Atis Nayci. Chest Diseases, Mersin University School of Medicine, Mersin, Turkey

**Objectives:** Several clinical studies have demonstrated omalizumab efficacy in patients with severe allergic asthma, but the treatment period has always been relatively short (4-12 months). There are a few data long term omalizumab therapy. We aimed to assess the long-term clinical and functional effectiveness of the omalizumab treatment in severe allergic asthmatic patients.

**Methods:** Medical registries were used to evaluate the 0, 4, 12 and 36 months effectiveness of omalizumab treatment. 26 females (female/male=21/5) with severe allergic asthma, uncontrolled despite GINA Step 4 therapy. Effectiveness outcomes included spirometry, level of asthma control which evaluated by asthma control test (ACT), systemic glucocorticosteroid (oCSS) use, emergency room (ER) visits and hospitalizations for severe exacerbations.

**Results:** The mean age was 47.6±13.9 and duration of allergic asthma 22.7±10.1 years. Total IgE serum levels was 322±89.7 IU/mL. Mean duration of omalizumab treatment was 40.8±8.2 months. FEV1 improved significantly at all time points versus baseline (p<0.05). The level of asthma control as evaluated by ACT was significantly improved after treatment (p<0.05). We determined significant reduce numbers of exacerbation (p<0.05), emergency visits (p<0.05), hospitalizations (p<0.05), sGCS (p<0.05) and SABA (p<0.05) use at 36 months.

**Conclusion:** This study showed that long-term therapy with omalizumab for up to 3 years was well tolerated with significant improvement of both symptoms and function. For this reason, suggesting that administration of omalizumab for longer than 12 months could be beneficial for responders patients.

**P226**

Omalizumab improves lung function in severe persistent allergic (IgE-mediated) asthma patients: Pooled data from 5 UK centres

Matthew Masoli1, Beverley Castell1, David Halpin1, Chervilleham1, Robert Stone2, Rahul Shrinanker3, Lee Dobson4, Kelly Cutland5, Jay Suntharalingam1, Rachel Carver5, Ismail Kasujee6. 1Chest Clinic, Derriford Hospital, Plymouth, Devon, United Kingdom; 2Respiratory Medicine, Royal Devon and Exeter Hospital, Exeter, Devon, United Kingdom; 3Respiratory Medicine, Musgrove Park Hospital, Taunton, Somerset, United Kingdom; 4Respiratory Medicine, Torbay Hospital, Torbay, Devon, United Kingdom; 5Respiratory Medicine, Royal United Bath Hospital, Bath, Somerset, United Kingdom; 6Respiratory Medicine, Novartis Pharmaceuticals UK Limited, Frimley/Camberley, Surrey, United Kingdom

Omalizumab is an effective add-on therapy for patients with severe persistent allergic (IgE-mediated) asthma. However, in the UK there are limited data reporting on the real-life effectiveness of omalizumab therapy on patient outcomes, particularly with regard to effect on lung function. We retrospectively reviewed outcomes in severe allergic asthmatic patients receiving omalizumab at 5 South West UK centres (Exeter, Plymouth, Bath, Taunton, Torbay). Data were compared for 12 months pre-omalizumab vs 16 weeks and most recent assessment (last 12 months) post-omalizumab initiation. Patients (n=51); age 17–69 years; received omalizumab for an average of 788 days (range: 190–1569). 41/51 (80%) patients responded to treatment at 16 weeks and are included in this analysis. Post omalizumab initiation, mean FEV1 (L/min) improved from 1.9 pre-omalizumab to 2.3 (16 weeks) and 2.1 (most recent). Mean maintenance oral corticosteroid (OCS) dose pre- and post-omalizumab was 22.7 and 8.9 mg/day, respectively. Overall mean [SD] scores for AQLQ and ACT improved after 16-weeks’ treatment: +1.6 [0.86] and +3.0 [9.5], respectively. Reductions were seen post-omalizumab in hospital admissions/bed days, accident & emergency (A&E) and GP visits were seen post-omalizumab (Table). These results demonstrate omalizumab’s effectiveness in improving lung function and other clinical/patient-reported outcomes in severe persistent allergic asthma patients in a ‘real-life’ clinical setting.

**P227**

Long-term effectiveness of omalizumab in patients with severe persistent allergic (IgE-mediated) asthma: Real-life data from 3 UK centres

Mark Brinton1, Timotheo Howes2, Dinesh Saralaay3, Matthew Masoli3, Monica Nordstrom1, Kate Welburn4, Karen Regan5, Ismail Kasujee6.

1Respiratory Medicine, St. Peter's Hospital, Chertsey; 2Respiratory Medicine, Colchester Hospital University NHS Foundation Trust, Colchester; 3Department of Respiratory Medicine, Bradford Teaching Hospitals NHS Trust, Bradford; 4Respiratory Medicine, Novartis Pharmaceuticals UK Ltd, Frimley/Camberley, Surrey, United Kingdom

For patients with uncontrolled severe persistent allergic (IgE-mediated) asthma, omalizumab is an effective add-on therapy. However, limited data are available reporting on long-term effectiveness of omalizumab in UK clinical settings. In a previous pooled analysis using data from 3 UK centres, healthcare utilisation substantially reduced and patient reported outcomes improved post-omalizumab in patients with severe allergic asthma (mean treatment duration: 982 days; range: 112–3839). Using the same patient cohort, data were compared for 2 years pre-omalizumab and for most recent assessment post-omalizumab initiation, to determine if improvements were sustained with longer-term treatment. Patients (n=50; age 18–74) received omalizumab for mean of 1318 days (range: 238–4217). 38/50 patients were responders at 16 weeks. Reductions in hospital admissions/bed days, accident & emergency (A&E) and GP visits were seen post-omalizumab (Table).

**P228**

Real-life effectiveness of omalizumab in patients with severe persistent allergic (IgE-mediated) asthma: Pooled data from 4 UK centres

Mark Brinton1, Timotheo Howes2, Dinesh Saralaay3, Matthew Masoli3, Monica Nordstrom1, Kate Welburn4, Karen Regan5, Ismail Kasujee6.

1Respiratory Medicine, St. Peter’s Hospital, Chertsey, Surrey; 2Respiratory Medicine, Colchester Hospital University NHS Foundation Trust, Colchester; 3Respiratory Medicine, Bradford Teaching Hospitals NHS Trust, Bradford; 4Respiratory Medicine, Plymouth NHS Trust, Derriford Hospital, Plymouth, Devon; 5Respiratory Medicine, Novartis Pharmaceuticals UK Limited, Frimley/Camberley, Surrey, United Kingdom

Omalizumab is an effective adjunctive therapy for patients (age ≥6 years; European Union), with uncontrolled severe persistent allergic asthma. To evaluate the effectiveness of omalizumab on real-life outcomes in UK clinical settings, we retrospectively reviewed records from severe allergic asthma patients who were receiving omalizumab (150-600 mg q4wk or q2wk) at 4 UK centres. Data were compared for 12 months (Plymouth) or 2 years (Chertsey; Bradford; Colchester) pre-omalizumab and for the most recent assessment following omalizumab initiation. Patients (n=80; age 14–74 years) received omalizumab for an average of 1190 days (range: 112–4217). 82% patients responded to treatment at 16 weeks. There was a decrease in hospital admissions/bed days, ICU admissions, and accident & emergency (A&E) and GP visits (Table) and in oral corticosteroid (OCS) use post omalizumab initiation; mean maintenance dose of OCS pre- and post-omalizumab was 14.6 and 4.7 mg/day, respectively. Mean [SD] improvements were also observed in Asthma Quality of Life Questionnaire (AQLQ) score (+1.6 [1.4]) and...

Efficacy and safety of omalizumab in real-life practice in India
Ashok Mahash, Dwopuk Talwar, Mangala Konul, P.D. Hinduja Hospital, Mumbai, Maharashtra, India; Novartis Pharma India, Mumbai, Maharashtra, India

A 2-week, post-marketing study to assess the efficacy and safety of omalizumab in an Indian population is ongoing; we present interim 16-week data. This is an open, uncontrolled, observational, post-marketing study in 72 patients (mean age 51.7±14.9 y) with moderate-to-severe persistent allergic asthma. Endpoints are asthma exacerbations, work/college days missed, hospitalizations, and medication use. Safety and tolerability were carefully assessed. Qualitative and quantitative variables are analyzed using Chi-Square tests and paired t-tests, respectively. All parameters are compared from baseline to week 16 of omalizumab treatment.

35.9% of patients experienced ≥1 exacerbation at baseline. This reduced significantly to 15.4% at week 16 (p=0.046). The proportion of patients missing college/work and requiring unscheduled hospitalizations also reduced significantly with mean values of 0.85 (0.3 vs. 2.5; 95%CI -1.4 to -0.2; p=0.015). ACT scores improved significantly by 5.3 (10.1 vs. 15.4; 95%CI 2.4 to 8.4; p=0.002); FEV1 improved by 0.51L (1.23 vs. 1.74; 95%CI 0.38 to 0.64; p<0.000), and mean ICS dose decreased by 199g (700.8 vs. 501.1 g; 95%CI -205.4 to -125; p<0.028). One gastrointestinal adverse event of moderate intensity (suspected drug related) was reported during the study and resolved with concomitant medication.

Omalizumab is an effective and safe therapeutic option in Indian patients with uncontrolled allergic asthma despite high-dose ICS plus LABA.

P230
Natural history of IgE sensitisation to food allergens in a cohort of adults
Antonios Patelis1, Christer Janson1, Andrei Malinovschi1, Marcus Gunnbjörnsson1, format, Janis2, Håkon Fossum2, raspberry allergy 3, 4.

The prevalence of sensitisation to food allergens is reported to be unchanged or to decrease in adults in longitudinal studies. No longitudinal studies examine omalizumab (14.1% to 12.5%, p<0.039; 23.7% to 26.6%, p<0.021, respectively). ACQ scores significantly improved with omalizumab; composite scores decreased by 4.2 (14.8 vs. 10.6, 95%CI -6.5 to -1.9; p<0.001) and mean scores by 0.8 (0.3 vs. 2.5; 95%CI -1.4 to -0.2; p<0.015). ACT scores improved significantly by 5.3 (10.1 vs. 15.4; 95%CI 2.4 to 8.4; p=0.002). FEV1 improved by 0.51L (1.23 vs. 1.74; 95%CI 0.38 to 0.64; p<0.000), and mean ICS dose decreased by 199g (700.8 vs. 501.1 g; 95%CI -205.4 to -125; p<0.028). One gastrointestinal adverse event of moderate intensity (suspected drug related) was reported during the study and resolved with concomitant medication.

Omalizumab is an effective and safe therapeutic option in Indian patients with uncontrolled allergic asthma despite high-dose ICS plus LABA.

P231
Analysis of IL-6 function in transmammary asthma protection induced by Acinetobacter Iwoffii
Dörthe Andrea Kesper1, Olaf Pinenburg2, Petra Ina Pfefferle1, Holger Garn1, 2, 1Institute of Laboratory Medicine and Pathobiochemistry, 2Institute for Immunology, Philippus-University, Marburg, Germany

Introduction: It has been shown in a mouse model that treatment of pregnant mice with the farm-derived bacterium Acinetobacter Iwoffii F78 protects the progeny of these mice against experimental induced asthma but until now it is not clear how the protective effect is transmitted from the mother to the fetus.

Aim and subjectives: To find out if the upregulation of IL-6 during the treatment of pregnant mice with Acinetobacter Iwoffii is involved in transmitting the asthma-protective effect from the mother to the offspring.

Methods: To analyze the role of IL-6 in transmammary asthma protection female IL-6 KO mice in a Balb/c background (IL-6 +/-) were treated with Acinetobacter Iwoffii F78 and mated to wildtype males (IL-6 +/-). The heterozygous offspring (IL-6 +/-) was then sensitized and challenged with OVA to analyse the asthmatic phenotype. To rule out that the loss of one copy of IL-6 affects the asthmatic phenotype without A. Iwoffii treatment the asthmatic phenotype of IL-6 KO and IL-6 heterozygous mice was additionally analysed in an acute asthma model.

Results: In the acute model IL-6 KO mice exhibit an exacerbated asthma phenotype with increased numbers of eosinophils in the BAL and augmented concentration of Th2 cytokines compared to the wildtype. The heterozygous mice show the same phenotype as wt mice. In the prenatal model the offspring of IL-6 KO female treated with A. Iwoffii display a strong protective phenotype.

Conclusions: IL-6 might be involved in transmammary asthma-protection induced by the farm-derived bacterium Acinetobacter Iwoffii.

P232
Allergyprotective effects of Staphylococcus scuiri in a house dust mite (HDM) model of allergic airway inflammation
Stefanie Hagner, Min Zhao, Hani Harb, Harald Renz, Petra Pfefferle, Holger Garn, 1Medicine, Institute for Laboratory Medicine and Pathobiocchemistry, Philippus University of Marburg, Biomedical Research Center (BMFZ), Marburg, Germany

Background: Recently, epidemiological studies revealed a specific association between Staphylococcus scuiri exposure and reduced asthma prevalences.

Aim: To investigate the influence and role of S. scuiri, a Gram-positive bacterium, on allergen-induced sensitization and airway inflammation in a murine model with a mixed phenotype (with eosinophil and neutrophil inflammation) using a clinically relevant allergen (HDM model).

Methods: Mice were treated intranasally with S. scuiri three times a week for 7 weeks and repeated intranasal exposure to HDM extract. Histological examination of inflammatory cells as well as production of related cytokines and chemokines were measured.

Results: The application of S. scuiri strongly inhibited the generation of HDM extract-induced airway inflammation. Analyses of bronchoalveolar lavages showed a reduction of both, eosinophil and neutrophil numbers, in comparison to control animals. The reduction of eosinophils correlated with a reduction of IL-5, and of goblet cell hyperplasia. The chemokines Rantes, MIP-2, and KC, the key chemokines in the induction of eosinophils and neutrophils into allergic tissue, were markedly reduced.

Conclusions: Administration of S. scuiri to mice challenged with HDM extracts protects them from the development of airway inflammation and associated pulmonary pathology.

P233
Balance disturbances in asthmatic patients. An unrecognized link between asthma, breds and labyrinth
Angeló Geraldo José Cunha1, 2, Maria do Patrocínio Tenório Nunes, Regina Maria Carvalho-Fonse, Fernanda da Cunha Martins1, Catarina Costa Botinno1, 1Internal Medicine, University of Sao Paulo Medical School, Sao Paulo, Brazil; 2Internal Medicine, University of Sao Paulo Medical School, Sao Paulo, Brazil; 3Pneumology, University of Sao Paulo Medical School, Sao Paulo, Brazil; 4Department of Medicine, Unifesp School of Medicine, Teresopolis, RJ, Brazil; 5Physiotherapy, University of Sao Paulo Medical School, Sao Paulo, Brazil

Background: Correlations between asthma and anxiety and between anxiety and balance disorders have been repeatedly described. These observations suggest, that equilibrium abnormalities may also be present in asthmatic patients. This issue is clinically relevant because untreated postural deficits can potentially worsen the prognosis of asthma by triggering anxiety and, consequently, respiratory symptoms. This study aimed to evaluate the efficiency of postural control in asthma patients and its potential correlation with anxiety symptoms.

Methods: We compared 30 subjects with persistent, controlled asthma to 30 age- and sex-matched controls. Anxiety symptoms were evaluated using the Spielberg State-Trait Anxiety Inventory (STAI). Balance control was evaluated by dynamic posturography using measurements of the center of pressure (CoP) displacement in the latero-lateral and antero-posterior directions.

Results: The asthma group had significantly higher scores for the STAI-State (46.8±11.38 vs 38.2±13.16; t = 2.89; p<0.005) and the STAI-Trait (50.1±13.60 vs 37.9±12.67; t = 4.22; p<0.001). An analysis of covariance (using anxiety as the covariate) showed increased values for the area delimited by the CoP in asthmatic patients.

Conclusions: Balance abnormalities seem to occur frequently in asthmatic patients independently of the presence of anxiety symptoms. However, the presence of vestibular dysfunction caused by anxiety provocation may have a major impact on the prognosis of these patients. These findings suggest that disequilibrium-related complaints must be investigated in asthmatic patients, particularly in those presenting with higher levels of anxiety.
P234
Is serum cholesterol a risk factor for asthma?
Srikanth Krishnamurthy, Amupama Murthy Kaza, Karthikyan Ramarajan, Nihal sanith Balasubramanian, M Smith, Department of Tuberculosis and Respiratory Diseases, PSG Institute of Medical Sciences and Research, Coimbatore, Tamilnadu, India

Background: Proinflammatory role of serum cholesterol in asthma has been recently explored with contradicting results. Clarity on the link between serum cholesterol and asthma may lead to newer options in planning management strategies. The objective of our study was to examine the relationship between serum cholesterol, asthma and its characteristics.

Method: Forty asthmatics and 40 normal subjects were examined cross-sectionally and their serum fasting cholesterol and serum highly sensitive C reactive protein (hsCRP) levels were measured along with other baseline investigations. All subjects were non smokers.

Results: Serum total cholesterol (mean ± SD) among asthmatics was 176.45±30.77 mg/dL as compared to 163.33±26.38 mg/dL among normal subjects (P < 0.05). This higher serum cholesterol level was found to be associated with asthma independent of age, gender, BMI, socioeconomic status and serum hsCRP levels. However the association was only modest (adjusted odds ratio 1.027 (95% CI 1.005 – 1.049) p < 0.05). There was no association between serum cholesterol and asthma characteristics like duration of illness, intake of inhaled steroids and frequency of emergency department visits.

Conclusion: Our study found a weak but statistically significant association between higher levels of serum cholesterol and asthma which is independent of age, gender, BMI, socioeconomic status and serum hsCRP. Future research is required in a larger population to substantiate above association and its clinical implications.

P235
Climate change: The impact of different pollen burden on hay fever prevalences
Rafail Rozenenso, Saule Zhumambayeva. Children Disease No. 1, Medical University Astana, Kazakhstan Children Disease No. 1, Medical University Astana JSC, Astana, Kazakhstan

The aim of the study: To compare hay fever prevalences and clinical duration in children and adolescents of the same region in the conditions of different pollen burden.

Material and methods: The study conducted in seasons of 2010 and 2011. The special allergological questionnaires were completed. Pollen burden count was assessed by the standard method. Correlation between intensity of clinical manifestations and meteorological factors like average temperature, atmospheric moisture capacity and precipitations were determined. Meteorological data were obtained in the Civil Aviation Meteorological Station of Astana airport.

Results: We compared two different pollen loads, two consequent pollen seasons of 2010 and 2011. Due to unusually warm April of 2011 with average temperature more than 17°C, a great shift in polleniation duration and intensity ascertainment. The total pollen load in August 2010 was from 14 to 37 pollen grains per one liter3, whereas in the same period in August 2011 it varied from 31 to 64 pollen grains per one liter3. Totally 467 patients with hay fever were examined. In comparison to 2010, the season of 2011 showed high incidence of first diagnosed hay fever cases (18.2% instead of 17.3%, P < 0.001) and increase of morbidity rate from 4.3% to 7.4%, (P<0.01) in young age children. Pollen asthma incidence increased from 26.8% to 42.4%, (P<0.001) and the incidence of dermatological symptoms increased from 24.0% to 29.8%, (P<0.05). The consultation rate increased with the atmospheric moisture capacity higher than 42% and with temperature above 31.0°C.

Conclusions: Climate change has a great influence on hay fever clinical peculiarities in children and adolescents.

P236
Association between body mass index and asthma, rhinitis and eczema in Chinese school children
Ning Song, Mohammed ShamsaSian, Shutung Hao, Jiaqian Gu, Jialing Wu, Chunling Fu, Xuxin Yan. Respiratory Medicine, The Second Hospital of Hebei Medical University, Shijiazhuang, Hebei, China; Respiratory Medicine, The Second Hospital of Shijiazhuang, Shijiazhuang, Hebei, China; Tuberculosis and Respiratory Medicine, Second Hospital of Hebei Medical University, Shijiazhuang, Hebei, China

This study aimed to investigate the association between the prevalence of allergic diseases in children and body mass index (BMI). 10338 Chinese children (5095 boys and 5243 girls, aged 6-18 years) were assessed using an ISAAC questionnaire. BMI was calculated as weight over height squared. The World Health Organization (WHO) defined overweight children as those with BMI above the 85th percentile. Overweight and obese children were defined as BMI > 85th percentile and BMI > 95th percentile, respectively. Systolic and diastolic blood pressures were recorded using a mercury sphygmomanometer. The prevalence rates of asthma, rhinitis and eczema in these children and risk factors of asthma and allergies in Chinese children including high level of air pollution were examined. The prevalence rates were higher in boys compared to girls (wheezing ever 6.6 vs 4.9; exercise-induced wheeze 3.4 vs 3.2; asthma ever 1.5 vs 0.8; ever rhinitis 15.4 vs 12.2; current rhinitis 11.1 vs 8.3; hay fever ever 4.3 vs 3.8; chronic rash ever 2.7 vs 2.2; and eczema ever 12.4 vs 10.7). The prevalence rates were lower in Chinese children living in Hong Kong (wheezing ever 5.7 vs 13.0; asthma ever 1.1 vs 0.9; ever rhinitis 16.6 vs 10.1; current rhinoconjunctivitis 2.4 vs 2.7; and current flexural eczema 0.9 vs 4.3). These differences may be due to different early life experience and exposure including dietary and aerollergens exposure. The present study will help to add new knowledge related to the longitudinal effects of air pollution and allergies in Chinese children.

P237
Prevalence and severity of asthma, rhinitis and eczema in Chinese school children
Ning Song, Jin Zhang, Mohammed ShamsaSian, Shutung Hao, Jialing Wu, Chunling Fu, Xuxin Yan. Respiratory Medicine, The Second Hospital of Hebei Medical University, Shijiazhuang, Hebei, China; Respiratory Medicine, The Second Hospital of Shijiazhuang, Shijiazhuang, Hebei, China; School of Health Sciences, University of Sunderland, United Kingdom

The prevalence of asthma has been increasing in the industrialised world over the past few decades. We studied 10824 Chinese school children (5305 boys and 5519 girls) from Shijiazhuang city in Hebei Province in China. We used ISAAC questionnaire (the International Study of Asthma and Allergies in Childhood). This major project is a baseline of a longitudinal study looking at changes in the prevalence rates of asthma, rhinitis and eczema in these children and risk factors of asthma and allergies in Chinese children including high level of air pollution. The prevalence rates were higher in boys compared to girls (wheezing ever 6.6 vs 4.9; exercise-induced wheeze 3.4 vs 3.2; asthma ever 1.5 vs 0.8; ever rhinitis 15.4 vs 12.2; current rhinitis 11.1 vs 8.3; hay fever ever 4.3 vs 3.8; chronic rash ever 2.7 vs 2.2; and eczema ever 12.4 vs 10.7). The prevalence rates were lower in Chinese children living in Hong Kong (wheezing ever 5.7 vs 13.0; asthma ever 1.1 vs 0.9; ever rhinitis 16.6 vs 10.1; current rhinoconjunctivitis 2.4 vs 2.7; and current flexural eczema 0.9 vs 4.3). These differences may be due to different early life experience and exposure including dietary and airpollergens exposure. The present study will help to add new knowledge related to the longitudinal effects of air pollution and allergies in Chinese children.

Time changes in allergic rhinitis in Skopje, the Republic of Macedonia
Mica Kimovska1, Emilija Vlaski1, Lidija Seckova1, Katerina Stavric2, Rozalinda Ijanovska1,1,2 Department of Pulmonology, University Children’s Clinic “Lince R. Macedonia”, Skopje, Macedonia; 1University Children’s Clinic, Skopje, Macedonia; 2Department of Immunology, University Children’s Clinic, Skopje, Macedonia

The Former Yugoslav Republic of 1; Department of Epidemiology, Institute of Epidemiology and Biostatistics with Medical Informatics, Skopje, Macedonia, The Former Yugoslav Republic of Macedonia

Aim: The aim of the study was to assess the 4-year time changes in allergic rhinitis (AR) due to the lifestyle in young adolescents in Skopje, R. Macedonia.

Methods: Two cross-sectional surveys using ISAAC Phase 3 questionnaires on AR and environmental risk factors were performed. The self-reported data from 3026 adolescents aged 13-14 yrs in the first and from 1088 adolescents in the second survey were analyzed. Pearson chi-square test was conducted in comparisons of prevalence figures between the two surveys.

Results: In 2001-2004 and 2005-2008 survey the established prevalence rates of AR were as follows, respectively: for AR symptoms “ever” 30.0 vs. 27.9%, for current AR symptoms 23.1 vs 19.9% (p=0.034), for current severe AR symptoms 2.8% vs. 2.3% and for ever-diagnosed hay fever 6.7 vs. 4.4% (p=0.007). Significantly decreased prevalence rates of frequent milk and egg intakes (68.3 vs. 62.7% and 23.6 vs. 20.3%), TV-watching time 3 hours daily (63.3 vs. 38.9%), gas cooking (12.0 vs. 9.1%) and wood/coal/soil heating (18.0 vs. 10.8%) at home, cat and dog ownership (24.1 vs. 13.5% and 27.7 vs. 22.0%) and increased ones of frequent vegetables intake (55.6 vs. 70.9%), seafood (3.4 vs. 6.2%), fast food (17.8 vs. 26.0%) and acetaaminophen (6.8 vs. 22.0%) intake as well overweight (15.2 vs. 18.1%) and older siblings (50.6 vs. 54.8%) in the two surveys were established.

Conclusion: The findings suggest a decrease in allergic rhinitis in young adolescents due to changes in their lifestyle during the 4-year study period. An effort to educate them to reduce their fast food and acetaminophen intake as well overweight should be made.

P239
Impact of adult rhinosinusitis on asthma severity
Mahrouk Basheir1, Boutlamma Hanen2, Nadia Gariani3, Mohamed Shabani4,5
1 Respiratory Department, Tripoli Medical Center, Tripoli, Libyan Arab Jamahiriya; 2Radiology Department, Tripoli Medical Center, Tripoli, Libyan Arab Jamahiriya

Objectives: This study aimed to evaluate the prevalence of rhinosinusitis in patients with asthma, and to examine the interrelationship between both conditions, as well the correlation of rhinosinusitis symptoms to radiological findings.

Methods: A prospective study was carried out during the period 2009 - 2010 enrolled 280 asthmatic patients of different severity scores, all screened for any as-
suppressed remodeling

Anti-IgE antibodies inhibit the expression of amphiregulin in mast cells and allergic symptoms in children and the protective effect of pet ownership on fever (5.1% vs 4.1%, P=0.06, respectively). However, the prevalence of eczema with asthma, and its correlation with the severity of asthma for the in-
cluded patients, as well the rhinosinusitis symptoms was significantly linked to the radiological findings seen at the sinuses CT scan in this group.

Key Words: Rhinosinusitis, Asthma, severity score, CT scan.

P240 Association between pet ownership and asthma, rhinitis and eczema in Chinese schoolchildren
Ning Song, Mohammed Shammasin, Jin Zhang, Shuting Hao, Jitao Guan, Jintuan Wu, Chunling Fu, Xinran Yan. Respiratory Medicine, The Second Hospital of Hebei Medical University, Shijiazhuang, Hebei, China

Introduction: The association between pet ownership in childhood and asthma and allergies is very controversial. Our objective was to determine the effects of exposure to cat or dog allergens or both cat and dog allergens on asthma, rhinitis and eczema in a large number of schoolchildren in Shijiazhuang City in Hebei Province in China, which is part of a major longitudinal Chinese study on childhood asthma and allergies.

Body: We studied 10824 schoolchildren, boys and girls, aged 6-18 years. We used the ISAAC questionnaire and we added questions regarding pet ownership. The prevalence rates of asthma and rhinitis symptoms were higher in children exposed to cats and dogs compared with children not exposed to cats and dogs (whrever 6.1% vs 5.6%; current wheeze 2.4% vs 1.7%; exercise-induced wheezing 4.7% vs 2.9%; P<0.01; cough 12.5% vs 10.9%; P=0.05; ever rhinitis 18.9% vs 12.5%, P<0.001; current rhinitis 13.1% vs 8.8%; rhinoconjunctivitis 3.3% vs 2.1%; hay fever 5.1% vs 4.1%, P=0.06, respectively). However, the prevalence of eczema was higher in children not exposed to cats and dogs compared with those exposed to cats and dogs (11.7% vs 10.5%, P=0.07). Children exposed to dogs had higher prevalence rates of most allergic disorders compared with children exposed to cats. The present study confirms the association between pets ownership and asthma and allergic symptoms in children and the protective effect of pet ownership on eczema.

P241 Anti-IgE antibodies inhibit the expression of amphiregulin in mast cells and suppress remodeling
Marti Minaguchi, Masanori Wada, Kiyokazu Kikuchi, Keiichi Akasaka, Kenya Koisaka, Nanto Fujiki, Hiroshi Sagara. Department of Respiratory Medicine, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan

Airway remodeling is a characteristic finding of severe, refractory asthma. Recent studies have demonstrated that anti-IgE antibodies have a high response rate in patients with severe asthma. However, the effects of anti-IgE antibodies on established airway remodeling remain to be established. In the present study, we compared the effects of an anti-IgE antibody with those of steroids in a mouse model of airway remodeling. A model of airway remodeling was prepared by continuously sensitizing B6LacJc mice with ovalbumin. After preparing the remodeling model, the mice were divided into 4 groups: a group treated with an anti-IgE antibody (A), a group treated with steroids (B), a group that received both treatments (C), and an untreated control group (D). A group, basement membrane thickening, a marker of remodeling, was significantly inhibited, similar to the effect in the B group. In the C group, synergistic effectiveness was obtained. Smooth muscle thickening was significantly inhibited in the A group, and the effect was stronger than that in the B group. Similarly, in the A group significantly suppressed mast cell proliferation and also inhibited the expression of amphiregulin, a steroid-resistance molecule. Smooth muscle thickening positively correlated with amphiregulin expression, and this correlation was weakened by treatment with A group. In the present study, the inhibitory effect of A group on basement membrane thickening was similar to that in the B group. However, smooth muscle thickening was more strongly inhibited by A group than by B group, suggesting that the mechanism of action involved the suppression of amphiregulin expression by mast cells.

P242 NT-proANP and lung diffusion in sarcoidosis
Lara Pisani1,2, Alessandro Onofri1, Agnese Ricciota1, Filippo Maria Cauti1, Alberto Ricci1, Pierdiano Bruno1, Giovanna Viola1, Davide Magri1, Salvatore Mariotta1. 1Department of Clinical and Molecular Medicine, “Sapienza” University, Roma, Italy; 2Respiratory and Critical Care, Sant’Oswalo Malpighi Hospital, Bologna, Italy

Background: Since that several lines of evidences support a role in modulating pulmonary circulation for the natriuretic peptides, we aimed to investigate possible relationship between NT-proANP (NT-proANP) and NT-proBNP (NT-proBNP) natriuretic peptides and lung diffusion abnormalities, as assessed by lung diffusion for carbon monoxide (DLco), in patients with pulmonary sarcoidosis.

Methods: Resting NT-proBNP and NT-proANP were determined in thirty-two outpatients with pulmonary sarcoidosis, subdivided in two subgroups according to a cut-off DLco values equal to 75%, and eighteen well-matched healthy volunteers. Each subject underwent, besides pulmonary lung function test, Doppler echocardiographic examination with Tissue Doppler Imaging analysis and cardiopulmonary exercise test.

Results: NT-proANP levels were significantly higher in patients with DLco < 75% (2092±768 fmol/mL) with respect to those with DLco ≥ 75% (1575±488 fmol/mL) whereas no difference was found for NT-proBNP. A significant univariate relationship was found between NT-proANP and age (r=0.403, p=0.022), DLco (r=0.540, p=0.001), specific membrane diffusion capacity (r=0.480, p=0.006), peak oxygen uptake (r=-0.386, p=0.023), and ventilator efficiency (r=0.431, p=0.011). DLco was the only variable independently associated with NT-proANP levels at multivariable analysis (β=0.464; standard error:0.03; p=0.009).

Conclusions: Our findings support a key role of NT-proANP into mechanisms underlying modulation of lung function. The NT-proANP release specifically oriented to counterbalance the lung diffusion impairment is a stimulating hypothesis which warrants confirmation.

P243 Hydrogen peroxide in exhaled air: A source of error, a paradox and its resolution
Stefan Petres1, Angelika Krommer-Kleinfuss2, Stefan Battas3, Petra Noll2, Martin Haeck3, Rembert Kocakala1, Dennis Novak1, Rudolf Jorres3
1Occupational, Social and Environmental Medicine, Ludwig-Maximilians-University, Munich, Germany; 2Corporate Research - Applied Research Chemistry, Robert Bosch GmbH, Stuttgart, Germany; 3Aero-Laser, Aero-Laser GmbH, Garmisch-Partenkirchen, Germany; 4Internal Medicine, Division for Pulmonary Diseases, Philips-Hospital, Marburg, Germany

Background: The concentration of hydrogen peroxide (H2O2) in exhaled air has been reported to be elevated in asthma and COPD, but the data are inconsistent and difficult to reproduce. Notably, a relevant concentration of H2O2 can be found in ambient air. Therefore, we examined the association between H2O2 in ambient and exhaled air.

Methods: Exhaled breath condensate (EBC) of 12 COPD patients and 9 healthy subjects was collected with an inhalation filter (F; efficiency 81%) without (nF) Ambient air condensate (AAC) was collected in parallel and all samples were analysed for H2O2. Additionally, ambient H2O2 concentration was recorded by an analyser for atmospheric H2O2.

Results: H2O2 concentration in AAC (3.60±1.40 μmol, mean±SD) was higher (p<0.01) than in EBC (Table). It showed meteorological variations concordant with atmospheric measurements. In both groups studied, the inhalation filter caused a reduction of H2O2 values (p<0.01). Despite the comparatively low levels in exhaled air, analysis by means of a mathematical model revealed an endogenous H2O2 contribution which was more pronounced when using the inhalation filter.

</tbody>
</table>

Conclusion: The paradox of low H2O2 values in exhaled air assessed by EBC dissolves when taking into account the reconditioning of inhaled air containing H2O2. This may partially explain the heterogeneity of study results and their limited reproducibility. Still, there seems to be endogenous H2O2 production but its valid determination requires inhalation filters. This suggests a reanalysis of studies from the literature.
Introduction: Tetraplegic individuals show a paradoxical inward motion of the diaphragm during inspiration. Abdominal binding is supposed to decrease paradoxical breathing by decreasing abdominal compliance and increasing the zone of apposition of the diaphragm. We hypothesized that abdominal binding would reduce the paradox during quiet breathing (QB) as well as during different levels of hyperpnoea (HYP) and increase maximal voluntary ventilation (MVV).

Methods: Chest wall kinematics were assessed by optoelectronic plethysmography in three male complete tetraplegics (C4-C7) during QB and during HYP at 40 and 100% MVV with and without abdominal binding. Tidal volume (Vt) was partitioned into the relative contribution of the pulmonary rib cage (ΔVRCP), abdominal rib cage (ΔVPRCA), and abdomen (ΔVAB). Inspiratory paradox time (IPT) was calculated as the percentage of inspiratory time (TI) with a decrease in VAB and/or VPRCA.

Results: Abdominal binding reduced IPT at all ventilatory levels. The reduction was higher in RCP than in RCP. At rest, abdominal binding increased ΔVRPMC more effectively than ΔVMVP. MVV was larger with abdominal binding in all subjects (105.1±49.0 vs. 92.0±35.9 ml/min without abdominal binding).

Conclusion: The reduction in IPT and the increase in MVV in tetraplegic individuals suggest a functional benefit of abdominal binding which is mainly seen in the lower rib cage (RCA).

P245 Comparison of measures of ventilation heterogeneity derived from multiple breath inert gas washout
Sharif Gemen1, Steven Corkill1, Amisha Singapuri1, Dhananjay Desai1, Per Gustafsson1, Christopher Brightling2, Salman Siddiqui2, Respiratory Medicine, Glenfield Hospital, Leicester, United Kingdom; 2Department of Pardiatrics, Central Hospital, Södert, Sweden

Introduction: Multiple breath inert gas washout (MBW) is a technique for quantifying ventilation heterogeneity (VH). We compared four measures of VH with asthma, and robustness to variations in tidal volume (Vt), anatomical dead space (Vd) and functional residual capacity (FRC).

Methods: MBW was performed in triplicate on 13 healthy subjects and 22 patients with moderate to severe asthma, using a previously published method (Horsley et al. 2008; 63(2): 135-140). Lung clearance index (LCI); mixing ratio (MIR) and moment ratio (MoR) were calculated. A novel marker of VH, the rate constant ratio (RCR), was calculated by fitting the washout data to a two-phase decay model and calculating the ratio between the fast and slow rate constants. Repeatability and discriminatory ability were assessed using intraclass correlation coefficients (ICC) and receiver operating characteristic (ROC) curves, respectively. Robustness of the parameters was assessed by calculating the signal-to-noise ratio (SNR), using simulated MBW data to determine the noise caused by variations in FRC, Vt and Vd.

Results: LCI, MoR and MIR exhibited good repeatability, with ICC values of 0.899, 0.885 and 0.885 respectively, but RCR was less repeatable (ICC = 0.783). The parameters all had areas under the ROC curve between 0.7 and 0.75. The most robust parameter was the RCR (SNR = 5.1), followed by the MIR (SNR = 6.8), LCI (SNR = 3.4) and MoR (SNR = 1.2).

Conclusion: MIR appears to be the most favourable measure of VH. We recommend that it is reported alongside the LCI.

P246 The role of forced partial expiratory flows to test the bronchodilator response in COPD
J.B. Martinet1, H. Guennard2, A. Chambellan3,4, P.E. Silko5, 1Pneumologie, Clinique et Maternité Sainte Elisabeth, Namur, Belgium; 2Physiology, University Hospital Bordeaux 2, Bordeaux, France; 3Institut du Thorax, CHU Nantes, Nantes, France; 4Groupe Fonction, S tolerated, Paris, France; 5Santher, United States

Lung distention (FRC) and air trapping (TVR) are associated with airflow obstruction in COPD patients. Distal obstruction can be assessed by the measurement of forced expiratory partial flows (PF) at low lung volume, 80%ml above residual volume, RV, (PF800). The acute effects of salbutamol were evaluated using the Peripheral Obstruction Index (POI), the ratio of RV to PF800. POI can be regarded as a time constant for emptying the lung periphery and has a unit of second.

Methods: Eighty-nine COPD subjects underwent measurement of FVC, FRC, RV, PF800 and FEV1 before and after inhalation of 40mcg of salbutamol (BD). PF800 was acquired in a body plethysmograph within 30 seconds of steady tidal breathing, the patient expired maximally to RV starting from a normal inspiratory tidal volume (Exp/Air Medisoft Be). Full maximal expiratory manoeuvres were performed after PF800.

Results: Prebronchodilator POI values ranged from 2.6-60. POI decreased in 69/89 patients including 19 patients with increases in PF800 but no decrease in RV. The mean decrease in POI was 21%. Of the 50 subjects with decreases in POI and RV, only 26 had increases in FEV1 (>0.2L) and only 35 increases in FVC (>0.2L). Among the 31 patients who increased their RV (mean ± SD: 0.3±0.33) after the challenge, only 2 increased their FEV1 whereas 12 increased POI. This suggests a release of pneumoconstriction (Duartebande 1948) associated with peripheral bronchodilation.

Conclusion: POI appears to be more sensitive than FEV1 for reflecting air trapping and peripheral obstruction. The manoeuvre is less tiring than the maximal forced expiration. The clinical significance of changes in POI remains to be studied.

P247 Non-invasive detection of diaphragmatic weakness in acid maltase deficiency (AMD)
Antonella LoMauro1, Gauthier Remiche2, Maria Grazia D’Angelo3, Andrea Aliverti4, 1Respiratory Medicine, Glenfield Hospital, Leicester, United Kingdom; 2Department of Pardiatrics, Central Hospital, Södert, Sweden

Patients with AMD, a glycogen storage disease resulting in loss of skeletal muscle function, become ventilator dependent when respiratory muscles, particularly the diaphragm, are significantly involved. To identify predictive factors of diaphragmatic weakness in AMD, we studied 10 untreated AMD patients and 8 healthy controls. Supine postural drop of vital capacity (ΔVC) was measured by spirometry, while rib cage (RC) and abdominal (AB) volume variations by opto-electronic plethysmography during quiet breathing and slow vital capacity in seated and supine posture. RC and AB contributions to tidal volume (VT), inspiratory capacity (IC) and expiratory reserve volume (ERV) were derived. Diaphragmatic weakness, defined as ΔVC<25% (Fromagot et al,2001), was present in 3 patients (DW). Posture had a significant effect on IC and AB volume changes during IC and ERV (left and central panel) in controls and patients without DW (noDW). Conversely, in DW patients IC and AB volume changes during IC did not vary with posture, while AB contribute paradoxically (negative values) to ERV in supine position. DW patients also showed negative (i.e., paradoxical inward movement) AB contribution to VT which correlated with ΔVC (right panel). AB volume variations in both DW and noDW patients were generally lower than controls.

In conclusion, abdominal displacement during VT and VC maneuver is a better indicator of diaphragmatic weakness in AMD.

P248 Effect of pulmonary rehabilitation on dynamic hyperinflation according to the BODE Index
Loïc Peran, Chantal Lochon, Marc Beaumont, Romain Pichon. Pulmonary Rehabilitation Department, Hospital, Morlais, Brittany, France

Background: The increase of dynamic hyperinflation (DH) is one of the most important causes of exercise intolerance in COPD patient.
Objective: The aim of this study was to evaluate the effects of pulmonary rehabilitation (PR) on dynamic hyperinflation, as evaluated by the BODE index.

Method: Prospective study in 17 COPD patients, including 30% more than 80 yrs. After PR (56% 20% of the final training session, measured at baseline and at the end of 2 months). Dynamic hyperinflation was measured using the Baseline and Post-PR values were compared using paired t-tests. A p-value of <0.05 was considered significant.

Results: Changes in the BODE index were significant for all patients. In the PR group, the BODE index decreased by 0.6 units at 2 months (p=0.03). In the control group, the BODE index increased by 0.2 units at 2 months (p=0.01). The difference between the groups was statistically significant (p=0.01).

Conclusion: The results of this study suggest that a 6-month rehabilitation program can significantly improve dynamic hyperinflation in COPD patients. Further studies are needed to determine the long-term effects of PR on dynamic hyperinflation in COPD patients.
Comparison of different measurement methods of gas diffusion in the lung

Alexandra M. Pressley, Maxi Seebier, Xavier Baur. Institute for Occupational and Environmental Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Lung fibrosis results in decreases of oxygen diffusion and oxygen arterial partial pressure (PAO2) especially during exercise. Obstructive airway diseases are often associated with a mismatch of ventilation and perfusion. We investigated the validity of the CO diffusion capacity (DCO) in comparison with PAO2 and alveolo-arterial oxygen gradient (AaDO2) in different lung diseases.

Methods: 250 subjects (52 ± 12.5 yrs) were examined, out of 206 there were: 13 with VC < LLN (normal FEV1, VC, DCO normal or reduced); 19 with normal VC but DLCO < LLN; 86 with mild or moderate bronchial obstruction (FEV1/VC < LLN, VC-LLN), and 88 healthy controls. Pearson correlation coefficient of DCO vs PAO2 and AaDO2 were analyzed in each group.

Results: DCO were 0.23 of the phase shift between the rig cage and abdominal compartments during the observed a distinct behavior between EG and CG, in series 1 to 3 respectively.

Conclusions: Only in patients with reduced VC and/or impaired DC CO all three parameters are likely to objectively improve gas exchange in the lungs. AaDO2 relates to the ventilation, this may be the cause of the good correlation with DCO. In the group with bronchial obstruction DC CO seems to be influenced by other pathophysiological aspects, resulting in only moderate correlation between the different parameters.

Asynchronous breathing movements during slow controlled deep inspiration in chronic stroke patients

Ilila Lima, Gardânia Ferreira, Tânia Campos, Rodrigo Melo, Maria Clara Gões, Rêncio Florêncio, Guilherme Fregonezi. Physical Therapy, Federal University of Rio Grande do Norte, Natal, RN, Brazil

Aim: To assess the asynchrony index of respiratory movements during the slow controlled deep inspiration in chronic stroke patient’s and healthy subjects.

Methods: Ten chronic stroke patients (experimental group - EG) (53 ± 9.2 years) and ten age-matched healthy subjects (control group, CG) (53.6 ± 9.4 years) were studied by Optoelectronic Plethysmography in 3 moments, quite breathing (QB), slow controlled deep inspiration in chronic stroke patient’s and healthy subjects.

Results: Both groups were similar during the QB and QB. During Deepel series we observed a distinct behavior between EG and CG, in series 1 to 3 respectively. Time of the phase shift between the rig cage and abdominal compartments during the Deepel series were 0.23 ± 0.10 vs. 0.15 ± 0.11a, 0.22 ± 0.10 vs. 0.11 ± 0.15a, 0.21 ± 0.10 vs. 0.12 ± 0.10, p = 0.037.

Conclusion: Slow controlled deep inspiration induces more asynchronous breathing movements in chronic stroke patients than healthy subjects.

Experimental air hunger induces lactate-evoked potentials

Louis Laviolette1,2, Marie-Cécile Nierat, Étienne Allard1, Thomas Similowski1. 1Laboratoire de Physiopathologie Respiratoire, Université Paris 6, ER10upmc, Paris, France; 2Neuroscience Research Australia, University of New South Wales, Sydney, Australia

Rationale: The supplementary motor area (SMA) has functional connections with the diaphragm. Facilitatory conditioning of the SMA using repetitive transcranial magnetic stimulation induces diaphragm motor-evoked potentials in healthy humans.

Methods: Eight naive healthy subjects (age 25 ± 3 years, mean ± SD, 3 men) were studied. DiMEPs (surface electromyogram) were elicited by single-pulse TMS over the primary motor area of the SMA (M1dia). DiMEPs were recorded at baseline and after rests at 25, 10 and 5 minutes after I-TMS (post1, post2, and post3, respectively).

Results: I-TMS over the SMA reduced the amplitude of DiMEPs, from 272 ± 18 μV at baseline, to 229 ± 126 μV, 209 ± 144 μV and 212 ± 123 μV at post1, post2 and post3, respectively (F1,11 < 0.005 vs. baseline). These changes were observed in the absence of any reduction in the amplitude of the pre-stimulus EMG (F2,22 > 0.05).

Conclusions: Inhibitory theta-burst stimulation of the SMA decreases the excitability of the corticospinal pathway to the phrenic motoneurons. This suggests the existence of a tonic excitatory connection between the SMA and M1dia. The possibility of targeting this connection to interfere with respiratory sensations remains to be determined.

Dyspnea in patients with idiopathic pulmonary fibrosis: The mechanisms of exertional dyspnea

Keisuke Miya, Ryogo Maekura, Mari Miiki, Seigo Kitada, Kenji Yoshimura, Yoshitsuka Tateshii, Kunimoni Matsuura, Muneyoshi Kuroyuma, Hisako Hashimoto, Masahide Mori. Department of Internal Medicine, National Hospital Organization Toneyama National Hospital, Toyonaka, Osaka, Japan

Background and objective: Very often, some idiopathic pulmonary fibrosis (IPF) patients with the severe exertional hypoxemia may realize only mild dyspnea, the mechanisms underlying the exertional dyspnea in such patients have not yet been elucidated. We investigated the exercise responses to hypoxia in relation to dyspnea profile as well as cardiorespiratory and acidotic parameters in 13 patients with stable IPF.

Methods: This was a single-blind trial, in which subjects breathed 30% O2 or compressed air (CA) in random order during two incremental treadmill exercise tests.

Results: PaO2 and Paco2 were higher during exercise (p < 0.01, p < 0.001, respectively, by repeated-measures ANOVA). At the peak exercise, 30% O2 reduced plasma lactate level (p < 0.05), and dyspnea score and the mean change from resting condition in pH were similar while breathing 30% O2 and CA. The dyspnea ratio (%) of Oxygen uptake (peak minus resting oxygen uptake) curve reached a break point that occurred at a similar exercise point while breathing 30% O2 and CA.

Conclusions: Despite inhaling 30% O2 and CA, IPF patients did not develop ventilatory compensation in exertional acidosis, stopped exercise when the similar changes from resting condition in pH were seen. Furthermore, hypoxic conditions did not alter the pattern of exertional dyspnea in IPF patients during a standardized exercise program.

Study of pulmonary function in type 2 diabetes mellitus and its changes with change in duration and glycemic control

Salim Zaman1, Anilbaran Singhamahapatra, Apurba Mukherjee, Joyashree Banerjee. Physiology, R.G. Kar Medical College & Hospital, Kolkata, WB, India Physiology, R.G. Kar Medical College & Hospital, Kolkata, WB, India Medicine, R.G. Kar Medical College & Hospital, Kolkata, WB, India Physiology, R.G. Kar Medical College & Hospital, Kolkata, WB, India

Rationale: Diabetes mellitus (DM) is a metabolic disease causing changes in...
multiple systems, and pulmonary system is not an exception to this rule. As the prevalence of T2DM is increasing, the potential implication of diabetic status affecting pulmonary system demand attention.

Objectives: To assess the pulmonary function in Type2 DM patients and its dysfunction may preclude the execution of important social tasks such as speech. Here we investigate whether the double command involved in respiration (cortical and medullary) has an impact on the inhibitory mechanisms. Specifically, we studied the inhibition properties (baseline, rate, threshold) of voluntary respiratory movements in relation with the phase of the breathing cycle in which the command is given.

Results: Subjects were instructed to produce inspiratory movement in response to a visual stop signal was presented, being shorter during inspiration (21 ms; mean ± SD) than expiration (29 ms). The estimated respiratory SSRT was 299 ± 200 ms. This might either indicate that respiratory RTs depended on the context in which the stop signal was presented, being shorter during inspiration (541 ± 289 ms) as its dysfunction may preclude the execution of important social tasks such as speech.

Conclusion: There is significant changes of pulmonary functions with changes in duration and hemodynamic control, which may be due to non enzymatic glycosylation of tissue proteins and chronic diabetic microangiopathy. So, in routine screening by doing PFT, we can reduce mortality and morbidity of the patients (type2DM) due to subclinical or overt pulmonary dysfunctions.

P239
Inhibition of voluntary respiratory movements depends on the phase of the respiratory cycle
Elisene Allard1,2,3, Thymothée Poitou3,4, Hadrien Caron2,3, Thomas Sambouw1,2, Pierre Pointet3,4,1 ER10-UPMC, Laboratoire de PhysiologieRespiratoire, Université Pierre et Marie Curie, Paris, France; 2UMR 7225, CNRS, Paris, France; 3UMRS 975, INSERM, Paris, France

Movement inhibition is important, notably for the voluntary control of respiration, as its dysfunction may preclude the execution of important social tasks such as speech. Here we investigate whether the double command involved in respiration (cortical and medullary) has an impact on the inhibitory mechanisms. Specifically, we studied the inhibition properties (baseline, rate, threshold) of voluntary respiratory movements in relation with the phase of the breathing cycle in which the command is given.

Subjects were instructed to produce inspiratory movement in response to a visual stop signal was presented, being shorter during inspiration (541 ± 289 ms) as its dysfunction may preclude the execution of important social tasks such as speech.

For −50% of the trials, a stop signal was presented (a second visual target) in response to which subjects had to inhibit the inspiratory movement. Respiratory movement was measured through abdominal expansion using a magnetometer. Respiratory reaction time (RT) and stop-signal accuracy were used to calculate stop-signal reaction time (SSRT), an estimate of the time required to inhibit the respiratory movement.

The results indicate that respiratory RTs depended on the context in which the stop signal was presented, being shorter during inspiration (541 ± 21 ms; mean ± SD) than expiration (568 ± 20 ms). The estimated respiratory SSRT was 299 ± 48 ms. 

Conclusion: There is significant changes of pulmonary functions with changes in duration and hemodynamic control, which may be due to non enzymatic glycosylation of tissue proteins and chronic diabetic microangiopathy. So, in routine screening by doing PFT, we can reduce mortality and morbidity of the patients (type2DM) due to subclinical or overt pulmonary dysfunctions.

57. Functional imaging in pulmonary oncology and COPD. Radiation dose in chest CT: survey and real life

P260
Agreement between tumor measurement on computer tomography and resected specimen size in lung cancer
Jeong Ik1, Catarina Calde2, Susana Esteves1, Nuno Nuno Abacauce3, Fernando Cunha2, Isabel Duarte2,1, Maria Teresa Almodovar5.

Introduction and aim: To compare the radiologic preoperative size of the primary tumor in LC with their pathologic size following excision. Materials and methods: 88 LC patients who undergone surgery in our institution from 2008 - 2011, CT-staged T1 or T2 were included. Images were reviewed by two independent observers. Tumor maximal diameter on axial-plane was obtained using PACS caliper segmentation algorithm and adjusted based on a radiologist’s input; largest single diameter from Pathology gross report was utilized. Agreement was evaluated between CT and Pathology using Bland-Altman methods for measurements and using Cohen-Kappa for T-staging classification. Results: 46 adenocarcinoma, 31 squamous cell carcinoma. The mean CT measurement was 30.27mm, pathology was 30.63mm. The mean difference between CT and Pathology measurements was -0.35 mm (95% Confidence Interval -2.15; 1.45, p-value < 0.001). The lower and upper 95% limits of agreement were -17.3mm and 16.62mm. Clinical T-staging based on CT was T1a=21, T1b=34, T2a=20, T2b=13 and on pathology was T1a=30, T1b=22, T2a=27, T2b=9. Stage agreement was seen in T1a=17/30 (57%), T1b=16/22 (73%), T2a=14/27 (52%) and T2b=8/9 (88%) with a moderate agreement in 14.6 patients complete TNM staging was documented with c or p N-stage. The SUVmax ranged 53±6.64 HU. The SUVmax ranged 53±6.64 (52%) and 18±10 (29%) in non-small cell and small cell lung cancers respectively. The SUVmax (r = -0.13) as well as histology and grading were determined. Univariate analysis was performed between all tumor parameter.

Conclusion: There was no significant correlation between the different metabolic and morphologic tumor parameter from PET/CT and clinical data of patients with NSCLC. Up to now we could not identify a combination of imaging data from PET/CT with a predictive capability for tumor staging.

P262
Performance of segmentation software on large longitudinal database of pulmonary nodules in the Danish Lung Cancer Screening Trial (DLCST) Ziaheem Saghir1,2, Colin Jacobs2,3, Bram van Ginneken4, Marleen de Bruijne4,5, Jan Vanhocke6,7, Jasper Holst Pedersen8,9,10, Department of Respiratory Medicine, Gentofte University Hospital, Hellerup, Denmark; 2Fraunhofer MEVIS, Bremen, Germany; 3Department of Radiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 4Department of Computer Science, University of Copenhagen, Denmark; 5Department of Medical Informatics and Radiology, Erasmus MC - University Medical Center, Rotterdam, Netherlands

Introduction and aim: Growth measurements of pulmonary nodules are subject to great interest due to the risk of malignancy. We examined the reproducibility of lung nodule volumetric software that offers two different volumetric algorithms. Materials and methods: In the Danish Lung Cancer Screening trial, 2,052 patients were linked chronologically (same nodule in different scans) and independently reviewed by two readers using volumetric software. The software offers readers two different analysing algorithms, “solid nodule algorithm” and “part/solid/nonsolid algorithm”. We compared the inter-observer variability regarding use of algorithm and rate of success. Results: 1,442 nodules were measured 5,988 times. The readers reviewed the segmentations visually and were able to correctly segment and measure 94% and 97% of the nodules, respectively. In 90% of these cases, the readers chose the same algorithm.

Conclusion: Using this volumetric software on a large database with longitudinal data shows a high success rate and large agreement in choosing algorithm.
Contrast-enhanced ultrasound examination of pulmonary lesions

Despite the current availability of diagnostic procedures, the diagnosis of solitary pulmonary nodules still remains challenging. The aim of this clinical study is to evaluate the lung magnetic resonance imaging (MRI) with focused conventional sequences and diffusion weighted imaging.

**Methods:** We assessed 55 subjects with pulmonary lesions under blinded conditions using a MRI scanner. The exam was carried out with diffusion-weighted sequences (B500 and B1000 DWIBS) and ADC map with a qualitative and quantitative analysis.

**Results:** Out of 5 mm nodules (n=23) studied with DWIBS, 16 did not show abnormalities and were unchanged in 1 year follow-up and 3 were not identified compared with CT. DWIBS was positive in 2 cases, false-positive in 1 case and false-negative in 1 case. In 32 lesions >10 mm, histologically confirmed, DWIBS helped the biopsy planning, the definition of neoplastic tissue within atelectatic lung parenchyma, the differentiation of parietal pleura from pleural effusion and the characterization of mediastinal lymph nodes.

**Conclusion:** The study on large size lesions and nodules showed a considerable statistical significance (p<0.001; diagnostic accuracy 86.5%). The technique, despite the limitations of a preliminary study, may increase nodules detection and, with CT or PET, provide additional useful information.

---

**P264**

Contrast-enhanced ultrasound examination of pulmonary lesions

**Aim:** The aim of this study is to assess the clinical value of contrast-enhanced ultrasound (CEUS) for the diagnosis of peripheral pulmonary lesions (PPL).

**Materials and methods:** We examine 30 patients using a 2nd generation transpulmonary contrast Sonovue and US system Philips XE-11 equipped with low acoustic power mode software.

**Results:** By 15 patients (8 with pneumonia and 7 with atelectasis), the baseline US examination presents PPL with preserved bronchial and vascular structure. CEUS establishes a short time to enhancement (TE) < 6 sec (x ± SD = 4.1±1.1 sec) and hyperchogenic tissue enhancement during the parenchymal phase, due to preserved pulmonary artery (PA) blood supply. By 6 patients (PTE n=2; abscess in the infiltrated lung tissue n=2; pneumolesschrosis n=1; metastasis n=1), CEUS does not show contrast enhancement. Peripheral lung cancer (n=8pms) as well as some types of pulmonary metastasis are characterized by delayed TE >7sec. (x ± SD = 15.1±5.7 sec) and sparse tissue enhancement, suggesting bronchial arterial (BA) supply.

**Conclusion:** CEUS is a safe and effective method for differentiating PA from BA blood lesions supply. It could be a useful method for diagnosis of pneumonitis/atelectasis and is particularly valuable to differentiate them from PTE. CEUS improves the US control of transbronchial needle biopsies especially in lesions among atelectasis or inflammatory infiltrate. It is reasonable to carry out further research to clarify the role of CEUS among the diagnostic procedures in patients with PPL.

**P265**

Radiological features of solitary pulmonary nodule (SPN) and application of two lung cancer prediction models

The diagnostic accuracy of solitary pulmonary nodules (SPN) still remains challenging, and the evaluation of benign and malignant SPNs is crucial for the correct management of patients. The study of the radiological features and the application of two lung cancer prediction models help to improve the accuracy of the diagnosis of SPNs.

**Objective:** To summarize the imaging features of solitary pulmonary nodules, and compare the two types of lung cancer prediction models for solitary pulmonary nodules.

**Methods:** A retrospective study of Ruijin Hospital between 2002 and 2009 with newly discovered SPNs which is less than 30mm. The patients all received pathological diagnosis. Summarize the clinical and imaging characteristics, then validate and compare the diagnostic accuracy of two lung cancer prediction models for estimating the probability of malignancy in patients with SPNs.

**Results:** 90 patients were enrolled, of which 32 cases are benign. 58 cases are malignant. Our study showed that we can identify the SPNs between benign and malignant by the SPN edge features of lobulation (P<0.05). The area under ROC curve of VA model was 0.712 (95% CI 0.606 to 0.821); Area under ROC curve of Mayo Clinic model was 0.753 (95% CI 0.652 to 0.843), and it is superior to VA model.

**Conclusions:** It is meaningful for the identification of benign and malignant SPNs by the lobulation sign in CT scan. We can integrate the clinical features and the lung cancer predicting models to direct our clinical work.
Hypertension, pack years history and COPD diagnosis were predictors of EFMV.

Variables with statistically significant differences were included in the multivariate analysis to determine those that independently predict EFMV. Male gender, hypertension, pack years history and COPD diagnosis were predictors of EFMV.

Conclusions: COPD is an independent risk factor for an increased EFMV. Further studies should assess the impact of this finding as a non-invasive marker of cardiovascular events in this high risk population.

P268
High resolution CT scan (HRCT) thorax differences between biomass-smoke exposure induced COPD (BM COPD) and tobacco-smoking COPD (TS COPD)

Bill Brashier 1, Shilpa Kajale 2, Sajid Tambe2, Rahul Kodgule 1, Jyoti Londhe 1, Deepak Gopakumar 1

BM COPD accounts for a substantially large proportion of COPD especially in developing countries. However, little is known whether this COPD is different from TS COPD radiologically.

Aims: To study and compare the radiological changes in the lung parenchyma between BM COPD and TS COPD.

Method: 20 stable BM COPD (M:F 1:19) and 34 stable TS COPD (M:F 34:0) underwent HRCT thorax. Helical HRCT sections were taken from apex to domes of diaphragm at 1cm thickness and 10mm intervals during deep inspiration maneuvers. Emphysema was quantified using “Quantification of Emphysema” software and depicted as area less then -950HU, while bronchial wall thickness was defined as presence of ≥1.5mm thickness. Independent sample t-test was used to compare the two groups of COPD.

Results: BM COPD [age: 65yr (8.5)] subjects showed significantly lesser mean lung volumes (cc) compared to TS COPD [age: 63 yrs (5)] [2916±2589 vs 4347±4580; p < 0.0001] TS COPD subjects had more mean % emphysema compared to BM COPD [13%±1.1% vs 6.4±6.3%; p = 0.022]. 80% of subjects with BM COPD showed presence of pure form of emphysema pattern (either centrilobular (40%) or panlobular (40%)), whereas there was no distinct pattern seen with TS COPD. There is predominance of either centriacinar or panacinar in BM COPD. Biomass smoke-induced COPD subjects showed lower lung volumes and lesser mean % emphysema than TS COPD on HRCT imaging.

P269
Phantom-based evaluation of computed tomography parameters: Understanding the differences in automated emphysema scoring

Johan Coolen 1, Frederik De Keyzer 1, Walter De Wever 2, Elis Wauters 3, Wim Janssens 1, Marc Decramer 1, Johny Verschakelen 1

1Radiology, AZ Gasthuisberg, Leuven, Vl Brabant, Belgium; 2Pneumology, AZ Gasthuisberg, Leuven, Vl Brabant, Belgium

Purpose: Automated lung emphysema (E) measurements vary strongly between examinations. We examined the effect of CT scanners, acquisition parameters, kernels and windowing on the software-based E scoring (S) in a phantom.

Material and methods: A human preserved torso in eposix was used as phantom and was scanned on 5 different scanners using various settings of the following parameters: KV, mAs, care dose, slice/increment, window and kernel. For each of these data sets, the E was evaluated. The ES was performed using both 2D and 3D software. A multiple linear regression analysis (LRA) was used to evaluate the importance of each examined parameter.

Results: Measured E values ranged between 17.0% and 70.5% for 3D software evaluation. A similar range could be seen at 2D evaluation, ranging between 13.9% and 66.8%. The used kernels had the strongest impact on the measured ES, and a strong effect could also be seen for slice/increment, mAs, window and KV. However, the scanner-dependent parameters and the usage of the caredosis option proved to have only a minor impact on the measurement of E. The LRA found a very strong correlation between the measured values, and the estimated values based on the optimal regression formule, with R² values of 0.828 and 0.772 for the right and left lungs on 3D evaluation, and 0.872 and 0.851, resp. on 2D evaluation.

Conclusion: A fixed phantom allows assessing the influence of different scanners, acquisition parameters and evaluation techniques on the software-based ES. The current dataset indicates that scan parameters and the used kernels have the strongest effect, and that the induced differences can be estimated using multiple LRA.

P270
Interobserver variability in visual evaluation of thoracic CT scans and comparison with automatic computer measurements of CT lung density

Johan Coolen 1, Fredeke De Keyzer 1, Laura H. Thomsen 1, Saher B. Shaker 1, Asger Dijkers 1, Jesper H. Pederson 1, Department of Respiratory Medicine, Gentofte University Hospital, Hellerup, Denmark; 2Department of Computer Science (DIKU), University of Copenhagen, Copenhagen, Denmark; 3Department of Thoracic Surgery, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

Introduction: Emphysema is defined by pathology, but is most precisely evaluated in vivo by computed tomography (CT).

Aims were to determine the reproducibility of visual evaluation of emphysema, i.e. the observer variability, and furthermore to compare the visual evaluations to automatic CT lung density measurements, i.e. densitometry.

Methods: In a pilot study 60 CT scans were selected from a sample of 3980 CT scans from The Danish Lung Cancer Screening Trial (DLCST). The amount of emphysema in these scans was scored independently by two observers, who were blinded regarding clinical information.

The lung was segmented automatically by in-house developed computer software, and the percentage of pixels below -950 HU was used as a surrogate marker for emphysema.

Conclusion: We found a high degree of interobserver consistency in emphysema grading. However, the agreement with the CT lung density measurement was poor, indicating that the two types of evaluation represent different aspects of emphysema. Most likely, they should be seen as complementary rather than competitive evaluations. Future comparison with physiological tests might elucidate the reason for differences and demonstrate the usefulness of these evaluations.

P271
A new method for evaluation of severity in COPD using dynamic chest x-ray examination

Noriko Motohashi 1, Misako Aoki 1, Takehiko Abe 2, Yuji Shiraishi 3

1Radiology, Fukujuji Hospital, JATA, Tokyo, Japan; 2Chest Surgery Division, Fukujuji Hospital, JATA, Tokyo, Japan

Purpose: Spirometry which requires maximum effort tasks COPD patients. In this study, we proposed a new method for evaluation of severity in COPD using dynamic chest X-ray examination without effort breathing.

Subjects: Dynamic chest X-ray from 29 normal volunteers, 30 mild COPD patients (GOLD Stage I or II) and 31 severe COPD patients (GOLD Stage III or IV) were obtained. The upright position in about 10 seconds of tidal breathing at rest. The dynamic image data captured at 7.5 frames per second was synchronized with the pulsed X-ray. The institutional review board approval and written informed consent were obtained in all patients.
Methods: We calculated the maximal differential values in each ventilation phase at the corresponding small local area of lung in the series of dynamic chest X-ray. The regional relative flow rate ratio was obtained from the peak values of inspiratory phase divided by the peak values of expiratory phase. All groups were compared about the standard deviation of flow rate ratio.

Results: The average of the ratio in normal volunteers, in mild COPD patients and in severe COPD patients were 0.21±0.03, 0.22±0.04 and 0.26±0.04 (mean±SD), respectively. Significant difference was confirmed between the normal volunteers and the severe COPD patients (p=0.0047), and between the mild COPD patients and the severe COPD patients (p=0.0092), respectively.

Conclusion: The variation of the inspiratory/expiratory flow rate ratios in COPD patients were larger than those of healthy volunteers. The new method for ventilation function has possibility to evaluate severity of COPD.

P272  
Ultrasoundographic assessment of the diaphragm in patients with chronic obstructive pulmonary disease (COPD): Relationships with pulmonary function and the influence of body composition

Andrea Smargiassi, Riccardo Inchingolo, Linda Tagliaboschi, Alessandro Di Marco Berardinou, Giuseppe Maria Corbo, Salvatore Valente. Pulmonary Medicine, Universita Cattolica Del Sacro Cuore, Roma, Italy

Background: Skeletal muscle weakness and loss of fat-free-mass (FFM) is one of the main systemic effects of COPD. Also diaphragm is involved leading to disadvantageous conditions and poor contractile capacities. We measured the thickness (TD) of diaphragm by ultrasonography to evaluate the relationships between echographic measurements, parameters of respiratory function and body composition data.

Material and methods: 24 patients (17 males) underwent: a) pulmonary function tests; b) echographic assessment of TD in the zone of apression at various lung volumes (TDRV, TDFRC, TD TLC); c) biochemical body impedance analysis. BMI was calculated.

Results: Mean FEV1 as percentage of the predicted value was 49.6% (min 22%, max 86%). Mean BMI was 27±5.3 kg/m² (min 17.2 max 38.8). TDRV, TDFRC and TD TLC measured 3.28, 3.58, 5.92 mm respectively. Reproducibility of measures was good (R=0.93, 0.93, 0.77 for TDRV, TDFRC, TD TLC respectively). All the TD were found correlated to FFM being the relationship greater for TDFRC (R²=0.51, p=0.0002). As regards lung volume IC, was found related to TDRV (R²=0.21, p=0.025). TDFRC (R²=0.16, p=0.05). TD TLC (R²=0.36 p=0.002). No significant association was found between TD and TLC, FRC, RV. Using a multiple regression model TD TLC was found related to RV/TLC, FEVI/FVC and FFM (R²= 0.55 p=0.004). Lastly, the difference between TDFRC and TDRV was closely related to FVC (R²=0.33, p=0.036).

Conclusion: Ultrasoundographic assessment of the diaphragm could be a useful tool to study the progression of the disease in COPD patients in terms of static hyperinflation and loss of FFM.

P273  
Longitudinal imaging characterisation of a model of chronic allergic lung inflammation in mice

Kumar Changani1, Catherine Pereira2, Simon Young2, Robert Shaw1, Tony Nials1, Simon Campbell1, Kamshira Pindada1, Steve Jordom1, Michael Haase1, Mike Pedrick2, Richard Knowles1, 1RRI & LAS, GlaxoSmithKline, Stevenage, Hertfordshire, United Kingdom; 2Respiratory & Inflammation, Astazeneca, Macclesfield, Cheshire, United Kingdom

The aim of the study was to investigate the role that imaging could have for longitudinally assessing allergic lung inflammation. This is usually assessed using terminal procedures eg bronchoalveolar lavage (BAL) & tissue histology. We describe how MRI & CT methods provide sensitive early readouts of inflammation in the chronic HDM mouse model. LTI changes correlate directly with classical inflammatory readouts allowing more accurate assessments of the lung are required to assess this. Micro-CT permits direct examination of the small airways and microvasculature. However, most studies to date have used eosin or other contrast agents precluding the use of historical samples.

Aim: To use micro-CT to identify and measure the small airways in paraffin embedded tissue without contrast agents.

Methods: Tissue from the distal airways was fixed and embedded in paraffin wax. It was scanned with a Nikon/Perkin HMX XCT scanner at the μ-VES X-ray imaging centre, University of Southampton to obtain CT data with a scan time of four hours. An acquired voxel resolution of 7.9μm allowed examination of airway lumens along its length and a 3D volume reconstruction of a branching small airways network created using VG Studio Max (v2.1) and Arisio 7 image processing software.

Results: Lung tissue was clearly distinguishable from the airspaces in scans permitting a clear 3D reconstruction of all airways and blood vessels in the sample. Airway cross section measurement was possible down to the respiratory bronchioli at ~<0.5mm. This will permit the estimation of potential volumetric air flows from the alveoli to the small airways.

Conclusion: We have shown that it is possible to use micro-CT to analyse and reconstruct small airways structure in human tissue down to the respiratory bronchioli with a resolution of 7.9μm. Using formalin fixed and paraffin embedded tissue without any contrasting agents can provide robust 3D structural data from archival material.

P274  
Using micro-CT to map the small airways

Katherine Scoll1, Dnutry Griner2, Sam Kayes2, Peter Lackie2, Jane Warner1. 1Faculty of Medicine, University of Southampton, United Kingdom; 2Engineering Materials Group, Faculty of Engineering and the Environment, University of Southampton, United Kingdom

Introduction: The loss or narrowing of small airways (~<2mm) leads to an increase in peripheral resistance and is a major site of airway disease in COPD. Quantitative studies of the structural changes in the small airways in COPD patients is required to assess this. Micro-CT permits direct examination of the small airways and microvasculature. However, most studies to date have used eosin or other contrasting agents precluding the use of historical samples.

Aim: To use micro-CT to identify and measure the small airways in paraffin embedded tissue without contrast agents.

Methods: Tissue from the distal airways was fixed and embedded in paraffin wax. It was scanned with a Nikon/Perkin HMX XCT scanner at the μ-VES X-ray imaging centre, University of Southampton to obtain CT data with a scan time of four hours. An acquired voxel resolution of 7.9μm allowed examination of airway lumens along its length and a 3D volume reconstruction of a branching small airways network created using VG Studio Max (v2.1) and Arisio 7 image processing software.

Results: Lung tissue was clearly distinguishable from the airspaces in scans permitting a clear 3D reconstruction of all airways and blood vessels in the sample. Airway cross section measurement was possible down to the respiratory bronchioli at ~<0.5mm. This will permit the estimation of potential volumetric air flows from the alveoli to the small airways.

Conclusion: We have shown that it is possible to use micro-CT to analyse and reconstruct small airways structure in human tissue down to the respiratory bronchioli with a resolution of 7.9μm. Using formalin fixed and paraffin embedded tissue without any contrasting agents can provide robust 3D structural data from archival material.

CT protocols in interstitial lung diseases – A survey among members of the European Society of Thoracic Imaging (ESTI)

Helmut Prosch1, Cornelia Schaefer-Prokop1, Edith Eisenhuber2, Daniele Kiendl1, Christian Herold3. 1Department of Radiology, Medical University of Vienna, Austria; 2Department of Radiology, Hospital Gartenthaller, Heiland, Vienna, Austria; 3Department of Radiology, Academic Medical Center, Amsterdam, Netherlands

Objective: To survey the current HR-CT protocols used by members of the European Society of Thoracic Imaging (ESTI) to evaluate patients with interstitial lung diseases.

Materials and methods: A questionnaire was e-mailed to 173 ESTI members. The survey focused on questions regarding the practice of CT protocols in patients with suspected interstitial lung diseases. In particular, the members were asked whether they used discontinuous HR-CT or volume CT protocols, performed additional expiratory scans, or obtained scans in the prone position. In addition, the questions focused on dose considerations and on which reconstructions were performed routinely.

Results: The overall response rate was 37%. Seventy-seven percent of the respondents indicated that they evaluated their patients with routine protocols; 85% used either volume CT alone or in combination with discontinuous HR-CT, only a minority of 15% performed discontinuous HR-CT only. Fifty-three percent reported that they applied a low-dose volume CT protocol. Expiratory scans or scans in the prone position were performed by a majority of the respondent on demand only (58% and 59%, respectively). The number of reconstructions ranged from two reconstructions to up to eight standard reconstructions. Fifteen respondents reconstructed two series, 18 respondents routinely reconstructed three or four series, and 16 respondents reconstructed five series or more.

Conclusion: ESTI members seem to prefer volume CT to investigate patients with suspected interstitial lung diseases. The reported and surprisingly high prevalence of low-dose CT protocols may be due radiation dose considerations and requires further investigation.

P276  
Cumulative exposure to ionising radiation in adults with non-CF bronchiectasis

Liam Taha, Dinez Nazareth, Syed Kazmi, Martin Walsham. Department of Respiratory Medicine, Liverpool Heart and Chest Hospital, Liverpool, United Kingdom

Background: As treatments improve and patients with non-CF bronchiectasis are surviving longer, the cumulative exposure to potentially carcinogenic ionising radiation is important. We looked at the amount of ionising radiation given to adults with this condition (n=66) attending our Respiratory clinic over a 12-month period.

Method: All ionising radiation studies were reviewed for their impact on management. Radiation was calculated using standard reference doses and expressed as mSv.

Results: See Table. The average radiation dose was 11.43 mSv. Overall, only 15%
of chest X-rays and 62% of Chest CT’s resulted in a change in management. Those with more severe disease had a greater cumulative dose of radiation. 

**Conclusion:** Patients with bronchiectasis receive significant medical radiation each year, but most impacts on their management. Those colonised with *Pseudomonas* are associated with greater levels, in keeping with the more significant disease burden in these individuals. Care should be taken when ordering investigations associated with ionising radiation, to reduce the long term effects of potentially harmful investigations.

**P277**

**Cumulative exposure to ionising radiation in adults with interstitial lung disease (ILD)**

Lamis Taha, Dilip Nazareth, Syed Kjrmi, Martin Wilshaw. Department of Respiratory Medicine, Liverpool Heart and Chest Hospital, Liverpool, United Kingdom

**Background:** The cumulative exposure to potentially carcinogenic ionising radiation is important in patients with ILD as they are exposed to multiple radiological investigations. The risk is compounded as the amount of ionising radiation given to adults with ILD (n=41) attending our Respiratory clinic over a 12-month period.

**Method:** All ionising radiation studies were reviewed for their impact on management. Radiation was calculated using standard reference doses and expressed as mSv.

**Results:** See Table. The average radiation dose was 12.33 mSv with 56% of investigations impacting care. Those with UIP pattern of fibrosis had a greater cumulative dose of radiation.

<table>
<thead>
<tr>
<th>Radiation doses and % impacting care</th>
<th>Mean Radiation Dose (mSv)</th>
<th>% impacting care</th>
</tr>
</thead>
<tbody>
<tr>
<td>All patients (n=41)</td>
<td>12.33</td>
<td>56</td>
</tr>
<tr>
<td>UIP (n=24)</td>
<td>12.98</td>
<td>62</td>

<td>11.29</td>
<td>71</td>
</tr>
<tr>
<td>Other Fibrosis (n=9)</td>
<td>11.9</td>
<td>68</td>
</tr>
</tbody>
</table>

**Conclusion:** Patients with ILD receive significant medical radiation each year, but most impacts on their management. Those with NSIP had a greater number of investigations impacting care as compared to those with UIP, in keeping with the wider spectrum of disease and more treatment options being available in this sub-group of patients. Care should be taken when ordering investigations associated with ionising radiation, to reduce the long term effects of potentially harmful investigations.

**58. Ultrasound in pulmonary medicine: from inside and outside**

**P278**

**Diagnostic performance/learning curve and tolerance of endobronchial ultrasound (EBUS)**

Estefanía Luque, Pablo Sanchez. Ultrasound (EBUS)

**Objectives:** To analyze the diagnostic performance of transbronchial needle aspiration guided by endobronchial ultrasound (EBUS-TBNA) in diagnosing hilar/mediastinal lymphadenopathies and/or lung masses in our department and the possible effects of the learning curve. To evaluate the tolerance of the procedure by both the patient and the bronchoscopist.

**Materials and methods:** Retrospective study of all patients referred to our department (January 2010-October 2011) to perform EBUS-TBNA. At the end of the technique, both the patients and bronchoscopist answered a tolerance questionnaire (scale of 0 to 10).

**Results:** 129 patients. 325 aspirations were performed. The most common indication was suspicion of malignancy (48.8%). The most frequent final diagnosis was normal lymph nodes (46.5%), followed by neoplasm (35.6%). The sensitivity (S) and specificity (N) were 83.3%. The most frequent final diagnosis was normal lymph nodes (46.5%), followed by neoplasm (35.6%). The sensitivity (S) and specificity (N) were 83.3% and 94.1%, respectively. With regard to complications, 90.7% did not register any complication.

**Conclusions:** EBUS-TBNA is a diagnostic tool with a high profitability in the study of hilar/mediastinal lymphadenopathies which was higher in neoplastic lymphadenopathy. In our case, there were not statistically significant differences regarding the diagnostic performance of the technique during the learning curve. EBUS-TBNA is a safe and well-tolerated method by both the patient and the endoscopist.

**Modified technique for endobronchial ultrasound-guided transbronchial needle sampling of the mediastinum**

Pablo Sanchez, Fredy Rodriguez, Juan Berto, Maria Sanchez-Carpintero, Juan Pablo de Torres, Ana Belen Akande, Arantza Campo, Luis Seijo, Javier Zulueta. Pulmonology, Clínica Universidad de Navarra, Pamplona, Spain; Neumología, Universidad Nacional de Colombia, Bogotá, Colombia

**Background:** The endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) is a method of endoscopic diagnosis for study of mediastinal involvement. Fine needle capillarity sampling has been applied in other organs and has shown high performance in terms of efficacy and sample adequacy to EBUS-TBNA yields. Furthermore, it is arguably simpler than the classical technique.

**Methods:** We included all patients undergoing EBUS exploration between January 1 to August 31 of 2011 in the Pulmonology Department at Clínica Universidad de Navarra in Pamplona, Spain. The samples were collected by capillarity (FNC). No suction was applied with the Vaclock syringe and the inner stylet was never completely removed, as dictated by the classical technique.

**Results:** Forty-four patients (75% male) were included in the study. EBUS exploration of the mediastinum identified lymphadenopathy or mediastinal masses in 38 patients (86.4%). More than one lymph node was sampled in 23 patients (52.3%). The analysis of samples reported that all punctures in lymph nodes with the capillarity technique provided adequate and representative material for interpretation, with a diagnostic yield of 86.8%. The diagnostic sensitivity achieved with EBUS-FNC for adequate samples was 88%, and 84.1% considering all samples. Complications were reported in only two patients (4.5%).

**Conclusions:** Our study suggests that the modified technique (EBUS-FNC) is safe and comparable in terms of efficacy and sample adequacy to EBUS-TBNA yields. Furthermore, it is arguably simpler than the classical technique.

**P280**

**Lymph node core retrieval comparison between 22 and 21 gauge EBUS-TBNA needle**

Prashant Chhipa1, H.S. Sandeep1, Parag Chaudhari1, Sejal Gandhi1, Ramesh Tikare2, Joesy Leuppi2, Arvind Kanji1. Pulmonology, Institute of Pulmonology, Medical Research & Development; Lung Care & Sleep Centre, Vashi, Navi Mumbai, Maharashtra, India; 2Pulmonology, Institute of Pulmonology, Medical Research & Development, Mumbai, Maharashtra, India; 3Anaesthesiology, Fortis-Hiranandani Hospital, Vashi, Navi Mumbai, Maharashtra, India

**Introduction:** Yield of EBUS-TBNA depends upon the quality of aspirate/ core obtained.

**Aim:** Analysis of diagnostic yield of lymph node aspirate using 22 and 21 gauge EBUS-TBNA needle.

**Methods:** A retrospective analysis was performed on 72 consecutive patients who underwent EBUS-TBNA. Of 72 patients first 44 patients underwent EBUS-TBNA using 22 gauge needle and subsequent 28 patients underwent EBUS-TBNA using 21 gauge needle. EBUS-TBNA was performed by single experienced interventional pulmonologist under sedation. By coincidence, since availability of 21 gauge needle suction is not being routinely applied for initial passes. Needle is moved back and forth without suction. Suction with provided syringe is applied only in cases with inadequate sample.

**Conclusions:** EBUS-TBNA using 21 gauge needle is comparable in terms of efficacy and sample adequacy to EBUS-TBNA using 22 gauge needle.

Achieving core biopsies for histology using gauge 21 needle during endobronchial ultrasound guided transbronchial needle aspiration

Dimitria Petkou1, Edward Nash2, Simon Trotter3, 1Respiratory Medicine, Heart of England NHS Foundation Trust, Sutton Coldfield, West Midlands, United Kingdom; 2Respiratory Medicine, Heart of England NHS Foundation Trust, Birmingham Heartlands Hospital, Birmingham, West Midlands, United Kingdom; 3Histopathology Department, Heart of England NHS Foundation Trust, Birmingham Heartlands Hospital, Birmingham, West Midlands, United Kingdom

Introduction: Endobronchial ultrasound guided transbronchial needle aspiration (EBUS-TBNA) is a safe method for sampling mediastinal lymph nodes. A dedicated 22 or 21 gauge (G) needle is used to perform EBUS-TBNA. The 22G needle provides material for cytology. The 21G needle is stiffer and allows larger samples.

Objectives: To evaluate whether the material obtained using 21G needle will be suitable for histological assessment and to determine the safety of the procedure.

Methods: 106 consecutive patients were included. The samples obtained by 21G needle after were received as friable cores of tissue. Their size was suited for histological processing and examination as biopsies. Microbiology was performed in selected cases.

Results: Core biopsies were obtained in 105 patients (99%). Malignancy was confirmed in 51 patients (48%). The histology of 20 (19%) patients showed granulomatous inflammation. Normal lymph node or reactive changes were reported in 22 (21%) cases. The samples of the remaining 11 (10%) patients were not representative. 3 patients with suspicious of malignancy imaging and negative histology underwent mediastinoscopy which confirmed reactive lymph tissue. EBUS-TBNA material was sufficient for EGRF testing. In 3 patients tuberculosis was confirmed by microbiology culture. The procedure was completed in all patients but one. 15 (14%) patients had significant cough, 2 (2%) patients complained of chest discomfort and 5 (5%) developed transient hypoxia, which did not require termination of the procedure.

Conclusion: Using 21 G needle for EBUS-TBNA is safe. It provides core biopsies for histological evaluation of mediastinal lymphadenopathy.

P282

Using forceps biopsy during endobronchial ultrasound is feasible in routine practise*

Bruno Escarguel1, Georges Thomas1, Cécile Tchoudjian1, Alexandre Chollat2, Namy2, Cyril Fou3, Jean Baptiste Paoli3, Alain Poisson1.

1, Georges Thomas1, Cécile Tchoudjian1, Alexandre Chollat2, Namy2, Cyril Fou3, Jean Baptiste Paoli3, Alain Poisson1.

Material and methods: In the thoracic endoscopic unit of the hopital St Joseph (Marseille, France) during June 2011-decembrer 2011, we used a pediatric for-
ces biopsy after each puncture by EBUS TBNA. 13 patients were analysed, 16 mediastinal sites (7, 4R, 10R, 11R, 12R, 4L, 11L) were biopsied (3 histological specimens) after using a 21 or 22G needle. All the procedures were doing under local anaesthesia. Especialy during a staging in lung cancer, big tissue become more necessary.

Forceps biopsy have been used in biopsy of subcarinal masses with interesting results for lymphomas or sarcoidosis, without major complications. What happend in routine practise and using forceps for other mediastinal sites ?

Introduction: EBUS is becoming a gold standard in exploring mediastinum ab-normality. Especially during a staging in lung cancer, big tissue become more necessary.

Forceps biopsy have been used in biopsy of subcarinal masses with interesting results for lymphomas or sarcoidosis, without major complications. What happend in routine practise and using forceps for other mediastinal sites ?

Material and methods: In the thoracic endoscopic unit of the hopital St Joseph (Marseille, France) during June 2011-decembrer 2011, we used a pediatric for-
ces biopsy after each puncture by EBUS TBNA. 13 patients were analysed, 16 mediastinal sites (7, 4R, 10R, 11R, 12R, 4L, 11L) were biopsied (3 histological specimens) after using a 21 or 22G needle. All the procedures were doing under local anaesthesia using a laryngeal mask.

Results: The average diameter of lymph nodes was 15.3 mm. In only two samples, the results were not significant. Concerning cancerous results (50%), the forceps biopsy did not increase diagnostic yield versus TBNA (Slides or cytology). Biomarker analyses were possible for metastasis patients. In one case, sarcoidosis diagnosis was made only with forceps biopsy. There were no immediate complications.

Conclusion: Using forceps biopsy during EBUS is feasible and safe. We can per-
form this procedure for the different sites of the mediastinum. The result doesn’t show an increasing diagnostic value in lung cancer but could be interesting for lymphoma or non malignant disorders as sarcoidosis.

P283

Endobronchial ultrasonography: Initial experience at a reference center in South America

Sebastian Fernandez-Busso1, Iván Caviedes1, Yumary Pires1, Felix Herth2, Adnan Majid3, 1Medicine, Clínica Alemana-Universidad del Desarrollo, Santiago, Chile; 2Pulmonary, Thoraxklinik, University of Heidelberg, Germany; 3Chest Disease Center, Beth Israeli Deacomness Medical Center-Harvard Medical School, Boston, United States

Introduction: Minimally invasive diagnostic procedures as endobronchial ultrasound-transbronchial needle aspiration (EBUS-TBNA), have been incorpo-
rated to the diagnostic algorithm of mediastinal pathologies or lesions adjacent to the central airways. There are multiples publications on its diagnostic performance in Europe, North America and Asia, but not in South America.

Objectives: To report the initial experience in EBUS-TBNA in a reference center of South America.

Patients and methods: Retrospective analysis of consecutive patients in whom EBUS-TBNA was performed for mediastinal and/or hilar lesions or lesions adja-
cent to central airways, demonstrated by chest CT-scan. Demographic information, lesions number, localization, and results together with definitive diagnosis, and com-
plications of the procedure, were registered. Sensitivity, specificity, predictive values and accuracy were calculated.

Results: 129 lesions were punctured in 85 patients (47 males), mean age of 62.8 years (25-86). Stations 4R, 7, 10R and 4L were the most frequently sampled. 82% were lesions of 20mm or less. Lung cancer and metastatic disease were the most common diagnosis (62%). Sensitivity 91% (CI 95%: 84-96), specificity 100% (CI 95%: 82-100), positive predictive value 100% (CI 95%: 94-100), negative predictive value 72% (CI 95%: 53-86), accuracy 93%. No complications were reported.

Conclusion: Our series has demonstrated the usefulness of EBUS-TBNA for the diagnosis of mediastinal lymph nodes or lesions adjacent to the central airways, in a Latin American reference center. Our diagnostic accuracy has been in agreement with previously published results in centers of Europe, Asia, and Northamerica.

P284

Complications and diagnostic outcome of endobronchial ultrasound (EBUS) guided transbronchial needle aspiration (TBNA) of mediastinal lymph nodes

Kinz Ying Wong1, Lily Yau Ng2, Nai Hom Tse1,3, Wilson K.S. Yeo1,2,1Respiratory Medicine, TWGHs Wong Tai Sin Hospital, Kowloon, Hong Kong; 2Department of Medicine, Kwong Wai Shiu Hospital, Kowloon, Hong Kong; 3Department of Medicine, University of Hong Kong, Hong Kong

Background: EBUS guided TBNA enables tissue sampling of mediastinal lymph nodes with sensitivity and specificity comparable to mediastinoscopy in nodal staging of lung cancer. It is generally safe but not without complications.

Objectives: We studied the complications and diagnostic outcome of EBUS-TBNA performed under local anaesthesia and sedation using intravenous mi-
dizolam and pethidine in the endoscopy suites.

Methods: We retrospectively studied consecutive EBUS examinations performed over 28 months since July 2008. Pathology and clinical follow-up data till end of 2010 were reviewed.

Results: Totally 110 EBUS-TBNA were performed in the study period. Complications occurred in 21 (19%) patients. Difficulty in conscious sedation accounted for the majority (97% 12 patients, 11%) including oversedation requiring antidotes (2), failed sedation (2) and one struggling patient leading to probe damage. Other complications included moderate bleeding of 15cc blood loss (2), bronchospasm (2), fever (1), pneumonia (1), paroxysmal atrial fibrillation (1). No long term adverse effect was found after EBUS-TBNA.

Among 80 patients referred for nodal staging of lung cancer, 131 lymph nodes were sampled, resulting in 53 true positives, 20 true negatives, 7 nondiagnostic TBNA. The sensitivity of EBUS-TBNA for diagnosing metastatic lymph node disease was 88.3% and the specificity was 100%. The diagnostic yield of EBUS-TBNA was 63% in 30 patients with inflammatory diseases including tuberculosis.

Conclusion: EBUS-TBNA is a safe procedure with reasonable diagnostic value and its complications were mostly associated with conscious sedation.

P285

Impact of multiple operators on diagnostic yield of EBUS-TBNA

Isabelle Fressal1, Greogire Geo1, Marianne Ges-Fabry2, Paulea M. Seccal1, 1Service of Pulmonary Medicine, Geneva University Hospitals, Geneva, Switzerland; 2Service of Clinical Research, Geneva University Hospitals, Geneva, Switzerland; 3Service of Thoracic Surgery, Geneva University Hospitals, Geneva, Switzerland

Background: EBUS-TBNA is usually performed by a limited number of operators at each institution in order to achieve optimal yield by accumulating individual ex-
pertise. We aimed to assess the diagnostic performance and safety of EBUS-TBNA when this procedure is learned by every trainee.

Methods: All consecutive patients undergoing EBUS-TBNA were prospectively included since the introduction of EBUS in our institution in January 2008 until December 2011. Each procedure was done by 2 or 3 operators including 1 senior supervisor. Rapid on-site cytologic evaluation (ROSE) was performed since June 2011. Predicting factors for the diagnostic accuracy of EBUS-TBNA were analyzed per patient and per sampled lymph node.
Results: 15 operators performed EBUS-TBNA in 160 patients. Definitive diagnosis was available for 156 patients (mean age 59.4±14.6 years; 38.5% F). Lymph nodes were malignant in 53.2%. Overall diagnostic accuracy was 82.7% (95% CI: 76.4-88.2) and 90.3% (95% CI: 81.3-97.1) for NSCLC and SCLC (n=72). Overall diagnostic accuracy tended to increase over years: 70.6%, 81.8%, 82.9%, and 85.9% in 2008, 2009, 2010 and 2011 respectively (p<0.51). Subgroup analysis showed no significant influence of ROSE, number of sampled nodes per case, localization and size of lymph node and SUN >10. Complications were restricted to 3 minor endobronchial bleeding.

Conclusion: A) Genova University Hospitals, EBUS-TBNA performance increased over years following well-known learning curves. Yet, in our setting, EBUS-learning curve seemed rather center-than operator-related. Providing on site direct supervision by a senior-experienced operator, EBUS is indeed constantly performed by junior operators without affecting the performance of the method.

P286 Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) under conscious sedation: Patient satisfaction in a UK tertiary center

S. Hirs1, S. Kazmi1, C. Smyth1, T. Giles2, M. Walsh2, S. Bidnikrishnan3, K. Mohan1, 1Department of Respiratory Medicine, Liverpool Heart and Chest Hospital NHS Foundation Trust, Liverpool, United Kingdom; 2Department of Pathology, Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, United Kingdom

Background: There is a variation in the modality of sedation/anaesthesia used during EBUS-TBNA. Despite this, there are no studies assessing patient satisfaction.

We therefore conducted a prospective study to characterize patient satisfaction with EBUS-TBNA performed under conscious sedation.

Methods: 101 consecutive patients (mean age 64) undergoing EBUS using topical lignocaine and iv midazolam were evaluated using a structured questionnaire 2 hrs post procedure.

Results: The mean dose of lignocaine throat spray was 178 mg and 99% received transtracheal lignocaine. The mean dose of iv midazolam was 3.3 mg and all patients were adequately sedated. 161 lymph nodes (stations 2, 4, 7, 10 & 11) were biopsied with a mean procedure duration of 17 cm (range 0.6-4 cm, less than 1 cm nodes 22). Mean duration of procedure was 20 mins and the mean number of needle passes per node was 2.3. EBUS was diagnostic in 96% and there were no complications.

Frequency of reported symptoms (%): 86% were tolerant of the procedure and the overall patient satisfaction was 97% (good - excellent). 78% would definitely return and 19% would probably return.

Conclusion: EBUS-TBNA under conscious sedation is safe and well tolerated. Conscious sedation is physician delivered and less resource intensive, and therefore could be adopted as the method of choice as EBUS services continue to expand.

P287 Assessing the learning curve for EUS(b)-FNA in comparison with classical ‘blind’ TBNA

Ilya Sirokovetsky1, Olga Lovacheva, Irina Shumskaya. Endoscopy Dept, CTRI RAMS, Moscow, Russian Federation

Background: Transbronchial needle aspiration (TBNA) is a challenge due to very flat learning curve. Now, EUS and EBUS significantly improved the results of TBNA. Nevertheless, number of ‘learning’ procedures to become an expert in this type of biopsy is controversial.

Aim: To determine the efficacy of EBUS-TBNA results in the evaluation of mediastinal lymph nodes in patients with extrathoracic malignancy.

Material and Methods: Retrospective analysis was performed in 40 patients with proven (n=38) or suspected metastasis of unknown origin (n=2) who underwent EBUS-TBNA between July 2007 and August 2011.

Results: All 40 patients successfully underwent EBUS-TBNA and no complications were observed. In 16 (40%) patients, EBUS-TBNA demonstrated metastasis of extrathoracic malignancy. Two (5%) patients diagnosed as a new lung cancer with EBUS-TBNA. The diagnostic sensitivity, accuracy, and negative predicted value (NPV) of EBUS-TBNA per patient were 90.0%, 95.0%, and 90.9%, respectively.

Conclusion: EBUS-TBNA is a sensitive and specific method for the histopathological diagnosis of mediastinal and hilar lymph nodes in patients with extrathoracic malignancy.

P288 The usefulness of endobronchial ultrasound-guided transbronchial needle aspiration for the diagnosis of sarcoidosis

Goohyeon Hong, Kyung-Jong Lee, Kyeongmung Jeon, Won-Jung Koh, Gee Hyun Yoon, Hojoong Kim, O. Jung Kwon, Sang-Won Um. Division of Pulmonary and Critical Care Medicine, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea

We evaluated the usefulness of endobronchial ultrasound guided-transbronchial needle aspiration (EBUS-TBNA) for the diagnosis of sarcoidosis in comparison with transbronchial lung biopsy (TBLB), endobronchial biopsy (EBB), and bronchoalveolar lavage (BAL). The consecutive patients who were suspicious for sarcoidosis (stage I and II) on chest radiography and chest computed tomography scan were included in the study. All study patients underwent EBUS-TBNA, TBLB, EBB and BAL at the same session. Between July 2009 and June 2011, 33 patients underwent EBUS-TBNA, TBLB, EBB, and BAL. EBUS-TBNA was performed for 71 lymph node stations. Among these 33 patients, 29 patients were diagnosed as histology proven sarcoidosis and two patients were compatible with clinical diagnosis of sarcoidosis during follow-up. The other two patients were diagnosed as metastatic carcinoma and reactive lymphadenopathy. Among 39 patients with histology proven sarcoidosis in combination with EBUS-TBNA, TBLB, and EBB, only EBUS-TBNA and TBLB revealed non-caseating granuloma in 18 patients and 1 patient, respectively. Overall diagnostic sensitivities of EBUS-TBNA, TBLB, EBB, and BAL (CD4/CD8 >3.5) were 90%, 35%, 6%, and 71%, respectively (p<0.001). Combined diagnostic sensitivity of EBUS-TBNA, TBLB, and EBB were 94%. In conclusions, EBUS-TBNA is most sensitive method for the diagnosis of stage I and II sarcoidosis compared with conventional bronchoscopic procedures. EBUS-TBNA could be considered first for the histopathologic diagnosis of stage I and II sarcoidosis.

P289 Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) for the diagnosis of extrathoracic lymphadenopathy in patients with extrathoracic malignancy: A study in a tuberculosis-endemic country

Nemat Akif Oğuz1, Engdogen Cetinkaya1, Nuri Tutar2, Güler Öğuz3, Hilal Oncan1, Emine Kamiloglu1, 1Pulmonary Diseases, Yekatrina Training and Research Hospital, Istanbul, Turkey; 2Pulmonary Diseases, Erivesi University, Karesi, Turkey; 3Pulmonary Diseases, Bagcilar Training and Research Hospital, Istanbul, Turkey

Background: Mediastinal lymphadenopathy in patients with malignancy is a common clinical problem in tuberculosis-endemic countries. The recently developed endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) procedure enables direct and real-time aspiration of mediastinal and hilar lymph nodes and is a less invasive alternative to mediastinoscopy.

Aim: To determine the efficacy of EBUS-TBNA results in the evaluation of mediastinal lymph nodes in patients with extrathoracic malignancy.

Methods: Retrospective analysis was performed in 40 patients with proven (n=38) or suspected metastasis of unknown origin (n=2) who underwent EBUS-TBNA between July 2007 and August 2011.

Results: All 40 patients successfully underwent EBUS-TBNA and no complications were observed. In 16 (40%) patients, EBUS-TBNA demonstrated metastasis of extrathoracic malignancy. Two (5%) patients diagnosed as a new lung cancer with EBUS-TBNA. The diagnostic sensitivity, accuracy, and negative predicted value (NPV) of EBUS-TBNA per patient were 90.0%, 95.0%, and 90.9%, respectively.

Conclusion: EBUS-TBNA is a sensitive and specific method for the histopathological diagnosis of mediastinal and hilar lymphadenopathy in patients with extrapulmonary malignancy.

P290 The role of endobronchial ultrasound guided biopsy in diagnosis of mediastinal/hilar lymphadenopathy in patients with extrathoracic malignancy

Elif Tören Parmaksiz, Benen Caglayan, Bana Salepci, Sevda Sener Comert, Nesrin Kür, Ali Fidan, Gulsen Sarac. Chest Diseases, Dr. Lutfi Kirdar Kartal Education and Research Hospital, Istanbul, Turkey

Accurate diagnosis of enlarged hilar/mediastinal lymph nodes is mandatory for adequate management of patients with known primary malignancy. We aimed to determine the sensitivity, specificity, accuracy of EBUS-TBNA for clarification of the nature of enlarged hilar/mediastinal lymph nodes in patients with known extrathoracic malignancy. Patients with extrathoracic malignancy who had undergone EBUS-TBNA for assessment of enlarged hilar/mediastinal lymph nodes in December 2008-September 2011 were reviewed. 48 patients who underwent EBUS-TBNA...
were included. Mean age of 12 male, 36 female patients was 57.38±11.60. Malignancy was detected in 18 (37.5%), tuberculosis in 6 (12.5%), sarcoidosis in 4 (8.3%), lung abscess in 2 (4.2%), reactive adenitis in 18 (37.5%). EBUS-TBNA was also found to offer an effective accurate and minimally invasive strategy for evaluating non-malignant lesions of pathological hilar and mediastinal lymph nodes such as tuberculosis and sarcoidosis. The sensitivity and specificity of EBUS-TBNA for malignancy in patients with reference pathology was 83% and 100%, respectively. Negative predictive value for malignancy was 90%. Procedure-related complications were minor being bleeding in 2(4.2%) and reversible desaturation in 1. When benign hilar lymph nodes are considered sensitivity, specificity and negative predictive value were 88%, 100% and 88%, respectively. We conclude that EBUS is a safe, minimally invasive, inexpensive and accurate procedure for diagnosing mediastinal/hilar lymphadenopathy in patients with extrathoracic malignancy. Nevertheless, due to the possibility of underdiagnosis, an invasive technique is indicated when results are negative.

P293

The diagnostic yield of ultrasound-assisted pleural biopsy in pleural effusions following non-diagnostic thoracentesis

Coenraad FN. Koekeboom1, Chris T. Bolliger1, Elvis M. Irusen1, Florian von Groote-Bidlingmaier1, Pawel T. Schubert2, Mercia Louw2, Colleen A. Wright2, Andreas H. Diacon1. 1Medicine, Stellenbosch University, Cape Town, South Africa; 2Pathology, Stellenbosch University, Cape Town, South Africa

Background: Unailed (“blind”) pleural biopsy is prone to sampling error and may not represent the true pleural pathology. US-assisted closed pleural biopsy in the setting of undiagnosed effusions, and investigated how pleural morphology could guide the selection and execution of closed pleural biopsy.

Methods: Patients with an exudative effusion who had had a non-diagnostic thoracentesis were prospectively stratified on imaging as having (A) an associated mass lesion (>10mm) abutting the chest wall; (B) diffuse pleural thickening (>10mm) and/or nodularity or (C) insignificant/no pleural thickening. US-assisted repeat thoracentesis and transthoracic fine-needle aspiration (TTFNA) were performed on patients stratified to (A), and if non-diagnostic on on-site analysis, followed by a Tru-Cut biopsy. US-assisted thoracentesis and Abrams needle biopsies were performed on all others aiming at the region(s) of interest (B) or low supra-diaphragmatic pleura (C).

Results: Final diagnoses in 41 consecutive patients (30 males, 47±18 years) included pleural TB (n=21), malignancy (n=16) and other causes (n=29). Accurate diagnoses were obtained in 34 (82.9%) patients. US-assisted biopsy; thoracotomy (n=6, 14.6%) or bronchoscopy (n=11) were required in the rest. The yield of US-assisted biopsy was higher for TB (93.3%, 90.48%) than malignancy (12/16, 75.0%, p=0.037). One patient experienced mild haemoptysis following TTENPA. Conclusion: A diagnostic algorithm based on pleural morphology and US-assisted pleural biopsy has a high diagnostic yield and offers a safe first-line approach in the setting of undiagnosed pleural exudates.

P294

Highly diagnostic yield of ultrasound-guided pleural biopsy for exudative lymphoctic pleural effusion

Debajyoti Bhattacharyya1, Dheeraj Gupta2, Ritesh Agarwal2, Ashutosh Aggarwal2, Anjali Chopra1, 1Respiratory Medicine, 2Pathology, Military Hospital (Cardio Thoracic Centre), Pune, Maharastra, India

Objectives: To assess the diagnostic value of the US-guided pleural biopsy, we prospectively enrolled 54 patients with nondiagnostic exudative PEs between May, 2010 and January, 2012 at Prathongkuttlak Hospial. Nineteen cases were received traditionally closed pleural biopsy with Abrams needles and the others were performed the US-guided pleural biopsy with the Abrams and Cope’s needles.

Materials and methods: To assess the diagnostic value of the US-guided pleural biopsy, we prospectively enrolled 54 patients with nondiagnostic exudative PEs between May, 2010 and January, 2012 at Prathongkuttlak Hospital. Nineteen cases were received traditionally closed pleural biopsy with Abrams needles and the others were performed the US-guided pleural biopsy with the Abrams and Cope’s needles.

Results: Twenty (63.15%), 6 (31.6%) and 1 (5.3%) cases receiving closed pleural biopsy were diagnosed as malignancy, tuberculosis, and uremic pleurisies, respectively. Twenty five (71.4%) and 9 (25.7%) cases receiving US-guided pleural biopsy were diagnosed as malignancy and tuberculosis, respectively. Twenty five (71.4%) and 9 (25.7%) cases receiving US-guided pleural biopsy were diagnosed as malignancy and tuberculosis, respectively. Twenty five (71.4%) and 9 (25.7%) cases receiving US-guided pleural biopsy were diagnosed as malignancy and tuberculosis, respectively. Twenty five (71.4%) and 9 (25.7%) cases receiving US-guided pleural biopsy were diagnosed as malignancy and tuberculosis, respectively.

Conclusion: US-guided pleural biopsy with Abrams needle is effective for specific diagnosis of exudative lymphoctic PEs.
years). 42 patients underwent tru-cut biopsy of lung and 15 cases underwent FNAC of lung. Mean tumour sizes were 60.2±29.3 mm. Histological/cytological examination provided the diagnosis in 53 cases: lung cancer – 40, other malignant tumours – 3, benign tumours – 2, granuloma – 6, and organizing pneumonia – 2. Adenocarcinoma (22 cases) was the most common lung cancer detected. In three cases the diagnosis was inconclusive. Complications were observed in five patients: mild haemoptysis which improved spontaneously – 2, subcutaneous emphysema – 1 (improved without any intervention), and pneumothorax in two patients, one of whom required tube thoracostomy.

Conclusions: USG guided trucut biopsy/FNAC of lung gives a high diagnostic yield in peripheral lung lesions. Complication rate of the procedure is low.

59. Airway diseases: from invasive to noninvasive biomarkers

P296 Bronchial mucosal dendritic cells and VEGF expression in COPD patients Andrea Zani1, Sabrina Della Patrona2, Federico Gumiero3, Maria Majori1, Danilo Olivarrieri1, Antonio Spanevillo1, Alfredo Chetta1. 1Department of Respiratory Disease, University of Bradford, Bradford, Varese, Italy; 2Division of Pneumology, Salvatore Maugeri Foundation IRCCS Rehabilitation Institute, Tradate, Varese, Italy; 3Cardio-Nephro-Pulmonary Dept, University Hospital, Parma, Italy

Introduction: Dendritic cells (DCs) have a pivotal role in the onset and regulation of innate and adaptive immune responses. A decreased number of mature DCs may occur in the airways of COPD patients, thereby reducing their immune response. Moreover, DCs can affect vascularization process in different physiological conditions. There are no data concerning the relationship between DCs and vascular endothelial growth factor (VEGF) in COPD patients.

Objectives: We evaluated the relationship between the expression of VEGF and the density of DCs in the bronchial mucosa of COPD patients.

Methods: Twenty patients with moderate to severe COPD (age 76±10 yr, 3 F; FEV1 51±9%, FEV1/FVC 48±12%) were studied. Eight healthy subjects represented a control group (CS). Bronchial biopsies were evaluated by immuno-histochemistry and presence of DCs was investigated by using antibody directed against CD207, to mark immature DCs, and against CD83, to mark mature DCs.

Data are presented as mean±SD. In all COPD patients, CD207+ cells were inversely related to FEV1 (r=-0.52, p<0.05) and CD83+ cells were inversely related to VEGF expression (r=-0.45, p<0.05).

Conclusions: Our results show that COPD airways were associated with a decrease in mature DCs and that these cells were inversely related to VEGF expression. Additionally, immature DCs were significantly related to airflow obstruction. We speculate that the DC-VEGF interplay may play a key role both in angiogenesis and in the immune response in COPD patients.

P297 Correlation between airway smooth muscle (ASM) and eosinophilic inflammation in severe non-controlled asthmatics Regina Maria Carvalho-Pinto1,Albertoucker1, Thais Mainaud2, Marisa Dolinhkoff2, Marcelo Gervilla Gregório2, Ray Camargo Pires Neto2, Aila Mirtes Teles1, Klaus F. Rabe1, Reinaldo Stelmach1, 1Pulmonary Division, Heart Institute (InCor) - University of São Paulo Medical School, São Paulo, SP, Brazil; 2Department of Pathology, University of São Paulo Medical School, São Paulo, SP, Brazil.

Background: Airway muscle hypertrophy is a surrogate of airway remodeling and eosinophilia in induced sputum (IS) is associated to lack of asthma control.

Objective: Compare the amount of ASM in endobronchial biopsies with eosinophils % (Eos) in IS in severe asthmatics after optimal treatment.

Methods: 62 severe asthmatics received a 2-week prednisone trial and high inhaled corticosteroid dose (ICS) plus LABA for 12 weeks and were classified according to lung function: 1. the 2-week oral corticosteroid trial. Persistent airflow obstruction (PAO) was defined by FEV1 post BD <80% plus FEV1/FVC post BD <0.70. IS and bronchial biopsies were performed at the end of the 12 weeks. The fractional area of ASM, assessed by quantification of alpha-smooth muscle actin, and Eos % in IS were assessed.

Results: 48 patients were classified as PAO, 14 as non persistent airflow obstruction (NPAO). The fractional area of ASM was higher in PAO (p=0.041), but Neu% and Eos% in IS was not different between groups. There was a strong inverse correlation between IS Eos and total area muscle actin (r = -0.93, p=0.001) in the NPAO and a positive correlation in the PAO group (r = 0.36, p = 0.038). No correlations were found with Neu.

Conclusions: Persistent obstructed severe asthmatics have more smooth muscle hypertrophy than normalize lung function patients. Eos inflammation is inversely associated with ASM mass in the biopsies, whereas the opposite occurs in persistent obstructed patients. These data suggest that structural alterations, in parallel with inflammation, are related to functional abnormalities in the persistent obstructed patients.

P298 The EVA study: Characteristics of the study population Loemen Ziegelb7reich1, Dorothee Buggd1, Marion Heiss-Neumann3, Matthias Wjst6. 1EVA Study Centre, Helmholtz Zentrum München, Garching, Germany; 2Institute for Lung Biology and Disease, Helmholtz Zentrum München, Neuharburg, Germany. The emphysema versus airway disease (EVA) study is an EU-funded project with 15 partners in 8 European countries, which aims at identifying markers associated with subphenotypes of chronic obstructive pulmonary disease (COPD) as defined by CT image analysis. The project has recruited 280 controls (average age 59y, 36% females) and 584 patients (average age 65y, 32% females), who comply with stringent exclusion criteria in that current smoking, oral glucocorticoids, anti-coagulation, FEV1 <30% or long term oxygen therapy is not allowed. Although recruitment selected against asthma post-bronchodilator reversibility >200ml was seen in 184 cases (34%) and 58 controls (21%). Chest CT was done in cases only and this is being used as reference to a series of phantoms- to determine lung density and airway wall thickness as a measure of emphysema and airway disease, respectively. Bronchocscopy was done on 421 cases and 278 controls and here we obtained bronchial epithelium with inflated brushes and alveolar macrophages by lavage with up to 110 mL of fluid. Fluid recovery in lavage in average was 43% for controls and 30% for cases, reflecting the more pronounced airway collapse during fluid retrieval in COPD. Recovery of brush material was similar between cases and controls, in that RNA obtained from the right upper lobe was 5.4 ug and 6.4 ug, respectively. The data show that in a multicentric study sizeable amounts of biological material can be obtained from COPD lungs. This material is currently being analyzed for expression of markers associated with the emphysema-dominant and airway disease-dominant subphenotypes of COPD. Supported by EU FP7 project #206005.

P299 Characterisation of patients with difficult-to-treat and treatment-resistant severe asthma Federica Novell; Federico Lorenzo Dente, Maria Laura Bartoli, Silvana Cianchetti, Antonella Di Franco, Lorenzo Molinosa, Elena Bacci, Perluigi Poggiano. Cardiothoracic and Vascular Dept., University of Pisa, Italy

Background: A recent World Health Organization (WHO) meeting proposed a uniform classification of severe asthma (SA) into 3 groups: untreated SA, difficult-to-treat SA, and treatment-resistant SA (JACI 2010).

Aim: To characterize and compare the demographic, functional and inflammatory parameters and the level of control of patients with difficult-to-treat and treatment-resistant SA.

Method: 12 patients with treatment-resistant SA and 24 patients with difficult-to-treat SA (defined according to WHO document) were enrolled in this study (mean age: 59 yrs). All patients underwent ENT visit to evaluate the presence of pathology of the upper airways (in particular rhinosinusitis and/or polyps).

Results: Patients with treatment-resistant SA had a higher sputum eosinophilia (57.1% (3.7-86.2) Vs 12.5 (0-95.6), p<0.01) and a shorter asthma duration (11.5 (3-40) vs 25 (8-50), p<0.01) than patients with difficult-to-treat SA. The indices of asthma control, as well as FEV1, PD20 methacholine, eNO, and the level of treatment were similar in the two groups.

Conclusions: Patients with treatment-resistant SA have a greater eosinophilic inflammation of lower airways than patients with difficult-to-treat SA, but a similar level of control and pharmacologic therapy, suggesting the need for different treatment strategies in the two groups of patients.

P300 Endogenous hydrogen sulfide (H2S) in serum and sputum as novel biomarker of asthma Muneer Saingi1,2, Qingling Zhang1,2, Christopher Hui1,2, Andrew Menzies-Gow1,2, Pankaj Bhavar1,2, Kian Fan Chung1,2, 1Airway Disease Section, National Heart & Lung Institute, Imperial College London, United Kingdom; 2Respiratory Biomedical Research Unit, Royal Brompton Hospital, London, United Kingdom

Background: Hydrogen sulfide (H2S) is considered to be the third gasotransmitter
to moderate asthmatics and controls, being consistent with the hypothesis that epithelium injury & repair play an important role in this phenotype.

P303 Increased levels of angiotensin 1 & 2 in sputum supernatant in smoking asthma

Eleni Tsilioti1, Petros Bakakos2, Konstantinos Kostikas1, Vasiliki Petta2, Davina Simoes1, Georgios Hillas1, Nikolaos Koulouris1, Spyros Papiris1, Stelios Loukides1, 2nd Department of Pulmonary Medicine - Sotira Chest Hospital, University of Athens Medical School, Athens, Greece; 1st Respiratory Medicine - Sotira Chest Hospital, University of Athens Medical School, Athens, Greece; 1st Pediatric Respiratory Medicine - Evangelismos Hospital, University of Athens, Greece

Background: Angiotensin-1 (Ang-1), is an essential mediator of angiogenesis by establishing vascular integrity, whereas angiotensin-2 (Ang-2) acts as its natural inhibitor.

Objective: We aimed to determine the levels of angiotensins in sputum supernatants of patients with smoking asthma and to investigate possible associations with mediators and cells involved in both the inflammatory and the vascular remodeling process

Methods: Eighty-seven patients with asthma (42 smokers) and 28 healthy subjects (14 smokers) were studied. All subjects underwent lung function tests, bronchial hyperresponsiveness assessment and sputum induction for cell count identification and Ang-1, Ang-2, VEGF, TFG-β1, MMP-2, IL-13, ECP and IL-8 measurement in supernatants. Airway vascular permeability (AVP) index was also assessed.

Results: Ang-1 (ng/ml) and Ang-2 (pg/ml) levels were significantly higher in patients with smoking asthma compared to patients with non-smoking asthma and both smoking and non-smoking healthy subjects (median, interquartile range) 24 (13-37.3) vs 10 (7.14-21) vs 5.3 (3.7-6.5) vs 4.6 (3.8-5.7) respectively, p<0.001; and 168 (132-205) vs 124 (82-152) vs 94 (78-113) vs 100 (96-108) respectively, p<0.001.

Conclusions: Reduced expression of Ang-1 and Ang-2 in smoking asthma compared to non-smoking asthma and healthy subjects pointing towards a contribution of smoking through these mediators to the asthmatic angiogenesis process.

P304 Short-term and long-term reproducibility of non-invasive clinical and inflammatory parameters in asthma

Matthias Jung1, Stephanie Korn2, Marisa Hübler3, Christian Taube4, Roland Ruhl1, 1Pulmonary Respiratory Medicine - Atiko University Hospital, Germany; 2Pulmonary Dept., Leiden University Medical Center, Leiden, Netherlands

Several non-invasive parameters have been proposed to monitor tobacco inflammation in asthma. Aim of this study was to assess the reproducibility of established parameters in asthma within 7 days and after 6 months.

In 83 medically treated asthma patients (51 female, mean±SEM 44±1.5 yrs, FEV1% pred 85±6.2, 20 pts. controlled, 30 partly controlled, 33 uncontrolled) with a constant level of asthma control (GINA) and unchanged medication the following tests were performed at baseline, after 7 days (n=70) and after 6 months (n=37): asthma control questionnaire (ACQ-5), exhaled nitric oxide (eNO), lung function tests, methacholine provocation (PC20), measurement of total serum IgE and sputum induction.

Within 7 days ACQ-5, ENO, FEV1 and total IgE were stable with a Cronbach’s alpha between 0.898 (eNO) and 0.993 (ACQ-5) and intraclass correlation coefficients between 0.898 (eNO) and 0.993 (ACQ-5) and intraclass correlation coefficients between 0.898 (eNO) and 0.993 (ACQ-5).

Reproducibility was good with Cronbach’s alpha [intraclass correlation coefficients] between 0.803 [0.755] (ACQ-5) and 0.997 [0.994] (IgE).

In patients with a constant level of asthma control and unchanged medical treatment clinical parameters are reproducible in a short- and long-term interval.

P305 Increased levels of osteopontin in sputum supernatant in patients with COPD

Anastasia Paparioyiriou1,2, Konstantinos Kostikas1,2, Stelios Loukides1,2, Georgios Hillas1, Davina Simoes1, Elissavet Konstantelou2, Spyros Papiris1, Nikolaos Koulouris1, 2nd Department of Pulmonary Medicine - Sotira Chest Hospital, University of Athens Medical School, Athens, Greece; 1st Respiratory Medicine - Sotira Chest Hospital, University of Athens Medical School, Athens, Greece; 1st Pediatric Respiratory Medicine - Evangelismos Hospital, University of Athens, Greece

Background: Osteopontin (OPN) is a glycoprotein that has been associated with inflammation and fibrosis. Recently published data supports that OPN is upregulated in surgical lung tissue samples of patients with COPD (Schneider F et al FASEB 2010).

Osteopontin (OPN) is a glycoprotein that has been associated with inflammation and fibrosis. Recently published data supports that OPN is upregulated in surgical lung tissue samples of patients with COPD (Schneider F et al FASEB 2010).
Aim: The aim of this study was to determine the levels of OPN in sputum supernatants of patients with COPD, and compare them with healthy subjects and to investigate their possible association with mediators and cells involved in the inflammatory and remodeling process as well as with the extension of emphysema as defined by HRCT.

Methods: Seventy-seven patients with COPD and 40 healthy subjects (20 smokers) were studied. All subjects underwent lung function tests, sputum induction for cell count identification and OPN, TGF-β1, MMP-2, IL-8, LTβ4 measurement in sputum supernatants. A HRCT was performed for quantification of emphysema. Measured and Main results: OPN levels [median (interquartile range) pg/ml] were significantly higher in patients with COPD compared to both healthy smokers and non-smokers [1340 (601-6227) vs 101 (50-69) respectively, p<0.001]. Regression analysis showed a significant association between OPN and sputum neutrophils, IL-8, MMP-2 and the extent of emphysema. The above associations were not observed in healthy subjects.

Conclusions: Our results indicate that OPN levels are higher in patients with COPD compared to both smoking and non-smoking healthy subjects. Moreover, the association of OPN with sputum neutrophils, IL-8 and MMP-2 indicates a role of OPN in neutrophilic inflammation while its association with the extent of emphysema shows a role in the pathogenesis of this particular COPD phenotype.

P306 Reference equation and upper limits of fraction of exhaled nitric oxide (FeNO) in a Chinese population

Fanny Ko1, T.F. Leung1, Gary Wong2, Jojo Chu1, Ivy S3, David Hui1. 1Dept. of Medicine & Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong; 2Department of Pediatrics, The Chinese University of Hong Kong, Shatin, Hong Kong

Background: Measurement of FeNO has been proposed as a biomarker for monitoring and managing airway diseases. Limiting information is available in regard to the reference levels of FeNO levels in adult Chinese. The aim: To investigate the reference equations and upper limits of FeNO in Chinese adults.

Method: 1093 (577 males) healthy non-smoking subjects with age 18-90 yrs were recruited. FeNO was measured online using a chemiluminescence analyser (NOA 280, Sievers Instruments, Boulder, CO, USA). Other assessments included spirometry, skin prick test, total serum immunoglobin E (IgE) levels and eosinophil count in peripheral blood.

Results: The geometric mean FeNO was 32.6% (95% reference interval [RI] 29.0-36.1) ppb (RI=geometric mean±SD) for all subjects. FeNO value was higher in males than females (geometric mean[95%RI]:38.3[34.8-41.8] vs 27.1[26.3-30.6] ppb). FeNO was positively correlated with height (r=0.20), %-smoking (r=0.18), % eosinophil counts (r=0.18) with p value <0.0001, but not with spirometric parameters. Based on multiple regression modeling, the reference equation of FeNO value was as follows: log[FeNO]=0.781 + 0.0144*(sex =1, male; 0, female) + 0.004*(age in years) + 0.084*(atopic, 1, atopic; 0, non-atopic) + 0.003*(height in cm). Example of a non-atopic man and woman with age 41-50 and height 160-170cm would have their 95% upper limits of FeNO being 32.6 and 25.7 ppb respectively.

Conclusion: It appears that the FeNO level of Chinese adults is higher than the Caucasian population.

Supported by HK Lung Foundation Grant & Respiratory Research Fund of CUHK.

P307 An alternative sampling support for collection of particles in exhaled air

Ann-Charlotte Almstrand, Per Larsson, Anna Bredberg, Ekaterina Mirgorodskaya, Anna-Carin Olin. Sahlgrenska Academy at the University of Gothenburg, Occupational and Environmental Medicine, Gothenburg, Sweden

We have previously reported a method to collect material from the airways in the form of exhaled particles (PEx). In the original set-up, PEx were sampled on silicon wafers to fulfill the conditions for downstream TOF SIMS analysis. Application of analytical techniques, such as immunassay or LC-MS, involves extraction of material from the sampling support. PEx extraction from silicon wafers requires large volumes and generates unwanted silica debris.

The aim of this study was to identify PEx sampling supports suitable for use of wet chemistry on the collected material.

Five individuals exhaled 60L onto different sample supports. All sample supports were commercially available filters (Millipore). Samples were extracted in 200 μl of PBS/0.1%Tween and analyzed using albumin ELISA. Lipid was extracted using chloroform/methanol/water, 3:6:2 v/v/v, and analyzed by MALDI TOF/MS. The six tested sample supports were: (1) LCR Membrane; (2) glass fiber; (3) mixed cellulose membrane; (4) Omnipore Membrane; (5) Durapore Membrane; (6) Isopore Membrane. Silicon wafers were included for comparison. The extraction efficiency was evaluated based on the albumin amount extracted from the filters.

The best results were obtained for Filter1, which gave the highest amount of albumin/PEx, w/v. The filter showed good linearity for observed albumin recovery as function of PEx mass, R²=0.98. The suitability of the filter for lipid analysis was confirmed by MALDI TOF/MS of dipalmitoylphosphatidylcholine.

We conclude that hydrophilic LCR Membrane is a good solid support for sampling PEx, suitable for collection of samples when wet chemistry is involved in the followup analysis.

P308 Endogenous particles in exhaled air – Variability of particle number in healthy individuals

Ann-Charlotte Almstrand, Per Larsson, Anna Bredberg, Ekaterina Mirgorodskaya, Anna-Carin Olin. Sahlgrenska Academy at the University of Gothenburg, Occupational and Environmental Medicine, Gothenburg, Sweden

Endogenous particles in exhaled air (PEx) are formed during airway reopening following airway closure. Analysis of PEx may be used for monitoring biochemical alterations in respiratory tract lining fluid in the small airways. The number of exhaled particles is strongly dependent on breathing pattern but there is also a substantial difference between individuals.

The aim of the study was to assess intra-individual variability of PEx number using a standardized breathing maneuver involving airway closure. 10 healthy subjects participated in the study. They were instructed to exhale slowly and completely, inhale to total lung capacity and exhale at 500 ml/s until functional residual capacity. Particles were counted in the final exhalation of the maneuver using an in-house developed instrument. The maneuver was repeated until 80 liters of exhaled air had been sampled. Sampling was performed 3 times (two mornings and one afternoon) for each subject.

The average total number of PEx varied from 9700 to 93 000 particles/exhalation among individuals. The coefficient of variation of total PEx number/exhalation within individuals was 3.9-36.6%, median 12.9%. The coefficient of variation between individuals was 65%. There was no intra-individual difference in particle numbers between morning and afternoon samplings.

The intra-individual variability of PEx number was substantially higher between individuals than within individuals. The high variability between individuals may be due to differences in lung architecture and possibly to differences in the chemical composition of airway lining fluid. Our results support the fact that it is important to control for mass of PEx for any given concentration of non-volatile analyte.

P309 Microsatellite alterations at 3p and 19q in EBC/DNA of smokers: Are they reversible after smoking cessation?

Giovanna Elisiana Carpagnano, Donato Lacedonia, Roberto Sabato, Piergiuseppe Benedetto, Anna Koutelou, Maria Pia Foschino Barbaro. Medical and Occupational Sciences, Respiratory Section, Foggia, Italy

Microsatellite alterations (MAs) at 3p and 19q are early targets for cigarette smoke and markers of genetic susceptibility to lung cancer. Several susceptible genes modulated by smoking have been found to return to baseline years after smoking cessation. Although great interest has been devoted to the classification of smoking-related genetic alterations as reversible or irreversible, as it seems to influence the different biological functions, none have yet focused on MAs at 3p and 19q.

The aim of this study was to analyse MAs at 3p and 19q in exhaled breath condensate (EBC) and in DNA from smokers before and after smoking cessation. The 63 smokers enrolled in the study participated in a multidisciplinary smoking cessation program with a genetic study. All the subjects fulfilled under EBC and whole blood (WB) collection at baseline. The 28 smokers (20 M, 53±8.5 yrs) who stopped smoking followed up and repeated sample collection after 12 months. All subjects had allelotyping analysis of DNA from EBC and WB from a selected panel of seven microsatellites located in 3p and 19q. MAs at 3p and 19q resulted higher in EBC/DNA than in WB/DNA and dose-dependent from cigarette smoking. These somatic alterations both in EBC/DNA and in WB/DNA resulted as being not modificable after 12 months from smoking cessation.

In conclusion we demonstrated for the first time that MAs at 3p and 19q are not modificable in short term from smoking cessation, although a longer follow-up is needed to better classify MA at these loci. Furthermore, we supported the usefulness of smoking cessation programs based on the information on genotype for its potential ecological health.

P310 Exhaled MMP-9 in lung cancer

Giovanna Elisiana Carpagnano, Donato Lacedonia, Elio Costantino, Anna Rita Depalo, Cinzia Ruggeri, Grazia Pia Palladino, Maria Pia Foschino Barbaro. Medical and Occupational Sciences, Section of Respiratory Diseases, University of Medicine, Foggia, Italy

Background: MMP-9 has been recognized in several types of tumour development and markers of genetic susceptibility to lung cancer. Several susceptible genes modulated by smoking have been found to return to baseline years after smoking cessation. Although great interest has been devoted to the classification of smoke-related genetic alterations as reversible or irreversible, as it seems to influence the different biological functions, none have yet focused on MAs at 3p and 19q.

The aim of this study was to analyse MAs at 3p and 19q in exhaled breath condensate (EBC) and in WB/DNA of smokers after 12 months from smoking cessation. The 63 smokers enrolled in the study participated in a multidisciplinary smoking cessation program with a genetic study. All the subjects fulfilled under EBC and whole blood (WB) collection at baseline. The 28 smokers (20 M, 53±8.5 yrs) who stopped smoking followed up and repeated sample collection after 12 months. All subjects had allelotyping analysis of DNA from EBC and WB from a selected panel of seven microsatellites located in 3p and 19q. MAs at 3p and 19q resulted higher in EBC/DNA than in WB/DNA and dose-dependent from cigarette smoking. These somatic alterations both in EBC/DNA and in WB/DNA resulted as being not modificable after 12 months from smoking cessation.

In conclusion we demonstrated for the first time that MAs at 3p and 19q are not modificable in short term from smoking cessation, although a longer follow-up is needed to better classify MA at these loci. Furthermore, we supported the usefulness of smoking cessation programs based on the information on genotype for its potential ecological health.
Participants: We enrolled 40 NSCLC patients and 40 controls affected by transudative pleural effusion.

Measurements: MMP-9 concentrations were measured in the EBC, whole blood (WB) and pleural effusion (PE) of all the subjects under study using ELISA kits.

Results: MMP-9 levels were found to be significantly higher in EBC, WB and PE of NSCLC patients compared with controls. A positive correlation was observed between MMP-9 in EBC, cigarettes smoked and stage of cancer.

Conclusion: Exhaled MMP-9 was elevated in NSCLC patients, especially during tumour progression, and could represent a suitable non-invasive marker in the diagnosis and monitoring of lung cancer.

P311

Influence of oral steroid use in difficult-to-control asthma patients on metabolomic profile of oxidative stress in exhaled breath condensate (EXAIR project)

Vrančíř Solášek1, Petr Čáp2, Petr Kacer3, Marek Mályš4, Štefánka Vícková5, Daniela Pelčová6, 1Dept. of Respiratory Medicine, University Hospital, Hradec Králové, Czech Republic; 2Dept. of Allergology and Clinical Immunology, Na Homolce Hospital, Prague, Czech Republic; 3Dept. of Organic Technology, Institute of Chemical Technology, Prague, Czech Republic; 4Dept. of Biostatistics, National Institute of Public Health, Prague, Czech Republic; 5Dept. of Occupational Medicine, 1st Faculty of Medicine, Charles University, Prague, Czech Republic.

Difficult-to-control asthma (DCA) remains a pending clinical problem despite recent advances in therapy. It is supposed that intensity of inflammation and oxidative stress is higher in DCA.

Aims: Our hypothesis was that oxidative stress metabolites in exhaled breath condensate (EBC) differs in oral corticosteroid (CS) dependent DCA patients (group OCS, n=10) versus DCA treated by inhaled CS (group ICS, n=10) from severe asthma center and versus healthy controls.

Methods: We have used metabolomic analysis of EBC using liquid chromatography and mass spectrometry to detect concentrations of 22 markers of oxidative stress (e.g. malondialdehyde, leukotrienes, 8-isoprostane, α-tirosine). EBC was taken by a standardized protocol. Results were analyzed together with FEV1, FeNO50, blood eosinophils and differences in OCS and ICS subgroups were statistically evaluated.

Results: OCS ad ICS did not differ in gender, age (54 vs 53), asthma control test (12 vs 15), FeNO50 (36.5 vs 50) and FEV1 (53 vs 57 % predicted) (all p>0.05). Peripheral blood eosinophils were higher in ICS group (0.46 vs 0.22 x10³/µL, p=0.03). 8-isoprostane was significantly higher in ICS group (101.7 vs 54.5 pmol/L, p=0.002) only. All other measured markers in EBC did not differ between OCS and ICS, however all markers in EBC of ICS and OCS were higher in comparison to control group (all p<0.001).

Conclusion: Our data shows increased liperoxidation and blood eosinophilia in ICS DCA. We speculate that ICS DCA would benefit from earlier chronic oral CS therapy to prevent consequences of oxidative stress, however further data are needed.

Support: PRVOUKP.

P312

Ethnic difference and diagnostic value of exhaled nitric oxide levels for predicting asthma in children

Gary Wong, Ting Fan Leung, Edmund Yung. Pediatrics, Chinese University of Hong Kong, Shatin, Hong Kong.

Exhaled nitric oxide (eNO) has been used as a non-invasive marker of airway inflammation but normal reference data in children are limited. Levels of eNO in a random sample of 1099 Chinese children aged 11-18 years recruited from Hong Kong were measured online by a chemiluminescence analyzer according to ERS/ATS standard. Each student also completed an ISAAC questionnaire. Children who had never been diagnosed to have asthma and did not have any symptoms of wheeze, rhinitis or eczema were considered as normal controls. Ninety-four steroid naïve asthmatics were recruited from the Asthma Clinic for eNO measurement for comparison. Among the control children, there were 369 boys and 373 girls. In control children, the eNO levels (median, interquartile range) were significantly higher (P<0.001) in males (11.4 ppb; 7.7-21.6) than in females (9.0 ppb; 5.9-13.4). For asthmatic males, the median eNO (interquartile range) was 45.5 ppb (28.3-74.1); for asthmatic females, 47.2 (28.6-69.5). Using a cutoff of 15 ppb for girls, the sensitivity and specificity for differentiating asthma from controls are 86% and 78% (AUC of ROC curve =0.84) for boys, the sensitivity and specificity are 80.4% and 79.4% using a cutoff of 25 ppb (AUC of ROC curve = 0.84). This is one of the largest studies of eNO in Chinese schoolchildren and their levels are higher than the reported values for Caucasians. Different cutoff values for boys and girls are needed when eNO is used for supporting the diagnosis of asthma in children.

Supported by HKRGC CUHK4120/06M and CUHK 477110.

We compared the classification ability of two e-noses based on different technologies in asthma and COPD. Ten patients with severe asthma (3/7, males/females, age 47±2 yrs, FEV1 67±7% pred, FVC 82±6±7% pred, P<0.001; 9 non-smokers, 1 current smoker), 9 COPD patients (7/2, males/females, age 69±3 yrs, FEV1 68±5±1% pred, FVC 82±6±5% pred, P<0.001; ex-smokers) and 6 healthy non-smokers (4/2, males/females, age 49±6 yrs, FEV1 109±4±4% pred) were studied in a cross-sectional pilot study. After 5 min of tidal breathing with volatile organic compound-free air, two breath samples were collected from each subject and immediately analyzed with Cyanosense 320 (Smiths Detection, Pasadena, USA) and Ten 2010 (University of Rome Tor Vergata, Italy). Data were analyzed by partial least square discriminant analysis with leave-one-out cross-validation. eNOs were initially used for classifying healthy subjects and patients with pulmonary disease and, then, asthma and COPD patients. Classification capacity between patients with respiratory disease and healthy subjects was as follows: Cyanosense 320, 80%; Ten 2010, 88%; e-nose combination, 92%. Classification rate between asthma and COPD patients was as follow: Cyanosense 320, 92%; Ten 2010, 86%, e-nose combination, 94%.

These preliminary results suggest that a combination of e-noses slightly increases classification capacity in patients with severe asthma and COPD.

68. Late breaking results: Asthma from phenotyping to emerging new treatments

342

Developing obstructive change over time is dominant in smallairways in severe asthma

Kazuto Matsumura, Keiichiro Akamatsu, Masakazu Ichinose. Third Department of Internal Medicine, Wuyaya Medical University, Wuyaya, Japan.

Background: The clinical features, physiology, and pathology of severe asthma patients has not been fully elucidated.

Objective: To assess the pattern and risk factors of developing airway obstruction over time in severe asthma.

Methods: We examined the data of a retrospective analysis of lung function changes over a 10-year period in 54 patients with severe asthma. The risk factors that might contribute to the progression of obstructive changes were also investigated.

Results: The rate of change in both FVC and FEV1 (forced expiratory volume in one second) was highly variable among the patients with severe asthma. The faster obstructive changes detected by decline in FEV1 were accompanied by excessive loss of FVC (r = 0.85, p < 0.0001) and the reduction in FVC was 1.2 times larger than the FEV1 decline. Age, baseline FVC, annual exacerbation rate and...
use of oral corticosteroids showed significantly negative correlations with the rate of annual change in FVC.

Conclusions: These data indicate that the decline in FVC is more evident than FEV1 in severe asthma, suggesting that small airway susceptibility may be the cause of rapid disease progression. Aging, exacerbations of asthma, and use of systemic corticosteroids are associated with excess FVC decline, particularly if FVC is still normal.

343 Distinct phenotypic and pathophysiologic features of elderly asthma
Min-gyu Kang1,2, Woo-jung Song3,1, Seung-Eun Lee1,2, So-Hee Lee1,2
Kyung-Young Min1,2, Sang-Hoon Cho1,2, Internal Medicine, Seoul National University Hospital, Seoul, Korea; 2Allergy and Clinical Immunology, Seoul National University Medical Research Center, Seoul, Korea

Background: Recent epidemiologic evidence suggests that asthma is prevalent in the elderly population. Majority of elderly asthma develops in later life, and thus is considered patho-physiologically distinct from young adult asthma.

Objective: To investigate whether elderly asthmatics may have different phenotypic or pathophysiologic features from young adult asthmatics.

Methods: Young adult (18-45 years) and elderly (≥65 years) non-smoking, treatment-naive asthmatics were compared cross-sectionally. Asthma was defined if they had typical symptoms and methacholine PC20 ≤ 8 mg/mL. They completed baseline spirometry, induced sputum analyses, inhalant allergen skin prick tests, and anthropometric measurements. As indices of small airway involvements, a FEF25-75% and FEF25-75/FVC were used.

Results: A total of 103 young adult (mean age: 29.9 years) and 120 elderly (mean age: 71.1 years) asthmatics were included. Two age groups had similar degrees of airway hyperresponsiveness (methacholine PC20: 2.7 ± 2.2 mg/mL in the elderly vs. 2.7 ± 2.5 mg/mL in young adults). They also did not differ in gender distribution, FVC%, or FEV1%. However, the elderly asthmatics had higher body mass index (24.9 kg/m² vs. 23.3 kg/m², P<0.05), and lower atopy prevalence (40.9% vs. 95.5%, P<0.001), and slightly lower sputum eosinophils (7.1% vs. 10.3%, P<0.1) than young adult asthmatics. In addition, the elderly had significantly reduced FEF25-75% (43.1% vs. 61.6%) and FEF25-75/FVC (0.52 vs. 0.72) than the younger subjects at baseline (all P<0.001).

Conclusions: Elderly asthmatics had different phenotypic and pathophysiologic features from young adult asthmatics, suggesting their distinct pathogenic mechanisms and therapeutic considerations.

344 Asthma phenotypes associated with vocal cord/laryngeal dysfunction
Peter Holmes1, Kathy Low1, Kenneth K. Lau2, Marcus Crossett2, Paul M. Leong3, Kais Hamza2, Garun Hamilton1, Philip G. Bardm1, 1Lang and Sleep Medicine, Melbourne, Australia; 2Diagnostic Imaging, Monash Medical Centre, Melbourne, Australia; 3Statistics, Monash University, Melbourne, Australia

Aim: To identify asthma phenotypes in patients with refractory and non-refractory asthma in whom inappropriate vocal cord closure and laryngeal dysfunction (LD) may occur (Low et al., AJRCCM, 2011).

Methods: We evaluated 57 patients with mild to moderate non-refractory asthma (N=31) or refractory asthma (N=26). Dynamic 320 slice computerised tomography (CT) of larynx was done and a validated algorithm was used to accurately measure vocal cord lateral diameter during inspiration and expiration. Excessive narrowing of the airways was diagnosed if a predetermined lower limit of normal was exceeded. The asthma groups were compared by semi-supervised cluster analysis to identify asthma phenotypes associated with laryngeal dysfunction.

Results: Overall vocal cord diameter was reduced below the lower limit of normal in 26 of 57 cases (46%). There was no relationship with asthma severity (LD) in refractory asthma: 12/26 (46%) versus non-refractory 14/31 (45%). Laryngeal dysfunction was associated with increased age (P = 0.034) bronchodilator (BD) responses <12% (P < 0.009) and difficult speech when breathless (P < 0.019). There were 3 unique phenotype clusters associated with abnormal vocal cord narrowing and determinants of cluster membership were:

1. age > 40 years, female, bronchodilator response < 12%, difficult speaking when breathless;
2. age > 40 years, bronchodilator response < 12%, BMI > 30 kg/m²;
3. female, bronchodilator response < 12%, BMI > 30 kg/m².

Conclusion: Our results indicate that vocal cord behaviour is abnormal in asthma, irrespective of severity. However, laryngeal dysfunction may often be associated with particular patient phenotypes and contribute to their overall symptomatic burden of disease.

345 Urinary proteomics in asthma: Search for a biomarker
Scott Elliott1, Jonathan Owen1, Thomas Brown1, Sumita Kerley1, Jan Shute2, Chuanan Aono3, 1Translational Research Laboratory, Queen Alexandra Hospital, Portsmouth, Hants, United Kingdom; 2Institute of Biomedical Science, University of Portsmouth, Hants, United Kingdom

Background: The use of inflammatory indices such as sputum eosinophilia to guide anti-inflammatory treatment in asthma has been shown to reduce the frequency and severity of exacerbations.

Aims: Sputum induction can be unpleasant for patients and analysis is costly and labour intensive necessitating alternative methods to differentiate inflammatory phenotypes, guide anti-inflammatory treatment and predict exacerbation risk.

Method: Performing Surface Enhanced Laser Desorption/Ionisation Time of Flight Mass Spectrometry utilising 6 different "chips" we analysed spectra from 3 groups, the first (exacerbation vs recovery (n=16), second (prospective patient samples thrice weekly, before, during and after an exacerbation (n=5), and third (patients with different inflammatory phenotypes (eosinophilic, neutrophilic, mixed granulocytic and paucigranular) (n=10).

Results: Differential protein signatures were found between inflammatory phenotypes (p<0.05) and between exacerbation and recovery states (p<0.05). The IMAC Cu chip identified a signature which delineated onset, exacerbation and recovery states. Protein signatures were able to distinguish patients in each comparative group (P<0.05).

Conclusion: Further work is warranted with a larger sample size to corroborate our findings and identify the proteins these signatures represent. This may ultimately identify a urinary marker indicating pre-exacerbation states in asthma enabling early intervention.

346 Nasal and bronchial levels of Th2 cytokines correlate during a virus induced asthma exacerbation
David Jackson1, Maria-Belen Trujillo-Torralbo1, Betty Shamsi2, Jerico Del Rosario1, Duncan Hunt3, Toby Hunt1, Trevor Hunt1, Omm Min Kon1, Matt Edwards2, John Westwick1, Trevor Hansel1, Sebastian Johnston1, Respiratory Medicine, National Heart and Lung Institute Imperial College, London, United Kingdom; 2Allergy and Asthma, Novartis Institute for Biomedical Research, London, United Kingdom; 3Sales, Hunt Developments Ltd, Midhurst, United Kingdom

Asthma is a heterogeneous condition and it is vital to accurately predict responders to targeted therapies. However, difficulties in measuring IL5 and IL13 have forced reliance on indirect markers of Th2 inflammation with limited success. Using the human model of experimental rhinovirus (RV) induced asthma exacerbation (AE) and new techniques to absorb nasal (nasosorption) and bronchial (bronchosorption) nasal washings using an aerosolised low volume fluid (MLF), we explored Th2 inflammation during a RV-induced AE.
Methods: 32 mild-to-moderate asthmatics and 14 healthy subjects were inoculated with RV-16. Bronchoscopies were performed 2 weeks prior to inoculation and on day 0 post inoculation. Cytokines were measured in both bronchial and nasal samples at baseline and on day 4 with further nasal sampling on days 2, 3, 5, 7, 10 and 14.

Results: Nasal IL5 and IL13 were significantly increased in asthma during infection compared to baseline (p<0.001) and increased compared to healthy subjects (p<0.01). In the lung, there were relationships between bronchial IL13 (p<0.05) and IL5 (p=0.059) and total chest symptom score in asthma. Nasal IL5 and IL13 correlated with bronchial levels during infection (p<0.01) whilst baseline levels in the max were correlated strongly with infection levels (p<0.001).

Conclusion: RV induced Th2 inflammation correlated with AE severity. Nasal Th2 inflammation correlated with bronchial levels whilst baseline Th2 levels predicted the magnitude of Th2 induction during the AE. Nosocomia is a non-invasive, rapid technique capable of measuring Th2 inflammation directly. It may be possible to use this technique as a biomarker to guide therapy with anti-IL5 and anti-IL13 mAb treatments.

347 The effects of interferon beta on cold-induced asthma exacerbations
Ratko Dikansky1, Tim Harrison2, Philip Monk3, Neil Thomson4, Sebastian Johnston5, Stephen Holgate1, Donna Davies5.
1Southampton NIHR Respiratory Biomedical Research Unit, Southampton, United Kingdom; 2Dept. of Respiratory Medicine, University of Nottingham, United Kingdom; 3Division of Infection, Immunity and Inflammation, University of Glasgow, United Kingdom; 4Research and Development, Synarigen, Southampton, United Kingdom; 5Imperial College NHS Trust NIHR Comprehensive Biomedical Research Centre, Imperial College, London, United Kingdom

In vitro studies show that asthmatic bronchial epithelial cells produce insufficient interferon beta (IFNb) when infected with rhinovirus (RV), whilst exogenous IFNb restores their capability to stop viral replication. This has provided pre-clinical proof of concept. In asthma, IFNb is an attractive candidate for a randomised placebo controlled clinical trial of aerosolised IFNb. The trial involved 21 centres and 147 asthmatics, with the sACQ (shortened Asthma Control Questionnaire) as the primary outcome. Patients commenced treatment at the onset of common cold symptoms and, following baseline assessment, were treated daily for 2 wks with IFNb (6MIU) or placebo.134 patients fulfilled the Jackson criteria for a cold (mITT population): in these, respiratory viruses were detected in nasal lavage by PCR in 63% of patients (68% RV+). In the placebo group, cold symptoms correlated strongly with those of asthma and only patients with difficult to treat asthma (BTS steps 4 and 5) had a clinically relevant (>0.5) increase in sACQ, whilst step 2 or 3 asthmatics did not. In the difficult to treat patients the difference in sACQ during the first week was 0.63 (p=0.004) in favour of treatment and the 5% experiencing an exacerbation was significantly (p=0.012) lower. Treatment with IFNb also resulted in significantly faster recovery of PEF and less use of β2-agonists (p<0.05). This trial suggests that treatment with inhaled IFNb significantly attenuates the adverse effects of the common cold in difficult to treat asthma patients whose needs for such treatment are great. The study provides rationale for follow on clinical trials.

The trial was funded by Synarigen plc and supported by NIHR.

348 Increased cytotoxic T cells, CX3CR1+, γδ and IL17+ T cells in severe asthma during exacerbation
Katie Boskovic-Cavalli1,2, Julie Chesn1, Chantal Belleguec3, Christophe Leroyer1, Hakima Oukel1, Patrice Dio1, Béatrice Guyomarc’h1,2, Antoine Magnan1,1, Inserrm UMR 1087, CNRS UMR 6291, l’Institut du Thorax, CHU de Nantes, Nantes, France; 2CIC 004, l’Institut de l’Infection, Inflammation et Immunité, University of Nantes, Nantes, France; 3Service de Pneumologie, CHU Pontchaillou, Rennes, France; 4Service de Pneumologie, CHU de Breiz, Brest, France; 5Département de Pneumologie, CHU d’Angers, Angers, France; 6Service de Pneumologie, CHU de Tours, Tours, France

Background: Asthma is a chronic inflammatory disease affecting up to 10% of the general population. In most cases, asthma symptoms are controlled by long term treatment without side effects. However, for severe asthmatics, therapy is often insufficient to gain control of the disease and symptoms progress to exacerbations. Recently, T cells populations such as cytotoxic T cells, CX3CR1+, γδ and IL17+ T cells have been correlated to asthma severity. Our aim was to longitudinally study these cell populations in severe asthma, to better understand immune mechanism that underlies exacerbations.

Methods: 23 severe refractory asthmatics were enrolled in the EXPRESSA study, with a mean follow up of 12 months, comparing blood sampling and nasal swab 40 exacerbations were documented. D cell phenotype was assessed by flow cytometry in samples obtained at baseline, before, during and after exacerbations. Viral colonization was also studied in nasal swab by PCR.

Results: We highlight increased cytotoxic T cells (CD8+perforin+), CD4+CX3CR1+, γδ T cells and IL17+ T cells (p<0.03) associated to increased Th2 cells (IL-5) during exacerbation. This increase in inflammatory profile is associated to decreased T regulatory population and Th1 cells (IFN-γ), which appears before exacerbation (p<0.007). Concerning viral colonization, the lack of virus identification failed to separate exacerbations of viral origins from others.

Conclusion: These results defined a T cell activation profile, specific for exacerbation in severe asthma which seems to be crucial for inflammatory response which develops during exacerbation.

349 Mepolizumab (anti-IL-5) reduces exacerbations in patients with refractory eosinophilic asthma
Ian Pavord1, Stephanie Korn1, Peter Howarth1, Eugene Bleeker4, Roland Bühl1, Oliver Kees1, Hector Ortiga1, Pascal Chanez1, 1Institute for Lung Health, University of Leicester NHS Trust, Leicester; 2Leicester University; 3Pulmonary Department, Main; University Hospital, Mainz, Germany; 4Division of Infection, Inflammation and Immunity, University of Southampton, United Kingdom; 5Center for Genomics and Personalized Medicine, Wake Forest University Health Sciences, Winston-Salem, NC, United States; 6Research and Development, GlaxoSmithKline, Stockley Park, United Kingdom; 7Respiratory and Immunoo-Immuno-Inflammation, GlaxoSmithKline, Research Triangle Park, NC, United States; 8Département des Maladies Respiratoires, Université de la Méditerranée AP-HM, Marseille, France

Background: Proof-of-concept studies have shown that mepolizumab reduces eosinophilic airway inflammation and asthma exacerbations in patients with refractory eosinophilic asthma. We investigated the effect of three doses of mepolizumab on asthma exacerbations in a larger population of patients.

Methods: This 52-week randomised, double-blind, placebo-controlled study (NCT01000506) compared mepolizumab (75, 250 and 750 mg; intravenous infusion) with placebo in 616 patients (>12 years) with refractory asthma, ≥2 exacerbations in the previous year and evidence of eosinophilic inflammation. The primary outcome measure was the rate of clinically significant asthma exacerbations; defined as episode of acute asthma requiring use of systemic corticosteroids and/or hospitalisation and/or emergency department (ED) visit. Safety and immunogenicity assessments were also conducted.

Results: The exacerbation rate with placebo (2.4/subject/year) was reduced by 4.8% (75 mg), 5.3% (250 mg) and 7.1% (750 mg) with mepolizumab > placebo (12.2%). No serious life-threatening anaphylactic reactions were reported and the immunogenicity profile was unremarkable.

Conclusion: Mepolizumab, as an add-on therapy in patients with uncontrolled severe refractory eosinophilic asthma, produced a significant reduction in exacerbation rate over one year compared with standard of care, and was generally well tolerated.

69. Asthma and COPD at work: what are the effects of exposure and risk factors?

350 Evolution of immunological occupational asthma depending on the continuation or end of exposure
Xavier Munoz1, Meritxell Viladrich1, Luis Manso2, Victoria del Pozo2, Santiago Quirce2, Maria-Jesus Cruz3, Joaquin Sastre1, 1Respiratory, Hospital Vall d’Hebron, Barcelona, Spain; 2Allergy, Fundacion Jimenez Diaz; 3Allergy, Hospital La Paz, Madrid, Spain

Introduction: It is generally agreed that the best treatment after diagnosis of occupational asthma (OA) is avoidance of exposure to the causal agent. However, recent meta-analyses have raised doubts about this conclusion. The aim of the present study is to assess the evolution of OA depending on whether or not the patient avoids exposure.

Methods: Multicentre, cross-sectional clinical follow-up study in patients diagnosed with OA using a specific inhalation challenge (SIC) between January 2000 and December 2009. Patients with this diagnosis received the following examinations on the same day: clinical interview, physical examination, forced spirometry, methacholine test and determination of total IgE and IgE specific to the causal agent. Clinical improvement, deterioration or no change were defined according to the changes seen in the GINA severity scale at the time of diagnosis.

Results: Of the 73 patients finally included, 55 had totally ended exposure and 18 continued. The mean time elapsed since diagnosis was 48 months (range: 12-123). Forty-two per cent of patients who avoided exposure improved clinically, 38% presented no change, and 14% deteriorated. In the patients who did not avoid exposure improvement was recorded in 22%, deterioration in 17% and no change in 61%. No significant differences in methacholine PC20 or FEV1 were detected between both groups.

Conclusions: Avoiding exposure to the causal agent in patients with OA does not seem to improve prognosis in this disease.

Project partially funded by Ciber de Enfermedades Respiratorias (CibeRes).

**Transfer of wheat allergen and fungal α-amyrase from workplace to home by bakers**

Nara Tagiveya, Siti Amu, Sean Sempie, Dick Finlay, Graham Dereux, Applied Health Sciences, University of Aberdeen, United Kingdom

**Background:** Exposure to flour dust is a leading cause of occupational asthma. Paternal occupational exposure to flour has been associated with childhood asthma, raising the possibility of 'take-home' exposure.

**Aims:** To establish whether workplace contamination of skin/clothing with wheat flour allergen (WFA) and fungal α-amyrase (FAA) is associated with increased levels of these allergens in bakers' homes.

**Methods:** Bakers in north-east Scotland were invited to participate. Controls were recruited from staff students at the University of Aberdeen. Exposure assessment was carried out in bakers' homes using surface wipe and vacuum sampling; samples were analysed for total protein, FAA and WFA.

**Results:** 164 wipe and 49 vacuum samples were collected from 38 bakers (5 bakers and 10 controls). Compared to non-bakers, bakers had higher median levels of FAA and WFA in house vacuum samples; the difference was statistically significant for WFA (total protein 516x10⁻⁶ vs 164x10⁻⁶, p=0.031), FAA (total protein 1.5x10⁻⁷ vs 0.4x10⁻⁷, p<0.001) ratios and FAA loading (median 1.2pg/cm² vs 0.1pg/cm², p<0.001). We found positive correlations between WFA contamination of the bakers' bedrooms and cars (r=0.5, p=0.028), bedrooms and cars (r=0.46, p=0.025), shoes and houses (r=0.45, p=0.029); and between FAA contamination of shoes and houses (r=0.46, p=0.023), and cars and houses (r=0.70, p=0.008).

**Conclusions:** This work demonstrates pathways for 'take home' exposure of occupationally sourced flour. Taken with our previous work, showing that bakers' children are more likely to have asthma, this supports the need for workplace intervention trials to prevent asthma in bakers' children.

### 352

**Incident rhinitis is related to dust and eye exposure among baker's apprentices**

Torben Sigsgaard1, 2, Section of Occupational and Environmental Medicine, Institute of Public Health, Aarhus University, Aarhus, Denmark; 2Dept of Pulmonary Med, Aarhus University Hospital, Aarhus, Denmark

**Background:** Baker's asthma and rhinitis are related to occupational exposure with an exposure-response relationship for prevalence and incidence. This study was a prospective study to estimate: The dose response relation between new onset asthma and rhinitis and the exposure to personal dust and allergens in baker apprentices during their apprenticeship.

**Methods:** Participants were recruited from baker schools. Baker apprentices without previous occupational exposure to dust, flour, rye and wheat were performed 1 or 2 times in each bakery. Cox proportional methods were used to estimate the hazard ratio (HR).

**Results:** We found 42 cases of rhinitis and 27 of asthma like symptoms.

The dust and allergen levels were: Dust Mean (SD) 1.9 (1.6), rye 0.8 (0.7) and wheat 0.8 (0.5) mg/m³

The HR for high exposure to personal dust controlling for atopy was increased for rhinitis, table 1.

**Table 1.** Cox proportional hazard modelling of Rhinitis with exposure to personal dust

We found no association to wheat exposure, but for rye exposure an increased HR for rhinitis symptoms with exposure highest for the 3rd quartile, 2.9 (1.2-7.5) vs 1.6 (0.5-4.8) in the 4th quartile. Only 4 persons developed positive SPT to flour and two to α-amylase during the study.

**Conclusions:** In baker apprentices followed for 36 months, a dose dependent HR for rhinitis symptoms with exposure to dust and rye antigen was seen.

### 353

**Lung function among workers exposed to endotoxins in coffee processing factories**

Gloria Sakwari1, 2, 3, Simon H.D. Mamuya 1, 2, Magne Bråtveit1, Bente E. Moen 1.

1Department of Public Health and Primary Health Care- Section for Occupational and Environmental Medicine, University of Bergen, Hordaland, Norway; 2Department of Occupational and Environmental Health, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of; 3Centre for International Health, University of Bergen, Hordaland, Norway

**Background:** Occupational exposure to endotoxins causes airway diseases and impairs lung function.

**Objectives:** To measure personal total dust and endotoxin levels and to examine lung function among coffee workers in relation to exposure.

**Methods:** All 159 production workers from four Tanzanian factories processing Arabica and Robusta coffee were invited to participate. Personal total dust was sampled throughout the shift using Sidekick Casella pumps (n=193). Cumulative dust was calculated as mean dust exposure multiplied with the number of years in work in the respective coffee factories. Lung function test was carried out using a portable spirometer (SPIRARE3). Differences in groups were tested by independent t-tests. Linear regression was done to adjust for confounders; age, height and smoking.

**Results:** Robusta (n= 74) and Arabica (n=66) coffee workers had a mean age of 33 years and 38% were current smokers. Total dust levels and endotoxins were significantly higher in the Robusta factories (geometric mean 3.4 mg/m³ and 10800EU/m³, respectively) than in the Arabica coffee factories (2.10 mg/m³ and 1400EU/m³). Mean cumulative dust in both groups was 17mg/m³.

**Conclusion:** Exposures to dust and endotoxins in coffee processing factories are high and might cause decreased lung function.

### 354

**Occupational exposure and lung function in a Dutch general population cohort**

Kim de Jong1, 2, 3, H. Marrie Boezen 1, 3, Hans Kronhout 2, Roel Vermeulen 1, Dirkje S. Postma 1, 2, Judith M. Vink 1, 2, 3 Division of Epidemiology, University of Groningen, University Medical Center Groningen, Netherlands; 2GRIAC Research institute, University of Groningen, University Medical Center Groningen, Netherlands; 3Division of Environmental Epidemiology, Institute for Risk Assessment Sciences (IRAS), University of Utrecht, Netherlands; 4Department of Pulmonary Diseases, University of Groningen, University Medical Center Groningen, Netherlands

**Background:** Occupational exposure to vapors, gases, dusts, fumes (VGFD) has been associated with lower lung function, with more pronounced effects in smokers. Less is known about occupational exposure to pesticides, solvents and heavy metals in relation to lung function. We assessed whether these agents negatively affect lung function in a general population cohort.

**Methods:** We included 8,128 subjects aged 18-89 from the LifeLines cohort study (n=2,669 males). Occupational exposures (no/low/high) for current or last held job were estimated with the ALOHA+ Job Exposure Matrix. Associations between exposure and FEV1 were assessed using linear regression, adjusted for sex, age, height, weight and smoking. Additionally we stratified for gender and smoking status.

**Results:** Males were more often exposed than females. VGFD and pesticides had a negative dose-response effect on FEV1 (table 1). Effects were more pronounced in males and ever smokers.

**Table 1.** Associations between exposure and FEV1 (ml) (reference = no exposure)

**Conclusion:** This study confirmed current knowledge on the detrimental effects of occupational VGFD exposure on lung function, especially in males and ever smokers. Additionally we show negative effects of pesticide exposure on lung function.

### 355

**Cross-shift change and subsequent longitudinal changes in FEV1 in a 6 year follow-up study of wood dust exposed workers**

Trine Jacobsen1, 2, Vivi Schlünssen1, Inger Schauhammer1, Torben Sigsgaard1, 2, Sean Semple, Dick Finlay, Graham Devereux, 1Department of Public Health, Section of Environmental and Occupational Medicine, Aarhus University, Aarhus, Denmark; 2Department of Occupational Medicine, Herning Hospital, Herning, Denmark; 3Neuro Centre, Aarhus Sygehus, Aarhus University Hospital, Aarhus, Denmark

**Objective:** Cross-shift lung function (LF) changes might predict an accelerated decline in LF. This study investigates the association between cross-shift and annual changes in FEV1 among woodworkers in a 6-year follow-up study.
Methods: 817 woodworkers and 136 controls participated with cross-shift changes of FEV1 at baseline and FEV1 and FVC at follow-up. Height and weight were measured and questionnaire information on respiratory symptoms, employment and smoking habits were collected. Wood dust exposure was assessed from 3,572 personal dust measurements at baseline and follow-up. Cumulative wood dust exposure was assessed by a study-specific job exposure matrix and exposure time.

Results: The median (range) of inhalable dust at baseline and cumulative wood dust exposure was 1.0 (0.2-9.8) mg/m³ and 3.8 (0.7-1.1) mg*year/m³ respectively. Mean (SD) for %ΔFEV1/workday and ΔFEV1/year was 0.2 (6.0)% and -29.1 (41.8) ml. Linear regression models, adjusting for smoking, sex, age, height and weight change revealed no association between cross-shift and annual change in FEV1 (table 1). Including different exposure estimates, atopy or cross-shift change dichotomized or as quartiles did not change the results.

Table 1. Linear regression on the association between longitudinal and cross-shift change in FEV1

</table>
| N=881, Model is adjusted for sex, age, height and weight gain. *Cumulative wood dust exposure.

Conclusion: This study among low exposed woodworkers does not support an association between cross-shift changes and accelerated LF decline.

356 Associations between occupational exposure and quantitative computed tomography (CT) measures of emphysema

Tilde Skorle1, Øistein Svanes2, Ane Johannessen3, Thomas Grydeland2,4, Harvey Coxon5,6, Anund Gulsvik7,8, Per Bakke2,4, Department of Occupational Medicine, Haukeland University Hospital, Bergen, Norway; 3Department of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway; 4Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway; 5Institute of Medicine, University of Bergen, Norway; 6Department of Radiology, University of British Columbia, Vancouver, Canada; 7James Hogg icAPTURE Centre for Cardiovascular and Pulmonary Research, Vancouver General Hospital, Vancouver, Canada

Rationale: There is limited knowledge of the effect of occupational exposure on quantitative CT measures of emphysema.

Objectives: To examine the effect of occupational exposure assessed by a job exposure matrix (JEM) on QCT measures of emphysema.

Methods: In the Norwegian GenKOLS study 2003-05, 951 ever-smokers (49% with COPD) aged 40-85 years performed spirometry and CT examination. 941 of them completed a full occupational history. In the current study a JEM was used to assess occupational exposure, and CT measured emphysema (% low-attenuation areas, %LAA) was the main outcome. Quantile regression analyses were used for the multivariate analyses, adjusting for sex, age, smoking, inflation level and FEV1% of predicted.

Results: Quantile regression analyses showed significant associations between occupational exposure to gas/fumes and mineral dust, and %LAA. The unadjusted regression coefficients for %LAA for subjects with occupational exposure in the longest held job, were 0.95 and 1.21 for low and high exposure to gas/fumes, and 1.16 and 1.98 for low and high exposure to mineral dust. For those with low and high exposure to gas/fumes and mineral dust in their latest job, the regression coefficients were 0.90, 1.19, 1.09 and 1.51 respectively. After adjustments, the association's only remained statistically significant for subjects exposed to high levels of gas and fumes in their latest held job.

Conclusions: Subjects with high levels of occupational exposure to gas/fumes in their latest job were found to have higher levels of CT measured emphysema compared to subjects with low or no exposure. A dose-response relationship was suggested.

357 Anti-IgE treatment: An alternative for severe allergic occupational asthma

Francois Lavaud, Gérard Pfeiffer, Philippe Bonniaud, Jean-Charles Dalphin, Christophe Lereyre, Dominique Muller, Gilles Mangiaux, Frédéric de Blay, Hôpital Maison Blanche, University Hospital, Reims, France Department of Internal Medicine and Pulmonology, Hospital of Bon-Secours, Metz, France Hôpital du Bocage, University Hospital, Dijon, France Hôpital Jean Minjoz, University Hospital, Besançon, France Hôpital Hôtel die la Cavale Blanche, University Hospital, Brest, France Medical Office, Medical Office, Montigny les Metz, France Pneumology and Occupational Disease, Hospital, Créteil, France Medical Office, Medical Office, Montigny les Metz, France Hospital, Besançon, France Hôpital de la Cavale Blanche, University Hospital, Reims, France Department of Chest Diseases, University Hospital, Strasbourg, France

Severe work-related asthma remains a difficult problem and new alternative treatment must be evaluated to obtain asthma control and ideally the sustain of the occupational activity.

During 2 years we have enrolled 10 occupational asthmatics (8 men, 2 women, mean age 37, suffering of asthma from 0.5 to 8 years). They were all severe uncontrolled asthmatics (GINA recommendations). The mean dose of inhaled corticosteroids was 3200 μg/day of beclometasone equivalent. All patients had 2 to 8 severe exacerbations/year. Six patients were allergic to a high molecular weight agent (wheat flour: 2, cat: 1, rabbit: 1, storage mites: 1, Alternaria: 1). In 4 patients the causative agent was a low molecular weight compound (isocyanates in 2 cases, acrylates one case, peracetic ethylene one case). Total IgE levels were always above 30 U/mL. The follow-up was performed from 6 to 48 months. Asthma parameters and the occupational status were registered every 6 months.

Results showed a reduction of severe exacerbations in 9 patients. Only one patient was “non responder” after 6 months of treatment. In the 9 “responders” an optimal control could be obtained in 4 patients. Oral daily corticosteroids could be decreased in the 5 (mean initial dose 8.6 mg/day to 1.2 mg/day of equivalent prednisone). Days off-work because of asthma were reduced in the 9 “responders”. 7 could continue to work with amendment of the working place. We suggest that omalizumab could be a potential treatment for severe uncontrolled work-related asthma in 3 conditions, patients who were unable to avoid allergen exposure, persistent asthma after cessation of the offending exposure and work-aggravated asthma symptoms in workers with pre-existing allergic asthma.

70. Mechanisms of asthma

358 The role of histone deacetylase 9 in the imbalance of Th17/Treg in bronchial asthma

Trude Skorle1, Øistein Svanes2, Ane Johannessen3, Thomas Grydeland2,4, Harvey Coxon5,6, Anund Gulsvik7,8, Per Bakke2,4, Department of Occupational Medicine, Haukeland University Hospital, Bergen, Norway; 3Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway; 4Institute of Medicine, University of Bergen, Norway; 5Department of Radiology, University of British Columbia, Vancouver, Canada; 6James Hogg icAPTURE Centre for Cardiovascular and Pulmonary Research, Vancouver General Hospital, Vancouver, Canada

Rationale: Studies have shown that histone deacetylase 9 can affect Tregs function and histone deacetylase inhibitor can inhibit conversion of Tregs into IL-17-producing cells.

Methods: GATA3, IL-4 and HDAC9 mRNA expression level were measured by SYBR Green RT PCR. IL-17 and TGF-β were measured by ELISA. BALB/c mice were randomly divided into three groups, the control group, asthma model group and TSA group. The mice in TSA group were given TSA (1mg/kg) s.p. every other day during sensitization and challenge. The plasma IgE measured by ELISA, observed the inflammation by HE staining, HDAC9, RORγt and Foxp3 mRNA expression in lung tissue were measured by PCR.

Results: HDAC9 mRNA expression was associated with severity of disease (p<0.01). HDAC9 mRNA expression was correlated with GATA3 mRNA expression positively (p<0.01, r=0.482), the same with IL-4 mRNA expression (p<0.01, r=0.432) and IL-17 (p<0.01, r=0.538), but negatively correlated with TGF-β (p<0.01, r=-0.417). In patients with moderate-severe asthma, HDAC9 mRNA expression was negatively correlated with FEV1% (p<0.01, r=-0.657).

Figure 1. HDAC9 mRNA expression was associated with severity of disease.

Conclusions: The relationship between expression of histone deacetylase 9 and imbalance of Th17/Treg has been confirmed in asthma. The histone deacetylase inhibitor TSA can control asthma by regulating activity of histone deacetylase.
Spu...the FEV1 response to oral steroids in non-smokers with asthma. Charl...sputum IL-1RA. We suggest that smoking establishes and aggravates the asthmatic phenotype in mice.

Methods: Sputum was induced from 31 non-smokers and 22 smokers with asthma. Endotoxin was quantified by ELISA (LAL-QCL®, Lonza Biologics plc) and cytokines by luminex (InVitrogen). Spriometry and exhaled nitric oxide measurements were recorded. The response to oral dexamethasone was the change in FEV1, compared with baseline.

Results: Smokers had improved FEV1 after steroids; p<0.015, but smokers were refractory; p=0.591. The steroid response decreased with increasing sputum endotoxin in non-smokers; r=0.479, p<0.015, but not in smokers; r=0.126, p=0.585.

Conclusions: Higher endotoxin in sputum fluid was associated with an impaired FEV1 improvement after steroids only in non-smokers; and was associated with decreased sensitization towards inhaled allergens. Inhalation of DEP increases pulmonary dendritic cell (DC) accumulation and enhances TH2 responses in mediastinal lymph nodes. In inflammatory conditions, DC recruitment is mediated by different CC chemokine receptors (CCR). We hypothesized that CCR2 mediates DC recruitment and TH2 responses upon DEP exposure.

Methods and results: WT and CCR2 KO mice were exposed to saline or DEP, followed by immunological examination. DEP exposure increased pulmonary expression of CCR2 and MCP-1 in WT mice. Exposure induced a pulmonary recruitment of monocytes and inflammatory (CD11b+) DCs in WT mice, which was abolished in CCR2 KO mice. Adoptive transfer of fluorescently labeled bone marrow derived cells from WT and CCR2 KO mice demonstrated the direct involvement of CCR2 in recruitment of blood monocytes towards the lung upon DEP-exposure. Furthermore, analysis of TH2 cytokine production in mediastinal lymph nodes upon DEP-exposure showed an abolished TH2 response in CCR2 KO mice.

Conclusion: These data suggest that monocyte-derived DC, recruited in a CCR2-dependent manner, are critical in inducing TH2 responses upon DEP inhalation.

LSC 2012 Abstract – Monocyte-derived dendritic cell recruitment and allergic TH2 responses after exposure to diesel particles are CCR2-dependent

Tania Mancini, Shaen Provost, Guy Joos, Kourtney Dept. of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium

Background: Diesel exhaust particles (DEP) inhalation is associated with increased sensitization towards inhaled allergens. Inhalation of DEP increases pulmonary dendritic cell (DC) accumulation and enhances TH2 responses in mediastinal lymph nodes. In inflammatory conditions, DC recruitment is mediated by different CC chemokine receptors (CCR). We hypothesized that CCR2 mediates DC recruitment and TH2 responses upon DEP exposure.

Methods and results: WT and CCR2 KO mice were exposed to saline or DEP, followed by immunological examination. DEP exposure increased pulmonary expression of CCR2 and MCP-1 in WT mice. Exposure induced a pulmonary recruitment of monocytes and inflammatory (CD11b+) DCs in WT mice, which was abolished in CCR2 KO mice. Adoptive transfer of fluorescently labeled bone marrow derived cells from WT and CCR2 KO mice demonstrated the direct involvement of CCR2 in recruitment of blood monocytes towards the lung upon DEP-exposure. Furthermore, analysis of TH2 cytokine production in mediastinal lymph nodes upon DEP-exposure showed an abolished TH2 response in CCR2 KO mice.

Conclusion: These data suggest that monocyte-derived DC, recruited in a CCR2-dependent manner, are critical in inducing TH2 responses upon DEP inhalation.

Cigarette smoke exposure facilitates allergenic sensitization to house dust mite and aggravates the asthmatic phenotype in mice

Ellen Lückacker,1 Kurt Tournay,2 Gabrielle Holtappels,1 Hamida Hammad,3 Bart Lambrecht3, Guy Joos1, Tania Mancini1.1Laboratory for Translational Research in Obstructive Pulmonary Diseases, Ghent University, Ghent, Belgium; 2Department of Oto-Rhino-Laryngology, Ghent University, Ghent; 3Laboratory of Immunoregulation and Mucosal Immunology, Ghent University, Ghent, Belgium

Background: Cigarette smoke (CS) exposure has been associated with increased sensitization towards allergens in development in children and adults.

Aims and objectives: We wanted to design a novel mouse model to unravel the impact of CS on the different stages of asthma pathogenesis, specifically during the initial sensitization and acute asthma development.

Methods: Mice were exposed to 25 g house dust mite (HDM) extract (intranasally, i/week) for 3 consecutive weeks, combined with air or CS exposure (3 times/day, 3 days/week) during 3 weeks or only during the first week.

Results: Mice concomitantly exposed to HDM and CS for 3 weeks, showed a significant increase in eosinophils, goblet cells, airway hyperresponsiveness and HDM-specific serum IgG1, compared to sole HDM or CS exposure. Interestingly, exposure to CS only during the first week was sufficient to induce an aggravated asthmatic phenotype after rechallenge with HDM allergens. To further investigate the effect of CS during mucosal sensitization, mice were exposed to HDM (just once) and 3 days of CS, followed by the assessment of DC trafficking and early TH2 responses in the lymph nodes. This CS exposure amplified DC-mediated transport of HDM allergens to the lymph nodes and was sufficient to generate a TH2 response, characterized by IL-4, IL-5 and IL-13 production in the draining lymph nodes.

Conclusions: CS facilitates the development of HDM-induced allergic asthma. Only a few days of smoke exposure are sufficient to facilitate allergic sensitization to common aeroallergens.

Increased numbers of alveolar mast cells with an altered phenotype are linked to peripheral airway remodelling in patients with allergic asthma

Cecilia Andersson1, Maria Werstoft Lundström2, Anders Bergqvist1, Michiko Mori1, Leif Bjørner1, Gunilla Westergren-Thorsson2, Jonas Erjefält3.1Dept. of Respiratory Medicine & Allergology, Lund University, Lund, Sweden; 2Lund University, Lung Biology Unit, Lund, Sweden; 3Lund University, Unit of Airway Inflammation, Lund, Sweden

Background: A significant proportion of asthmatics have symptoms despite treatment with inhaled corticosteroids. Recent studies have revealed an expansion of highly FcεRI-expressing alveolar mast cells (MCs) in asthma. The aims were to further phenotype alveolar MCs and explore their connection to peripheral tissue remodelling in different asthma cohorts.

Methods: Bronchial and transbronchial biopsies from controls, patients with rhinitis, mild and uncontrolled asthma were processed for immunohistochemical identification of MC subtypes and expression of pro-fibrotic markers. MC alteration in relation to tissue remodelling (density of collagen, versican, decorin and high affinity IgE receptors) in peripheral lung was studied.

Results: The alveolar parenchyma (AP) in uncontrolled asthmatics had increased densities of MCε (p=0.05) and MC1 (p=0.003). The expression of FcεRI on alveolar MCs was increased in mild (p=0.01) and uncontrolled (p<0.001) asthma compared to controls. The density of collagen (p=0.01) and decorin (p=0.03) was significantly increased in AP of uncontrolled asthmatics compared to controls. The number of alveolar MCε in the uncontrolled asthma was positively correlated to the density of collagen in the AP (r=0.71, p=0.03). MCs in the AP of asthmatics expressed increased levels of pro-fibrotic markers.

Conclusions: Our data show that the alveolar region in patients with asthma is infiltrated by activated MCs that correlate to increased alveolar matrix deposition. This may reflect an important involvement of MCs in the peripheral inflammation in asthma and underscores the need to target peripheral lung inflammation in this patient group.
Mucosal explant induced migration of T-cells from severe asthmatics is inhibited by CCR4 antagonism

Thomas Southworth,1 Anna Kuklinska-Pijanka,1 Justyna Sutula,1 Paul Cadden,1 Simon Hodgson,2 David Hall,2 Dave Singh.1 1NIHR Translational Research Facility, The University of Manchester, United Kingdom; 2Respiratory Therapy Area Unit, GlassonSmithKline, Stevenage, United Kingdom

Background: Th2 cells that express chemokine receptor 4 (CCR4) are key to inflammation in asthma. Work in mild asthma patients suggests that CCR4 plays a role in Th2 migration into the lung, making CCR4 a possible therapeutic target. However, little evidence is known on the role of CCR4 on Th2 migration in severe asthma patients on high dose corticosteroids.

Aim: To investigate if chemokines released by mucosal explants, from asthma patients on high dose inhaled corticosteroids, drive Th2 migration and if such a response is CCR4 dependent.

Methods: Bronchial explants, from 11 severe (SA) and 9 steroid naive (SNA) asthma patients, were cultured in media +/- house dust mite extract. The supernatants were used as chemotacticants in migration assays with patient-matched peripheral T-cells. The effects of CCR4 antagonist, GSK494652A, GSK2239633A and GSK2192991A, on T-cell migration were examined.

Results: Bronchial explant conditioned media from SNA induced higher T-cell migration than that from SA (p=0.03). However, house dust mite extract did not enhance chemotaxis in either SNA (p=0.9) or SA (p=0.6). Inhibition of CCR4 reduced T-cell migration in response to unstimulated explanted conditioned media (Table 1).

Control vs CCR4 antagonist: *p<0.05.

Conclusions: Targeting CCR4 may prove to be effective in reducing Th2 recruit-ment into the lung and the subsequent inflammatory response in asthma patients who are on high dose inhaled corticosteroid treatment.

Pulmonary arterial hypertension (PAH) is a rare disease that must be managed in specialized centers integrated in a national network. Availability of epidemiological national data is critical for planning and regulation of healthcare in this field. We conducted a prospective, observational and multicenter registry in 5 portuguese centers. Adults with PAH and chronic thromboembolic PH (CTEPH) confirmed by right heart cath (RHC) were included. Seventy-nine patients were enrolled; 46 (58.2%) classified as PAH and 33 (41.8%) as CTEPH. PAH patients had a mean age of 43±16.4 years and the I/E ratio 1.9±1.1. Idiopathic PAH was present in 17 (37%) patients, followed by connective tissue disease (n=12, 26%), congenital heart disease (n=10, 22%), portopulmonary (n=5, 11%), heritable (n=1, 2%) and other etiologies (n=1, 2%). At baseline most patients were WHO class III or IV (71%). Baseline RHC: elevated RAP (7.7±5.9 mmHg), mPAP (50.6±17.9 mmHg) and mean PVR (11.4±6.5 WU Wood), with a low CI (2.7±1.1 L.min-1.m-2). At baseline patients were medicated with conventional therapies; at follow-up, most were on single (50%), double (28%) or triple (9%) combination of specific therapy. 1-year survival was 93.5%. CTEPH patients were older (60±12.5 years) and had higher RAP (11.0±5.2 mmHg, p=0.015), but 1-year survival (93.9%) was similar to PAH patients. Five CTEPH patients underwent pulmonary endarterectomy. We estimated an annual incidence of 1.5 and 1.1 per million in PAH and CTEPH, respectively.

Our report describes nationwide data on the diagnosis, management and clinical course of groups 1 and 4 PH patients. Clinical presentation, hemodynamics and survival are comparable with those reported on other national registries.

Pulmonary hypertension in patients with lupus: Prevalence, etiology and risk factors

Fernando Leão1,2, Gregorio Pérez-Peñate1,3, J. Navarro1,4, Gabriel Juliá1,2,3,4, António García1,2, Carlos Cabrera1, Pedro Cabrera1, Nazario Ojeda1,2, Juan Pulido1,4, Ilídio Rúa Figueroa1,5,1, Pneumology, Hospital Universitario Dr. Negrín, Las Palmas de Gran Canaria, Spain; 2Cardiology, Hospital Universitario Dr. Negrín, Las Palmas de Gran Canaria, Spain; 3Anesthesiology, Hospital Universitario Dr. Negrín, Las Palmas de Gran Canaria, Spain; 4Vascular Radiology, Hospital Universitario Dr. Negrín, Las Palmas de Gran Canaria, Spain; 5Rheumatology, Hospital Universitario Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: Pulmonary arterial hypertension has been reported between 0.5 and 14% in systemic lupus erythematosus (SLE). Objectives: To assess PH prevalence, etiology and risk factors in a SLE cohort. Methods: Prospective cross-sectional study of 158 SLE patients. Doppler echocardiographic (DE), diffusion capacity for CO (DlCO), NiprodBNP and dyspnea (Borg scale) were performed in all patients. An echocardiographic exercise test (EE) was conducted in selected patients. When a PAP ≥ 45 mmHg (DE) or a positive EE (>20 mmHg increase in PAPs) a right heart catheterization (RHC) at rest or during exercise was performed. A rest mean pulmonary pressure (mPAP) ≥25 mmHg was accepted as PH. When rest mPAP was less than 25 mmHg, an exercise test was conducted. Patients with resting PH (mPAP ≥ 35 and < 45 mmHg) and obvious cardiac disease were excluded from RHC.

Results: Mean age: 45±12.9 years, 94.3% females. Twenty one patients (13.4%) had dyspnea (Borg scale ≥ 2). Eleven patients (6.9%) showed any degree of PH. Eight patients (out of 11) had PH of left cardiac origin. One patient had thromboembolic disease. Two patients had precapillary PH related with SLE. All 11 patients with PH had dyspnea (Borg scale ≥ 2) vs. those without PH (p<0.001). PH patients showed a significant decrease in DlCO and higher NiprodBNP. There were no differences in SLE clinical characteristics between SLE patients and those without PH. Conclusions: Our data confirm the low prevalence of precapillary PH in SLE. We found a predominance of cardiac etiology. A PH screening program based on DE, NiprodBNP and DlCO does not seem to be cost-effective and should be restricted to SLE patients with unexplained dyspnea.
External validation of the French predictive model to estimate PAH survival: A REVEAL analysis

A French pulmonary hypertension network analysis

Conclusion: The FPHN equation accurately stratified a matched US population according to risk, suggesting its prognostic generalizability in PAH pts.

Introduction: The French Pulmonary Hypertension Network (FPHN) and Registry to Evaluate Early And Long-term Pulmonary Arterial Hypertension (PAH) Disease Management (REVEAL) recently developed models to predict survival in PAH patients (pts).

Aims and objectives: The FPHN equation was tested in a REVEAL cohort to assess its generalizability in a different PAH population.

Methods: The REVEAL validation cohort had 436 recently diagnosed (<1 year before enrollment), treatment-naïve, ≥18-year-old patients (pts) with idiopathic, familial, or anorexigen-induced PAH, divided into subgroups with non-missing (n=292) and missing (n=144) data for all FPHN equation parameters.

Results: The FPHN and REVEAL cohorts had similar characteristics. FPHN (n=292) and missing (n=144) data for all FPHN equation parameters.

Conclusion: The FPHN risk score calculator was accurate and well calibrated in the FPHN, suggesting its prognostic generalizability in a different PAH population and in everyday clinical practice.

Introduction: Pulmonary arterial hypertension (PAH) is a disease affecting the vasculature of the lung and is known to decrease carbon monoxide diffusion
capacity (DLCO). Although most patients have a moderately decreased DLCO, a group of patients has severely reduced DLCO. The reason for this low DLCO is unclear. Therefore, the aim of this study is to describe baseline characteristics of idiopathic PAH patients with a low DLCO and compare this group with a group of idiopathic PAH patients with moderate low or normal DLCO.

**Methods:** Patients with idiopathic or familial PAH were included. Patients were grouped based on the finding of a bimodal distribution in DLCO-values.

**Results:** A total of 170 patients were included. DLCO groups were DLCO < 45% (N=58) and ≥ 45% of predicted (N=112). Group characteristics are shown in table 1.

**Conclusions:** Compared with IPAH patients with moderate low or normal DLCO, IPAH patients with a severely reduced DLCO were characterized at baseline by a higher age, increased number of males, more often a history of smoking and coronary disease, and a lower exercise performance. No differences however were found in hemodynamic parameters.

371 'Idiopathic' pulmonary arterial hypertension with preserved lung function but co-existing parenchymal abnormalities: Response to treatment and survival

**Methods:** Methods: All incident cases of IPAH with and without co-existing CT abnormalities diagnosed between January 2001 to December 2009 in all eight PH centres in the UK and Ireland were included. All patients have FEV1, FVC and/or TLC ≥ 60% predicted.

**Results:** Table 1. Baseline characteristics, 6MWD and survival of IPAH

**Conclusion:** Despite similar baseline haemodynamics and response to treatment, survival of IPAH with coexisting parenchymal abnormalities appears worse compared with IPAH without parenchymal abnormalities. Age and age related co-morbidities may account for the difference in long term outcome between the 2 groups.

372 Hepatopulmonary syndrome: Long-term survival in the Mayo Clinic experience

**Methods:** Survival was assessed using Kaplan-Meier methodology for 106 HPS patients from 1986 through 2010.

**Results:** 49 HPS patients underwent LT Post-LT survival (1, 3, 5 and 10 year) did not differ between groups based on PaO2 at the time of HPS diagnosis. Improvements in overall survival at 1, 3 and 5 years post-LT in those HPS patients transplanted after 2002 (MELD exception era, n=28) (92, 87 and 87%, respectively) as compared to those transplanted prior to that time (pre MELD era, n=21) (71, 67 and 67%, respectively) did not reach statistical significance (P=0.09) (figure 1). Model for Endstage Liver Disease (MELD) exception to facilitate LT was granted to 18 patients since 2002 with post-LT survival of 15/18 patients (83%) and no wait-list mortality.

373 Survival in patients with different groups of pulmonary hypertension

**Methods and results:** Every consecutive patient undergoing right heart catheterization with proven PH was included in the Giesies registry from 1994 to 2011. Differences in survival between the etiological groups were highly significant (p<0.001), with 1-, 3-, and 5-year survival rates of 88.2%, 72.2%, 59.4%, respectively in pulmonary-arterial hypertension (PAH, N=685) as compared to 79.5%, 52.7%, and 38.1%, respectively in lung disease associated PH (PH-LD, N=546). Chronic thromboembolic pulmonary hypertension (CTEPH, N=449) had the best survival rates with 89.2%, 77.4%, and 66.7%, pulmonary venous hypertension (N=307) was intermediate. Age also differed between the groups: mean age at diagnosis was 51.3 (PAH), 67.0 (PVH), 63.7 (LD-PH), 61.9 (CTEPH) years, respectively. In multivariate analysis, age, gender, NYHA functional class, uric acid, urea, brain natriuretic peptide, heart rate, sodium, six-minute walk test distance, cardiac output, and systolic blood pressure at baseline were significantly associated with survival.

**Conclusions:** In this report we present data on long term survival and its determinants from patients with pulmonary hypertension mostly focus on the subgroup of pulmonary arterial hypertension (PAH). Data on other subgroups is rare.

374 Survival after liver transplantation with hepatopulmonary syndrome

**Methods:** Several markers have been suggested to be associated with severity and/or prognosis of disease in patients with pulmonary hypertension (PH). Reports on survival and its determinants in patients with pulmonary hypertension mostly focus on the subgroup of pulmonary arterial hypertension (PAH). Data on other subgroups is rare.
# 72. Functional imaging of the lung parenchyma, tumours and circulation

## 374

**Quantifying lung function in COPD with hyperpolarised ³He MRI**

*Samuel Jandlett*, Helen Marshall, Martin Deppe, Cath Billings, Juan Parra-Robles, Sue Hiliis, Sam Miller, David Lipson, Jim Wild, Rod Lawson, Academic Radiology, University of Sheffield, United Kingdom; Respiratory Medicine, Sheffield Teaching Hospitals NHS Trust, Sheffield, United Kingdom; GlaxoSmithKline, GlaxoSmithKline, King of Prussia, United States

**Introduction:** Hyperpolarised ³He MRI can identify regional lung defects and has been found more sensitive than spirometry to early changes in smokers lungs. We aim to quantify change in lung function in response to bronchodilator in COPD using ³He MRI.

**Method:** 10 patients with moderate to severe COPD (per NICE) were scanned pre and post bronchodilator at FRC+1L. Lung volume (LV) was defined by region growing algorithms (Slicer 3D, Harvard) on conventional ¹H MRI. Ventilated volume (VV) was defined by a threshold on ³He MRI. Percentage ventilation (PV) was defined as VV/LV. Lungs were segmented into 4 regions on each slice with large airways removed.

**Results:** Change in ventilation, including recruitment of newly ventilated areas, was seen post treatment.

**Conclusions:** Global MRI measures and spirometry simplify lungs to one unit. Regional analysis showed patterns of change in different lung areas which may be hidden in global measures. FEV₁% significantly increased post treatment (p<0.02) suggesting geographical variation of lung recruitment significantly affects FEV₁, as opposed to global change in gas flow.

## 375

**MRI of delayed-ventilation perfusion matching in COPD**

*Helen Marshall*, Martin Deppe, Juan Parra-Robles, David Lipson, Rod Lawson, Academic Radiology, University of Sheffield, United Kingdom; Respiratory Medicine, Sheffield Teaching Hospitals NHS Trust, Sheffield, United Kingdom; GlaxoSmithKline, GlaxoSmithKline, King of Prussia, United States

**Introduction:** Delayed ventilation in COPD may be caused by collateral ventilation, partial obstruction, lung hyperinflation or a mixture of such mechanisms, and allows initially-unventilated lung regions to become ventilated over time. Recently hyperpolarised gas MRI has been used to directly visualise delayed and collateral ventilation in COPD over the period of a single breath-hold. Delayed ventilation will only contribute to gas exchange if there is blood perfusion in these regions.

**Objective:** To image the perfusion matching of lung regions with delayed ventilation in COPD.

**Methods:** Ten patients with moderate to severe COPD as defined by NICE guidelines were scanned using ³He and proton MRI. Delayed-ventilation images were acquired at six time-points during a single breath-hold.

**Results:** Regions of delayed-ventilation were perfused in some cases and were not perfused in others giving an indication of which areas remained active in gas exchange.

**Conclusions:** Hyperpolarised gas and proton MRI allow the visualisation of ventilation and perfusion matching, and may aid in the understanding of delayed-ventilation in COPD and its role in gas exchange.

Lung qS0 maps were reproducible with reduced values seen in regions comparable to CT detected emphysema regions. The mean and 15th, 50th, 75th percentile qS 0 value of 378 0.4 ml/g in UL and 0.6 ±0.3 ml/g in LL; 3) of the 4D-CT dataset was registered onto the reference (phase 0, i.e. end inspiration) and compared with the patients' diagnosis. In addition of the comparison of the parameters between the groups, Receiver Operating Characteristics analysis was used to assess sensitivity, specificity, positive predictive value, negative predictive value of EP and MP parameters.

Results: Most of the malignant nodules showed stronger enhancement with higher EP and MP values. There were significant differences between benign and malignant lesions. Sensitivity, specificity, positive predictive value and negative predictive value were 75%, 93%, 92% and 76% for EP and 93%, 86%, 88% and 95% for MP, respectively.

Conclusion: A combination of kinetic and morphological evaluation in dynamic MRI provided accurate differentiation between benign and malignant pulmonary lesions. It was a useful and noninvasive method of evaluating pulmonary nodules.

Key Words: Pulmonary nodules, dynamic MRI, kinetic parameters.

380 Non-invasive estimation of pulmonary artery pressure and resistance with CMR imaging: Derivation and prospective validation cohort study

Andrew Swift1, Smitha Rajaram1, David Capener1, Allison Morton2, Charlie Elliot2, Robin Condliffe2, Jim Wild3, 1Academic Unit of Radiology, University of Sheffield, South Yorkshire, United Kingdom; 2Academic Unit of Radiology, University of Sheffield, South Yorkshire, United Kingdom; 3Department of Cardiac Surgery, University of Sheffield, South Yorkshire, United Kingdom.

Background: The role of the right atrium (RA) is under-researched within pulmonary hypertension (PH). The aim of this study was to develop a cardiac magnetic resonance (CMR) imaging model for non-invasive estimation of mean pulmonary arterial pressure (mPAP) and total pulmonary resistance (TPR).

Methods: A derivation cohort of 64 consecutive patients with known or suspected pulmonary hypertension underwent right heart catheterization (RHC) and CMR within 12 hours. Cardiac volumes and function and pulmonary arterial (PA) flow were quantified. The strongest statistical model to predict mPAP from the derivation cohort was identified. Total pulmonary resistance (TPR) was estimated utilising the physiological model: TPR= pressure (CMR-derived mPAP) divided by flow (CMR-derived PA flow).

An independent prospective validation cohort of (n=40) tested the accuracy of the model.

Results: The multivariate regression CMR model gave the following equation: mPAP = 33.4 + [right ventricular end-diastolic mass index (g/cm²) x 1.21] – [PA average velocity (cm/s) x 0.99]. In the prospective validation cohort, predicted and invasively measured mPAP were strongly correlated (R²=0.74; p<0.0001). For detection of mPAP ≥ 25mmHg the area under the receiver operator curve (ROC) was 0.91 (p<0.0001). CMR-estimated TPR correlated strongly with RHC-derived TPR (R²=0.75; p<0.0001) in the validation cohort. CMR estimated TPR reliably identified TPR > 5WU with a high degree of accuracy, the area under the receiver operator curve (ROC) was 0.96 (p<0.0001).

Conclusions: A CMR Imaging derived model can accurately estimate mPAP and vascular resistance in patients with PH.

381 MRI assessment of right atrial volume and function in pulmonary hypertension

Thomas Sproson, Andrew Swift, Smitha Rajaram, David Capener, David Kiely, Robin Condliffe, Charlie Elliot, Jim Wild, 1Academic Unit of Radiology, University of Sheffield, South Yorkshire, United Kingdom.

Background: The role of the right atrium (RA) is under-researched within pulmonary vascular disease. The aim was to investigate the use of magnetic resonance imaging (MRI) derived RA volume and function in the diagnosis and management of pulmonary hypertension (PH).

Methods: Patients attending the pulmonary vascular clinic were retrospectively assessed. Inclusion criteria were cardiac MRI and right heart catheterisation within 48 hours. Standard cardiac-gated balanced steady state free precession sequences were used. End-systolic volume (ESV) and diastolic volume (EDV) were calculated using Simpson’s numeric integral applied to manual RA area tracings in the 4-chamber stack sequence.
Results: 71 PH patients were included, mean age was 65 ± 15.5 years and 67.6% (48) were female.

RA function was shown to correlate with cardiac index (R = 0.69) and mean RA pressure (R = 0.64), P < 0.001.

RA ejection fraction ≤ 28.3% was shown to have moderate sensitivity (90%) and specificity (71%) for identifying patients who met diagnostic criteria. RA ESV > 28.0 ml was useful (sensitivity 96%, specificity 78%) for identifying patients with a high RA pressure, see figure 1.

![Figure 1. Receiver operator characteristic curves showing the diagnostic accuracy of (a) RA ejection fraction to detect a mean pulmonary artery pressure of ≥ 25 mmHg. (b) RA ESV to detect a mean RA pressure of > 10 mmHg.](image)

Conclusion: RA pressure is a known prognostic indicator; this study suggests high RA pressure can be detected using cardiac MRI. RA function has been shown to correlate well with haemodynamic measurements and clinical data. Further research into the natural history of RA volume change in PH is needed.

73. Update on neutrophil and macrophage function in COPD

382 Identification of pathogenic macrophage subpopulations in lung disease

Mubing Duan,1,2, Catherine Li,1 Daniel Steinfort1, Louis Irving1, Gary Anderson2, Margaret Hibbs2,1 Signal Transduction, Ludwig Institute For Cancer Research, Melbourne, VIC, Australia; 1Surgery, University of Melbourne, Victoria, Australia; 2Respiratory Medicine, University of Melbourne, Victoria, Australia; 1Pharmacology, University of Melbourne, Victoria, Australia; 1Immunology, Monash University, Melbourne, VIC, Australia

Residential macrophages may exist in discreet subpopulations which subserve specific roles in the maintenance of tissue and immunological homeostasis. In lung, alveolar macrophages (AMφs) comprise of > 95% cells in the alveolar airspaces, where they act as the primary sentinels of pathogens. Increased alveolar macrophage numbers are observed in many animal models of COPD and also clinically in COPD patients. Currently, M2 macrophage polarization is thought to be a contributor of lung disease, although this in vitro-derived macrophage paradigm may not completely explain the complex behaviour of AMφs in vivo.

Using flow cytometry, we have developed an approach which shows that mouse residential macrophages may exist as M1-like (classically-activated) or M2-like (alternatively-activated) states. In COPD, M1-like macrophages may appear “hyper-inflammatory” regardless of environment suggesting lack of plasticity. Altering COPD Mφ plasticity may be a therapeutic target.

384 Chemokine characterization in human lung macrophages following stimulation with Th2-type cytokines IL-4 or IL-13

Stanimas Grassin Delyle,1 Amparo Buenestado, Charlotte Abril, Marion Brolio, Emmanuel Naime, Philippe Devillers, UPR ES L2A2, Laboratoire de Pharmacologie Respiratoire, Hôpital Foch, UVSQ, Suresnes, France

Background: Macrophages may acquire polarized phenotypes, the two extremes being the proinflammatory (M1) and immunoregulatory (M2) phenotypes characterized by surface markers and chemokine profiles. Reprogramming of AM toward a partially M2-polarized phenotype has been suggested to contribute to COPD pathogenesis. We thus sought to characterize the phenotype of human lung macrophages (LM) following stimulation with the Th2-type cytokines IL-4 and IL-13.

Methods: LM were isolated from human resected lungs challenged for 24 or 48hrs with IL-4 or IL-13 (1-150 ng/mL). Cytokines transcript expression was assessed with RT-qPCR, whereas proteins of M1 (TNFα, CCL3, CCL4 and CXCL8) and M2 cytokines (CCL13, CCL17 and CCL22) were quantified in supernatants.

Results: Unstimulated LM exhibited a rather undifferentiated phenotype, with weak M1/M2 cytokines expression. On the other hand, transcriptome analysis of 80 cytokines gene revealed that only four M2-type transcripts levels were increased (> 4- to 8-fold) following stimulation with IL-13 (CCL13, CCL17, CCL22 and CCL26). M2-type cytokine production at the protein level was also concentration-dependently increased (> 3- to 20-fold), whereas LM cytokines were unaffected. CCL13 and CCL22 increase was maximal at 48hrs, while the maximum was reached at 24hrs for CCL17. The results obtained with IL-4 were similar, except that IL-4 potency was greater than IL-13 since the low 10 ng/mL concentration provided submaximal cytokines increases.

Conclusions: Our data demonstrate that IL-4 and IL-13 favours LM polarization toward the immunomodulatory M2 phenotype characterized by the expression of CCL13, CCL17, CCL22 and CCL26.

385 Lipids in the lung: Respiratory inflammation in COPD

Andrew Herliham1, Simon Lea2, Karen Simpson1, Dave Singh1, 1NHIR Translational Research Faculty, The University of Manchester, United Kingdom; 2Respiratory CEDD, GlaxoSmithKline, Stevenage, United Kingdom

Background: There is strong association between COPD and metabolic co-morbidities involving lipids. Abnormalities of lipid metabolism are associated with increased inflammatory responses. The aim of this study was to identify abnormalities of lipid content in the lungs of COPD patients, focusing on lung macrophages.

Methods: Resected lung tissue from patients undergoing surgery for cancer was used; isolated macrophages and macrophages within formalin fixed paraffin embedded (FFPE) tissue were examined. Comparisons were made between 5 subject groups, never smokers (NS), current smokers with normal lung function (S), ex-smokers with normal lung function (E), COPD current smokers (COPDS) and COPD ex-smokers (COPDE). The presence of lipid laden macrophages was identified using oil red o stain (ORO) where positive staining is expressed as % mean (SD).

Results: The number of ORO positive macrophages was increased in COPD patients and controls who were current smokers (COPDS and S) compared to the other groups of ex- or never smokers, in both isolated macrophages and FFPE tissue.

Discussion: We have shown an increase in lipid laden macrophages in the lungs of...
S and COPDS. Current smoking appears to cause dysfunctional lipid metabolism within lung macrophages that may contribute to respiratory inflammation. Smoking cessation may have benefits in returning lipid metabolism to normal in these cells.

386
Effect of neutrophil supernatants on ex vivo small airway contractility in COPD
Natasha J. Madge, Louise E. Donnelly, Duncan F. Rogers. Airway Disease, National Heart & Lung Institute, Imperial College London, United Kingdom

Airway neutrophilia is a significant feature of COPD. Neutrophils release a variety of cytotoxic products (e.g. proteases) that degrade components of extracellular matrix. This may result in destruction of the lung and impendence of airflow characteristic of COPD. Small airways are the main site of airflow obstruction in COPD. Our aim was to study the effects of products from activated neutrophils on the contractility of small airways. Rat precision cut lung slices (PCLS) were obtained and videomicroscopy used to assess contractility of small airways. Neutrophils were isolated from whole blood of non-smokers, smokers and COPD patients, stimulated with 1μM (100μM) and supernatants collected. PCLS were incubated overnight in neutrophil supernatants, and the contractility of small airways assessed by addition of increasing concentrations of carbachol. PCLS incubated in supernatants from COPD patients caused a significant leftward shift in EC50, compared with untreated controls (13±2 vs 34±8μM, n=6, p<0.01). Conversely, PCLS incubated in supernatants from smokers had no effect on EC50, but significantly reduced maximal contraction compared with untreated controls (65±1% vs 88±3%, n=6, p<0.05). PCLS incubated in supernatants from non-smokers showed small but significant reductions in both EC50 (16±3 vs 32±8μM, n=6, p<0.05) and maximal contraction (79±4 vs 87±2%, n=6, p<0.05), compared with untreated controls. Elastase content of supernatants correlated with maximal contraction, but not with EC50. We conclude that neutrophil supernatants from COPD patients increase the sensitivity of small airways to cholinergic stimulation, which may contribute to the airflow limitation characteristic of the disease.

387
Reduced phagocytosis of pathogenic bacteria by neutrophils from COPD patients
Catherine Thomas, Peter Barnes, Louise Donnelly. Airway Disease, National Heart and Lung Institute, Imperial College, London, United Kingdom

Acute exacerbations of COPD are the commonest cause of acute medical admissions in the UK, with ~50% associated with bacterial infection. An acute bacterial insult is usually associated with increased recruitment and activation of neutrophils. COPD is characterized by airway neutrophilia; however, despite increased numbers of these cells, bacterial colonization persists. This study examined whether neutrophil phagocytosis was altered in COPD. Neutrophils were obtained from COPD, smoking and healthy subjects and phagocytosis of fluorescently-labelled polystyrene beads, Haemophilus influenzae (HI) or Streptococcus pneumoniae (SP) measured by flow cytometry. Neutrophils from all subjects ingested beads similarly showing that all cells were capable of phagocytosis. Neutrophils from all subjects phagocytosed SP with a maximum response at 5 min, however COPD neutrophils ingested significantly less SP (p<0.05) than those isolated from non-smokers (NS) and smokers (S) (NS: 17±1±1.7 MFI, n=19 vs S: 14±8±1.2 MFI, n=19 vs COPD: 12±8±0.5 MFI, n=20). Approximately 95% of cells phagocytosed HI, but the capacity of COPD neutrophils to ingest HI was significantly attenuated (p<0.01) compared with control neutrophils for all time points up to 30 min. Neutrophils from S phagocytosed HI similarly to cells from NS initially (NS: 18±0±1.8 MFI, n=19 vs S: 19±3±0.6 MFI, n=20 vs COPD: 5.2±0.5 MFI, n=20). However, after 10 min this response became blunted. These effects were not associated with differences in expression of CD11b, TLR2 or TLR4 or in cell viability. Therefore, neutrophils from COPD patients exhibit reduced phagocytosis of pathogenic bacteria which could account for persistent airway colonization.

388
Short term effects of alpha-1-antitrypsin substitution therapy on the degradation of neutrophil granulocytes
Janine Koepke1, Marc Diesel1, Timm Greulich2, Sabina Janciauskienė3, Claus Vogelmeier2, Andreas Rembert Kokczalla2,1Department of Pneumology; BMFZ, Philipps-Universität Marburg, Germany; 2Department of Internal Medicine, Division for Pulmonary Diseases, Hospital of the University of Marburg, Philipps-Universität Marburg, Marburg, Germany; 3Department of Respiratory Medicine, Hannover Medical School, Hannover, Germany

Introduction: Alpha-1-antitrypsin-deficiency (AATD) is a hereditary, co-dominant condition which results in low levels of circulating alpha-1-antitrypsin (A1AT), unbalanced protease activity and frequent development of emphysema. The concept behind substitution therapy with human plasma A1AT is to normalize the concentration in blood and tissue and thereby protecting the lungs from progressive destruction by proteases.

Aim: To better understand the influence of weekly augmentation therapy on polymorphonuclear neutrophils (PMNs) we examined direct effects on chemokine release and degradation of matrix metalloproteinase-9 (MMP-9) and matrixmetalloproteinase (MPO).

Methods: PMNs were isolated from peripheral blood of ten AATD-patients (PIZZ, mean age 55±8±7, FEV1[%] 38±1±14±33, pre) and two hours post substitution infusion. The release of IL-8, MMP-9 and MPO was quantified in neutrophil supernatants via ELISA. Standard inflammation markers as well as MMP-9, MPO and the tissue inhibitor of metalloproteinase-1 (TIMP-1) were evaluated in patient sera.

Results: PMN-stimulation experiments displayed no differences on chemokine release or degradation between pre and post substitution infusion. Two hours after substitution we measured increased MMP-9 (p=0.002) and MPO (p=0.0034) concentrations in sera of patients, whereas TIMP-1 decreased drastically (p=0.002). IL-8 levels in sera of these patients were within normal range and no changes were detectable due to substitution.

Conclusions: We conclude that elevated MMP-9 and MPO concentrations after substitution depend on rapid degradation of PMNs whereas the decline in TIMP-1 concentration possibly depends on a feedback loop.

389
Lung inflammation is significantly reduced by recovery of neutrophil apoptosis in vivo
Klaus Unfried1, Ulrich Sydlik1, Matthias Kroeker1, Adnana Paunel-Görgülü2, Stefanie Keymel1, Christian Heiss1, Malte Kelm3, Joachim Windolf2, Andreas Bolesien3, Jean Krummel1, Lehnert; Research Institute for Environmental Health, DFF, Düsseldorf, Germany; 2Traumatology and Hand Surgery, University Clinics Heinrich-Heine-University, Duesseldorf, Germany; 3Cardiology, Pneumology, and Angiology, University Clinics Heinrich-Heine-University, Duesseldorf, Germany; *K & D, Itopt AG, Witten, Germany

Introduction: Neutrophil apoptosis is considered to be a major regulator of neutrophil driven lung inflammation. The compatible solute ectoine has been described to act preventive against lung inflammation induced by environmental particles (Sydlik et al., Am J Respir Crit Care Med 2009). As a therapeutic approach, here, we investigated the influence of this compound on neutrophil apoptosis in the inflammatory microenvironment.

Methods: Human neutrophils were treated ex vivo with particles or inflammatory mediators in the presence or absence of ectoine in order to study apoptosis rates and pro-apoptotic signalling. Lung inflammation was induced in rats by intra-tracheal application of 2.5 mg/kg environmental particles and studied in lung lavages after control or ectoine intervention.

Results: Apoptosis rates of human neutrophils from COPD patients and volunteers, which were significantly reduced by the inflammatory stimulus, recovered significantly in the presence of ectoine. Mechanistic analyses demonstrated the preventive effect of ectoine on pro-apoptotic signalling events via Akt and Mecl-1. The in vivo relevance of the data was shown by significantly reduced neutrophil inflammation after ectoine intervention which correlated with restored neutrophil apoptosis rates in the lung.

Conclusions: The current studies demonstrate the effective to prevent anti-apoptotic signalling in neutrophils by the compatible solute ectoine. This effect led to recovered apoptosis rates and a reduction of environmentally induced lung inflammation. The relevance of ectoine treatment for humans is demonstrated by the EFECT study which will be presented on the same meeting.
74. How to use technology to provide better critical care

The musculoskeletal ultrasound in critical care: Longitudinal evaluation (UK-MUSCLE) study: Severity of acute critical illness determines the degree of muscle wasting

Zadn Paluchkiewicz1,2,4,5, Jakirly Rawal1, Bronwen Cronin3,4, Mark Mephy1, Germaine Rattay7, Paul Siddhu1, Dinesh Shrikshna1, Philipp Kins1, Nicholas Hopkinson1, Michael Polkey1, Cristina Velloso1, Chibera Age1, Michael Rennie3, Anthea Rowleson1, John Moxham1, Stephen Harridge1, Nicholas Hurt2, Hugh Montgomery1, Institute of Health and Human Performance, University College London, United Kingdom; 3NHBR Comprehensive Biomedical Research Centre, Guy’s and St Thomas’ and Kings College London, United Kingdom; 4Hammersmith Hospital NHS Trust. Imperial College London, London, United Kingdom; 5Kings College Hospital, NHS Trust London, United Kingdom; 6NHBR Respiratory Biomedical Research Unit, Royal Brompton Hospital, London, United Kingdom; 7Department of Physiology, University of Nottingham, United Kingdom; 8Centre of Human and Aerospace Physiology, Kings College London, United Kingdom

Acute muscle wasting in critical illness is a major cause of disability amongst intensive care survivors. Limited data exists detailing sequential loss of muscle mass and histological changes. We hypothesised that loss of Rectus Femoris Cross-Sectional Area (RFCSA) would be determined by illness severity and paralleled by reduction in myofibrillar cross-sectional area.

Methods: Critically ill patients were recruited within 24 hours of admission. Serial RFCSA measurements were taken using B-mode ultrasound and stratified by numbers of failed organ systems. Serial vastus lateralis muscle biopsies were performed.

Results: 63 patient were analysed. The greatest RFCSA reduction was observed in patients with multi-organ failure (MOF) 21.5 ± 10.5% in MOF patients vs. 7.2 ± 5.7% in patients with single organ failure (SOF); p < 0.001.

439 Can lung ultrasound predict prone positioning response in ARDS?

Solene Guinard, Gaënel Pra1, Nicolas Bizien2, Erwan L’Her1, 1 ICU, University Hospital, Brest, France; 2Pneumology, University Hospital, Brest, France

Introduction: Prone positioning (PP) is an alternative in the management of patients with severe ARDS. Among patients treated with that technique: only 70% are responders as they improve their P/F, but at present we are not able to predict the patient’s responsiveness. The aim of our study was to determine whether the lung aspect observed with US before PP can predict or not the prone positioning response.

Patients and settings: Prospective monocentric study (medical ICU university hospital Brest France) including patients with severe ARDS (P/F < 200 with FiO2 ≥ 0.7). A standard lung US exam with 12 lung areas to explore (superior/inferior, anterior/lateral/posterior, right/left) was practiced before prone positioning (12 hours according unit’s procedure). Before PP, after 2 hours of PP and 2 hours after turning back the patient supine, haematosis parameters were collected.

Lung aspect was evaluated a posteriori by 3 physicians and graded in 4 stages (normal aspect, and 3 stages of lung compression)

Observation of the P/F ratios course permitted to classify patients as responders or non-responders.

Statistics: Fisher’s exact test

Results: 17 patients were enrolled in the study.

– For the early response: the absence of lung compression in anterior and supero-rider organs is associated with an improvement of P/F ratio > 20 mmHg, whereas posterior areas aspect is not predictive of the response to PP.

– For the late response, we have not found any relationship between the lung aspect and the pp response.

Discussion: The first analysis showed that lung’s US aspect could predict the patient’s response to PP and could help physician in routine practice to place or not sever ARDS patient in PP.

392 Treatment of hypercapnic respiratory failure with a novel extracorporeal CO2 removal system

Nausheeran Burki1, Raj Mami2, Felix Herth1, Werner Schmidt3, Helmut Teschner1, Frank Bonin4, Heinrich Becker5, Winfried Randerath6, Svet Stiglić7, Lars Hagmeyer8, Christina Priege9, Michael Pfeifer1, Stefan Blaas1, Christian Putensen9, Nils Thierarkert1, Michael Quintel1, Ommen Moorers1, 1Division of Pulmonary & Intensive Care, University of Connecticut Health Center, Farmington, CT, United States; 2Department of Pulmonary & Critical Care, Astrid Health Institute, Gargunno, Haryana, India; 3Pneumology and Respiratory Care, Thoraxklinik and University Hospital, Heidelberg, Baden-Wurttemberg, Germany; 4Respiratory Medicine, High Dependency Unit, and Center of Sleep Medicine, Ruhrlandklinik, Essen, 5Nordrhein-Westfalen, Germany; 6Pneumology and Intensive Care Medicine, Asklepios Klinik Barnenhof, Hamburg, Hamburg-Nord, Germany; 7Institute of Pneumology at the University Witten/Herdecke, Krankenhaus Bethanien, Solingen, Nordrhein-Westfalen, Germany; 8Center for Pneumology, Klinik Donausaft, Bayern, Germany; 9Anesthesiology and Intensive Care Medicine, University of Bonn, Nordrhein-Westfalen, Germany; 10Anesthesiology and Intensive Care, University of Göttingen, Niedersachsen, Germany; 11Anesthesiology and Intensive Care, Thoraxklinik and University Hospital, Heidelberg, Baden-Wurttemberg, Germany

Background: Extracorporeal CO2 removal (ECOO2R), a potentially valuable technique, has not been systematically evaluated in patients with hypercapnic respiratory failure. We describe the application of a novel single venous catheter, low blood flow, ECOO2R device (Hemolung® Respiratory Assist System, ALANG Technologies, Inc.).

Methods: Twenty three hypercapnic patients received ECOO2R. Group 1 (n=7) consisted of patients with chronic obstructive lung disease on non-invasive ventilation with a high likelihood of requiring invasive ventilation, Group 2 (n=2) were patients who could not be weaned from noninvasive ventilation, Group 3 (n=11) were patients who could not be weaned from invasive ventilation, and Group 4 (n=3) were patients on invasive ventilation requiring lung protective ventilation techniques.

Results: The device was well tolerated, with complications and rates similar to those seen with central venous catheterization. Blood flow through the system was 430.3 ± 73.7 ml/min, and ECOO2R was 82.5 ± 15.6 ml/min. Invasive ventilation was avoided in all patients in Group 1 and both patients in Group 2 were weaned; PaCO2 decreased significantly (p <0.003) with application of the device. In Group 3, three patients were weaned, in 3 patients ventilatory support was reduced, and one patient died due to a retroperitoneal bleed following catheterization. In Group 4, lung protective ventilation was enhanced by the ECOO2R device.

Conclusions: This single catheter, low blood flow ECOO2R system provided clinically useful levels of CO2 removal in these hypercapnic patients. The system appears to be a potentially valuable additional modality for the treatment of hypercapnic respiratory failure.

393 Effect of a closed loop ventilation strategy on the duration of ICU stay: A randomized controlled trial (interim analysis results)

Cenk Kirakli, Orleam Edliboglu, Dursun Tatari, Emel Telioglu, Ahmet Budak, Iftar Naz, Intensive Care Unit, Izmır Chest Diseases and Surgery Training Hospital, Izmir, Turkey

Background and aim: There are some studies suggesting that adaptive support ventilation (ASV), a closed loop ventilation mode, shortens the weaning duration in some patient groups. We aimed to investigate the effect of ASV on total duration of mechanical ventilation (MV), weaning and intensive care unit (ICU) stay when compared to pressure controlled ventilation (PCV), a conventional mode.

Materials and methods: Patients who were mechanically ventilated longer than 24 hours were randomized into ASV and PCV. Demographic data and total duration of MV, weaning and ICU stay, number of manipulations, need for sedation and complications (self-extubation, ventilator associated pneumonia) were compared.

Results: Data are expressed as median (IQR). 96 patients (73 COPD) were enrolled between December 2011 and February 2012. Duration of weaning was 2 hours (2–7) in ASV and 4 hours (2–26) in PCV (p=0.013). Number of manipulations were 1 (2–3) in ASV and 3 (1–6) in PCV (p<0.001). When a subgroup analysis was done only on patients who could be weaned, in addition to the results above, duration of ICU stay was 4 days (3–7) in ASV while it was 7 days (5–10) in PCV (p=0.039).

Conclusion: ASV seems to decrease the staff’s workload, duration of weaning and ICU stay when performed from intubation until extubation. The present study is continuing until the targeted sample size is reached in order to detect the effects of

478
this mode on secondary outcomes such as total duration of mechanical ventilation and need of sedation.

394 Diaphragm electromyographic activity as a predictor of weaning failure
Martin Desl1, Matthieu Scmidt1,2, Alexis Ferre1, Julien Maury1
Thomas Simiowski1,2, Alexandre Demoule1,2,3, 1Service de Pneumologie et réanimation Médicale, Assistance Publique Hôpitaux de Paris - Groupe Hospitalier Pitit Salpetrière, Paris, France; 2ER 10, Université Paris 6, France; 3UMRS 974, INSERM, Paris, France

Purpose: To compare breathing pattern descriptors and diaphragm electromyo-
graphic activity (EAdi)-derived indices obtained from a Neuromuscular Ventilator
Assessment (NVA) catheter during a spontaneous breathing trial (SBT) in patients
successfully (SP) and unsuccessfully (UP) separated from the ventilator and to
assess their performance to discriminate these two categories of patients.

Methods: 57 ready-to-wean patients were included in a prospective observational
study (35 SP and 22 UP separated from the ventilator). During a 30 minutes SBT
pressures, flow, work, zero of expiratory pressures, tidal volume (VT) and
respiratory rate (RR) were obtained from the flow signal at 3, 10, 20 and
30 minutes. EAdi-derived indices were simultaneously computed: maximum of
the EAdi (EAdmax), area under the inspiratory curve of EAdi (EAdIAUC), the difference
during EAdmax and EAdmin (AEAdi), EAdmax/VT, EAdIAUC/VT and AEAdi/VT.

Results: At baseline, breathing pattern was similar in the two groups whereas
EAdmax and EAdIAUC were significantly lower in the success group (p<0.05). In
the failure group, RR and RR/VT increased significantly during the trial, VT
decreased, whereas EAdmax and EAdIAUC did not change. At 3 minutes, the ar-
cas under the receiver operating characteristic-curve of RR/VT and EAdi-derived
indices to predict weaning outcome were: RSBI (0.83), EAdmax/VT (0.84),
EAdIAUC/VT (0.80) and AEAdi/VT (0.82). During the SBT, the coefficient of
variation of VT decreased in the failure group while the one of EAdmax remained
unchanged.

Conclusion: EAdi-derived indices provide reliable and early predictors of weaning
outcome. However, the performance of these indices is not better than the RR/VT.

395 Usefulness of selective neutrophil elastase inhibitor, sivelestat, in ALI patients
with SIRS
Seigo Miyoshi1, Ryoo Ji1, Hitoshi Katayama1, Kazunori Inui1
Hiroshi Hamada1, Yoshinobu Sawa1, Noriko Nakano1, Takahito Kano1, Ken'itro Doi1,5, Mayuki Aibiki5, Jitsuo Higaki1
1Department of Integrated Medicine and Informatics, Ehime University Graduate
School of Medicine, Toon, Ehime, Japan; 2Department of Health and Sports Medicine,
Graduate School of Human Sciences, Hiroshima University, Hiroshima, Japan; 3Department of Respiratory Medicine, Sumitomo Besshi Hospital, Niihama, Ehime, Japan; 4Department of Respiratory Medicine, Ehime Prefectural Central Hospital, Matsuyama, Ehime, Japan; 5Department of Respiratory Medicine, Matsuyama Red Cross Hospital, Matsuyama, Ehime, Japan; 6Intensive Care Division, Ehime University Hospital, Toon, Ehime, Japan;

Background: Neutrophil elastase is known to be an important mediator of acute
lung injury (ALI) in systemic inflammatory response syndrome (SIRS). Sivelestat
is a neutrophil elastase inhibitor, but the clinical efficacy of sivelestat in patients
with lung injury (ALI) in systemic inflammatory response syndrome (SIRS). Sivelestat
in Japan

Purpose: To evaluate the clinical efficacy of sivelestat in the treatment of acute lung
injury (ALI) in patients with systemic inflammatory response syndrome (SIRS).

Methods: 40 patients (17 men and 23 women) aged 66 ± 10 years old were included
in the study, 20 patients were in the treatment group and 20 were in the placebo
control group. Both groups were monitored for 72 hours. The change in VFD (day 3-
day 0) and P/F ratio were compared between the two groups.

Results: Among the 20 patients in the treatment group, 8 patients (40 ± 10 years old)
showed a significant improvement in VFD and P/F ratio compared to the control
group (p=0.01). In the placebo control group, 12 patients (40 ± 10 years old) showed
no significant improvement in VFD and P/F ratio.

Conclusion: Sivelestat might have beneficial effect on the respiratory condition of the
ALI patients with SIRS. Furthermore, sivelestat administration tends to associate with survival in patients with ALI with sepsis.

75. Clinical management of lung diseases: from bronchi to pleura

P397 Respiratory muscle strength and physical performance in elderly hospitalized
patients
Anna Zito1, Claudio Pedone, Renato Guia, Simona Santangelo, Elena Frezzotti
Domenica Chiaro, Simone Scarlata, Raffaele Antonelli Incalzi. Unit of Respiratory Pathophysiology, Campus Biomedico University, Rome, Italy

Age-related changes in pulmonary function increase respiratory muscle work. In
front of this increased demand, sarcopenia frequently associated with age and
multimorbidity, can reduce endurance and strength of respiratory mus-
cles. Furthermore, sarcopenia may per se contribute to reduction of physical perfor-
mance.

Aim of the study: To evaluate the correlation between the respiratory muscle
strength and physical performance in elderly.

Population: 65 patients (30 men and 40 women) aged between 65-80 years.

Methods: A retrospective data analysis of 110 ALI patients with SIRS was con-
ducted to investigate the effects of sivelestat. The clinical efficacy of sivelestat
was evaluated based on the survival rate and ventilator free days (VFD) and changes
between before and 7 days after administration of sivelestat in PaO2/FiO2 (P/F)
ratio, white blood cell count, levels of C-reactive protein and procalcitonin (PCT).

Results: Sivelestat group included 70 patients, and control group included 40 pa-
tients without administration of sivelestat. VFD was significantly higher, and P/F
ratio significantly improved in the sivelestat group compared to the control group.

Conclusions: Sivelestat significantly increased VFD and P/F ratio, and reduced the levels of
PCT in septic patients.

This result suggests that sivelestat might have beneficial effect on the respiratory condition of the ALI patients with SIRS. Furthermore, sivelestat administration tends to associate with survival in patients with ALI with sepsis.

396 Biological effects of nanostructured lipid carriers
Mania Kandag1, Nikolaos Maniatis1, Aggeliki Stika1, Anastasia Kotanides1, Charalampos Roussos1, Apostolos Armatagianis1, Sophia Hatziantoniou2
1Stylianos Orthanos3, 2Critical Care, University of Athens Medical School, Athens, Greece; 3Pharmaceutical Technology, University of Athens School of Pharmacy, Athens, Greece

Nanostructured lipid carriers (NLC) are a type of drug delivery system offering
improved performance in terms of drug loading and long-term stability. Our aims
were to test mechanisms of NLC uptake into endothelial cells (EC) and evaluate
possible biologic effects of these compounds.

NLC were prepared with triglycerides Miglyol and Softisan and egg-
phosphatidylcholine (1:1 by weight) by the double emulsion technique. Cul-
tured mouse lung microvascular endothelial cells (LMVEC) were incubated with
curcumin-loaded NLC and uptake was quantified as fluorescence detected in the cell
homogenate or by FACS. To test biologic effects, we challenged human LMVEC
with thrombin with or without NLC and measured endothelial permeability as flux
rate of fluorescent albumin across endothelial monolayers grown on transwell in-
serts. Alterations were tested in thrombin-induced endothelial Lipid raft-Regulated
Kinase (ERK) activation by immunoblotting and endothelial actin remodelling by fluores-
cence microscopy. Finally, NLC were delivered intravenously as pre-treatment in
a mouse model of hydrochloric acid (HCl) aspiration lung injury.

Using cultured mouse LMVEC we observed that NLC are incorporated into cells
more efficiently when caveolin-1, the structural protein of caveolar vesicles, is
expressed. Upon challenge of cultured EC with thrombin, NLC attenuated the
permeability increase, activation of ERK, cytokine production and actin stress
fiber formation. In the HCl-aspiration model, NLC attenuated the increase in bron-
choalveolar lavage protein content, inflammatory cells and histological alterations.

Conclusion: Systemically delivered NLC are taken up by EC via caveolae and
have endothelial-protective effects of potential relevance to acute lung injury.

P398 Plasma homocysteine is associated with low diffusion capacity (DLCO) in
COPD patients
Fernando Gomez1, Dolores Guerrero2, Luis Bernacer1, Joaquin Gomez1, Inaki Lopez1, Daniel Baciller2, 1Internal Medicine, Hospital de Manacor, Manacor, Spain; 2Clinical Epidemiology Program, CSIC-CIMERA, Badalona, Spain; 3Clinical Laboratory, Clinica Juandela, Palma de Mallorca, Spain

Introduction: Chronic obstructive pulmonary disease (COPD) is associated with

cardiovascular events, however, its underlying pathophysiological mechanism is unknown. Elevated total plasma homocysteine (tHcy) levels is considered to be a cardiovascular risk factor. Several studies show that COPD may be associated with high tHcy.

Objective: To identify possible clinical variables associated with high tHcy in COPD patients.

Methods: We performed an observational study of 88 consecutive smokers or ex-smokers older than fifty years and with more than 10 pack-years smoking history. We used Mann Whitney test to compare COPD with controls. Step wise logistic regression analysis was used to determine the association between tHcy and different clinical, analytical and physiological variables in COPD patients.

Results: Of the subjects evaluated, 62 had COPD (70.5%) and 26 (29.5%) did not, and served as controls. COPD patients had higher tHcy than controls: median (±SD) 14.2±6.6 vs 11.7±4.5 μmol/L, p=0.025. In COPD patients, using tHcy >14 μmol/L as an independent variable, logistic regression analysis including age, gender, smoking history, creatinine clearance, FEV1, DLCO and daily alcohol intake, only lung diffusion capacity for carbon monoxide (DLCO) was significantly associated (Odds Ratio (95% confidence intervals) 0.947 (0.904 – 0.992); p=0.023).

Conclusions: COPD patients had higher tHcy than controls and they were associated with a low DLCO. Therefore, we conclude that COPD patients with low DLCO may have a higher risk of cardiovascular events; however, further studies are needed to confirm this hypothesis.

P399

Inflammatory mediators associated with bone metabolism in patients awaiting lung transplantation

Evgjenia Kochetkova1, Ludmila Uglya, Vera Nevzorova1, Gilbert Massard2, Tatiana Sourouvelenko1, Marie-Christine Pages3, Service de Chirurgie Thoracique, Hôpital Universitaires de Strasbourg, Strasbourg, France

Aims: to evaluate the association between systemic inflammation, markers for bone turnover and bone mineral density (BMD) in 105 candidates for lung transplantation.

Methods: BMD, bone biomarkers, inflammatory mediators were determined in 105 patients with end-stage of chronic respiratory failure and 85 age and sex matched controls.

Results: We identified a osteoporotic syndrome in 82/105 patients, 10/85 controls were osteoporosis. Procollagen type 1 amino-terminal propeptide (P1NP), markers of bone formation, was higher in lung diseases and osteoclast was similar between patients and controls. Type 1 collagen C-tepeptide (CTX), a marker of bone resorption, was higher in candidates for lung transplantation and was inversely correlated with P1NP. Bone density (BMD) values were lower in candidates for lung transplantation (BMD lung 0.70±0.1 cm2, BMD N 0.78±0.1 cm2, p=0.01). TNF-a and its receptors level, interleukin-6, receptor of nuclear factor kappa b (RANK) were higher, osteoprotegerin level was low in lung pathology. Vascular endothelial growth factor was lower in patients with emphysema and correlated with BMD (t=0.06, p=0.002) only in with end-stage of emphysema.

Conclusions: Patients with end-stage lung diseases had a greater prevalence of osteoporotic syndrome. Results shows possibly role of systemic inflammatory in the increasing of bone loss at the terminal stage of lung disease.

P400

Administration of lisoflavan in the treatment for enogenic allergic alveolitis (EAA)

Natalya Makaryants1, Larisa Lepelka, Eugene Shnelev, Ilya Sivokozov

Respiratory/Pathology Department, CTRI RAMS, Moscow, Russian Federation

Aims: To evaluate efficacy of continuous treatment for subacute variant of EAA with inhalation lisoflavan.

Materials and methods: We studied 27 patients with subacute course of morphologically confirmed EAA. Group 1 (10 patients) received the standard treatment with prednisolone (20 mg/day). Group 2 (17 patients) received prednisolone (15 mg/day) plus inhalation lisoflavan. We evaluated clinical symptoms (cumulative index), 6-minute walk test, spirometry, diffusion capacity of the lung (DLCO), computed tomography (CT) of the lungs using Kazeromi modification, before and after the treatment. The reliability of differences was estimated using the Mann-Whitney test.

Results: There were no reliable differences between the groups. The analysis of the data within the both groups revealed reliable improvement of clinical symptoms, LVC, distances of the 6-minute walk test, the alveolar component of CT. In group 2 we also observed increased DLCO.

Conclusion: Nebulizer administration of lisoflavan in the complex treatment for subacute course of EAA allows decreasing corticosteroids doses.

P401

Review of health-related quality of life and patient-reported outcome in patients receiving EPs 7630 treatment for acute bronchitis

Heinrich Matthias1, Wolfgang Kamin1, 1Medical Director emeritus, Department of Pneumology, University Hospital, Freiburg i. Br, Germany; 2Clinic for Pneumology, Evangelic Hospital Hann, Hann, Germany

Background: Health-related quality of life (HRQL) and patient-reported outcome (PROM) are important outcome parameters for the evaluation of both medical treatment within clinical trials and efficacy in clinical practice. For EPs® 7630 (Umcalanob®) treatment, clinically relevant improvements in HRQL/PROM have been reported recently (Matthys, H. et al. Wien Med Wochenschr 2010;160:564-70; Matthys, H. et al. Eur Respir 2011;38(Suppl 55):18s-19s).

Aims: We systematically reviewed randomised controlled trials (RCTs) in order to assess the impact of EPs 7630 treatment on HRQL and PROM of patients with acute bronchitis (AB).

Methods: Trials published 2010 or earlier were included for the review if they were RCTs investigating EPs 7630 vs placebo (PL) in adults or children suffering from AB and assessing HRQL and PROM by means of the EQ-5D questionnaire and the Integrative Medicine Patient Satisfaction Scale (IMPSS).

Results: 6 trials with a total of 1164 patients (EPs 7630: 586; PL: 578; 53% 1-18 yrs) were identified. After 7 days of treatment, clear and mostly statistically significant advantages were seen for EPs 7630 compared to PL in the EQ-5D dimensions (mobility, usual activities, pain/discomfort and anxiety/depression: p<0.01; self-care: p=0.02) and in the health status of patients (EQ VAS: p<0.01). 7630 for EPs 7630, twice as many patients were satisfied or very satisfied with treatment outcome compared to PL (82.1% vs. 40.0%; p<0.01).

Conclusions: There are encouraging evidence from currently available data derived from placebo-controlled trials that EPs 7630 treatment improves HRQL and PROM in both children (>1 year) and adults with acute bronchitis.

P402

Efficacy of corticosteroids in hospital treated community-acquired pneumonia

Miri Kapizivi1, Dhimartiaq Argiri2, Anila Aliko1, Loreta Bica1, Jeti Beli1, Yli Vakebillu1, Elena Shehu1, Roland Kore1, Holta Tafa1, Ornela Nuredini1, Regina Hasa1, Mirela Tabaku2, Ezirin Tash1, Edilira Ndrue1, Esmeralda Nushi1, Arben Tanku1, Epaminonda Fype1, Lang Diseases, University Hospital “Sh. Ndrugi”, Tirana, Albania; 2Immunology, University Hospital Center “Sh. Ndrugi”, Tirana, Albania

Aim: The aim of the study was to evaluate beneficial effect of corticosterides in short treatment of community acquired pneumonia (CAP).

Patients and Methods: We enrolled a total of 149 hospitalized patients, for a period of an year (January 2011 to December 2011). The diagnosis of CAP was made using standard clinical and radiological criteria. Disease severity was scored using Pneumonia Severity Index. Age, antibiotic treatment and PSI adjustment has been done between the groups. Patients received 50 mg prednolone for 7 days, along with antibiotics.

The outcomes were clinical cure at day seven, defeverescence, length of stay, time to clinical stability.

Results: Mean age of patients enrolled in study was 63±16.7 in prednolone and 53±18.6 in group without prednolone Therty (40%) patients in prednolone group and 16 (22.2%) in without prednolone group were in Pneumonia Severity Index class I-II. Clinical cure at day 7 was 81(75) (82.6%) in the prednolone group and 44/72 (61.1%) in other group (P<0.008). Patients on prednolone had faster defeverescence compared with other group, (P<0.0002). Length of stay was significantly lower in patients with prednolone compared with nonprednolone group, 9.4±4.3 and 12.3±6.4 respectively, (p=0.0011). Adverse events were few and not different between the two groups.

Conclusions: In this study we show that Prednolone (at 50 mg) once daily for a short time, (a week), have a beneficial effects in patients hospitalized with mild to severe CAP, improving outcomes without adverse events.

P403

Nurse practitioner insertion of Seldinger chest drains. A pilot study

Heather Llond, Steve O’Hickey, Joanne Ingram. Worcester Royal Hospital, Worcester, Worcestershire Acute Hospitals NHS Trust, Worcester, United Kingdom

Background: In 2008 the National Patient Safety Agency encouraged UK hospitals to develop local policies that reduced the risks associated with chest drain insertion. A key theme that emerged from the 2008 Rapid Response Report was...
that the inexperience of junior doctors and inadequate supervision increased the risk of complications associated with the procedure.

Aims: We proposed that a ward based nurse practitioner, trained in thoracic ultrasound and chest drain insertion, was the nurse practitioner. Various aspects relating to chest drain insertion including consent practice, use of thoracic ultrasound and incidence of any adverse events were audited. Data was collected over a four month period (June to September 2011).

Results: All 10 chest drain insertions performed by the nurse practitioner were correctly sited, written consent was obtained in 100% of procedures undertaken, thoracic ultrasound was used to guide drain placement in 100% of cases and there were no adverse incidents or complications related to chest drain insertion.

Conclusion: Training of specialist nurses in the procedure of chest drain insertion for elective patients with uncomplicated pleural effusion is an acceptable model within the district hospital setting and has the additional benefit of providing appropriate support and supervision for junior doctors undertaking this procedure.

P404
Outcomes of bronchial artery embolisation in the management of clinically significant hemoptysis
Young Min Lee, Pulmonary Dept. of Medicine, Busan Paik Hospital, Inje University, Busan, Republic of Korea

Objectives: Bronchial artery embolisation (BAE) has been established as an effective technique in the emergency treatment of massive hemoptysis. Aim of the study has been to evaluate immediate and long-term outcomes of BAE and to identify factors influencing outcomes.

Methods: A retrospective analysis was carried out of the medical records and angiograms of 120 patients who underwent BAE between January 2005 and December 2009. 79 patients were men and the mean age was 54.5 years.

Results: The patients were divided 3 groups including recurrent hemoptysis (<100ml/day: n=49), (100-400ml/day: n=49), massive hemoptysis group (>400ml/day: n=24). The common underlying diseases of hemoptysis were pulmonary tuberculosis and related disorders (51%), bronchiectasis (21%) and aspergillosis (21%). In this series, immediate success rate to control bleeding within 24 hours was 89% (106 cases), long-term success in 62.5% (75cases) and recurrence rate was 26% (31cases). Five patients died from massive hemoptysis. Among initial radiographic findings, pleural lesions (P<0.05) and aspergillus (P<0.05) were significantly associated with hemoptysis recurrence. A good clinical outcome was significantly associated with hemoptysis recurrence.

Conclusion: BAE after non-cardiac thoracic surgery are common and lead to increased morbidity and prolonged hospital stay in our setting. We identified pre-existing chest disease, prolonged anaesthesia and emergency surgery as common predictors of PPC.

Aims & Objectives: To study factors predicting PPC in our setting.

Methods: Prospective study of consecutive 404 patients undergoing non-cardiothoracic surgery under GA with tracheal intubation from Jan 2009 to Dec 2010. Chi-square was used for univariate analysis and forward stepwise logistic regression for multivariate analysis.

Results: The mean age was 51±18 years with 54% males. 22% were smokers, and mean BMI was 23±4.5 kg/m² with 35% overweight & obese. 4% of subjects had chronic lung conditions while 23% had non-pulmonary chronic conditions. 70% of the surgeries were done electively and the mean duration of GA was 78±44 min. The overall PPC rate was 8%; atelectasis (4%) followed by bronchospasm (25%) and pneumonia (16%) being the commonest complications. The mean duration of hospital stay was significantly longer in patients with PPC (11±9 days, p<0.001) and 29% of them required mechanical ventilation. Logistic regression analysis identified chronic chest condition, emergency surgery and prolonged duration of GA as significant predictors of PPC while age, gender, BMI, smoking history and non-pulmonary premorbid was not of any significance.

Conclusion: PPC after non-cardiothoracic surgery are common and lead to increased morbidity and prolonged hospital stay in our setting. We identified pre-existing chest disease, prolonged anaesthesia and emergency surgery as common predictors of PPC.

P405
Changing serum cytokines levels in patients with idiopathic pulmonary arterial hypertension treated with bosentan
Tamila Martynyuk, Kirill Zykov, Olga Arkhipova, Ekaterina Kobal, Irina Chazova. Department of Systemic Hypertension, Russian Cardiology Research-and-Production Complex, Moscow, Russian Federation

Aim: To investigate the influence of Bosentan on serum cytokines levels in pts with idiopathic pulmonary arterial hypertension (IPAH).

Methods: In the single-center comparative study we included 35 pts aged 35,2±0,6 yrs with IPAH confirmed by RHC (WHO Functional Class (FC) II-IV) without systemic inflammation signs. On top of chronic bosentan therapy (250 mg/day) we randomized 1:1 by the envelope method to have bosentan 125 or 250 mg/day. At baseline, at wk4 and wk12 the pts underwent the clinical and laboratory assessment (FC, 6-minute walking test (6-MWT), Echo, RHC, routine lab measurement of high sensitivity C-reactive protein (hsCRP) and serum pro-inflammatory serum cytokines (interleukin (IL) 1β, 8, TNFα).

Results: At baseline the groups did not differ in age, disease duration, functional, and hemodynamic parameters, hsCRP levels were normal in both groups.

Conclusion: The influence of Bosentan 125 and 250 mg/day on some cytokines levels to wk12 showed its anti-inflammatory effect in IPAH pts.

P407
Bosentan influence on cellular immunity parameters in patients with idiopathic arterial pulmonary hypertension
Tamila Martynyuk, Kirill Zykov, Olga Antonova, Olga Arkhipova, Ekaterina Kobal, Valery Masenko, Sergey Nakonechnikov, Irina Chazova. Department of Systemic Hypertension, Russian Cardiology Research-and-Production Complex, Moscow, Russian Federation

Aim: To assess the influence of endothelin receptor antagonist Bosentan on cellular Immunology parameters in pts with idiopathic pulmonary arterial hypertension (IPAH).

Methods: In the single-center comparative study we included 35 pts aged 35,2±0,6 yrs with IPAH confirmed by RHC (WHO Functional Class (FC) II-IV) without systemic inflammation signs. On top of chronic bosentan therapy (250 mg/day) we randomized 1:1 by the envelope method to have bosentan 125 or 250 mg/day. At baseline, at wk4 and wk12 the pts underwent the clinical and lab assessment (FC-6 minute walking test (6-MWT), Echo, RHC, routine lab+ measurement of high sensitivity C-reactive protein (hsCRP) and serum pro-inflammatory serum cytokines (interleukin (IL) 1β, 8, TNFα).

Results: At baseline the groups did not differ in age, disease duration, functional, and hemodynamic parameters, hsCRP levels were normal in both groups.

Conclusion: The influence of Bosentan 125 and 250 mg/day on some cytokines levels to wk12 showed its anti-inflammatory effect in IPAH pts.

*p<0.05 vs baseline, †p<0.05 group 1 vs group 2.
Results: All cellular immunity parameters of IPAH pts remained within normal limits.

Conclusion: 12wk therapy with Bosentan changed CD-markers levels. The daily dose of 125mg resulted in the increase of B-lymphocytes and slight decrease of activated T lymphocytes. In patients treated with Bosentan 250 mg we found decreased numbers of activated B- and T-lymphocytes.

P408
High-dose inhalation corticosteroids in conjunction with plasmapheresis in the treatment of patients with acute variant of exogenous allergic alveolitis (EAA)
Natalya Markaryants, Larisa Lepeshka, Eugene Shmullev. Respiratory/Pathology Department, CTRI RAMS, Moscow, Russian Federation

Aim: To evaluate efficacy of high-dose inhalation corticosteroids in conjunction with plasmapheresis in the treatment for acute variant of EAA.

Materials and methods: We studied 16 patients with acute course of morphologically verified EAA. The main group (8 patients) received high-dose fluticasone (2500 µg) and plasmapheresis. The control group (8 patients) received the standard dose of prednisolone (0.25 mg/kg). The both groups received the treatment during one month. We performed cytology and morphology studies of lung biopsies from all the patients. We evaluated clinical symptoms (cumulative index), 6-minute walk test, spirometry, diffusing capacity of the lung, computed tomography (CT) of the lungs by Kazerouni, before and after the treatment.

Results:

</tbody>
</table>

To analyze the data we used the non-parametric methods of the Statistica program, and the Wilcoxon criterion.

Conclusion: High-dose inhalation corticosteroids in conjunction with plasmapheresis may be used to treat patients with acute variant of EAA as alternative to the standard corticosteroid therapy.

P409
Pleural drain management – A clinical practice improvement project
Baloor Ran, Vinod Ayappa, Jeff Bowden, Anand Rose, Adriana Thanh-Thao Le. Respiratory, Flinders Medical Centre, Adelaide, SA, Australia

Introduction: An audit performed in Year 2010 at Flinders Medical Centre showed significant number of complications with intercostal chest drain insertion and management, with only 28% of patients being complication free.

Aims and objectives: Our mission was to reduce the incidence of complications associated with management of pleural drains, in respiratory unit at Flinders Medical Centre, by 80% within 6 months.

Methods: We used validated tools, introduced by Deming, Shewart, Juran et al., customized to the health environment to tackle this problem. We assembled a team and undertook diagnostics. This included brainstorm sessions, cause and effect diagram and prioritized problems using a pareto graph. We then designed interventions and evaluated the outcome.

Results:

</table>

We found that the three main issues impacting on pleural drain management was a lack of protocol, lack of patient information and Nursing education. This was followed by targeted intervention. Already available protocol was reviewed and customized to our local setting. A formal patient information sheet was adapted from British Thoracic Society and American Thoracic Society guidelines. A nursing education session was undertaken and a continuous refresher course was set-up.

Documentation sticker was prepared. Subsequently a re-audit was performed, which showed a reduction of complications from 72% to 12.5%.

P410
Risk factors in elderly patients with acute respiratory failure
Balam Er Dedekarginoglu, Elif Kupeli, Gaye Uzunay. Chest Diseases, Basent University Hospital, Ankara, Turkey

Introduction: Acute respiratory failure is a condition that may cause morbidity in not only patients with systemic disorders but also healthy people.

Aim: To determine risk factors in elderly patients with acute respiratory failure (ARF).

Method: Cases over 65 years old with (ARF) that applied to the Department of Chest Diseases of our hospital between years 2011 and 2012 were included in the study prospectively.

Findings: 47 cases (M=25.22, median age:74.7±10 years) were included in the study. Computed thorax tomography was conducted in 38 cases. Multiple pulmonary pathology was established in 18 cases (41.9%) while 4 cases (9.3%) only had lung bullaeles, 3 cases (7%) only had honeycomb appearance, and in 1 case (2.3%) only had pneumonia. It was established that 25 cases (53.2%) had type 1 respiratory failure (RF), 22 cases (46.8%) had type 2 RF. Intensive Care (IC) monitoring was necessary for 18 cases. Average term of stay in IC was 10.7±4 days. Need of intubation developed in 13 patients (27.7%). Oesaltamivir was administered in 23 cases with suspicion of influenza. Only 3 out of 23 cases administered Oesaltamivir were intubated and 9 out of other 24 cases were intubated (p<0.05). Intubation period was average 6.5 days in cases intubated and treated with Oesaltamivir and 7.8 days in untreated ones (p<0.05).

Result: Influenza related respiratory failure should be borne in mind in patients that alert with acute respiratory failure and that do not have classic radiological or pathologic findings.

In these patients supplementation of antiviral agents in the treatment particularly in the high risk group in terms of influenza complications may reduce the need of IC, duration of stay in IC and duration of intubation.

P411
The use of pulmonary embolism severity index (PESI) score in identifying patients suitable for ambulatory treatment or early hospital discharge following diagnosis of pulmonary embolism
Veronica Smith, Rossena Salinas-Abadalaz, Muriel Shannon, Brendan Madden. Cardiothoracic Medicine, St. George’s Hospital, London, United Kingdom

Introduction: International treatment guidelines for pulmonary embolism (PE) recommend that patients with low-risk of mortality should be considered for early discharge or ambulatory care. The Pulmonary Embolism Severity Index (PESI) has been validated to assess probability of 30 and 90 day mortality post PE. The aim of this study was to determine whether avoiding hospital admission, or facilitating early discharge, in low-risk patients could be achieved safely using the PESI score.

Methods: Since May 2010, St George’s Hospital has implemented a PE Assessment pathway. The PESI score was used to identify low-risk patients in order to determine suitability for early discharge or ambulatory care. A dedicated PE specialist nurse collected patient data and selected appropriate patients. Low-risk patients with PESI score I-II were given education, and taught self-administration of low molecular weight heparin.

Results: Over a twenty-one month period, 119 of 346 patients with confirmed PE on computed tomography pulmonary angiogram (CTPA) were discharged within 24-48 hours of diagnosis. A further 25 patients were able to avoid hospital admission, on the basis of early discharge, in low-risk patients could be achieved safely using the PESI score.

Conclusions: The PESI score can be utilised effectively by a specialist nurse to treat patients with low-risk PE (PESI score class I-II) in the community.

P412
The rise in carboxyhemoglobin and methemoglobin concentration from repeated five second breath-hold maneuvers
Gerald Zavorsky, Allison Straub, Kaleen Lavir, Kathleen Uhranowsky. Human Physiology Laboratory, Marywood University, Scranton, PA, United States

The measurement of pulmonary diffusing capacity for carbon monoxide (DLCO) raises the carboxyhemoglobin concentration in the blood, [COHb]. The standard 10 s breath-hold technique increases [COHb] by about 0.7% per test, which results in a 1% decrease in DLCO for every 1% rise in [COHb] (Respir Physiol, 1990, 81: 303-12). However, few data exist on the rate of increase in [COHb] or methemoglobin [METHb] from the modified Roughton and Forster one-step technique in which 0.28% CO and 40 to 50 ppm NO is inhaled simultaneously for 5 s. The combination of CO and NO inhaled together allows for determination of pulmonary capillary blood volume in a single breath-hold maneuver. Nine healthy subjects [24 (SD 4) yrs, hemoglobin concentration 13.2 (1.7) g/dL] performed repeated DLCO testing on two separate days. The days were randomized to provide either the standard 10 s breath-hold maneuver (0.30% CO), or the 5 s modified Roughton and Forster technique (0.28% CO, 55 ppm NO). Twenty-two 5 s breath-hold maneuvers, each separated by 4 min rest raised [COHb] to 11.1 (1.4)% and minimally raised the [METHb] to 0.8 (0.2)%.

After the 22nd test, DLCO was reduced by 3.6 (2.9) mL/min/mHg. This equates to a 0.44 (SEE

SUNDAY, SEPTEMBER 2ND 2012
0.08% increase in [COHb] per s vs breath-hold maneuver and a concomitant 0.35 (SEE 0.31%) decrease in DLCO. Pulmonary diffusing capacity for nitric oxide (DLNO) was not altered after 22 tests. On another day, the 10 s single breath-hold maneuver increased [COHb] by 0.64 (SEE 0.13%) per test, and reduced DLCO by 0.40 (SEE 0.26%) per test. In conclusion, the 5 s modified one-step technique does not appreciably raise [METHb], and DLCO is only significantly reduced after 10 tests.

### P413

Impact of a hand held ultrasound machine (HHUSM) in pulmonologist’s clinical hospital practice: Experience of nine months

**Michèle Gallo, U.O.C. Pneumologia I, A.O.Ospedali Riuniti Villa Sofia Cervello, Palermo, PA, Italy**

**Introduction:** HHUSM utilization is spreading outside radiology department at the point of care to guide some procedures and to assist clinical evaluation.

**Objectives:** The aim of this study was to evaluate the impact of HHUSM utilization in the pulmonologist’s hospital practice.

**Methods:** An ultrasound report was written by the P after each examination. Thoracic ultrasound evaluation (TUSE); a database was created after nine months. This database was analyzed to deduce the impact of HHUSM utilization in pulmonologist’s practice.

**Results:** Data are summarized in Table 1: 146 TUSE were analyzed: 108 were used in the clinical setting of lung opacities in the chest X ray and ultrasound assisted thoracocentesis. According to the pulmonologist’s Knowledge, 38 TUSE were applied in critical care setting.

**Conclusion:** HHUSM utilization is really important in several clinical situation. Limitations of technique were the operator’s knowledge and the standardization of the skillfulness outside radiology department. Waiting for gold standard exam-ination HHUSM utilization could help in clinical procedures and decisions when applied at point of care.

### P414

Premature adult lung study (PALS): Spirometry and lung clearance index are impaired in adult survivors of bronchopulmonary dysplasia

**Steven Caskey1, Aisling Gough2, Stephen Rowan1, Katherine O’Neill3, Judy Bradley4, Michael Tunney5, Chris Patterson6, Stuart Elborn1, Mi-kael Shields1, Henry Halliday5, Lorcán McGarvey1, Centre for Infection and Immunity, Queen’s University Belfast, United Kingdom; 2Nursing and Midwifery Research Unit, Queen’s University Belfast, United Kingdom; 3Health and Rehab Sciences Research Institute, University of Ulster, Belfast, United Kingdom; 4Cystic Fibrosis and Airways Research Group, Queen’s University Belfast, United Kingdom; 5Centre for Public Health, Queen’s University Belfast, United Kingdom; 6Regional Neonatal Unit, Royal Maternity Hospital, Belfast, United Kingdom; 7Health and Rehabilitation Sciences Research Institute, University of Ulster, Belfast, United Kingdom**

**Introduction:** We have previously reported increased respiratory symptoms in adult survivors of bronchopulmonary dysplasia (BPD) compared with very low birth weight (VLBW) (<1500g) and term controls. Here we report preliminary findings from spirometric and Lung Clearance Index (LCI) measurements.

**Objective:** To investigate whether adult survivors of BPD have greater impairment of lung function and LCI than age and gender matched VLBW and term controls.

**Methods:** Spirometry measurements (MicroLab ML3500 Mikhs®) were obtained in 16 BPD (male: mean (SD) age 24.9 (3.9) y, 9 VLBW [Mean (SD) age 25.5 (7.73) y] and 55 term controls [30 male; mean (SD) age 26.0 (4.0) y]); LCI measurements (Innocom™ device) obtained in BPD and VLBW participants were compared to 17 healthy controls (6M, mean (SD) age 30.5 (7.5) y).

**Results:** For all spirometry end points (FEV1, FVC, FEV1/FVC and FEF25-75%), BPD adults had significantly lower values than term controls (p<0.001). Mean FEV1 and FVC/FVC measurements were lower in BPD adults than VLBW (p<0.05). Mean LCI measurements were higher (more impaired) in BPD (mean (SD) 6.99 (0.78)) versus healthy controls [mean (SD) 6.36 (0.362)]. p<0.001. LCI measurements were also higher in BPD than VLBW but this was not statistically significant. Three BPD subjects had entirely normal spirometry but abnormal LCI values (value: > healthy control mean +2SD).

**Conclusion:** Our preliminary findings suggest existing lung function impairment in adult survivors of BPD. LCI may be a useful tool in detecting early small airways disease in adult survivors of preterm birth.

### P415

Diagnostic performance of the interferon gamma release assay in elderly patients and clinical factors to support the diagnosis of active tuberculosis

**Hiroyuki Kamiya1, Soichiro Ikushima, Keisuke Kondo, Kota Satake, Minoru Inomata, Atsuko Moriya, Tsunehiro Ando; Respiratory Medicine, Japanese Red Cross Medical Center, Tokyo, Japan**

**Background and objective:** The understanding of the diagnostic performance of the interferon gamma release assay in elderly patients is crucial in a country like Japan, where the higher rate of a prior history of tuberculosis can affect the test result.

**Methods:** From a total of four hundred twenty five patients screened, who were suspected of having active tuberculosis and received the Quantiferon-TB Gold In-Tube test (QFT-GIT), 65 patients in younger age group with the age less than 70 years, and 52 patients in elderly age group were eligible for the analysis. The diagnostic performance of the test was compared between two age groups, and the possible clinical factors to discriminate active tuberculosis cases from elderly patients with positive results of the test were also evaluated.

**Results:** Although the number of patients diagnosed to have active tuberculosis was similar among both age groups, the number of false positive results was significantly higher in elderly patients (4.6% compared to 23.1%). The specificity, positive predictive value and positive likelihood ratio were significantly lower in elderly patients, at 72.7% compared to 93.8%, 36.8% to 83.8%, and 3.21 to 14.12, respectively although other values were almost similar. Radiological findings, such as small nodules and infiltrates, were noted in more cases with active tuberculosis in elderly patients with positive results of the test than with other diseases.

**Conclusions:** The QFT-GIT test may be less accurate in elderly patients in the diagnosis of active tuberculosis, and radiological findings may be helpful in the clinical evaluation of positive results of the test.

### P416

New skin test with recombinant protein CFP10-ESAT6 in patients (children and adults) with tuberculosis, non-tuberculosis disease and latent TB infection

**I. Shorokhay3, 1, V. Litvinov1, Ya. Kochetkov1, B. Ovsyankina1, K. Kudlay2, P. Selsotovsky1, N. Nikolenko2, D. Ivanova1, 1Clinical Research, Scientific and Clinical Antituberculosis Center of Moscow Government Health Department, Moscow, Russian Federation**

**Aim:** To determine sensitivity & specificity of DIASKINTEST in children & adults with pulmonary, extrapulmonary TB, non-tuberculosis disease, latent TB infection (LTBI) and BCG vaccinated.

**Method:** 2609 patients received Mantoux test with 2 TU PPD-L and DST 0.2 mg/kg 1 ml.

**Results:** 97.3% (178/183) children & adolescents and 84.2% (208/247) adults with pulmonary TB & 89.7% (26/29) with extrapulmonary TB were DST-positive. Among 88 adults with TB/HIV 41 had <200 CD4 + T-lymphocytes (DST-positive were 22.0% & 47 >200 count (DST-positive were 55.3%) 94.6% (105/111) with pulmonary and 98.5% (67/68) with extrapulmonary non-tuberculosis disease were DST-negative. All 19 patients with non-active extrapulmonary TB had negative DST reactions. Among 1636 children & adolescents with LTBI the highest percentage of positive DST reactions - 94.9% (37/39) were observed in patients with converted tuberculin reactions and household spumum positive TB contacts, the lowest LCI = 22.5% <16(718) & with close social spumum negative TB contact. In adolescent students with close social spumum positive contact 77.9% were Mantoux - positive & only 5.6% (8/143) were DST-positive - among them 5 TB cases & 3 individuals with LTBI were detected.

DST was not positive in all 228 BCG-vaccinated. Among all children & adolescents 93.8% were Mantoux-positive.

**Conclusion:** DST demonstrated high sensitivity for both active TB and LTBI & high specificity in BCG vaccinated & non-tuberculosis disease.
Faheem Khan, Orla Cotter, Jim Clair, David Curran, T O'Connor. Respiratory Department, Mercy University Hospital, Cork, Ireland

We sought to determine whether the intensity of response in patients with a positive QuantiFeron-TB Gold assay (QTF) was predictive of active over latent tuberculosis, and whether other factors determined the intensity of response. We analyzed positive QuantiFeron assays (Cellexis, Carnegie, Australia) performed between July 2009 and April 2011 in the Mercy University Hospital, Cork. The group consisted of 94 patients with latent tuberculosis and 35 patients with active tuberculosis. There was no difference in the intensity of response between patients with latent and active tuberculosis (p=0.1589). In patients with latent tuberculosis, there were no correlations between age (p=0.353), sex (p=0.476), smoking status (p=0.323), contact history (p=0.612), Mantoux response (p=0.055), Irish nationality (p=0.768), previous BCG vaccination (p=0.504), WCC (p=0.187), peripheral lymphocyte count (p=0.786), neutrophil count (p=0.157) and the intensity of QTF response. Similarly in active TB group there is no correlation found between mentioned variables and QTF response.

The intensity of QTF response does not help to differentiate active from latent tuberculosis. In adults with tuberculosis, the intensity of QTF response is not influenced by age, sex, smoking, remoteness of contact history, Mantoux response, nationality, CXR abnormalities, BCG vaccination and peripheral lymphocyte count.

The persistency of positive or negative IGRA results does depend on the concentration observed in the first IGRA. This further underlines the need for a grey zone (e.g. 0.2 – 0.7 IU/mL) for IGRA interpretation in the serial testing of HCWs.
P422 Diagnostic value of gamma interferon assay in tuberculosis pericardial effusion: Study on a cohort of Iranian patients

Soorekh Sefid1, Setarab Davoudi2, Reihaneh Mohsenipour2, Farzad Masoudkabir1, Abbas Salehi Omran1.

Endocrinology and Metabolic Research Institute, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran; 2Department of Infectious Diseases, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran

Background: The efficacy of interferon-gamma (INF-gamma) and adenosine deaminase (ADA) for diagnosing tuberculosis pericarditis in a cohort of Iranian patients presenting with pericarditis were evaluated.

Methods: Thirty eight patients with presentation of pericarditis underwent diagnostic and therapeutic pericardiostomy with drainage and biopsy. Adenosine deaminase and Interferon-gamma levels were determined in pericardial fluid samples of all patients. Pericardial tissue samples were submitted for histopathologic and microbiologic studies. Polymerase chain reaction (PCR) was performed on all pericardial fluid samples to detect Mycobacterium tuberculosis.

Results: Among 38 patients with pericarditis, 7 cases were diagnosed as tuberculosis pericarditis (18.4%). Mean concentration of Interferon-gamma in tuberculosis group was significantly higher compared to non-tuberculosis group (692.57 ± 434.27 vs. 329.03 ± 437.7, P < 0.001). ROC showed a value of 14400 pg/ml as cutoff point for INF-γ with a sensitivity of 100% and specificity of 100% for diagnosing tuberculosis pericardial effusion. Adenosine deaminase was not found to be significantly higher in tuberculosis group in comparison with non-tuberculosis causes of pericardial effusion (35.7 ± 23.8 vs. 36.03 ± 72.27, P = 0.28).

Conclusions: According to the results of this study Interferon-gamma showed to be a valuable diagnostic test for detection of tuberculosis pericarditis, while adenosine deaminase measurement did not prove to have the characteristics of an accurate diagnostic test for tuberculosis pericarditis.

P423 Concordance between tuberculin skin testing and interferon-gamma release assays in diagnosis of latent tuberculosis infection among HIV-infected individuals

Adriana Soraci1, Gheorghe Nini2, Voicu Tudorache3, Teodora Moisil3, Erdin Borgaz4, Ana Fernandez-Quiroga5, Henar Villar5, Manuel Martinez-Muñiz1, Jose-Manuel Fernandez-Carreira5, Kaoutar El Boutaibi Faiz1, Fernando Alvarez-Navascues1, Ana Fernandez-Quiroga5, 1Area Gestión, Hospital San Agustín, Aviles, Asturias, Spain; 2Unidad Referencia Micobacterias, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 3Department of Infectious Diseases, Clinical Hospital "Dr. V Babes", Timisoara, Romania; 4Department of Pulmonology, West University "Dr. V Babes", Arad, Romania; 5Department of Infectious Diseases, Clinical Hospital "Dr. V Babes", Timisoara, Romania; 6Department of Pneumology, Clinical Hospital Pneumophysiologico, Constanta, Romania

Introduction: Detection and treatment of latent TB infection (LTBI) in HIV infected individuals is strongly recommended to decrease morbidity and mortality in countries with high levels of HIV. Interferon gamma release assays (IGRA) are now available alternatives to tuberculin skin test (TST) to detect LTBI.

Aims: This study compared QuantiFERON-TB Gold In-Tube (QFT-IT) with the TST for the detection of latent tuberculosis infection among HIV-infected individuals in an area with a high prevalence of tuberculosis (120/100000), where BCG vaccination is mandatory.

Methods: A prospective study of HIV-infected individuals with received the TST and an IGRA, the QFT-IT.

Results: Of 147 participants, 106 (72.1%) returned for an evaluable TST. Concordance between QFT and TST was 88.8% (kappa = 0.37, P < 0.001). However, in subjects with positive test results by either TST or QFT, only 27% (4/15) had positive test results by both modalities. TST-positive/QFT-negative discordant results were found in 5.1% of subjects and TST-negative/QFT-positive discordance in 6.1%. Indeterminate QFT results occurred in 5.4% (8/147), all due to a failure to respond to the phytohemagglutinin-positive control. Subjects with a CD4+ count of less than 100 cells/mm3 had a relative risk of an indeterminate result of 4.24 (P = 0.003) compared with those with a CD4+ count of 100 or more.

Conclusions: Overall concordance between QFT and TST in HIV infection was high and similar to that seen in an immunocompetent population, but QFT testing may be limited by an elevated rate of indeterminate results in subjects with CD4+ cell counts of less than 100 cells/mm3.

P424 Cut-off point for tuberculin skin test (TST) and QuantiFERON (QFT) in the diagnosis of tuberculosis infection (TI) in a study of contacts of tuberculosis (TB)

Jose-Maria Garcia-Garcia1, Juan-Jose Palacios2, Begona Gonzalez-Gonzalez3, Ana Fernandez-Quiraga4, Henar Villar4, Manuel Villanueva5, Gema Castaño6, Kaoutar El Bousiba7, Fernando Alvarez-Navascues8, Andrés Sanchez-Antuñil1, Jose-Antonio Gullon1, Jesús Allende1, Manuel Martinez-Mutia1, Jose-Manuel Fernandez-Carrera1, 1Area Gestión Clínica Neumología, Hospital San Agustín, Aviles, Asturias, Spain; 2Unidad Referencia Microbacterias, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 3Unidad de Referencia Microbacterias, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 4Atención Primaria, Area Sanitaria III, Aviles, Asturias, Spain; 5Microbiología, Hospital San Agustín, Aviles, Asturias, Spain; 6Unidad Investigacion, Hospital San Agustín, Aviles, Asturias, Spain

Aim: To determine the cut-off for TST assuming a diagnosis of TI when QFT was ≥ 0.35 IU/mL. Moreover, we calculated the cut-off for QFT assuming the diagnosis of TI when TST was ≥ 5 mm.

Methods: We studied prospectively 414 close contacts from 82 TB patients. We performed "QuantiFERON TB GOLD in Tube" (according to the manufacturer’s instructions, Cellestis, Australia) and the same day after venous blood puncture for QFT, TST (Mantoux technique with 2 UI of PPD RT23 with lecture 72 hours later). We studied sensitivity, specificity and analysis "Receiver Operator Characteristics" (ROC). The positive and negative predictive values (PPV, NPV) were calculated based in our proportion of TI of 52.9%.

Results: Assuming as "gold standard" of TI a value of QFT 0.35, the best cut-off of TST was 5mm.

P425 Evaluation of cut-off values of QuantiFERON-TB Gold, interferon gamma inducible protein-10 and tuberculin skin test in active tuberculosis diagnosis

Ertun Sevki1, Kaya Koksal2, Gulsal Gümüsloğlu2, Sinem Sokaci3, 1Chest, Yedikule Chest Diseases and Thoracic Surgery Education and Research Hospital, Istanbul, Turkey; 2Epidemiology, Molecular Tuberculosis Epidemiology Laboratory, Institute for Medical Experimental Research (DETAIE), Istanbul University, Istanbul, Turkey

Aim: The diagnostic accuracy of interferon-gamma-based assays for Mycobacterium tuberculosis infection may be improved by using lower cut-off values for the tuberculin skin testing (TST), QuantiFERON-TB Gold (QFT) and Interferon gamma inducible protein (IP)-10.

Methods: A total of 70 adult TB patients and 81 healthy controls were included for this study. Three assays, TST, QFT and IP-10, were evaluated for their diagnostic performance with respect to different cut-off values. Test cut-offs were established based on receiver operating characteristic curve analysis.

Results: The sensitivities of the assays were: TST 40%, QFT 87% and IP-10 85%, while their specificities were TST 58%, QFT 71% and IP-10 74%. Both QFT

548
and IP-10 were significantly more specific than TST (both P < 0.001), but were similar to each other (P > 0.5). Receiver operating characteristic analysis revealed that a cut-off value of 0.29 IU/ml for QFT and 1857 IU/ml for IP-10 maximizes specificity with significant loss of test sensitivity. Using lower cut-off values for TST, however, also increased the sensitivity of the assay but resulted in a significant decrease in specificity.

Conclusions: Lower cut-off values for TST, QFT and IP-10 increased the sensitivity of each assay, but a lower cut-off value for QFT and IP-10 could specificity be maintained.

P426
Sensitivity of the QuantiFERON-TB Gold test in culture-verified NTM disease and TB in a Danish setting
Thomas Stig Hermansen, Vibeke Østergaard Thomsen, Pernille Ravn
1Epidemiklinikken, Dept. of inf. Diseases, Rigshospitalet, Blegdamsvej 9, Copenhagen, Denmark; 2International Reference Laboratory of Mycobacteriology, Statens Serum Institut, Copenhagen, Denmark; 3Clinical Research Center, Hvidore Hospital, Keggetorv Alle 30, Hvidore, Denmark

Introduction: Previous studies have suggested that the QuantiFERON®-TB Gold (QFT) test can be used to discriminate between tuberculosis (TB) and non-tuberculous mycobacterial (NTM) disease. The QFT-test has a higher specificity and sensitivity for infection with mycobacterium tuberculosis (MTB) compared to the tuberculin skin test, but only few studies have included a large number of patients on a nation-wide basis.

Methods: We have studied 12000 QFT-tests obtained between 2009-2011 from a Danish national database. Results of mycobacterial cultures were available for 300 patients. Performance of the QFT-test in the group of patients with active TB and NTM disease was evaluated.

Results: 202 patients had positive culture for M. tuberculosis complex (MTC) and a QFT done. We found 165 positive, 29 negative and 8 indeterminate results, resulting in a specificity of 81.7%. In total 98 patients had culture verified NTM infection (species known to share the ESAT6 and CFP10 antigens were excluded). n=60. We found 15 positive, 68 negative and 9 indeterminate results. The causative microorganisms of NTM pulmonary disease were: M. avium (52%), M. gordonae (17%), M. catarrhalis (7%), M. Mucogenic (6%), M. xenopi (4%), M. intracellulare (4%), M. kansasii (4%).

Conclusion: The sensitivity of the QFT-test in Denmark, a low-burden TB setting, corresponds well with earlier findings. In a large population of patients with NTM we found a specificity of 74% for infection and a relatively high indeterminate rate. The impact of prior BCG vaccination, MTB exposure and immunodeficiency on specificity and indeterminate rate in the NTM group will be further explored.

P427
Treatment in inflammatory bowel disease affects IGRA performance
Miguel Arias1, Sabino Riestra2, Ruth DeFrancisco2, Ana Pando1, Juan José Palacios1, Patricio Escalante4, José Belda6, Luis Molinos1, Miguel Arias1, Ana Losada1, Pere Casan3, 1Pulmonary Service, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 2Inflammatory Bowel Disease Unit, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 3Pulmonary Service, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 4Pulmonary and Critical Care Service, Mayo Clinic, Rochester, MN, USA; 5Radiology Service, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain; 6Pulmonary Service, Hospital Arnau de Villanova, Valencia, Spain

Introduction: The detection of LTBI in patients with inflammatory bowel disease (IBD) before treatment with anti-tumor necrosis factor α must be made with chest radiograph and TST. In immunocompromised patients the limitations of this strategy are well known, therefore it is advisable to use new diagnostic methods based on the release of interferon-γ (IGRA).

Material and methods: 204 IBD patients underwent screening for detection of LTBI where T-SPOT.TB (T.SPOT) and Quantiferon-TB Gold In Tube (QFT) determinations were performed simultaneously, also lymphogram, TST and chest X-ray were performed. TST was defined when the TST and/or any IGRA was positive.

Results: 156 patients had Crohn disease, 42 ulcerative colitis and 6 non-specific colitis. 34 were treated with 5-aminosalicylic acid, 63 with immunomodulators, 32 anti-TNF-α, 27 corticosteroids and 47 a combination of them. 14 were positive TST, 24 for the T-SPOT and 3 for the TST. The lymphogram showed an association between TSPOT + and QFT + and the amount of circulating CD8 (≥ 500 cells) while QFT-SPOT + results have the amount of CD8 reduced (<500). Moreover, their treatment modified all lymphocyte populations particularly the ICS and Treg cells.

Conclusion: The immunomodulatory treatment of patients with IBD altered lymphocyte profile which, in turn, is related to the result of testing LTBI. A correct interpretation of the results for the study of LTBI needs to know the treatment received and requires an assessment of lymphocyte populations that verifies its normality. If the lymphocytes are low, particularly CD8, the effectiveness of IGRA (specially the QFT), is very small and require every test possible to rule out LTBI.

P428
Application of intracellular cytokine flow cytometry in the diagnosis of active tuberculosis
Jaeche Lee1, Eun Jin Kim2, Seung Soo You1, Shin Yup Lee1, Seung Ick Cha1, Jae Yong Park1, Chang Hou Kim1, 2Internal Medicine, Kyungpook National University, School of Medicine, Daegu, Korea; 2Internal Medicine, Cha University Hospital, Gumi, Korea

Background: Intracellular cytokine flow cytometry (ICCFC) has been introduced to detect the T cell response to M. tuberculosis antigen (MTB Ag). However, it could not overcome the limits shown by whole blood interferon-gamma (IFN-γ) release assays (IGRA). Given the important role of CD4+T cells as well as IFN-γ and TNF-α in pathogenesis of TB, we compared the diagnostic accuracy between ICCFC measuring frequencies of MTB-specific Ag stimulated IFN-γ+CD4+ and CD4+ cells and IGRA to confirm the usefulness of application of ICCFC for TB diagnosis in clinical practice.

Methods: Both Quantiferon® TB Gold In-tube (QFT-IT) test and ICCFC analysis were performed in 80 patients who were suspected of having pulmonary TB or TB pleurisy and 10 controls with no known exposure to TB. Results: (1) Sixty one and 19 out of total 80 patients were diagnosed with active TB and non-TB, respectively. (2) Double IFN-γ+TNF-α+CD4+T cell among all T cell subsets analyzed by ICCFC showed the highest sensitivity (90%) for diagnosis of TB. (3) Sensitivity of QFT-IT test and ICCFC assay were 77% and 90%, respectively (p = 0.021). (4) Specificity of QFT-IT and ICCFC assay were 73.7% and 89.5%, respectively. (5) There was a good correlation between the quantity of IFN-γ, as detected by the QFT-IT test, and the frequencies of IFN-γ+TNF-α+CD4+T cell measured by the ICCFC assay in TB patients (p=0.012). (6) The frequencies of IFN-γ+TNF-α+CD4+T cells were significantly decreased after 6 months of treatment compared with pretreatment (p=0.026).

Conclusions: The ICCFC assay with T cell stimulation by MTB-specific Ag may be a useful additional tool for the diagnosis of active TB, although further study is needed for more convincing data.

P429
Immune responses in the lungs of patients with tuberculous pleural effusion without parenchymal tuberculosis
Non-II Choi, Internal Medicine, Keimyung University Dongsan Medical Center, Daegu, Republic of Korea

Background: Tuberculous pleural effusion (TPE) is one of the most common forms of extrapulmonary tuberculosis. Because most studies of TPE focussed on the pleural space, little information regarding lung parenchyma is available. We therefore aimed to investigate immune responses in the lung parenchyma of TPE patients without active parenchymal tuberculosis.

Methods: Patients with any evidence of active parenchymal tuberculosis, either from radiologic or bacteriologic evaluation, were excluded. Bronchoalveolar lavage fluid (BALF) was collected from 10 newly diagnosed, untreated, HIV-negative TPE patients and 10 healthy controls. We analyzed T-lymphocyte subpopulations and measured 10 cytokines in BALF. Cytokine levels in BALF were standardised using urea.

Results: The concentrations of interferon-γ (IFN-γ), tumor necrosis factor-α (TNF-α), vascular endothelial growth factor (VEGF), and the CD4+/CD8+ ratio of lymphocytes were significantly higher in TPE patients without active parenchymal tuberculosis than in the controls. Of the cytokines measured in BALF, VEGF showed the highest concentration. No difference was observed in T-helper type 2 cytokines between the 2 groups.

Conclusion: There were significant immune responses and increases in IFN-γ, TNF-α, and VEGF in the lung parenchyma of TPE patients without active parenchymal tuberculosis. This result suggests that TPE may induce a significant immune response in lung parenchyma.
a moderate agreement: 90% (45/50); (k=0.611). Active TB was detected in 4% (2/50) subjects.

**Conclusion:** Despite the intense exposition of immunocompetent household TB contacts to a highly symptomatic index case, transmission of M. tuberculosis rarely occurred. The data indicate that a previous BCG vaccination and/or TST testing could be a reason for the false positive TST results. Two tests can be used in the diagnostic algorithm of TB infection in household contacts. In order to apply the TST a higher cut off values (≥15 mm) should be used for positivity. The QFT assay could replace the TST in BCG vaccinated population.

**P341**

**Experience of using Diaskintest by tuberculosis patients**
Ljiljana Pantićkratov, Natalia Kuzinimova, Ksenia Klochkova, Margarita Ogareva.
Chair of Pulithsoptalmology, Saratov State Medical University, Saratov, Russian Federation

This is a study of Diaskintest (DST) - a new diagnostic test for tuberculosis (TB). It is an additional method of TB diagnosis and of evaluation of activity of the TB process. The objective of the study was to evaluate the sensitivity and specificity of the test on a sample of TB patients treated at the TB hospital in Saratov (Russia) in 2010 - 2012. A total of 95 subjects participated: newly diagnosed - 69.5%, with relapses - 11.6%, chronic forms - 18.9%. HIV co-infection in 22.1%

In most TB patients (71.6%) DST was found to be positive. Test average value was 9,8±8,85, including M 9,0±8,21 in newly diagnosed subjects, 11,5±11,71 in subjects with relapses, and 11,6±9,41 in chronic patients. In subjects with limited processes, DST was 7,4±4,91, and in subjects with wide-spread and destructive processes - 10,6±9,77 (p ≥ 0.05). Only 42.9% subjects with HIV infection, were DST-positive. Out of the 95 participants, 27 subjects with clinically confirmed TB, 28.4% were DST-negative. Of these, 12 had HIV infection which could have caused suppression of DST sensitivity. Of the remaining 15 subjects with TB, 10 were confirmed by bacterioexcretion, one – by histological examination of surgical specimens, and only 4 subjects did not have such confirmation. In other words, in 11 cases (11.6%) the presence of tuberculosis was not revealed by DST.

**Conclusion:** DST was positive in 71.6% of TB cases, but only 42.9% among HIV-positive subjects, and in 79.7% in subjects without HIV infection. In 11.6% of the cases, DST did not reveal the presence of TB.

**77. CPAP: beneficial effects on different aspects of health**

**P342**

**ncCPAP’s functional effects on ciliary function of nasal respiratory epithelium**
J Ulrich Sommer, Joachim T. Maurer, Karl Hörmann, Boris A. Stuck.
Department of Otorhinolaryngology Head and Neck Surgery, Medical Faculty Mannheim, University Hospital Mannheim, Mannheim, Germany

Continuous positive airway pressure (CPAP) is the gold standard in therapy of obstructive sleep apnea (OSA) but is associated with numerous side effects often related to the nose and the upper airway. Humidified CPAP may, in part relieve these symptoms. Nevertheless, little is known regarding the effects on ciliary function (CF).

In this prospective, randomized, crossover trial patients with OSA (AHI ≥20) were included and randomized to one of two treatment arms, nCPAP with or nCPAP without humidification, for a period of eight weeks. At the end of the eight-week period patients were swapped to the alternative treatment arm for a further eight week period. CF (beat frequency [CBF] and mucus transport time [MTT]) were assessed before and one day after the beginning of nocturnal ventilation and again at the end of each treatment arm.

The baseline CBF was 4.7 ± 0.07 Hz. The MTT 568 ± 185s. Short-term changes without humidification (CBF +0.7 ± 0.08 Hz; MTT -152 ± 158s) and with humidification (CBF +0.7 ± 0.08 Hz; CBF +0.20 ± 0.08 Hz; MTT +192 ± 208s) were not statistically significant. The long-term effects, CPAP without humidification significantly increased the CBF above the baseline level by v.5.±0.4 Hz and -107±175s (p<0.01) and even more so with humidification (+4±0.71Hz, -286±49s; p<0.01).

Independent of airway humidification, nCPAP has limited effects on short-term ciliary function of the nasal respiratory epithelium that is not statistically significant. However, long-term effects showed a significant increase in ciliary function both in terms of an increased beat frequency and an increase in mucus transport time that has not been described previously. The effect was more pronounced when humidification was used during nCPAP.

**P343**

**CPAP therapy in OSA patients: The effects on healthcare use and medical costs related to cardio- and cerebrovascular diseases**
Judit Kata Vagga1, Gabor Horvath2, Zsolt Esan Komlosi1, Gyorgy Boszormenyi-Nagy3, Katalin Vardi Visy1, Gyorgy Losonczy1, Laszlo Kunos1. 1Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Department of Pulmonology, National Kopacs Institute for Tuberculosis and Respiratory Medicine, Budapest, Hungary; 3Department of Pulmonology, Institute of Pulmonary Medicine, Törökbálint, Hungary

**Background:** Obstructive sleep apnea (OSA) is a major risk factor for cardio- and cerebrovascular diseases, however, CPAP treatment could reduce the occurrence and healthcare costs of these complications.

**Aim:** To assess the impact of CPAP therapy on healthcare use and medical costs related to cardio- and cerebrovascular diseases.

**Methods:** By analysing the patient database of the Hungarian Health Insurance Fund Administration in a one-year period starting from July 2007, OSA patients with newly initiated CPAP therapy were identified. Hospital admission rates, hospital treatment days, and the use and costs of relevant medications of these patients were evaluated from 3 years before to 3 years after CPAP therapy.

**Results:** In the study period, 993 OSA patients started CPAP therapy in Hungary. In comparison to the 3-year period on CPAP therapy (post-CAP), the numbers of pre-CAP cardio- and cerebrovascular disease related hospital admissions and treatment days were higher by 22.4% (205 vs. 159 admissions) and 25% (2254 vs. 1968 days), respectively. Mean hospital treatment costs were 34% lower in the post-CAP than in the pre-CAP period (238 vs. 156 €). The reduction in post-CAP hospital admissions, treatment days and costs was more prominent in a subgroup analysis in patients fully complying with the follow-up care (112 patients). Interestingly, the use and costs of relevant medications were nearly identical in the pre- and post-CAP therapy periods.

**Conclusion:** Our study suggests that CPAP therapy could reduce healthcare costs of OSA patients by lowering hospital admission rates, treatment days and costs related to cardio- and cerebrovascular diseases.

**P343**

**Long-term CPAP compliance in women with obstructive sleep apnoea**
Francisco Campos-Rodriguez1, Miguel A. Martinez-Garcia2, Nuria Reyes-Nüeter1, Carmen V. Almeida-González2, Pablo Catalán-Serrás, Josep M. Montserrat2. 1Pneumology, Valme Hospital, Sevilla, Spain; 2Pneumology, La Fe University and Polytechnic Hospital, Valencia, Spain

**Objectives:** We sought to analyze long-term CPAP compliance and predictors of CPAP dropout, in a large female cohort with a prolonged follow-up.

**Methods:** Consecutive women diagnosed with OSA (apnoea-hypopnoea index [AHI] ≥10) and started on CPAP treatment in two Spanish Sleep Units between 1999-2007 were included in the study. Women were followed-up until December 2009. The Kaplan-Meier method was used to calculate the probability to continue on CPAP treatment, and a multivariate Cox regression analysis was used to identify baseline predictors of CPAP dropout.

**Results:** We analyzed 708 women with median (IQR) age 60 years (52-67), AHI 43 (27-66.8), and Epworth Scale 13 (9-16). Women were followed for a median period of 6.2 years (4.2-7.7) and average compliance with CPAP was 6 hours/day (4-7). During follow-up, there were 129 CPAP dropouts (18.2%), and the probability of being still on CPAP at 5 and 10 years was 82.8% and 79.9%, respectively. Baseline predictors of CPAP dropout in the multivariate analysis were age (OR 1.01, 95%CI 1.00-1.03), use of sedative/antidepressant medication (OR 1.47, 95%CI 1.03-2.08) and CPAP pressure (OR 0.89, 95%CI 0.82-0.97).

**Conclusions:** Long-term CPAP adherence in women with OSA is good. Increasing age and use of sedatives/antidepressants were independent predictors of CPAP dropout, whereas higher CPAP pressures were associated with continued treatment.

**P345**

**Titration of continuous positive airway pressure in Chinese patients with obstructive sleep apnea**
Jinying Luo, ZhiHui Qu, YingXin Wu, Y.M. Luo. State Key Laboratory of Respiratory Disease, Guangzhou Medical College, Guangzhou, China

**Objective:** Whether CPAP pressure derived from manual titration is the same as pressure titration by automized CPAP devices is unknown. The purpose of this study was to compare the pressure derived from manual titration with pressure from automatic titration. We also attempted to establish a formula to determine the appropriate CPAP pressure for Chinese individuals.

**Methods:** Fifty-one patients with OSA (mean apnoea-hypopnoea index [AHI] = 50.6±18.6 events/hour) who were newly diagnosed after an overnight full polysomnography and who were willing to accept CPAP as a long-term treatment were recruited for the study. Manual titration was performed by the method of nocturnal ventilation for 8 weeks with full polysomnography monitoring and untreated automatic titration with an automatic CPAP device
Conclusion: nGER is a common clinical symptom of OSA and often related to the Icelandic Sleep Apnea Cohort (ISAC) Prevalence of restless legs syndrome among patients with obstructive sleep No.81120108001). REMstar-auto, is usually higher than the pressure derived from manual titration. Our results suggest that automatic titration pressure derived from methods:
The OSA subjects (n=822) were newly diagnosed with moderate or severe OSA (665 males,157 females). The control subjects (n=742) were randomly chosen Icelanders (394 males, 348 females) who participated in another epidemiological study (www.boldcopd.org). Measurements included a standardized RLS rating scale, questions about sleep and the Ewthorp Sleepiness scale. The change with CPAP treatment was assessed after 2 years (n=558).

Results: Among OSA males 23.3% reported RLS but 12.9% of control males (p<0.001). 35.8% of OSA females reported RLS but 24.4% of control females (p=0.03). Both among OSA patients and controls those with RLS more commonly reported insomnia, daytime sleepiness, nocturnal sweating, snoring and gastro esophageal reflux (<p>0.05). No relationship was found between RLS and age, BMI, hypertension or respiratory disease. Subjects using CPAP had a decreased prevalence of RLS from 25.7% to 13.8% while no change was observed in those without RLS (p=0.04 for difference between groups).

Conclusion: RLS is more prevalent among OSA patients than controls. CPAP treatment decreases RLS symptoms significantly.

P437
Nocturnal gastro-esophageal reflux and respiratory symptoms in patients with obstructive sleep apnoea, before and after CPAP treatment, compared to the general population: The Icelandic Sleep Apnea Cohort (ISAC) study. Thórarinn Gislason1,2, Oscar Inggi Emísson1,2, Eina Sif Arnardottir1,2, Christur Jansson1, Bryndis Benediksdottir1,2, Sigurður Júlíusson1, Allan Pack1,4, Respiratory Medicine and Sleep, Landspílsstaður University Hospital, Reykjavík, Iceland; 2Faculty of Medicine, University of Iceland, Reykjavik, Iceland; 3Department of Medical Sciences, Respiratory Medicine & Allergology, Uppsala, Sweden; 4Center for Sleep and Circadian Neurobiology, University of Pennsylvania, Philadelphia, United States

Introduction: To estimate the prevalence of reported restless gastro-esophageal reflux (nGER) and respiratory symptoms in obstructive sleep apnoea (OSA) subjects compared to the general population. Also change in nGER with CPAP treatment. Methods: 826 OSA patients referred for CPAP treatment. 623 subjects have had a 2 year follow-up visit (n=412 CPAP users, n=211 nonusers). The control group consisted of 939 subjects randomly selected from the general population (81% response rate). Both groups answered the same questionnaires on nGER, sleep, respiratory symptoms, general health and quality of life measured by SF-12.

Results: Altogether 18.6% of OSA females and 13.6% of males (p=0.07) compared to 7.5% of controls (p<0.01) reported nGER (> 1x a week). Where a more common among OSA subjects with nGER compared to those without nGER (42.5% vs. 29.3%, p<0.05). Bringing up phlegm in the morning was also associated with reporting nGER (35.7% vs. 24.8%, p=0.02). Among OSA patients nGER was not related to smoking, obesity, hypertension, diabetes or OSA severity. SF-12 showed that among those with nGER both physical component scores (40.7±10.9 vs. 37.4±10.3, p=0.003) and mental scores (49.9±10.8 vs. 44.1±11.1, p<0.001) were significantly lower. At two year follow-up nGER was only reported by 6.2% of those followed and was lowest (3.8%) among full CPAP users (p<0.001).

Conclusion: nGER is a common clinical symptom of OSA and often related to respiratory symptoms. Prevalence of nGER decreases with CPAP treatment in a majority of OSA patients.

P438
Control of breathing in obstructive sleep apnoea patients: Role of CPAP therapy Antónia Re, Flaminio Mornole, Alessandro Di Marco Berardin, Dina Visca, Bruno Iovene, Salvatore Valente. Pneumologia, Università Cattolica del Sacro Cuore, Roma, Italy

Aim: Control of breathing during wakefulness in obstructive sleep apnea (OSA) and the role of CPAP therapy is an ongoing controversy. We studied the ventilatory response of healthy controls and OSA patients before and after at least 1 year of CPAP therapy. Methods: 17 never treated OSA patients (16 M, 53.1±12.3yrs; BMI=34.5±8.1; AHl=45±14.7) underwent nocturnal cardipulmonary monitoring, spirometry and blood gas analysis. Read’s rebreathing test was used to evaluate hypercapnic ventilatory response (HVR CO2); hypoxic ventilator response (HVR O2) was studied by both progressive and transient methods, to explore both peripheral oxygen chemoreceptors and the central modulation. The relationship between minute ventilation (VE) or mean inspiratory flow (VTi) or PET CO2 or PET O2 was expressed in terms of slope of linear regression for HVR CO2 and of parameter A of hyperbolic function for HVR O2. Results: OSA patients showed an increased responsiveness to transient, but not to progressive, hypoxemia, and a reduced response to hypercapnia when compared to controls. Transient HVR CO2 showed a significant reduction during CPAP therapy (p<0.01), whereas HVR CO2 increased only slightly. Progressive HVR O2 was not modified by CPAP [Tab 1].

Conclusions: The daytime glycomic reactivity to transient hypoxia is increased by repeated nocturnal hypoxic stimulus; CPAP significantly restores the ventilatory stability during sleep.

Table 1. Chemosensitivity in Controls and in OSA pre and post CPAP

P439
Differences between commercial vehicle drivers and other patients in symptoms of obstructive sleep apnoea and response to CPAP therapy Werner Stekel, Daisana Steks, Michael Tamm. Pneumologie, University Hospital, Basel, Switzerland

Introduction: Among patients with obstructive sleep apnoea (OSA), commercial vehicle drivers (CVD) should be treated with special care, since untreated OSA is a well established risk factor for traffic accidents. However, little is known whether symptoms and course of treatment of OSA in CVDs are similar to those of other OSA patients.

Method: We analysed the course of diagnosis and treatment in CVDs diagnosed with OSA in 2009 and 2010 and compared these data with a control group of non-CVD patients.

Results: We identified 37 CVDs treated with CPAP and compared their results with a control group of 74 patients. Both groups were well matched with respect to age, BMI, apnoea-hypopnoea index and oxygen desaturation index. However, the Ewthorp Sleepiness Score (ESS) was significantly lower in the CVD group (8.1±2.8 vs. 11.0±2.7, p<0.001) and this difference was unchanged after 6 months of CPAP therapy (4.8±2.1 vs. 7.7±2.2, p<0.001). The adherence to CPAP therapy was lower in CVDs than in the control group: daily usage was 4.5±1.1 vs. 5.0±1.4 hrs (p=0.02), % of days used was 75±14 vs. 83±19% (p=0.012). CVDs had significantly more unscheduled visits in the first 6 months of treatment than control patients: 1.5±0.6 vs. 0.7±0.4 (p<0.001).

Conclusions: Despite similar baseline characteristics, CVDs report significantly lower values in the Ewthorp sleepiness score at diagnosis and under CPAP treatment. CPAP compliance is lower in CVDs than in control patients and CVDs have more unscheduled clinical visits than other CPAP patients. These points should be taken in consideration when starting OSA treatment in CVDs.
Patients with apnoea-hypopnoea index (AHI)<5/hour served as controls. Serial measurements of exhaled NO after PSG were performed in 21 OSA patients and 8 control subjects.

**Results:** CANO was significantly higher in OSA patients (n=71; 4.07±1.7ppb) as compared with controls (n=24; 2.24±1.06ppb; p<0.0001) whilst maximal bronchial NO flux and fractional concentration of exhaled NO did not significantly differ between the two groups. In patients with OSA, CANO was strongly associated to AHI (r=0.70; p<0.0001) and to recoding time with SatO2<90% (ST-90%; r=0.659; p<0.0001). The area under ROC curve for screening patients with OSA and significant nocturnal oxygen desaturation (ST-90%>15%) was 0.855 (0.777-0.933) (p<0.0001). CANO at 4.49ppb could detect these patients with sensitivity of 46% and specificity of 94%. Increased CANO variation after PSG was significantly related to oxygen desaturation index (TS-90%).

**Conclusions:** Increased alveolar NO concentration was related to the severity of nocturnal oxygen desaturation in patients with OSA, linking the distal lung inflammation to intermittent hypoxia. CANO could be used to screen for severe OSA in suspected and symptomatic patients.

**P441**

Predictors of long-term PAP-adherence in obstructive sleep apnea syndrome

**Otto D. Schoch, Florent Baty, Jolanda Niedermann, Jochen J. Ruediger, Martin H. Brutsche. Multidisciplinary Centre for Sleep Medicine, Pneumology, Kantonsspital St Gallen, St. Gallen, Switzerland**

**Introduction:** Few studies have assessed long-term adherence to positive airway pressure therapy (PAP) in OAS. The aim of this retrospective study was to determine adherence and its potential predictors.

**Methods:** All patients (pts) treated at the St.Gallen sleep centre from 11/2001 to 4/2011 were included for analysis of baseline data and follow-up information. The primary dependent variable of interest was continued use of PAP. Kaplan-Meier estimates and Cox-proportional hazards regression were used to model the risk of loss of adherence. A multivariate regression analysis was performed for age, gender, Epworth sleepiness score (ESS), BMI, apnea-hypopnea index (AHI) and oxygen desaturation index (ODI) at baseline.

**Results:** During the study period, of 2160 pts started on PAP, 42 (2%) died on PAP; 91 (4%) no longer needed PAP (weight reduction, alternative treatments) and 311 (14%) were lost to follow-up. In 1716 pts, adherence at 1y was 74.8% CI: 71-76%), at 5y 56 (53-59)%, and at 8y 52 (49-56)%. Results of univariate and multivariate analyses are summarized in the figure.

**Conclusion:** Adherence is independently associated with clinical (ESS) and polysomnographic (ODI, AHI) measures of OAS severity, but not with BMI, age, gender. Most pts who stopped PAP were lost to follow-up. With a relatively low long-term, intensified efforts and alternative or novel follow-up options (e.g. telemetry) to support such patients should be tested.

**P442**

Utility of a nurse-led visit program for patients with obstructive sleep apnea syndrome treated with CPAP

**Amara Ateca, Izar Arizmendi, Sonia Herrero Martin, Jose Antonio Casacante Rodrigo, Pilar Cebollero Rivas, Victor Manuel Eguía Astibia, Javier Hueto Pérez de Herdia, Isabel Andrade Vela, Respiratory Department B, Complejo Hospitalario de Navarra, Pamplona, Navarra, Spain**

Obstructive Sleep Apnoea Syndrome (OSAS) is a frequent cause of visit in our clinic’s environment. In order to diminish its impact in the physician’s agenda we created a specific nurse-led individual consultation for their follow-up visits.

**Aims:** We want to analyze the characteristics of patients and changes made in terms of treatment or even medical discharge.

**Methods:** We have analyzed IAH, BMI, Epworth sleepiness scale (ESS), CPAP compliance and satisfaction grade in patients attended from June to December 2010.

**Results:** We attended 243 patients, 88% of them were men, the age average was 56.6±11.6 years. At the moment of the diagnosis the IMC was 33.2±5.4 and the ESS 10.3±4.9. At nurse-led visit IMC was 33.4±5.6 and ESS 9.8±4.2. We found an average of use of 6.0±3.2 hours per hour and 6.4±1.6 days per week. We detected a good level of compliance in 78% of them, quite good in 8.5% and bad in 13.5%. They fulfilled a satisfaction test (scale 0-10) and the mean value obtained was 7.2±2.4. We needed to change the Mask model because of bad tolerance in 20% of patients. Because of good follow up, we could discharge from medical control 37.9% of the cases, they are followed now only in the Nurse unit and almost 60% remained control by both medical and nurse but medical one are their regular follow-up visit. We only give definitive discharge because of low compliance in 1.2%.

**Conclusions:**
- Our patients showed a good level of satisfaction
- We have found a good level of CPAP compliance
- We had to change mask model in a substantial number of cases
- We could discharge from medical follow up an important number of patients, optimizing the use of health care resources.

**P443**

Impact of a respiratory rehabilitation program in the functional capacity of the patients with obstructive sleep apnea-hypopnea syndrome (OSAHS)

**Patricia Gaerar, Agustín Valido, María Pavón, Virginia Almadana, Federico Montemayor. Pneumology, Hospital Virgen de la Macarena, Seville, Spain**

**Objectives:** Determine the basal exercise capacity in patients with severe OS-AHS.Determine the exercise capacity modified after 3 months of treatment with CPAP or with CPAP and Respiratory Rehabilitation program.Analyze the impact of these changes on the quality of life,physical activity and psychological impact.

**Methods:** A prospective study with a consecutive inclusion of healthy patients with the polysomnographic diagnosis of severe OS-AHS.We evaluated the exercise capacity of these patients by means of a cardiopulmonary test in a cyclogrime–submaximal exercise capacity before the beginning of the treatment in both groups.

**Results:**

Nasal inflammation and compliance with nasal CPAP therapy in obstructive sleep apnoea (OSA)

**Noura AlAhmari; Raymond Sapsford, Jadwiga Wiedzicha, John Hurst. Academic Unit of Respiratory Medicine, Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom**

**Background:** CPAP is the standard therapy for treating OSA (1). However, CPAP can cause undesirable nasal side effects that compromise compliance (2).

**Aims and objectives:** Over a six month period, we assessed the association between nasal inflammation using nasal wash interleukin (IL-6) concentration and compliance with therapy.

**Methods:** Twenty-two patients were recruited with new confirmed OSA. Daily CPAP use was prospectively recorded on diary cards. Nasal wash IL-6 and diary cards for compliance were performed at no CPAP and at 1, 3 and 6 months
post-CPAP Pearson correlation was conducted to assess the relationships. A P value < 0.05 was considered a statistical significance.

**Results:** The twenty-two patients (mean age±SD: 59.5±7.5 years) had AHI of mean (SD) 30.2±19.9.

*1At recruitment to the study.

We found a significant relationship between increased nasal IL-6 and decrease in compliance at baseline and six month of CPAP therapy, Pearson [r = -0.57; P=0.014].

**Conclusion:** Our results show that nasal inflammation relates to compliance with CPAP therapy in OSA.

Residual sleepiness in obstructive sleep apnea (OSA) patients on CPAP: Not only a symptom but rather a true syndrome?

Merce Gasal 1, Renaud Tamsis2,3, Marc Sapene3, Francis Martin4, Bruno Stach5, Yves Grillet5, Patrick Levy6,7, Jean-Louis Ponn6,7, on behalf of the Scientific Council of The Sleep Registry of the French Federation of Pneumology. 1INSERM U 1042, HPZ Laboratory (Hypoxia: Pathophysiology), Joseph Fourier University, La Tronche, France; 2Sleep Laboratory and EFCCR, Locomotion, Rehabilitation and Physiology Department, Grenoble University Hospital, Grenoble Cedex 09, France; 3Unité Sommeil et Vigilance, Polyclinique Bordeaux Cauderan, Bordeaux, France; 4Unité des Pathologies du Sommeil, Centre Hospitalier de Compignie, Compignie Cedex, France; 5Service de Pneumologie, Clinique Teissier, Valenciennes, France; 6Pneumologie, Cabinet Privé, Valence, France

**Background:** Hypoxic brain damage might explain persistent sleepiness in some CPAP compliant OSA. Since residual sleepiness (RES) on CPAP remains not fully understood, wake promoting drugs in RES are no longer allowed by the European Medicines Agency.

**Aim:** To describe RES phenotype in a large prospective sample of OSA patients.

**Methods:** RES was defined by an Epworth Sleepiness Scale (ESS) ≥ 10. Hypoxic insult is probably not the explanation for RES since OSA severity does not seem to be critical. Residual symptoms are not limited to sleepiness and this true “CPAP resistant syndrome” may justify treatment by wake promoting drugs.

**P446**

Home-based evaluation in patients with high risk for moderate to severe OSA

Mara Francesca Damiani1, Pierluigi Curtani2, Valentina Anna Ventura2, Ersilia Tedeschi3, Annamaria Milano1, Gabriella Gabitoa4, Vito Antonio Falcone5, Vitaliano Nicola Quanrant6, Riccardo Drigo7, Onofrio Resta1.

1University of Bari, Pulmonary Medicine, Bari, Italy; 2O.U.C. di Pneumologia, O.U.C. di Pneumologia, Feltre (BL), Italy

Obstructive sleep apnea (OSA) is a disorder characterized by recurrent obstruction of the upper airways during sleep. The high prevalence of this disease led to propose new strategies based on the home evaluation and management of patients. The aim of this study was to compare unattended home-based protocol with ambulatory in-laboratory analysis, in a sample of patients with high risk for moderate to severe OSA.

We enrolled 131 patients, who were randomly divided into 2 groups: group 1 (n=60) was diagnosed and titrated at home; group 2 (n=65) was analyzed in the sleep lab of our hospital. Diagnostic evaluations were carried out with portable monitoring at home, and with polysomnography in the sleep lab. Titation was performed with the same autoCPAP device in both groups.

At the end of the study, 13 (19%) subjects had dropped out in the group 1, and 9 (14%) in the group 2 (p= not significant). There were no significant differences among groups in both basal and with CPAP values of apnea-hypopnoea index (AHI), oxygen desaturation index (ODI), and total sleep time with oxyhemoglobin saturation below 90% (TST90). In the home group, therapeutic pressure values reached at the end of each unattended home titration night were similar. Home diagnosis and titration approach should be considered in a subset of patients with OSA. A single unattended titration night is sufficient to determine the therapeutic pressure.

**P447**

The heterogeneity of obstructive sleep apnoea: Congestion leads to longer respiratory cycle lengths in heart failure

Christina Efken, Thomas Bitter, Britta Körker, Kevin Bullert, Dieter Horstkotte, Olaf Oldenburg, Department of Cardiology, Heart and Diabetes Center North-Rhine-Westphalia, Ruhr University Bochum, Bad Oeynhausen, Germany

It is controversial if heart failure (HF) can influence obstructive sleep apnoea (OSA) per se. Previous studies documented increased cycle lengths (VL), ventilation lengths (VL), and circulatory delays (CD) of OSA in HF patients. Aim of the present study was to verify these results in a cohort of well-defined HF patients and to investigate possible interactions of HF and OSA.

**Methods:** 39 patients with OSA (apnoea-hypopnoea index, AHI > 10h) with (NYHA ≥ II, LV-EF ≤40%; n=26; male 18, 67.2±9.4 years) and without (EF ≥50%, NT-proBNP <400; n=13, 6 male, 72.7±8.5 years) HF underwent simultaneous right- and left-heart catheterization within 12h of cardiorespiratory polygraphy.

**Results:** AHI as well as obstructive apnoea-index (OA) were comparable in both groups (AHI: 32.3±26.5 vs. 32.3±18.0; p=n.s.; OA=5.7±5.8 vs. 10.0±10.8; p=n.s.). We were able to verify increased CL, VL, time to peak ventilation (TTPV) and circulatory delay (CD) in patients with HF (CL: 32.8±10.6 vs. 46.0±10.0s, p=0.024; VL: 25.1±4.6 vs. 35.4±6.3, p=0.044; TTPV: 9.3±2.5 vs. 10.6±3.0s, p=0.021; CD: 22.6±7.7 vs. 28.5±7.5s, p=0.005). Apnoea length (AL) was higher in HF patients (16.5±3.9 vs. 20.5±4.9s, p=0.013). Positive and robust correlations between parameters of OSA and degree of congestion were found in OSA patients with HF exclusively. CL, VL, and TTPV increased with elevation of PCWP (CL: r=0.53; p=0.006; VL: r=0.55; p=0.004; TTPV: r=0.47; p=0.015).

**Respiratory parameters of OSA (CL, VL, TTPV) correlate with the degree of congestion in patients with OSA and HF, but not in non-HF patients with OSA. These results point to a reciprocal relationship of HF and OSA severity.

**P448**

Coexistence of central sleep apnea or periodic breathing pattern in patients with congestive heart failure and obstructive sleep apnea

Michael Arzt1, Gerhard Weinreich2,3, Olaf Oldenburg1, Andrea Graml1, Helmut Teschler1, Karl Wegscheider2, Erland Erdmann2, Holger Woehrle3,4, for the SchlafHF Investigators. 1Dept. of Internal Medicine II, Pneumology, University Hospital, Regensburg, Germany; 2Dept. of Pneumology, RuhrlandKlinik, University Hospital Essen, Germany; 3Science Center, ResMed, Martinsried, Germany; 4Dept. of Cardiology, Heart and Diabetes Center North-Rhine Westphalia, University Hospital, Ruhr University Bochum, Bad Oeynhausen, Germany; 5Dept. of Medical Biometry and Epidemiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 6Clinic III for Internal Medicine, Heart Center, University Hospital, Cologne, Germany; 7Sleep and Ventilation Center Blaubeuren, Respiratory Center Ulm, Ulm, Germany

**Background:** The presence of altered ventilator control instability in congestive heart failure (CHF) patients with obstructive sleep apnea (OSA) may have signif-
ificant therapeutic implications. Indicators for ventilator control instability can be significant proportions of central sleep apnea (CSA) and/or a periodic breathing (PB) pattern. The aim of the present study was to determine the prevalence of such indicators in CP patients with OSA.

Patients and methods: The ongoing German multi-center SchlaFHF registry prospectively included 7007 stable CHF patients (NYHA class ≥II and LVEF ≤45%) from cardiology practices and cardiology departments of hospitals. Patients were studied with a two-channel screening device (nasal airflow, pulse oximetry, ApnoeaLink, ResMed, Sydney, Australia) that detects PB patterns based on an algorithm. The pattern recognition was performed with suspected SBH detected polysomnography (PSG) with certified scoring.

Results: Of the 2183 PSG-patients 1583 (73%) had an AHI ≥15/h, of whom 49% had OSA (±50 apneas and hypopneas were obstructive). In such CP patients with OSA the prevalence of a significant proportion of central apneas and hypopneas (20-49%) was 35%. The prevalence of objectively assessed PB was 44% in OSA patients. 358 (59%) heart failure patients with OSA presented with either a significant proportion of CSA and/or a PB pattern.

Conclusions: The high prevalence of a significant proportion of CSA and objectively assessed PB pattern in CHF patients with OSA suggests ventilator control instability that may have an impact on the appropriate modality of positive airway pressure therapy to suppress apneas and hypopneas.

P449 Pulmonary diffusion capacity is not associated with severity of Cheyne-Stokes respiration in heart failure patients

Oldf Oldenburg, Britta Korber, Thomas Bitter, Thomas Fischbach, Dieter Horskotte. Department of Cardiology, Heart and Diabetes Center North Rhein-Westfalia, Ruhr University Bochum, Bad Oeynhausen, Germany

A recent study in severe heart failure (HF) patients indicates a possible pathophysiological role of an impaired pulmonary diffusion capacity and respiratory disturbance during sleep, especially the degree of Cheyne-Stokes respiration (CSR). The aim of the present study was to verify this hypothesis in a larger cohort of HF patients.

In 87 patients (male, age 68±9 years) with polysomnography confirmed and untreated CSR due to cardiac failure (NYHA ≥ II, LVEF ≤45%), pulmonary diffusion capacity (TLCO and KCO) were prospectively investigated using the single-breath method. Apnoea-hypopnoea-index (AHI) was 38.4±7%, TLCO 67±20% of normal, and alveolar-volume corrected diffusion capacity (KCO) 85±20% of normal. Correlation analysis using Spearman rank order correlation revealed no significant correlation of AHI and TLCO (r = 0.071, p = 0.516) or AHI and KCO (0.019, p = 0.863).

In our cohort of HF patients with untreated CSR no correlation of respiratory disturbance during sleep and pulmonary diffusion capacity was found. Thus, a significant role of an impaired pulmonary diffusion on CSR genesis seems to be unlikely.

P450 Prevalence and under-diagnosis of airflow limitation and other lung function abnormalities in patients with ischaemic heart disease: an interim analysis of the ALACE study

Joan Senaca1, Nicolas Roche1, John Cockcroft4, Klaus Rabe9, Mark Kearney7, Charles Gilbert5, Louise McRae9, Andrea Gershon4.

1Fondation Cauchet-CIMERA Ile de Balleurs, CIMERA, Banyuls, Spain; 2Program Development Centre, CIRO, Hong Kong; 3Respiratory and Intensive Care Medicine, Bichat-Druze Hospital, University Hospital of the Descartes, Paris, France; 4Wales Heart Research Institute, Cardiff University School of Medicine, Cardiff, United Kingdom; 5Department of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium; 6Department of Oncology Haematology and Respiratory Diseases, Section of Respiratory Diseases, University of Modena & Reggio Emilia, Modena, Italy; 7Multidisciplinary Cardiovascular Research Centre, University of Leeds Medical School, United Kingdom; 8Department of Internal Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden; 9Department of Medicine, University Kiel, Germany; 10Respiratory Centre of Excellence, ClaccsmithKline, Uxbridge, United Kingdom; 11Hospital Lu Dec, IdiPAZ, Madrid, Spain; 12Excellence Medicale, GSK France, Marly Le Roi, France

Background: Although ischaemic heart disease (IHD) and chronic pulmonary diseases, eg COPD, share similar risk factors, the prevalence and rate of diagnosis of airflow limitation (AL) and other lung function abnormalities, in patients with IHD are largely unknown.

Methods: In a cross-sectional study conducted in 15 sites across nine European countries (Belgium, France, Germany, Greece, Ireland, Italy, the Netherlands, Spain, and Sweden), we investigated the prevalence of airflow limitation compatible with COPD (defined as post-bronchodilator (BD) FEV1/FVC <0.70) and other lung function abnormalities in outpatients with documented IHD who were ≥40 years, and current or former smokers. Each participating center completed a core questionnaire and performed full pre- and post-BD spirometry. Quality control of spirometry readings was performed by a centralized system.

Results: Up to April 2012, we studied 1803 evaluable IHD patients, 86.0% male, mean±SD age of 65±9.8 years. The prevalence of AL was 30.6% (95% CI 28.5%-32.8%, n=552) and, from 547 with available data, only 29.4% (n=161) of these had a prior diagnosis of COPD. In addition, we found a restrictive lung disease prevalence of 11.0% (defined as pre BD FVC<80% predicted and post BD FEV1/FVC<70% predicted) in a subset of 1685 patients with available data.

Conclusions: Airflow limitation, compatible with COPD, and spirometry results suggestive of restrictive lung disease are frequent in individuals with IHD and are largely under-diagnosed, which has implications for the treatment and prognosis of both respiratory and cardiovascular diseases.

P451 Prevalence of osteoporosis in steroid naive postmenopausal women with COPD in Indian subjects

Deepraj Talwar, Amit Goel, Salik Raza. Pulmonary and Critical Care, Metro Hospitals and Heart Institute, Noida, UP, India

Study objective: Osteoporosis in elderly female COPD on inhaled or systemic corticosteroids had been reported. We looked into prevalence of osteoporosis by BMD analysis in steroid naive COPD patients presenting to COPD clinic for first time.

Material & Method: Retrospective analysis done by computerized search of patient’s OPD records between Jan 10 & Dec 10. 1084 patients visited clinic for COPD and 411 underwent DEXA scan within 2 weeks. 253 post menopausal women identified COPD. 122 were steroid naïve (on rescue salbutamol and no records of using labelled systemic or local steroids). Severity of COPD was classified as per GOLD. Statistical analysis done using one way ANOVA.

Results: Of 122 patients with COPD 61 (50%) had osteoporosis. 6/20 (30%) GOLD stage I patients, 23/35 (66.7%) stage 2, 17/27 (62.9%) stage 3 and 15/22 (68.1%) in stage 4 had osteoporosis. Low BMD (T-score at AP spine < -1) was observed in 17/20 (85%) stage 1, 44/53 (83.01%) stage 2, 21/27 (78.5%) stage 3 & 19/22 (86.36%) stage 4. Significantly lower BMD were observed in stage 1 (0.88±0.11 gm/cm²), Stage 2 (0.84±0.19 gm/cm²), Stage 3 (0.83±0.18 gm/cm²) & Stage 4 (0.78±0.16 gm/cm²) compared to normal age matched postmenopausal women (1.04±0.22 gm/cm², p-value <0.003, p-value <0.001, p-value <0.001 and p-value <0.001 respectively.

Conclusion: In our subset of postmenopausal steroid naive COPD women low BMD is seen in 86% of patients being lowest in most severe COPD. Hence, it would be prudent to do DEXA scan at initial visit of such patients particularly in stage 3 and 4 COPD, where add-onICS could worsen BMD.

P452 The prevalence of chronic obstructive pulmonary disease (COPD) in individuals with diabetes, hypertension, asthma, or mood/anxiety disorders: A Canadian population study

Pat Camp,1 Darcy Marcuniak2,3, Mariouc Doucet1, Teresa Tr5, Robert Prosser4, Anita Kozersky5, Nancy Garvey2, Kim Reznier4, S. Vanderloos5, Charles Gilbert5, Louise McRae9, Andrea Gershon4.

1James Hogg Research Centre, University of British Columbia, Vancouver, Canada; 2Respiratory Division, University of Saskatchewan, Saskatoon, Canada; 3Institut National de Sante Publique, Government of Quebec, Quebec, Canada; 4Institute for Clinical Evaluative Sciences, Institute for Clinical Evaluative Sciences, Toronto, Canada; 5RJ Prosser and Associates, RJ Prosser and Associates, Vancouver, Canada; 6Department of Pediatrics, University of Alberta, Edmonton, Canada; 7Ministry of Health and Long Term Care, Government of Ontario, Toronto, Canada; 8Ministry of Health, Government of British Columbia, Victoria, Canada; 9Public Health Agency of Canada, Government of Ottawa, Canada

There is little information on the prevalence of COPD among people with other chronic conditions. We determined the cross sectional prevalence of COPD among Canadians with diabetes, asthma, hypertension, and mood/anxiety disorders. We also compared the all-cause mortality between individuals with these other diseases without COPD.

Methods: Using the Canadian Chronic Disease Surveillance System (CCDSS), we analyzed 2008/2009 administrative health data for Canadians aged 35 years.
and older, from 12 of 13 provinces/territories. COPD, diabetes, hypertension, mood/anxiety disorders and asthma were identified using ICDC/10 codes from physician billing and hospitalization records.

Results: The prevalence of COPD among Canadians aged 35 years and older was 8.2%. The prevalence of COPD among people with diabetes, hypertension, mood/anxiety disorder and asthma was respectively 11.4% (95% confidence interval (CI) 11.1, 11.7), 11.0% (95% CI 10.9, 11.1), 11.6% (95% CI 11.5, 11.7), 11.6% and 26.3% (95%CI 26.20, 26.35). In addition, a diagnosis of COPD was associated with a 140% increase in mortality among people with diabetes and a 154% increase in mortality among people with hypertension (compared to mortality among people with asthma or mood/anxiety disorders could not be calculated because the data were not available).

Conclusions: COPD is a prevalent comorbid condition for individuals with asthma, mood/anxiety disorder, diabetes and hypertension and comorbid COPD is associated with higher mortality. An integrated care approach to these patients may optimize health outcomes and reduce the burden of chronic disease.

P453 Comorbidity between chronic obstructive pulmonary disease and type 2 diabetes in adult twins Howraman Meteran1, Bocker Vibeke1, Kyvirk Kirsten Ohn2, Axel Skythle1, Simon Francis Thomsen1, 1Department of Respiratory Medicine, Bispebjerg Hospital, Copenhagen NV, Denmark; 2Institute of Regional Health Services Research & Odense Patient Data Explorativ Network, University of Southern Denmark, Odense, Denmark; 3The Danish Twin Registry, University of Southern Denmark, Odense, Denmark.

Aim: To examine the relationship between chronic bronchitis and chronic obstructive pulmonary disease (COPD) and type 2 diabetes in adult twins.

Methods: Questionnaire data on chronic bronchitis and hospital data on diagnosed COPD on 13,649 twins, 50-71 years of age, from the Danish Twin Registry, were cross-linked with hospital discharge diagnosis data on type 2 diabetes from the Danish National Patient Registry.

Results: The type of type 2 diabetes was higher in subjects with symptoms of chronic bronchitis compared with subjects without symptoms of chronic bronchitis (3.5 vs. 2.3%), OR=1.5 (1.09 - 2.15), p<0.012; and in subjects with diagnosed COPD compared with subjects without diagnosed COPD (6.6 vs. 2.3%), OR=2.97 (1.95-5.3), p<0.000. The results were significant after adjusting for age, sex, and smoking. Correlations between genetic effects on chronic bronchitis and type 2 diabetes; and between genetic effects on diagnosed COPD and type 2 diabetes, respectively, were 0.25 (0.00-0.59), p=0.130 and 0.35 (0.00-0.72), p=0.134.

Conclusions: Patients with chronic bronchitis and COPD have an increased risk of type 2 diabetes independently of sex, age, and smoking. Furthermore, comorbidity between these diseases seemed not to be explained by shared genetic factors. The increased risk of type 2 diabetes must be accommodated in the management of patients with chronic bronchitis and COPD.

P454 Angiotensin II receptor blockers, ACE inhibitors, lung function and percent emphysema: the MESA lung study John Austin1, Kevin Rolston2, Gina Lovasi6, Karol Watson7, Karen Hinkley3, Bonnie Klibanski1, 1Department of Radiology, University of Iowa, Iowa City, IA, United States; 2Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, NY, United States; 3Department of Radiology, Columbia University College of Physicians and Surgeons, New York, NY, United States; 4Division of Pulmonary and Critical Care Medicine, Northwestern University, Chicago, IL, United States; 5Department of Social and Economic Research and Policy, Columbia University, New York, NY, United States; 6Division of Cardiology, UCLA School of Medicine, Los Angeles, CA, United States; 7Department of Biostatistics, University of Washington, Seattle, WA, United States

In a murine model of emphysema, angiotensin receptor blockers (ARB) improved airway and airspace architecture and lung function. We hypothesized that use of ARBs and angiotensin-converting enzyme (ACE) inhibitors would be associated with higher lung function and less emphysema compared to ARB and ACE inhibitor use in the Multi-Ethnic Study of Atherosclerosis (MESA) recruited participants age 45-84 yrs, free of clinical cardiovascular disease. Percent emphysema was estimated on full-inspiration cardiac CT scan using a threshold of -910 HU. Spirometry was measured following ATS/ERS guidelines. Linear regression models adjusted for age, sex, race/ethnicity, body mass index, smoking status, pack-years, exposure to second-hand smoke, educational attainment, hypertension, diabetes, asthma, family history of emphysema, statin use, female hormone replacement therapy, fish oil use and scanner type. Among 3,599 participants (mean age 61±10 years, 51% female; 35% white, 26% black), 22% Hispanic, 16% Chinese), the proportion of participants using ARBs or ACE inhibitors was 5.5% and 11.8%, respectively. The mean square root transformed percent emphysema was 3.85±1.52, the mean FEV1 (L) was 3.54±0.7. Participants using ARBs or ACE inhibitors had slightly less square root transformed percent emphysema (0.12, 95% CI, -0.31, 0.07; P=0.22) and participants using ACE inhibitors had slightly higher levels of FEV1 (19 ml; 95% CI, -35, 73; P=0.50) compared to others, but neither difference was statistically significant. In cross-sectional analysis, adjusting for various confounders, there was no evidence that use of ARB or ACE inhibitors was associated with less emphysema or better lung function.

P455 Inflammatory biomarkers and comorbidities in chronic obstructive pulmonary disease Marcie Thomas1, Morten Dahl1, Peter Lange2, Jorgen Vestbo4, Birge Noodenstedt1, 1Clinical Biochemistry, Herlev Hospital, Copenhagen University Hospital, Herlev, Denmark; 2Respiratory Section, Hvidovre Hospital, Copenhagen University Hospital, Hvidovre, Denmark; 3Clinical Biochemistry, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; 4Respiratory Research Group, Manchester Academic Health Science Centre, University Hospital South Manchester NHS Foundation Trust, Manchester, United Kingdom

Background: Patients with chronic obstructive pulmonary disease (COPD) have evidence of systemic inflammation that may be implicated in the development of comorbidities. We tested the hypothesis that elevated levels of three inflammatory biomarkers are associated with increased risk of comorbidities in COPD.

Methods: We measured baseline C-reactive protein (CRP), fibrinogen, and leukocyte count in 10,052 COPD patients from two large population studies. During a median 5-years follow-up we recorded hospital admissions due to ischemic heart disease, myocardial infarction, heart failure, type II diabetes, lung cancer, pneumonia, pulmonary embolism, hip fracture, and depression as endpoints.

Results: Multifactorially adjusted risk of ischemic heart disease was increased by a factor of 2.19 (95% confidence interval 1.48 to 3.23) in individuals with three biomarkers elevated (CRP above 3 mg per liter, fibrinogen above 14 μmol per liter, and leukocyte count above 9 x10^9 per liter) versus individuals with all three biomarkers at or below these limits. Corresponding hazard ratios were 2.32 (1.34 to 4.04) for myocardial infarction, 2.63 (1.71 to 4.04) for heart failure, 3.54 (2.03 to 6.19) for diabetes, 4.00 (2.12 to 7.54) for lung cancer, and 2.71 (2.03 to 3.63) for pneumonia. There were no consistent differences in risk of pulmonary embolism, hip fracture, or depression as a function of these three biomarkers.

Conclusions: Simultaneously elevated levels of CRP, fibrinogen, and leukocyte count are associated with a 2 to 4-fold increased risk of major comorbidities in COPD. These findings may enable clinicians to conduct stratified management of comorbidities in COPD patients.

P456 Comorbidity in chronic obstructive pulmonary disease (COPD): Data from the fourth Korean National Health and Nutrition Examination Survey (KNHNES IV) Chunoong Moon, Saey Byol Kim, Kyung Soo Chung, Seo Cheol Park, Won Jai Jung, Eun Young Kim, Ji Ye Jung, Young Ae Kang, Moo Suk Park, Young Sam Kim, Se Kyu Kim, Chul Min Ahn, Joon Chang. Division of Pulmonology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

Introduction: Many comorbidities frequently coexist with chronic obstructive pulmonary disease (COPD) and they could influence on poor prognosis. We tried to determine which comorbidities frequently coexist in individuals with COPD using population based nationwide survey.

Methods: We used data obtained in the first (2007) and second year (2008) of the Fourth Korean National Health and Nutrition Examination Survey (KNHNES IV) and included participants aged ≥40 years. Subjects with FEV1/FVC<0.7 was defined as individuals with COPD. Participants with history of asthma, pulmonary tuberculosis and bronchiectasis were excluded.

Result: Baseline characteristics were not significantly different between COPD group (n=357) and control group (n=357) except spierometric findings. COPD group was associated with increased risk of low BMI (<18.5 kg/m²) (OR 3.53, 95% CI 1.29-9.68; p=0.014) and associated with decreased risk of hypertension (OR 0.73, 95% CI 0.54-0.99; p=0.042) and hypercholesterolemia (OR 0.59, 95% CI 0.37-0.93; p=0.022). The incidence of low BMI uniquely increased with the severity of airflow obstruction (1.4% in control subjects, 3.6% in GOLD stage I, 4.5% in GOLD stage II and 30% in GOLD stage III; p<0.0001). However, the incidence of hypertension and hypercholesterolemia did not.

Conclusion: Incidence of low BMI uniquely increased with the severity of airflow limitation. However, more study is needed to confirm whether low BMI is the cause of COPD or the result of COPD.

P457 Ventilatory function and markers of metabolic disorders in adults Vanessa Garcia Larsen1, Peter Burney1, Joannis Bakolis1, Hugo Amigo2, Patricia Bustos3, Roberto Rona1, 1Respiratory Epidemiology & Public Health, National Heart and Lung Institute, Imperial College London, London, United Kingdom; 2Department of Nutrition, Faculty of Medicine, University of Chile, Santiago, Chile; 3Department of Psychological Medicine, Weston Education Centre, King’s College London, United Kingdom

Background: Metabolic disorders are related to poor lung health in adults but...
there is limited evidence of this effect in young adults. Early identification of these risk factors could contribute to improve lung function and to prevent COPD later in life. In this study we investigated the relationship between measures of ventilatory function and markers of metabolic disorders in young adults.

**Methods:** A cross-sectional study was performed in 1000 subjects aged 22-28 years old from a semi rural area in Chile. Forced vital capacity (FVC) and the ratio FEV1/FVC were the outcomes. Serum levels of fasting insulin, high-density lipoprotein, triglycerides and plasma glucose were also measured. Insulin resistance status (Homeostatic Model Assessment (HOMA-IR)) and metabolic syndrome (MS) were calculated.

**Results:** 970 participants had valid lung function data and complete information on exposures. The mean value of HOMA-IR was 2.59 in males and 2.48 in females (reference cut off point 2.53). 12% of males and 11% of females had MS (defined according the ATP III guidelines). After adjusting for potential confounders, FVC (L) was statistically negatively related to high HOMA-IR (difference of means -0.11 [95% Confidence Interval CI] -0.17 to -0.05, P value <0.0001). FVC was also statistically negatively associated with MS (difference of means -0.18 [95% CI -0.27 to -0.09, P value <0.001]. No association was found between FEV1/FVC and these markers.

**Conclusion:** Presence of metabolic disorders had a deleterious effect on ventilatory function in the young adults studied.

**Waist circumference and lung function parameters: The PLATINO study**

Ana Maria B. Menezes1, Fernandez C. Wehrmeister1, Rogelio Perez-Padilla2, Mariza Simon1, Adanio Murillo3, Carlos Talavera2, Maria Montes de Oca2, Jose R. Jardim3, Gonzalo Valdivia1.

1Post-Graduate Program in Epidemiology, Federal University of Pelotas, Brazil; 2National Institute of Respiratory Diseases, University of Mexico, Mexico City, Mexico; 3University of the Republic, University of the Republic, Montevideo, Uruguay; 4Hospital Maciel, Hospital Maciel, Montevideo, Uruguay; 5Central University of Venezuela, Caracas, Venezuela; 6Federal University of Sao Paulo, Federal University of Sao Paulo, SP, Brazil; 7Catholic University of Chile, Santiago, Chile

**Background:** Obesity is a known risk factor for chronic diseases. Recently, studies have shown that abdominal fat, measured by waist circumference, rather than BMI, is a more important predictor for the development of non-communicable chronic diseases.

**Objective:** To evaluate the association between waist circumference (WC) and lung function parameters among adults.

**Methods:** A cross-sectional study was performed in five Latin America countries (Brazil, Chile, Mexico, Uruguay and Venezuela), named the PLATINO study. The data was collected from 1999 to 2002 and 2008 among 1000 adults. WC and FVC were measured using spirometry pre and post bronchodilator. WC was measured by trained interviewers. Data analyses were performed using multiple linear regression models and were stratified by sex.

**Results:** The correlation coefficients (r) between WC and FVC and FEV1 were negative, although for WC and FEV1/FVC the coefficients were positive. After adjusting for age, height, weight, BMI and smoking, the increase of 1 cm in WC decreased FEV1 by 0.018 liters [95%CI -0.023, -0.013] in males, and 0.009 liters [95%CI -0.011, -0.006] in females. For FVC, the results showed the same direction, but were more expressive (males β = -0.024 [95%CI -0.057, -0.018] and females β = -0.016 [95%CI -0.031, -0.001]). When we evaluated the predicted values for FEV1 and FVC, an inverse relationship with WC was also found. For FEV1/FVC, only females showed a direct relationship with WC (values for FEV1 and FVC, an inverse relationship with WC was also found. For females β = 0.018; 0.114).

**Conclusion:** WC is an important risk factor for chronic diseases. The effect of WC on lung function is more pronounced in females.

**Effects of BMI changes on lung function in COPD subjects from two longitudinal general population studies**

Francesco Pistelli1, Francesco Di Pede2, Anna Bengtsson3, Karl Franklin1, Kjell Toreen3, Bryndís Benediktsdóttir1,4, Amir Farkhooy6, Joost Weyler7, Sandra Baldacci2.

1Faculty of Medicine, University of Iceland, Reykjavik, Iceland; 2Department of Respiratory Medicine and Sleep, Landspitali University Hospital, Reykjavik, Iceland; 3Department of Respiratory Medicine and Allergy, Uppsala University, Uppsala, Sweden; 4Department of Epidemiology and Social Medicine, University of Antwerp, Belgium; 5Department of Pulmonary Medicine, University of Antwerp, Belgium

**Background:** Nocturnal gastroesophageal reflux (nGER) is associated with asthma and obstructive sleep apnea in observational studies, but prospective epidemiological studies are lacking. Our aim was to investigate whether nGER is a risk factor for onset of asthma, respiratory and OSA symptoms in a prospective population based study.

**Methods:** We invited 2640 randomly selected subjects from Iceland, Sweden and Belgium for two evaluations with a nine years interval (participation rate 66.7%). They participated in a structured interview, answered a questionnaire regarding respiratory symptoms and were underwent spirometry and a methacholine challenge. Blood samples were analysed for specific IgE.

**Results:** Subjects with persistent nGER (n = 123) had an increased risk of asthma and OSA follow-up after 9 years, independent of gender, age, location, smoking history, BMI at baseline and change in BMI (OR (95% CI): 2.3 (1.1-4.9). Persistent nGER was also independently related to the onset of various respiratory symptoms (OR (95% CI): 3.0 (1.6-5.6). The risk of developing symptoms of OSA was increased in subjects with new onset ≥ 2.01 and persistent ≥ 2.01 (95% CI): 2.2 (1.3-1.6) and 2.0 (1.0-3.7), respectively). No significant independent association was found between nGER and lung function or bronchial responsiveness.

**Conclusions:** Persistent nocturnal gastroesophageal reflux contributes to the development of asthma and respiratory symptoms. The risk of new onset of OSA symptoms is also higher among subjects with nGER. These findings further support the conclusion that nGER may play a causative role in the genesis of respiratory symptoms and diseases.

**P461**

**Patients with depressive symptoms presenting to the emergency department for asthma have worse clinical status**

Carol A. Mancuso1, Margaret G.E. Peterson, Jose L. Fernandez, Robert H. Birkhahn, Theodore J. Gaeta. Medicine, Hospital for Special Surgery/Weill Cornell Medical College, New York, NY, United States Research Division, Hospital for Special Surgery, New York, NY, United States Emergency Medicine, New York Presbyterian Hospital, New York, NY, United States Emergency Medicine, New York Methodist Hospital, Brooklyn, NY, United States

**Background:** Depressive symptoms are associated with worse long-term asthma but less is known about their effects on acute exacerbations.

**Methods:** This analysis compared clinical characteristics according to depressive symptoms among 296 patients presenting for asthma to emergency departments (EDs) in New York City. At presentation patients completed valid surveys measuring asthma variables and depressive symptoms. Patients received follow-ups for 16 weeks.

**Results:** Mean age was 44 years, 72% were women, and 23% had a positive screen for depression. Compared to those with a negative screen, those with a positive screen were more likely to know what triggered the exacerbation (11% vs 22%, p<0.01), and to report worse asthma-related quality of life (<0.001), worse asthma control (p=0.002), and worse asthma self-efficacy (p<0.001). These relationships persisted in multivariate analysis when controlled age, sex, and long-term asthma severity (p<0.05). There were no differences in hospitalization rates for the current exacerbation based on depressive symptoms, but among those admitted (n=184), more patients with a positive screen had a length of stay that exceeded the median of 3 days (45% vs 71%, p=0.004). At 4 weeks (n=269) and 16 weeks (n=281) patients with a positive screen were more likely to have taken rescue beta agonists (67% vs 84%, p=0.01) and to have had a repeat ED visit for asthma (17% vs 27%, p=0.09).

**Conclusions:** Asthma ED patients with a positive screen for depression had worse self-report clinical status and more short-term resource utilization. Depres-
sive symptoms may be modifiable and should be addressed in relation to acute exacerbations.

### P462

The combined association of anxiety or depression symptoms and obesity with incident asthma: The HUNT study

Ben Brumpton, Linda Leivseth, Yue Chen, Arnulf Langhammer, Pål Romundstad, Xiao-Mei Mai. Department of Public Health and General Practice, Norwegian University of Science and Technology, Trondheim, Norway

Department of Epidemiology and Community Medicine, University of Ottawa, Canada

Anxiety and depression may increase the risk of developing asthma. We conducted a prospective study to test this hypothesis and additionally investigate the potential joint effect of these symptoms and obesity. We studied 23,199 adults who were 19-55 years old at baseline in the Norwegian Nord-Trøndelag Health Study (HUNT). The participants were followed for 11 years. The Hospital Anxiety and Depression Scale (HADS) was used to measure anxiety (HADS-A ≥ 8, range 0-21) and depression (HADS-D ≥ 8, range 0-21) symptoms. Obesity was defined as having a body mass index of ≥30.0 kg/m². Incident asthma was self-reported. Odds ratios (ORs) for incident asthma associated with anxiety or depression were calculated using logistic regression models. To test the joint effect of anxiety or depression and obesity we calculated the relative excess risk due to interaction (RERI).

At baseline, 4,151 participants (17.9%) had anxiety or depression symptoms. There was a significant association of anxiety or depression with incident asthma (OR 1.36, 95% CI 1.15-1.61). Compared to non-obese without anxiety or depression, obese women with anxiety or depression had a significantly higher risk of incident asthma (OR 2.13, 95% CI 1.44-3.15). The relative excess risk due to interaction for obese women with anxiety or depression and obesity was 1.08 (95% CI 3.02-3.15). This study suggests that anxiety and depression symptoms contribute to incident asthma in adults. Obesity may interact with anxiety and depression symptoms in increasing the risk of asthma.

### P463

Asthma in pregnancy and risk of preterm delivery

David Gluva1, Lennart Bråbäck1,2, Bertil Forsberg1,2, Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 2Research and Development, Sundsvall Hospital, Sundsvall, Sweden

The effects of asthma on pregnancy outcomes differ between studies. A recent review indicates that the conflicting results are related to study design, where larger database studies have reported increased risks, and smaller clinical prospective cohort studies have not found significantly increased risks. We study the effects of asthma within a large study of air pollution and preterm birth; is there an increase in preterm birth and how common are exacerbations in pregnancy resulting in outpatient hospital visits?

Our study cohort from Stockholm, Sweden, is constructed by matching live births 1998-2006 from the Medical Birth Registry with information on the mother from the Patient Registry (1987-2010 for hospital admissions and 2001-2010 for outpa- tients). Compared to the population from this area, we define all mothers who had at least one hospital visit for asthma or had asthma medication as having asthma. We used logistic regression to assess the relation between asthma and preterm birth. We adjusted the model for education, previous preterm birth, origin, parity, date of conception and maternal age. The prevalence of preterm birth was 5.4% among mothers with asthma (n=13,261) and 4.4% in the rest of the population (n=111,931). The odds ratio for giving birth preterm was 1.27 (p < 0.01) for women with asthma compared to non-asthmatic mothers. 1.9% of the asthmatic mothers had a hospital contact for asthma during pregnancy, and 4.8% of them delivered preterm. Asthma is associated with an increased risk of preterm birth, particularly in women with exacerbations of the asthma during pregnancy.

### P464

Respiratory function in elderly with ‘senile’ or ‘juvenile’ pulmonary phenotype: Results from the KORA-Age study

Holger Schäfer,1 Jürgen Behr,2 Rudolf M. Huber,1 Dennis Nowak,2 Joachim Heinrich,1 Annette Peters,1 Rudolf A. Jürges,3 Stefan Karrasch,3 Institut für Epidemiologie I. Helmholtz; Zentrum München, Neuharzburg/München, Germany; 2Institut für Epidemiologie II. Helmholtz; Zentrum München, Neuharzburg/München, Germany; 3Division of Respiratory Medicine, Department of Medicine, Innenstadt, Ludwig-Maximilians-University, Munich, Germany

Background: Lung function, typically assessed by spirometry, is a strong predictor for overall morbidity and mortality. To improve our mechanistic understanding we examined whether poor spirometric lung function is associated with general respiratory limitations in elderly subjects with apparently healthy lungs.

Methods: Spirometry was performed in a random population sample from the region of Augsburg, Germany (n=935, aged 65-90y). From subjects free of lung disease (COPD, Asthma) two subgroups with either poor (‘senile’; n=87) or favourable (‘juvenile’; n=82) lung function were selected from the lower and upper 10% of the FEV1/FVC distribution. TLC, DCO, peak inspiratory pressure at RV (Pimax), the decrease in airway pressure at 0.1s (P01), and 6MWD were determined.

Results: P01 and P01/MV were not affected by age, while spirometric values, DCO/VA and Pimax showed an age dependent decline. ‘Senile’ phenotype subjects had 10% lower DCO/VA (P=0.05), while DCO/VA was not affected. P01, P01/MV and Pimax were increased by at least 45% and Pimax reduced by 13% in the ‘senile’ group (p<0.05). Multiple regression analysis in ‘senile’ and ‘juvenile’ subjects revealed that limitations in DCO and Pimax contribute to a reduced 6-MWD.

Discussion: Elderly subjects with poor spirometry, while being free from overt lung disease, also suffer from age related limitations in gas exchange capacity, reduced muscle strength, and increased workload during breathing. This limited respiratory capacity may contribute to reduced physical fitness and morbidity. Supported by German Federal Ministry of Education and Research (BMBF FKZ 01ET0713) as part of the ‘Health in old age’ program.

### P465

Poorer quality of life in asthma patients is associated with rhinosinusitis, smoking and decreased lung function – Results from the Swedish GA²LEN survey

Alexandra Ek1, Roelinde Middeldoft1, Helen Berrilsson3, Linda Ekerjung4, Jan Lötvall5, Andreas Malinovitch6, Charit Wahlgren7, Sven-Erik Dahlén8, Christer Janson9, Experimental Asthma and Allergy Research, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; 2Centre for Allergy Research, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; 3Department of Occupational and Environmental Medicine, Umeå University, Umeå, Sweden; 4Krafting Research Centre, Institute of Medical Sciences, Sahlgrenska Academy, University of Gothenburg, Sweden; 5Department of Medical Sciences, Uppsala University, Uppsala, Sweden

Introduction: We have previously reported that patients with both asthma and rhinosinusitis have impaired quality of life compared to asthma patients without rhinosinusitis.

Aim: The aim of the current study is to further analyze quality of life in asthma. The study was part of the Global Allergy and Asthma European Network (GA²LEN) survey and follow-up.

Methods: A total of 499 asthmatics (age 17-76) completed the Juniper mini- questionnaire on Lung Function (mAQLQ) in four centres in Sweden, as part of a clinical follow-up visit of the GA²LEN survey. Lung function and exhaled nitric oxide (FeNO) were measured, and the patients were interviewed. Asthma was defined as self-reported diagnosis of asthma and presence of at least one asthma symptom or use of asthma medication. Rhinosinusitis was defined as having at least two sinusitis symptoms, providing that nasal blockage or nasal discharge were reported. Multiple regression analysis was used.

Results: The overall mAQLQ score was related to having rhinosinusitis (-0.51 units, P<0.0001), current smoking (-0.42 mAQLQ units, P=0.015), lower FEV1 (-0.08 units per 10% predicted decrease, P=0.004) and high age (62-76 years compared to 17-32 years: -0.44 units, P=0.009). The analysis did not show any significant relationship between mAQLQ and BMI or FeNO. These results remain statistically significant also after adjusting for gender, centre and inhaled corticosteroid use.

Conclusion: Co-existing rhinosinusitis, current smoking, lower lung function and high age are related to poorer quality of life in asthma patients.
3.53 (1.17, 10.60) compared to women, while age, sex, BMI, waist-hip ratio and smoking. Women with postBD FEV1/FVC <0.7 had an increased risk of OSAS with an OR of 3.53 (1.17, 10.60) compared to women with an FEV1/FVC >0.7, but this relationship was not present among men; OR 0.70 (0.31-1.58).

Conclusions: Chronic airflow limitation, assessed by post bronchodilator spirometry, was associated with OSAS among women only. There was no relationship between OSAS and FEV1 or FVC.

P468
Associations between obstructive sleep apnea syndrome (OSAS) and chronic airflow limitation in a general Norwegian population
Trygve Jonassen 1, Tomas M.L. Eagan 2,3, Sverre Lehmann 1,2,3. 1Department of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway; 2Section of Thoracic Medicine, Institute of Medicine, University of Bergen, Norway; 3The Norwegian Medical Centre for Home Mechanical Ventilation, Haukeland University Hospital, Bergen, Norway

Background: Several studies have investigated associations between OSAS and obstructive airway disease, but with inconsistent results.

Aim: To study the relationship between OSAS and pulmonary function in a general Norwegian population.

Methods: An age and sex stratified random sample of all adults aged 47-48 and 71-73 living in Bergen, Norway, were invited to a cross-sectional study. The 3506 attendants completed a questionnaire including symptoms of OSAS. Subjects were classified as having OSAS if they reported snoring, breathing cessations, and daytime sleepiness using the Karolinska Sleep Questionnaire, previously validated against polysomnography. Spirometry including bronchodilator test inhaling 400 ug Salbutamol was performed by all subjects. Logistic regression analyses, including interaction analyses between sex and pulmonary function, were used to examine associations between OSAS and pre- and postbronchodilator (postBD) FEV1, FVC and FEV1/FVC.

Results: The prevalence of OSAS was 4.8% (20/422) in subjects with chronic airflow limitation as defined by postBD FEV1/FVC<0.7 and 4.4% (119/2829) in subjects with FEV1/FVC<0.7 (P=0.74). FEV1 and FVC (% of predicted) were not associated with increased risk of OSAS, after adjustment for age, sex, BMI, waist-hip ratio and smoking. Women with postBD FEV1/FVC<0.7 had an increased risk of OSAS with an OR of 3.53 (1.17, 10.60) compared to women with an FEV1/FVC>0.7, but this relationship was not present among men; OR 0.70 (0.31-1.58).

Conclusions: Chronic airflow limitation, assessed by post bronchodilator spirometry, was associated with OSAS among women only. There was no relationship between OSAS and FEV1 or FVC.

79. Gene–environment treatment and asthma

паутинная, респираторий синктивал и пикомаровirus) were examined in the Canadian Asthma Primary Prevention Study using both family-based transmission disequilibrium test and case-control methods.

Results: IL6R2 and TLR2 SNPs were associated with atopy after correction for multiple comparisons. There is significant evidence that SNPs p virus interactions with these same SNPs modifies the risk for atopic asthma and AHR in a high risk birth cohort. In addition, an NFKBIA SNP was associated with atopic asthma. All three viruses demonstrated a skew in the distribution of SNPs p viral interactions (based on QQ plot) for AHR at 7 years of age. RSV was associated with an increased number of SNP p viral interactions for atopic and atopic asthma at 7 years of age. Conclusion: We have identified novel susceptibility genes for asthma and related traits and interactions between these genes and early life viral infections.

P469
cchnic rs37972 gene’s polymorphism correlation with response to oral glucocorticosteroids treatment in severe asthmatics from the BIOAIR cohort
Maciej Kupczyk 1, Lovisa Reinius 1, Roelinde Middeldyld 1, Barbro Dahlén 1, Juha Kere 2, Sven-Erik Dahlén 1,1 EEAF, IMM, Karolinska Institutet, Stockholm, Sweden; 2Department of Biosciences and Nutrition, Karolinska Institute, Stockholm, Sweden

A significant association of SNP rs37972 in GLCCI1 in a genomewide study was identified in children with asthma. Our goal was to evaluate biomarkers and pharmacogenetic determinants that may improve effectiveness of treatment in adults with asthma. Eighty five SA patients and 66 with mild-to-moderate asthma (MA) were included in the BIOAIR study. After optimization of treatment, they underwent a double-blind 2 week oral steroid intervention (prednisolone 0.5 mg/kg/day). DNA was extracted from whole blood and the rs37972 (C/T) polymorphism in the GLCCI1 gene was analyzed using TaqMan allelic discrimination on the ABI Prism 7500 detection system. The oral steroid intervention resulted in a significant increase in FEV1 (% predicted) in SA (6.6%, 95% CI 2.4 – 10.8, p=0.002, steroid treatment vs placebo) but not in MA (0.5%, 95% CI 3.4 – 2.4, p=0.38) or COPD (1.2%, 95% CI 1.7 – 4.0, p=0.30) (p=0.02, between group comparisons). The responsiveness to oral steroids was significantly better in patients characterized by the highest blood eosinophils (>0.44x10^9/L), the highest sputum eosinophils (>4%), the lowest sputum neutrophils (<4%) and the highest FeNO (>40ppb). A functional GLCCI1 variant was weakly associated with reduced improvement of lung function in response to glucocorticosteroids (p<0.05) and correlated significantly with the number of eosinophils in induced sputum and FeNO (<p<0.05).

In the majority of SA patients, systemic steroid treatment induces an improvement in lung function. The positive response to oral steroids may be associated with certain genotype and phenotypic markers that may improve therapeutic decisions.

P470
Two single nucleotide polymorphisms in TSLP gene promoter region are associated with asthma susceptibility in Chinese Han population
Wen Liu, Liang Dong. Dept. of Pulmonary Medicine, Qilu Hospital of Shandong University, Jinan, Shandong, China

Background: Asthma is a chronic inflammatory disease of the airway. Thymic stromal lymphopoietin (TSLP) can aggravate asthmatic lung inflammation.

Objective: To analyze the polymorphism of two single nucleotide polymorphisms (SNPs) Rs2289827 and Rs2289287 in TSLP gene promoter region to evaluate the association between the two SNPs and asthma susceptibility in Chinese Han population.

Methods: 531 asthmatic patients and 540 normal controls were collected and the genotypes of SNPs Rs2289827 and Rs2289287 were detected with polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP). genotype and allele frequency were calculated and analyzed with Chi-square test.

Results: The genotype and allele frequencies of the two SNPs in asthmatic patients were significantly different from those in the healthy controls.

Rs2289276 T allele was correlated with decreased FEV1; FVC (P<0.05).
contribute to the susceptibility to asthma, rhinitis and COPD, by candidate gene association analysis, in a large and accurately defined series of Italian subjects, even considering exposure to some environmental contexts and lifestyle.

Case-control association analysis of candidate genes in asthma, rhinitis and COPD: A preliminary report

Cristina Bombieri1, Anna Rita Lo Presti1, Francesca Belpinati1, Simone Accordini2, Alessandro Baldin1, Marcello Ferrari1, Giovanni Malerba1, Elisabetta Zanolini1, Pier Franco Pignat1, Roberto de Marco2
1Dpt. of Life and Reproduction Sciences, Section of Biology and Genetics, University of Verona, Italy; 2Dpt. of Medicine and Public Health, Section of Epidemiology and Medical Statistics, University of Verona, Italy

This study aims to determine the genetic involvement in the susceptibility to asthma, rhinitis and COPD by candidate gene association analysis, in a large and accurately defined series of Italian subjects, even considering exposure to some environmental contexts and lifestyle.

The study population included 1075 subjects (aged 20-66 years) from the general population, enrolled in the frame of the Gene Environment Interactions in Respiratory Diseases (GEIRD) study between 2007 and 2010. Cases and controls were diagnosed during a clinical examination that included a detailed interview, pre/post bronchodilator spirometry, methacholine challenge, skin prick tests. A panel of 384 Single Nucleotide Polymorphisms (Tag-SNP), representative of 63 candidate genes with a previous indication of possible association to the studied diseases, was genotyped by a customized GoldenGate Genotyping assay. Presently, genotyping of 725/1075 subjects are completed. A preliminary association study of candidate gene polymorphisms was conducted on these data, for the susceptibility to one or more of the studied phenotypes, by basic association test based on allele frequency comparison. Presence of association (unadjusted p<0.005) was observed between GSTP1 and non-atopic rhinitis, PDE4D and ever asthma with atopy, IL13 and past-asthma, TNS1 and chronic bronchitis. Moreover, a possible association (unadjusted p<0.02) was also found for IL1RL2 with ever asthma, chronic bronchitis, atopic rhinitis and non atopic rhinitis. The analysis is going on to complete the genotyping of all the enrolled subjects and to perform haplotype analysis, to confirm the involvement of these genes in the studied diseases.

P471 Association of TGFβ1 and IL-4Rα2 gene polymorphisms with asthma

Pedro J. Romero Palacios1, Juan Carlos Alavez Merino2, Carolina Cisneros Serna3, Pablo De Diego Fernández4, Francisco J. González Barcalaa5, José María Ignacio García6, Antonio Pereira Vega7, Luis Pérez de LLano8, Isabel Urrutia Landía9, 1Medicina, Facultad de Medicina, Universidad de Granada, Granada, Andalucía, Spain; 2Medicina Legal, Toxicología y Psiquiatría, Facultad de Medicina, Universidad de Granada, Granada, Andalucía, Spain; 3Servicio de Neumología, Hospital Universitario de la Princesa, Madrid, Spain; 4Servicio de Pediatría, Hospital Universitario Virgen de las Nieves, Granada, Spain; 5Servicio de Neumología, Hospital de Loures- Crepo, Pontevedra, Galicia, Spain; 6Servicio de Neumología, Hospital Serranía de Ronda, Málaga, Andalucía, Spain; 7Servicio de Neumología, Hospital Juan Ramón Jiménez, Huelva, Andalucía, Spain; 8Servicio de Neumología, Hospital Lucas Augusti, Lugo, Galicia, Spain; 9Servicio de Neumología, Hospital de Galdakao, Bizkaia, País Vasco, Spain

There are components of the asthma phenotype that appear to be strongly heritable. We have studied certain SNP variations in a set of genes related to the pathogenesis and evolution of asthma in patients with severe asthma and their immediate relatives, as well as in a control group of non-asthmatics patients.

Aims of this study: 1. To determine the existence of common genetic characteristics in individuals suffering from severe asthma.

2. To study whether there are common genetic patterns in relatives of patients with severe asthma.

Method: We selected patients diagnosed of severe persistent asthma according to the criteria proposed by the ATS Consensus for Definition of Severe/Refractory Asthma and their first-line relatives, symptomatic or non-symptomatic according to their responses to the European Community Respiratory Health Survey Questionnaire. A control group of non-asthmatic patients was included. We obtained saliva samples from 10 different SNPs located on different genes related to asthma (CHI3L1: rs4950928; ADRB2: rs1042713, rs1042714; DENND1B: rs1775456, ORMDL3: rs7216389, TMC06: rs2569190, ADAM33: rs2280991; IL4: rs2434250, TGFβ1: rs1800469, ILAR: rs1801275), by TaqMan SNP Genotyping Assay.

Results: We analyzed samples from 150 patients diagnosed of severe persistent asthma, 49 controls, 69 asymptomatic relatives and 83 symptomatic relatives. We found significant differences (p<0.05) between the group of patients and relatives with respect to controls in two pairs of the alleles studied: TGFβ1 rs1800469; IL-4Rα2 rs1801275.

Conclusions: We found a higher prevalence of TGFβ1 rs1800469 (AA and AG) in patients with severe asthma and their relatives; and IL-4Rα2 rs1801275 (AA) in asthmatics.

P472 Investigating the role of IREB2 genetic variants in susceptibility to COPD

Nose Kalishchek1, Sally Chappell1, Tamar Guetta-Baranes1, Aiman Alaseh2, 1Molecular Medical Sciences, The University of Nottingham, United Kingdom; 2Faculty of Applied Medical Science, The University of Umm Alaara, Miakkah, Saudi Arabia

The IREB2 gene encodes the iron-binding protein 2, which is a major regulator of iron homeostasis. Several studies have shown that the IREB2 locus is a contributor to COPD susceptibility. Previously, we observed significant associations of seven IREB2 genetic variants with increased risk of COPD in a large case-control study. Subsequent in-silico analysis showed that six of these SNPs were in tight linkage disequilibrium with two variants located within the promoter (rs2565070) and the 3'UTR (rs12899351) of IREB2 gene. The promoter SNP is predicted to disrupt the binding of two transcription factors while the 3'UTR SNP is located in a region that is predicted to be target site of mir-1285 and mir-5096. The aims of this study were to evaluate the functional effect of these variants on IREB2 expression.

To test the effect of the promoter SNP, two fragments (one for each allele) of the 3'UTR region of IREB2 were inserted upstream of the luciferase gene in the pGL3 Basic vector and then transfected into the A549 cells. Our results show that there was no difference in luciferase expression from cells transfected with rs2565070 wild type construct compared with the risk allele under basal conditions. Further analysis will be undertaken to examine the effect of the rs2565070 under different stimulatory conditions. For the 3'UTR SNP, two fragments (for both alleles) spanning the potential mRNA target site was cloned downstream of the luciferase gene in pmirGLO vector and then transfected into HepG2 cells that are known to express mir-1285. Luciferase assay showed that mir-1285 did not recognize the cloned sequence. Additional investigation will consider the regulatory role of mir-5096 on IREB2 expression.

Emile Mullie1, Robert Verheij4, W,he Van Der Velden2, Wieteke Bijdendijk2, M. J. Van Stiphout2, Wieteke Van Der Velden2, M. W. Van Velsen2, The J Peeters2, J. M. Van Beek1, P. L. Shupyk5, Kiev, Ukraine; 1Department of Allergology, Medical University of Gdansk, Poland; 2Department of Pneumonology, Medical University of Gdansk, Poland; 3Unit of RFLP analysis in 222 healthy people and 207 bronchial asthma (BA) patients
Results: The AC genotype of AT2R1 gene was significantly higher among RDS cases. Impact of O.felineus to GE model and it’s modifying role on genetic component control lung function can suggests that O.felineus is important environment factor that can modify genetic risk of asthma, but clinical and mechanical factor in the development of respiratory distress syndrome (RDS).

P479
Polymorphisms in genes associated with the development of steroids-induced adverse events
Krzysztof Specjalski1, Maria Porzezinska2, Alicja Sieminska1, Jan Marek Sliominski1, Ewa Jassem2, 1Department of Allergology, Medical University of Gdansk, Poland; 2Department of Pneumonology, Medical University of Gdansk, Poland
Glucocorticoids are widely used in the therapy of lung interstitial diseases or severe asthma because of their anti-inflammatory properties. Their actions are mediated through an intracellular receptor. Steroid - receptor complex translates to a nucleus and binds DNA fragments referred to as glucocorticoid-response elements (GREs). Transcription regulation is associated with both therapeutic results and unwanted effects e.g. hypertension, diabetes, osteoporosis.
Aim of the study: The aim of this study was to evaluate the frequency of polymorphisms in the selected genes (ESR2, ATP1B1, AT2R, Hind III) that may be responsible for the development of steroids-related complications in the population of Kashubia (north of Poland).

Patients and methods: Blood samples were collected from 250 participants randomly chosen from the population of Kashubia region. Presence of polymorphisms was determined by the means of PCR in the following locations: AT2R-3123 A/C, osteocalcin- rs1800247 C/T, ESR2- rs9489358 A/G, ATP1B1- rs1916264 C/T. In statistical analysis y 2 test was used to determine whether the genotypes were in Hardy-Weinberg equilibrium.

Results: For all the gene polymorphisms were found in the specified locations. The frequencies of variants were as follow: AT2R- AA 36%, AC 19%, CC 45%; HindIII (osteocalcin)- CC 9%, TC 31%, TT 60%; ESR2- AA 10%, AG 39%, GG 51%; ATP1B1- TT 1%, TC 19%, CC 80%. In ESR2, ATP 1B and osteocalcin genes variants were in Hardy-Weinberg equilibrium.

Conclusion: Polymorphisms in the genes that may be related to adverse events of steroids are frequent enough to continue to study the associations between polymorphic variants and presence of side effects of steroids.

P480

Is GLCCI1 associated with response to inhaled corticosteroids in asthma patients?

Longtie Hoaking1, Eugene Bleecker2, Lucy Frith1, Soumitra Ghosh1, Brett Haumann1, Loretta Jacques1, Mike Mosteller3, Deborah Meyers2.

1Medicines Discovery and Development, GlaxoSmithKline, London, United Kingdom; 2Center for Genomics and Personalised Medicine Research, Wake Forest University Health Sciences, Winston-Salem, NC, United States; 3Medicines Discovery and Development, GlaxoSmithKline, Philadelphia, PA, United States;

2Medicines Discovery and Development, GlaxoSmithKline, RTP, NC, United States

Inhaled corticosteroids (ICS) are the primary anti-inflammatory therapy for the treatment of asthma. Glucocorticoid-induced protein 1, also known as GLCCI1, is expressed in the airway epithelium and has been shown to be associated with airway hyperresponsiveness (AHR) and asthma outcomes. In this study, we aimed to investigate the association between GLCCI1 genetic variants and response to ICS in asthma patients.

Methods: A total of 200 asthma patients were recruited and genotyped for two GLCCI1 polymorphisms: rs2320670 and rs2320668. Response to ICS was assessed by changes in FEV1 and symptom scores following treatment.

Results: The frequency of the rs2320670 polymorphism was significantly different between responders and non-responders (p=0.03). The minor allele (C) was associated with a better response to ICS, with a mean increase in FEV1 of 123.5 ml in the C allele carriers compared to 64.2 ml in the non-carriers (p=0.02).

Conclusion: Our findings suggest a potential role for GLCCI1 genetic variants in predicting response to ICS in asthma patients. Further studies are needed to confirm these results and to elucidate the molecular mechanisms underlying this association.

P482

The effects of eccentric and concentric exercise training on muscle strength in COPD: Preliminary results

Riinu Sana1,2, Jacqueline Bell1,3, Sophia Kachpinsky1, Norah MacMillan1, Danielle Vieira Rocha1, Richard Rudy2, Helen Perrault1, Taivassalo Tanja1, Jean Bourbeau4,5.

1Respiratory Epidemiology and Clinical Research Unit, McGill University, Montreal, Canada; 2Physiotherapy, University of Fortaleza, Brazil; 3Physiotherapy, University of Minas Gerais, Belo Horizonte, MG, Brazil; 4Department of Sport Medicine and Functional Explorations, CHU Clermont-Ferrand and INRA UMR 1019, Clermont-Ferrand, France

Since eccentric exercise greater force is produced at a reduced oxygen cost, this modality of exercise could be attractive for pulmonary rehabilitation of severe COPD patients.

Objective: To estimate the extent to which eccentric compared to concentric exercise training produces greater increases in quadriceps force, and leads to better improvements in hamstring force, exercise capacity and physical activity.

Methods: Pilot randomized clinical trial in which COPD patients were randomly assigned to either a concentric (CON) or eccentric (EC) cycling protocol, 3 sessions/week for 10 weeks. In the CON group, target training intensity was set at 80% of peak work rate (Wmax) while in the EC group the target intensity was set as 4-58% 80% of Wmax. Lung function, muscle strength (Biodex), maximal work capacity (Wmax) and physical activity (Armband) were assessed.

Results: Preliminary analysis included 11 male COPD patients (69±6 years; FEV1: 14±10%pred; BMI: 27±4 k.g.m-2). After 10 weeks of training, isometric quadriceps force was 14% (20N)(95%CI: 2-26%, p=0.03) and concentric hamstring force was 27% (14N)(95%CI: 2-50%, p=0.03) higher in the EC. A trend for greater improvements in concentric quadriceps force was observed only in the ECC group (ECC=16% of change, p=0.06 vs CON=15%,p=0.06). Both ECC and CON training yielded similar improvements in Wmax (ECC 18%,p=0.03 vs CON 16%; p=0.03). Steps/day remained unchanged (p=0.05) in both groups.

Conclusion: Preliminary results show a trend for greater improvements in quadriceps muscle force with ECC compared to CON training in severe COPD patients.

Funding: McGill Health Centre Research Institute/pilot project and Edith Strauss.

Acute effect of chest wall muscle stretching on chest wall volumes distribution in chronic obstructive pulmonary disease: A randomized controlled trial

Rafaela S1, Shirley Campos1, Maira Pessoa1, Ana Gabriela Cavalcanti1, Cyda Reinaux1, Catarina Rattes1, Guilherme Fregonezi2, Andrea Aliverti2, Armele Donelas de Andrade3,4, Dept. Fisioterapia, Universidade Federal de Pernambuco, Recife, Brazil; 3Dipartimento di Bioingegneria, Politecnico di Milano, Milano, Italy; 4Fisioterapia, Universidade Federal do Rio Grande do Norte, Natal, Brazil

Inspiratory muscles function is compromised in COPD due to increased loads, reduced mechanical advantage, and increased ventilatory requirements. The hyperinflation of COPD reduces the flow and pressure-generating capacity of the diaphragm.

Aims: To analyze the acute effects of chest wall muscle stretching on chest wall volumes distribution in subjects with COPD.

Methods: It was a randomized controlled trial, involving 28 COPD patients divided into two groups: 14 subjects to treatment group (TG, mean age 61.79±8.31 years) and 14 to control group (CG, 62.38±8.32 years). TG was composed for patients that received a program of chest wall muscle stretching and patients allocated in CG remained at rest in the similar conditions as in TG. Respiratory variables were measured during quiet breathing by Opto-Electronic plethysmography (OEP) before and after one intervention. Statistical analysis was performed using independent samples t-test.

Results: Tidal volume (Vt) presented a significant increase immediately after the chest wall muscle stretching in rib cage pulmonary compartment (Vtccb, p=0.02), in rib cage abdominal compartment (Vtcca, p=0.04) and their percentages regarding thoracic wall, Vtcrp (p=0.04) and Vtcca% (p=0.02). Thus, there was...

Physiological performance of patients with COPD during activities of daily living after a physical training with and without inspiratory muscle training:

Preliminary results

Eliane Regoero1,2, Renata Baso1, Saulo Fabrini3, Caroline Martins4, Mauricio Janami5, Dércio Costa1,4, Thierry Troosters1,5, Valéria Pires Di Lorenzo1, *Physiotherapy-Postgraduate Programme in Respiratory Physiotherapy, Universidade Federal de Sao Carlos - UFSCar, Sao Carlos, SP, Brazil; 2Physiotherapy, Centro Universitário UNIFIBER, Bebedouro, SP, Brazil; 3Physiotherapy, Centro Universitário Claretiano - CECUCLAR, Batatais, SP, Brazil; 4Physiotherapy-Postgraduate Programme in Rehabilitation Sciences, Universidade Nove de Julho, Sao Paulo, SP, Brazil; 5Faculty of Kinesiology and Rehabilitation Sciences, Katholieke Universiteit Leuven - KULeuven, Belgium; 6Respiratory Rehabilitation and Respiratory Division, University Hospitals KULeuven, Belgium

Background: Physical training (PT) improves performance of activities of daily living (ADL), decreases dyspnea and enhances the inspiratory muscle strength in patients with COPD. Less is known on the physiological benefits during the execution of ADL in patients treated with general PT (GPT) or GPT plus inspiratory muscle training (IMT).

Aim: To compare changes on ventilatory and metabolic responses, dyspnea, SpO2 and time during a set of ADL after two PT programs.

Methods: A set of 5 ADL (making bed (1), taking shower (2), brushing teeth (3), lifting and lowering containers above eye level (4) and below the pelvic waist (5)) was performed by 28 patients before and after a 16 week: 13 GPT (aero- training) and 15 GPT+IMT with PowerBreathe (FEV1<1.5L) (p<0.01). A metabolic system was used during ADL.

Results: Both groups had significant reduction in VO2, VE, Borg, SpO2 and time in ADL within them, although there are no difference between GPT and GPT+IMT throughout the performance of ADL (Table 1).

Effect of positive expiratory pressure on sternocleidomastoid and parasternal muscles in patients with COPD: A randomized clinical trial

Danmyee Cardozo1, Renan Josi1, Rosana Werberich1, Cristina Alberton1, Isabella Albuquerque2, Dulciane Paiva2, Sérgio Menna Barreto1, *Serviço de Fisioterapia Pulmonar (LFIP), Departamento de Fisioterapia, Universidade Estadual de Londrina (UEL), Londrina, Brazil

Introduction: Chronic obstructive pulmonary disease (COPD) leads to chronic airway obstruction and air trapping, affecting diaphragmatic action and placing it at a mechanical disadvantage, requiring the recruitment of accessory muscles.

Objective: To investigate the effect of 10 and 15 cmH2O EPAP on the activity of sternocleidomastoid (SCM) and parasternal muscles in patients with stable COPD.

Methods: A randomized clinical trial with twenty-one COPD patients. Subjects were randomly allocated to two groups: 10 cmH2O Group (n=10) and a 15 cmH2O Group (n=11). We evaluated the electromyographic (EMG) activity of SCM and parasternal muscles in spontaneous breathing (Pre-EPAP), during application of EPAP by face mask for 20 minutes, and for 10 minutes after mask removal (Post-EPAP).

Results: The application of 10 cmH2O EPAP promoted reduction EMG activity in the SCM muscle (p<0.001) and increased parasternal muscle activity (p<0.001). The group submitted to 15 cmH2O EPAP showed a tendency towards greater EMG activity in the SCM muscle and a significant decrease in activity of the parasternal muscle (p<0.005).

Conclusions: In patients with stable COPD, 10 cmH2O EPAP induced a significant decrease in activity of the inspiratory accessory muscle and increased parasternal muscle activity after the application. This may have practical benefit to reverse the extreme use of the chest wall muscles and reduce their mechanical disadvantage in patients with COPD.

P486

Does tolerance of neuro-muscular electrical stimulation (NMES) relate to gender in patients with an acute exacerbation (AE) of chronic obstructive pulmonary disease (COPD)?

Emma Chaplin1, Linzy Houchen1, Neil Greening1, Theresa Harvey-Dunstan1, Michael Steiner1, Sally Singh1,2, Michael Steiner1,3, Renata Basso1, Saulo Fabrin3, Caroline Martins4, Rafael Mesquita1,2, Nildah Aparecida Hernandez1,2, Thais SantAnna2, Vanessa Suziane Probst1,5, Fábio Pitta1,6, *Centro de Pesquisa em Ciências da Saúde (CPCS), Centro de Ciências Biológicas e da Saúde (CCBS), Universidade Norte do Paraná (UNOPAR), Londrina, Brazil; 1Faculty of Fisioterapia Pulmonar (LFIP), Departamento de Fisioterapia, Universidade Estadual de Londrina (UEL), Londrina, Brazil

Introduction: The maximum intensity tolerated using NMES is relatively unknown in patients with an AECOPD. Previous data suggest that healthy males are able to tolerate higher intensities than females. The aim of this study was to compare the tolerance of NMES in patients admitted with an AECOPD between males and females.

Methods: 188 patients hospitalised with an AECOPD were recruited [58 male, MRC 4 (IQR 4-5), mean (SD) age 70.7 (±9.3) years, FEV1 1.38L ±70.1, BMI 26.7 ±7.0]. NMES was applied daily to both quadriceps muscles (30 mins, frequency 50Hz, pulse duration 300usec) for the duration of hospital stay.

Results: 175 patients completed the NMES intervention. A statistically significant difference between genders was seen in the intensity tolerated at both baseline and at discharge (p ≤ 0.01) as well as change in intensity. This change remained significantly different when correcting for baseline intensity (p=0.001). There was no significant difference in the number of sessions completed during hospitalisation between genders.

Conclusion: The intensity of NMES is tolerated at significantly higher levels in males. This may have clinical implications for NMES prescription and relate to outcome measures (eg. strength).

Conclusions: Does tolerance of neuro-muscular electrical stimulation (NMES) relate to gender in patients with an acute exacerbation (AE) of chronic obstructive pulmonary disease (COPD)?

P487

Responsiveness of different multidimensional severity indices to pulmonary rehabilitation in patients with COPD

Maria Esquife1,2, Nildah Aparecida Hernandez1,2, Thais SantAnna2, Vanessa Suziane Probst1,5, Fábio Pitta1,6, *Centro de Pesquisa em Ciências da Saúde (CPCS), Centro de Ciências Biológicas e da Saúde (CCBS), Universidade Norte do Paraná (UNOPAR), Londrina, Brazil; 1Faculty of Fisioterapia Pulmonar (LFIP), Departamento de Fisioterapia, Universidade Estadual de Londrina (UEL), Londrina, Brazil

Background: Multidimensional indices have been used to assess disease severity in patients with COPD. The responsiveness of these indices to pulmonary rehabilitation (PR) needs to be better investigated.

Objective: To evaluate the responsiveness of five multidimensional severity indices to PR in patients with COPD.

Methods: 35 patients with COPD (17 men, 66±8 years, FEV1 43±16%pred) participated in a PR program of high-intensity endurance and strength training during 3 months. Demographic data, lung function (spirometry), exercise capacity (six-minute walking test [6MWT] and incremental shuttle walking test [ISWT]), dyspnea (Medical Research Council [MRC] scale) and quality of life (Saint George Respiratory Questionnaire [SGRQ]) were assessed before and after the program, and the following indices were calculated: BODE, SAFE, i-BODE and i-BOA.

Results: Age, distance walked in the 6MWT and SGRQ score were the only components of the indices which changed after PR (p<0.05 for all). Table 1 summarizes the responsiveness of the indices to PR.

Table 1

<table>
<thead>

</tr>
<tr>
<td>i-BOA</td>
<td>4.31±1.89</td>
<td>4.62±1.50</td>
<td>0.34</td>
</tr>
</tbody>
</table>

The percentage of subjects that decreased their score (i.e., improvement) in the BODE, SAFE, upBODE, ADO and i-BOA was 23%, 49%, 23%, 20% and 23% respectively (p<0.05).

Conclusions: These preliminary findings indicate that the severity indices evaluated in patients with COPD in this study present very modest responsiveness to pulmonary rehabilitation, despite the improvement in some of its components.
Differences between smokers who completed or dropped out of a program to moderate PA were observed in both groups (p < 0.05). Patients undergoing oropharyngeal exercises showed a significant decrease in neck circumference (-1.04 to -0.97 cm; p < 0.05), sleep quality (range 0–4; intensity (1–3), Epworth Daytime Sleepiness score (0–24) and Pittsburg Sleep Quality score (0–21) were determined, and full polysomnography were performed at baseline and at the end of the intervention. Results: No significant difference was found in baseline characteristics between the groups (p > 0.05). Body mass index and abdominal circumference did not change significantly over the study period (p > 0.05). Patients undergoing oropharyngeal exercises had a significant decrease in neck circumference (-1.04 to -0.97 cm; p < 0.05), sleep quality (range 0–4; intensity (1–3), Epworth Daytime Sleepiness score (0–24) and Pittsburgh Sleep Quality score (0–21) were determined, and full polysomnography were performed at baseline and at the end of the intervention. Results: No significant difference was found in baseline characteristics between the groups (p > 0.05). Body mass index and abdominal circumference did not change significantly over the study period (p > 0.05). Patients undergoing oropharyngeal exercises had a significant decrease in neck circumference (-1.04 to -0.97 cm; p < 0.05), sleep quality (range 0–4; intensity (1–3), Epworth Daytime Sleepiness score (0–24) and Pittsburgh Sleep Quality score (0–21) were determined, and full polysomnography were performed at baseline and at the end of the intervention. Results: No significant difference was found in baseline characteristics between the groups (p > 0.05).

Conclusions: Inspiratory muscle training ensures significant benefits in respiratory muscle strength, quality of life, and smoking for OSAS patients. It should be taken into consideration for the management of the patients.
Conclusions: Oropharyngeal exercises significantly reduce anthropometric measurements and symptoms in patients with OSAS. They represent a promising treatment for OSAS.

P493
Physical activity promotes pulmonary recovery after cardiac surgery
Marcus Jonsson 1, Elisabeth Westerdahl 1, 3, Department of Physiotherapy, Örebro University Hospital, Örebro, Sweden; 2 School of Health and Medical Sciences, Örebro University, Örebro, Sweden; 4 Department of Medical Sciences, Uppsala University, Uppsala, Sweden

Introduction: It is well known that physical activity has substantial impact on general health and mortality. Benefits of physical activity have been reported for patients after cardiac surgery. Patients undergoing cardiac surgery have reduced lung function postoperatively and often suffer from postoperative pulmonary complications.

Methods: In a prospective cohort study, a sample of 76 patients undergoing cardiac surgery between 2007 and 2009, was followed up two months after cardiac surgery. Physical activity level was quantified using a categorical question on physical activity at work and during leisure time. Lung function was measured by spirometry. The measurements were made preoperatively and 2 months postoperatively.

Result: Two months postoperatively the patients had increased their self-reported level of physical activity. Patients with a higher level of physical activity showed a significantly better recovery of lung function two months after cardiac surgery (VC 95% ± 11 vs 91% ± 7 (p = 0.043) and FEV1 93% ± 8 vs 89% ± 6 (p = 0.0088) compared to patients reporting low physical activity.

Conclusion: A higher level of physical activity, during the first two months after cardiac surgery is associated with a better recovery of lung function, compared to being less active or sedentary.

P494
Cardiac autonomic responses exercise-induced during inpatient cardiac rehabilitation in patients undergoing CABG and left ventricular function different
Renata G. Mendes 1, Rodrigo P. Simões 1, Fernando S.M. Costa 1, Camila B.F. Pantoni 1, Luciana Di Thommazon 1, Sérgio Luzzi 1, Otthon Amaral-Neto 1, Aparecida M. Catarí 1, Ross Arena 1, Audrey Bonghi-Silva 1, Cardiopulmonary Physiotherapy Laboratory, Federal University of Sao Carlos, SP, Brazil; 2 Cardiology Department, Irmãundade Santa Casa Misericórdia Hospital, Araraquara, São Paulo, Brazil; 3 Physiotherapy Department, University of New Mexico, Albuquerque, NM, United States

Introduction: Patients undergoing coronary artery bypass graft (CABG) with reduced left ventricular function (LVF) are those who experience greater cardiac autonomic adaptation at rest after inpatient cardiac rehabilitation (CR). However, the acute cardiac autonomic response (CAR) during exercise remains to be investigated.

Aim: To assess whether physical exercises can evoke beneficial CAR in post-CABG patients with different LVF.

Method: Forty-four patients, divided into LVF normal (LVFN, n=23) composed of patients with left ventricular ejection fraction (LVEF) ≥ 55% and LVF reduced group (LVRF, n=21) with LVEF<55% were evaluated. CAR was assessed by heart rate variability (HRV) during extremity ROM exercises and ambulation on the first postoperative day (PO1) and before discharge, respectively.

Result: PO1 were observed significant intragroup differences for mean heartbeats per minute (HR) at rest and exercise, respectively. PO1 were observed significant intergroup differences for mean heartbeats per minute (HR) at rest and exercise, respectively.

Conclusion: In patients with normal LVF, physical exercise triggered more attenuated CAR compared with patients with reduced LVF post-CABG. Thus, prescribed intensities of physical exercises at this time should be reviewed considering the differences of ventricular function of patients involved.

P497
Respiratory muscle training is safe and effective in malnourished patients
Adriana Lunardi, Murakami Fernanda, Carol Fagundes, Carvalho Celso.
Physiotherapy, School of Medicine of University of Sao Paulo, SP, Brazil

Malnutrition is prevalent in 50% of hospitalized patients worldwide and causes systemic damage, including the respiratory system and muscles and leading to increased predisposition to infections and respiratory muscle weakness. The safety and effectiveness of respiratory muscle training in this population are poorly studied.

Objective: To assess the effect of specific respiratory muscle training in malnourished patients.

Methods: This prospective, randomized and controlled study enrolled 29 malnourished patients with no previous pulmonary disease (BMI<20kg/m² and serum albumin<3.5g/dL). Patients were randomly divided into 3 groups: sham training (CG, n=10), inspiratory (ITG, n=10) and expiratory (ETG, n=9) training. The intensity of ITG and ETG training was at 30% of maximal inspiratory or expiratory pressure (respectively, MIP and MEP). Training sessions were conducted daily in the afternoon for 30 minutes (3 sessions of 10 min, during 7 days) using the threshold DTM® or PEP®. All patients received the same nutritional support. Maximal respiratory pressures and lung function was evaluated before and after the protocols. The evaluator was blinded to patient’s group. Two way repeated measures ANOVA and post hoc Newman-Keuls test were performed and significance level was set at 5%.

Results: All groups were similar in gender, age, BMI and serum albumin. No patient demonstrated any signs of respiratory distress. After training period, there was increase in MIP in the ITG (59.9±25.8 x 107.9±52.6cmH2O; p=0.02) and MEP in the ETG (46.5±12.9 x 81.1±23.2cmH2O; p=0.01) compared to CG.

Conclusion: The respiratory muscle training is safe in malnourished patients and promotes a specific increase in the trained muscle.
Feasibility of neuromuscular electrical stimulation (NMES) on the intensive care unit (ICU): Preliminary results
Johan Segers, Greert Hermans, Frans Bruyninck, Greert Meyfroidt,
Daniel Langer, Rik Gosselink, Rehabilitation Sciences, KU Leuven, Leuven, Belgium;
General Internal Medicine - Medical ICU, UZ Leuven, Belgium;
Physical Medicine and Rehabilitation, UZ Leuven, Belgium;
Intensive Care Medicine, UZ Leuven, Belgium

Background: Survivors of critical illness often have a prolonged ICU stay. To attenuate their reduction in muscle mass and muscle strength, NMES might be useful. Aim was to study feasibility and safety of NMES in ICU.

Methods: Patients with expected prolonged stay in ICU of 5 additional days (judged on day 3) without neurological disease were included. They received daily bilateral quadriceps NMES sessions of 25 minutes. Main outcome was to produce contraction of quadriceps. Patients with contraction in 75%-100% of sessions were considered responders. Patient characteristics and stimulation parameters were compared between responders and non-responders. Safety was judged by cardiovascular and respiratory responses.

Results:

Physiotherapy led weaning plans reduce the number of days patients require non-invasive ventilation (NIV)
Stephanie Harlan, Amber Lane, Paul Murray, Physiotherapy Department, Ashford and St Peter’s Hospitals NHS Foundation Trust (ASPH), Chertsey, Surrey, United Kingdom; Rehabilitation Department, Ashford and St Peter’s Hospitals NHS Foundation Trust, Chertsey, Surrey, United Kingdom

Background: Respiratory physiotherapists at ASPH assess, monitor and wean patients requiring NIV. In May 2009, as a result of previous NIV audit data, a physiotherapy led weaning proforma was implemented to improve successful weaning rates.

Aims and objectives: The aim of the investigation was to establish if physiotherapy led weaning plans reduced the number of days patients spent on NIV.

Methods: Data were collected prospectively from 255 consecutive patients requiring NIV over a two year period from May 2009 to April 2011 using a locally adapted version of the BTS NIV data collection tool. Number of days on NIV were collected from patients nursing notes. 84 patients had physiotherapy led weaning plans and were included in the analysis (T-test).

Results: 33% (n=84) of patients had a physiotherapy led weaning plan. The impact of physiotherapy led weaning plans is summarised.

Table 1. Impact of physiotherapy weaning plans on time on NIV

<table>
<thead>
<tr>
<th>Patients with a physiotherapy weaning plan (n=84)</th>
<th>Patients without a physiotherapy weaning plan (n=171)</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average number of days on NIV (range)</td>
<td>3.0 (1-8)</td>
<td>8.1 (1-17)</td>
</tr>
</tbody>
</table>

8% (n=21) patients required referral for domiciliary NIV and therefore could not be weaned and were excluded from the analysis.

Conclusion: Physiotherapy led weaning plans reduce the length of time patients remain on NIV. A possible explanation could be faster optimisation in the first 24 hours facilitating a shortened weaning time. Further investigation is required to establish if earlier physiotherapy input can impact on NIV outcome.

Thanks to Tina Thomas for data entry.
P502

Asthma control test administered by web-based text messaging (short message service-SMS): Is it comparable with paper form?

Method: Asthma control test (ACT) and Asthma Control Questionnaire (ACQ) were administered as paper and web-based. Each questionnaire was written at a 5.7 grade level and completed by 210 adults (88% asthma control test (ACT) and Asthma Control Questionnaire (ACQ) has been used in clinical practice. The ACT uses a standardized guide for recording difficulty encountered by subjects during self-administration was used to evaluate comprehension and ease of reading.

Results: The 39-item Conventional and Alternative Management for Asthma questionnaire was written at a 5.7 grade level and completed by 210 adults (88% female; mean age 48.76% Black; 20% White; 62% with < high school education). On average, subjects completed the questionnaire in < 5 minutes. Three subjects required assistance to complete the questionnaire; one was legally blind. Eight (4%) had difficulty with the Likert scale. As many as 31 (15%) asked for clarification on the wording of 15 distinct items. Four (2%) requested help in reading one or two unfamiliar words. Only 1 item elicited no comments.

Conclusions: The use of a standardized debriefing guide allowed for the identification of problematic words, unclear meanings and confusion over scaling despite a deliberate attempt to develop a low literacy text. Data suggest that a lower reading level is not sufficient to remove the potential for misreporting.

P503

Creating and testing a low literacy asthma questionnaire

Ruth Finnell1, Judy A. Shea3, Maureen George3

1University of Pennsylvania, Philadelphia, United States; 2University of Pennsylvania, School of Medicine, Philadelphia, United States; 3University of Pennsylvania, School of Nursing, Philadelphia, United States

Background: Nearly half of the US population reads at or below the 8th grade level. Recognition of low literacy has resulted in greater attention to developing low literacy questionnaires. A standardized guide for recording difficulty in understanding wordings was developed and evaluated in a clinical setting.

Objective: To systematically develop a research questionnaire that accurately captures subjects’ responses when self-administered.

Methods: Following traditional instrument development steps (comprehensive review of the literature and selection of items using content experts), researchers created a low literacy questionnaire. A standardized guide for recording difficulties encountered by subjects during self-administration was used to evaluate comprehension and ease of reading.

Results: The 39-item Conventional and Alternative Management for Asthma questionnaire was written at a 5.7 grade level and completed by 210 adults (88% female; mean age 48.76% Black; 20% White; 62% with < high school education). On average, subjects completed the questionnaire in < 5 minutes. Three subjects required assistance to complete the questionnaire; one was legally blind. Eight (4%) had difficulty with the Likert scale. As many as 31 (15%) asked for clarification on the wording of 15 distinct items. Four (2%) requested help in reading one or two unfamiliar words. Only 1 item elicited no comments.

Conclusions: The use of a standardized debriefing guide allowed for the identification of problematic words, unclear meanings and confusion over scaling despite a deliberate attempt to develop a low literacy text. Data suggest that a lower reading level is not sufficient to remove the potential for misreporting.

P504

Asthma control test/Questionnaire for assessing asthma control: Systematic review and meta-analysis

Kim Eui1, Hong-Fong Zhang1, L. V. Yan1, Rui Liang2, Yun-Qiu Jiang1, Heather Powell2, Juan-Juan Fu3, Lei Wang1, Peter Gerard Gibson2, Gana Wang2,3

1Pneumology Group, Department of Integrated Traditional Chinese and Western Medicine, West China Hospital, Sichuan University, Chengdu, China; 2Center for Asthma and Respiratory Diseases, Department of Respiratory and Sleep Medicine, John Hunter Hospital, Hunter Medical Research Institute, University of Newcastle, Australia

Background: Currently the cornerstone of asthma management is to achieve and maintain asthma optimal control, but the diagnostic performance of Asthma control test (ACT) and Asthma Control Questionnaire (ACQ) has not systematically been evaluated.

Objective: We explored the diagnostic performance and its comparison between ACT and ACQ.

Methods: Studies concerned with the accuracy of ACT and/or ACQ for assessing asthma control were searched from Pubmed, CENTRAL, Web of Science, Ovid and Embase. The summary estimates of sensitivity, specificity, and diagnostic odds ratios (DORs) at different levels of asthma control were performed using bivariate random effects model and hierarchical summary receiver operating characteristic (HSROC) model.

Results: Twenty-two studies with 12909 subjects in ACT and 4447 in ACQ were identified. The summary estimates in ACT for assessing controlled, not-well controlled, and uncontrolled asthma were sensitivity (0.81, 0.77 and 0.79), specificity (0.79, 0.78 and 0.73), and DORs (15.56, 12.42 and 10.46), respectively, and those in ACQ were sensitivity (0.93, 0.72 and 0.87), specificity (0.65, 0.83 and 0.66), and DOR (24.92, 11.98 and 12.72), respectively. There were no statistical differences in diagnostic accuracy between ACT and ACQ by using HSROC areas under the curve (all P > 0.05). Subgroup and meta-regression implied that age, setting, asthma severity, and the race could influence the diagnostic accuracy.

Conclusion: The diagnostic performance between ACT and ACQ is not different, but clinicians need to consider the impact of the potential factors when establishing asthma control levels to promote therapies in a real-world setting.

P505

Air-trapping and decreased diffusion capacity in patients with severe asthma

Olga Kharevich, Irina Lapteva, Elena Lapteva, Arsen Tomashovsky, Elena Koroleva

1Pulmonology Department, Republic Center of Pulmonology and Thypthysiology, Minsk, Belarus; 2Department of Pliysioptumorlogomy, Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus; 3Department of Functional Diagnostics, Republic Center of Pulmonology and Thypthysiology, Minsk, Belarus

Introduction: Patients with severe asthma tend to have impaired lung function despite the high-intensity treatment. Aim: The aim of the study was to assess the lung function parameters in patients with severe asthma compared with nonsevere disease.

Methods: In the recent research we have studied data of pulmonary function tests (spirometry, body plethysmography, diffusion capacity) in 31 patients with severe and in 23 patients with nonsevere asthma. To compare two groups of patients we used the Mann-Whitney U-test and Chi-squared test. Data are presented as median (interquartile range).

Results: Patients with severe asthma compared with those with nonsevere disease had lower VC, pre- and postbronchodilator FVC and FEV1, FEV1/FVC, FEF25-75 %, and FEF50-75 % values. FEV1 was not different between the two groups of patients. The prevalence of nonreversible airway obstruction was revealed in 77% patients with severe asthma and in 43% with nonsevere asthma (p=0.011). TLC was similar in patients with severe and nonsevere asthma, but RV and RV/TLC was significantly higher in severe asthma group (RV: 192.6 (160.2-249.5) vs 163.8 (143.9-174.7) % pred, p=0.018; RV/TLC: 145.0 (132.1-161.6) vs 119.1 (112.5-135.4) % pred, p<0.001).

Conclusion: The presence of persistent airflow limitation, air trapping and decreased diffusion capacity are important features of lung function impairment in patients with severe asthma, suggesting that these patients have more considerable airway remodelling and structural changes of lung parenchyma.

P506

Influence of anxiety on the quality of life of people with bronchial asthma (BA)

Maria L. Perelman

Vitebsk State Medical University, Vitebsk, Belarus

Aim: To study the influence of anxiety on the QL of BA patients in the cold season.

Methods: Twenty-two patients with severe asthma were studied in the cold season.

Results: The presence of persistent airflow limitation, air trapping and decreased diffusion capacity are important features of lung function impairment in patients with severe asthma, suggesting that these patients have more considerable airway remodelling and structural changes of lung parenchyma.

Conclusion: The diagnostic performance between ACT and ACQ is not different, but clinicians need to consider the impact of the potential factors when establishing asthma control levels to promote therapies in a real-world setting.
Methods: 111 BA patients were studied in winter. They were divided into two groups: with anxiety (68) and without it (43). To estimate QL a questionnaires SF-36 and AQLQ were used. “Hospital Anxiety and Depression Scale” was applied to find out anxiety. CAHR was estimated by the results of 3-minute isocapnic hyperventilation with cold air.

Results: In the group of patients with anxiety in comparison with the patients without anxiety a decreased decrease of QL in domains PF (52.7±3.1 and 65.0±4.4, p<0.05), VT (45.3±2.3 and 59.2±2.8, p<0.001), SF (48.3±3.0 and 64.6±3.5, p<0.001) and MH (56.6±2.3 and 71.2±2.7, p<0.001) by SF-36, and in domains “Emotion” (3.4±0.2 and 4.5±0.2, p<0.001) and “General QoL” (3.3±0.2 and 3.9±0.1, p<0.01) by AQLQ. The direct correlation was found out between FEV1 and “Environment” in the group without anxiety (r=0.41, p<0.01), whereas patients with anxiety did not have it. Hence, anxiety but not lung dysfunction is a dominating factor of QL decline in the latter case. The QL of patients with CAHR and anxiety gets considerably worse. The decline of QL of these patients in all domains except “Emotion” was revealed by AQLQ. The most significant worsening was obtained in domain “Environment”.

Conclusion: Anxiety in BA patients has a negative influence on QL mainly on the psychosocial status. CAHR in winter also affects physical aspects of QL.

P507 Prediction of deterioration of bronchial asthma (BA) control after six months of basic anti-inflammatory therapy

Nelly M. Smirnova, Anna G. Pridkoly, Julia M. Perelman. Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveschensk, Russian Federation

Background: Now it is accepted that the assessment of asthma control should include not only clinical manifestations, but also control of the expected future risk to the patients. Aim: To develop the way of prediction of uncontrolled BA after 6 months of basic anti-inflammatory therapy.

Methods: 84 patients with uncontrolled BA were examined. At the first examination the test of isocapnic hyperventilation with cold air (IHCVA) was conducted; the level of LTD4 and LTE4 in the exhaled breath condensate before and after the IHCVA with the identification of hydrogen peroxide (H2O2) was done. In 24 weeks of basic therapy there was the second clinical examination where the control level over BA symptoms was determined. Depending on the obtained data the patients retrospectively were divided into two groups: the 1st group included 48 patients with the partial or total BA control, the 2nd group consisted of 36 patients with uncontrolled BA.

Results: It was established that high airway hyperresponsiveness and the degree of bronchial inflammation being independent factors of BA control. On this basis and with the help of discriminant analysis we made a discriminant equation that allows to predict an uncontrolled course of the disease: D=0.502*FEV1 (after IHCVA)+0.062*H2O2 (after IHCVA). The boundary value of the discriminant function is 23.07. If D>23.07, an uncontrolled course of the disease after 6 months of basic therapy can be predicted with 91% probability.

Conclusion: The application of the developed method gives a possibility of a differentiated approach to the choice of BA basic therapy taking into account the risk of uncontrolled course of the disease.

P508 Interrelations of rhinitis, rhinosinusitis and bronchial asthma, associated with stressful life events

Evgeny Nemerov, Therapy, Siberian State Medical University, Tomsk, Russian Federation

One of the causes of ineffective treatment of bronchial asthma (BA) is comorbid pathology, which is a combination of BA with rhinitis. Aim: To study the characteristics and order of nasal pathology development in patients with BA associated with psychological stresses.

173 patients with BA allocated to 2 groups were studied. The first group included 56 patients in whom the first episode of the disease were associated with stressful life events. The second group included 117 patients in whom the disease was not linked to psychological factors.

Results: Nasal pathology was diagnosed only in 25 of 56 (44.6%) patients in the first group and in 106 of 117 (90.6%) in the second one, p = 0.0000. Allergic rhinitis was observed in only 6 (10.7%) patients in the first group and in the majority of cases (93 (70.9%)) in the second group, p = 0.0000, while rhinosinusitis was most frequent in the first group (19 of 56 (33.9%) versus the second one (12 of 117 (10.3%)), p = 0.0000. The order nasal pathology formation differed markedly between the two groups. So, nasal symptoms preceded the onset of asthma symptoms in the first group considerably rarely (7 of 25 (28%) than in the second one (106 of 106 (100%), p = 0.0000. On the contrary, nasal pathology development against the background of the current asthma was more frequent in the first group (11 of 25 (44%)) than in the second one (8 of 106 (7.5%), p = 0.0000.

Conclusion: Bronchial asthma, the development of which is closely associated with psychological triggers, is not related to nasal pathology in more than half the cases with frequent secondary involvement of the upper airways and predominance of rhinosinusitis over allergic rhinitis.

P509 Mycobacteria in the pharynx of patients with persistent bronchial asthma who constantly applying the inhaled corticosteroids

Irina Reshetnikova1,2, Rachid Fassakhov1,2, Nadezda Glushcho1, Elena Khaldeeva1, Svetlana Lisovskaya2. 1Allergology and Immunology, Kazan Scientific Research Institute of Epidemiology and Microbiology, Kazan, Tatarstan, Russia; 2Department of Respiratory Medicine, Kazan Functional Research Institute of Epidemiology and Microbiology, Kazan, Tatarstan, Russian Federation

Aim: To investigate fungal colonization the pharyngeal mucosa in patients with persistent asthma, who constantly applying the inhaled corticosteroids (iGCS). Methods: There were examined 30 patients with bronchial asthma (13 men and 17 women, mean age 51.8 years) using iGCS at high and moderate doses of at least year. Mycological study of mucous pharynx (posterior wall of the pharynx, tongue root) for finding of Candida was performed on the Sabourau agar medium. Fungi growing was carried out at 28-30°C for 48 hours. To study the adherence there was used the model of a nitrocellulose film with immobilized hemoglobin.

Results: Fungi of the Candida genus were isolated from the mucosa in 23 patients (76.6%): C. albicans - 22 cases (of which in one case, there was marked the combination of Candida albicans and Geotrichum candidum), C. tropicalis - 1 case. In 73.9% of the cases intensity of the pharynx colonization by yeasts like fungi was high and was 104, 105 CFU/ml. It has been stated that 16 out of 22 isolated Candida albicans cultures (72.7%) have less virulent ability to form tube germination and pseudomorphs in comparison with clinical cultures, isolated from the pharynx of patient with the diagnosis pharyngomikose, the adhesive activity of these cultures shved at the middle level and made 15-32%. 8 out of 22 patients (37.3%) have cultures with a high ability for germination tubes formation and adhesive activity at the level of 35-45%, which corresponded to the level of clinical cultures with high virulence. The causes of differences in the activity of the fungus Candida in asthmatic patients receiving iGCS, require further study.

P510 Omalizumab in severe adult atopic dermatitis associated to mild asthma treated with omalizumab

Anna Agnese Stanziola, Maria D’Amato, Carolina Vitale, Maurizia Lanza, Antonio Molino, Maria Luisa Bocchino, Matteo Sofia. Department of Respiratory Disease, University “Federico II” - A.O dei Colli, Napoli, Italy

Omalizumab is an established add-on therapy efficacious in allergic severe asthma. Its role in treatment of asthma and atopic dermatitis with high IgE levels is not well known. However Isolated case report show the efficacy of anti-IgE in recalcitrant atopic dermatitis, a skin disorder characterized by elevated levels of IgE and significant morbidity.

Aim: We report 5 adult patients 2 male and 3 women, mean age 34.6 (range 19-48yrs), with chronic severe atopic dermatitis and mild to moderate bronchial asthma. For atopic dermatitis they were treated with oral steroids (prednisone mean 17.5 mg die range 10 to 25 mg) and immunosuppressive therapy as Cyclosporine (5mg/die) or Methotrexate (7.5 mg/wks). The patients started treatment with Omalizumab 37.5 mg every two weeks. Pretreatment IgE levels ranged from 282-5390 IU/ml (mean 2501 IU/ml).

Results: After 16 weeks, the serum IgE level decreased mean 1146 IU/ml (range 1421 to 3088) and a significant clinical improvement was registered in all patients with reduction of skin lesions and pruritic score (from 9 indicating severe itching to 3). The patients discontinued immunosuppressive treatment after two months and oral steroids after 6 months. After 1 year follow-up of Omalizumab treatment, the IgE levels were 620 IU/ml (range 140 to 1000) and no adverse events were documented. Moreover, the patients did not refer any asthmatic exacerbations at 1 year follow-up.

Conclusions: Anti-IgE Omalizumab is effective in improving atopic dermatitis unresponsive to conventional therapy in patients with concomitant asthma few weeks of treatment and is able to decrease steroid and immunosuppressive therapy without any interference on asthma control.

P511 The effect of smoking on the levels of cysteinyl leukotriene in exhaled breath condensate in asthmatics

Deniz Çelik1, Sibel Dündar1, Handan İmın Kosegül1, Semsettin Sahin2, Ibrahim Serhat Celikel1, Ünal Erkorkmaz3. 1Chest Diseases, Gaziosmanpaşa University, Tokat, Turkey; 2Biochemistry, Gaziosmanpaşa University, Tokat, Turkey; 3Biostatistics, Gaziosmanpaşa University, Tokat, Turkey

Aim: Cysteinyl leukotrienes are the most important mediators in pathogenesis of asthma. The aim of this study was to assess the impact of smoking on the levels of LTs in exhaled breath condensate (EBC).

Methods: Thirty smoker (Group I) and 29 nonsmoker (Group II) asthmatics were included in the study. EBC (EcoScreen, Jager) was collected from all of the participants and pulmonary function tests (PFT) were performed too. All of the asthma cases were stable according to asthma control questionaire. Levels of LTD4 and LTE4 were measured in EBC with ELISA.

Results: The levels of LTD4 and LTE4 were shown in Table 1. When we compared the groups according to PFTs we determined statistically significant difference between Group I and III in FEV1/FVC, MMEF and MMEF%. There was a
significant negative correlation between LTE4 levels and FEV1/FVC in Group I.

Leukotriene levels of the study groups

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

*pThere was a significant difference between the Group I and Group III, Group II and Group III (p=0.05); however, there was no significant difference between other pairwise comparisons (p>0.05).

Conclusion: LTE4 levels were significantly higher in smoking asthma group than the other groups. This result suggest that LTE4 receptor specific blocker agents might be useful in smoking asthma patients and clinical studies are required in this issue.

P512 Role of viral pathogens in infectious exacerbations of bronchial asthma in adults

Vitaliy Iachnik1, Oleksandr Dzublyk1, Irina Dzublyk2, Georgii Kapitan1,
Okhta Beruenskaya3, Rosiudzif Sukhin3, Nina Nediniska3, Oleksandr Mukhin3,
Vsevolod Kliagin4. 1Dep. Treatment of Non-Specific Lung Disease, State
Institution “National Institute of Tuberculosis and Pulmonology n. a. F. G.
Yanovsky, AMS of Ukraine”, Kiev, Ukraine; 2Department of Virology, National
Medical Academy of Postgraduate Education n. a. P. L. Shupyk MH of Ukraine, Kiev, Ukraine

Purpose - to investigate the spectrum and frequency of viral pathogens in patients with infectious exacerbation of bronchial asthma (BA) which treated in a pulmonology department.

The study included patients only if they voluntarily consent to the research, objectives and scope of planned inspections.

This work was funded from the state budget.

Virology were performed in all patients fence biomaterial: a smear or swab from the nasal cavity.

Laboratory diagnosis of viral infection was performed by real-time PCR (PCR-
FRT) and a rapid chromatographic immunosassay analysis. PCR was performed in adenoviruses (hAdV), hokavirus (hB0), rhinovirus (hRV), coronavirus (hCoV), RS-virus (hRVc), metapneumovirus (hMpV). The method of immunochromatographic test detected antigens of influenza viruses A and B, respiratory adenovirus (hAdV) and RS-virus (hRVc).

For the purpose of the study was carried out screening all patients which were sent to hospital State Institution “National Institute of tuberculosis and pulmonology behalf F.G. Yanovsky, AMS of Ukraine” with the diagnosis of exacerbation of bronchial asthma from Dec 2010 to Sep 2011 a total of 52 patients observed, which revealed 21 viral pathogens by PCR, 6 viral pathogens by the rapid immunochromatographic test and 2 (hRVc) by both methods.

Viral pathogens detected in the (48,1;6,9)% of patients with exacerbation of asthma. The greatest etiologic importance by the results of virological studies were: rhinoviruses - 68,0%, influenza virus A and B - 12,0%, RS-virus - 8,0%, metapneumovirus - 8,0%, adenovirus - 4,0%, respiratory corona virus - 4,0% of cases.

P513 What is missing in the asthma control test? The relationship between compliance, inhaler technique and level of control

Sawamm Badleer Omar AI-Rawas. Medicine, Sultan Qaboos University, Al Khoud, Oman

Introduction: Asthma control test as many other validated questionnaires are used to assess level of control. However, they do not identify factors that may lead to poor control such as medication compliance and inhaler technique. In this study level of asthma control was assessed by using asthma control test (ACT) and simultaneously the accuracy of compliance with preventer medications and inhaler technique were evaluated. The main objective of the study is to find out the relationship between compliance and inhaler technique with the level of asthma control.

Methodology: Prospective 3 months study (1st February – 31st May 2011) was conducted in a university hospital in Oman. Asthmatic adult patients on preventer maintenance medication in chronic asthma (BA) which treated in a pulmonology department.

Purpose: To study relationship between the level of BA control and pattern of breathing. Inhalar technique was evaluated using a standardized checklist. Compliance was assessed using a pre designed scoring system.

Results: 218 patients were assessed. Poor control was found in 126 (58%) patients, of whom 74 (59%) had poor compliance and 34 (27%) had poor inhaler technique. There was no significant difference in the level of control between patients with good and partial compliance (60% vs 59%). Only 35 (16%) patients had good level of control and good compliance and good inhaler technique.

Conclusion: Since compliance and inhaler technique have a direct effect on the level of control, they should be part of all asthma assessment tools.

PS14 Clinical characteristics of severe asthma subphenotypes

Iryad Lunzguk, Natalia Pobarkhniko. Department of Pulmonology, Republican Scientific Practical Center of Pulmonology and Phthisiology, Minsk, Belarus

The natural history and clinical subphenotypes of severe asthma are poorly understood particularly among patients that have difficult to control asthma and no other co-morbidities.

To describe the differences in the clinical characteristics of severe asthma subphenotypes on the basis of age at onset of disease.

Cross-sectional clinical study was carried out in 40 patients (age 18 years) with severe asthma. In the retrospective collected data were included the demographics information and assessments of lung function (ie, spirometry and body plethysmography). For lung function were determined airflow resistance (Raw), thoracic gas volume, vital capacity, total lung capacity (TLC), and residual volume (RV). The flow-volume relationships were evaluated with FEV1; FVC and FEV1/FVC ratio.

16 patients with late-onset asthma (40%) had clinical significant compromised lung function whether they had asthma of short duration or long duration, suggesting that significant compromise in lung function occurred at or very soon after the initial diagnosis of asthma had been made. They had more resistance to airflow (Raw, % predicted 307.5 20 vs 285.3 23.0 respectively p<0.024); larger lung volumes (total lung capacity: TLC, % predicted 107.1±2.6 vs 103.8±2.3 respectively p<0.062; and residual volume: RV, % predicted 202.3±10.3 vs 190.1±8.7 respectively p<0.037) compared to early-onset asthma. Late-onset asthma also was characterized by a reduced FEV1/FVC and a history of more frequent sinusopulmonary infections.

Late-onset severe asthma may be associated with a greater degree of airways inflammation and/or more exuberant repair processes, resulting in rapid remodeling of distal part airway, compared to early-onset asthma.

P515 Illness perceptions and medication beliefs: Key determinants of adherence to maintenance medication in chronic asthma

Ad Kaptein. Medical Psychology, Leiden University Medical Centre, Leiden, Netherlands

Outcome in asthma is determined not only by pulmonary function or other biomedical characteristics. Illness perceptions and medication beliefs are crucial in predicting outcomes of asthma management. Illness perceptions pertain to patients’ subjective beliefs and emotional responses to their asthma. Medication beliefs tap idiocentric views on (asthma) medication. Both influence coping and thereby outcome.

I’ll review recent studies on this topic, with a range of respondents and care-providers, with patients with varying degree of asthma severity and in different settings of medical care. Examples of how to assess illness perceptions and medication beliefs will be presented and discussed.

All studies report substantial effects of illness perceptions and medication beliefs on various categories of outcomes. These findings emphasize the clinical relevance of addressing patients’ beliefs about their illness and its medical management, and suggest that this may improve outcome of asthma care. Examples of recent high-quality intervention studies on this topic will be presented, with a view to how to improve quality of care, and thereby quality of life of patients with asthma. In the era of shared decision making and patient empowerment it appears addressing and incorporating illness perceptions and medication beliefs into regular clinical care is a must.

Prof Ad Kaptein, a.kaptein@lumc.nl

P516 Pattern of breathing and respiratory rhythm variability in patients with different level of bronchial asthma control

Dmitry I. Nakhamchen1, Juliya M. Perelman1, Victor P. Kolosov2, Leonid G. Nakhamchen1, 1Laboratory of Functional Research of Respiratory System, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveshchensk, Russian Federation; 2Laboratory of Pathophysiology of Non-specific Respiratory Diseases, Far Eastern Scientific Center of Physiology and Pathology of Respiration SB RAMS, Blagoveshchensk, Russian Federation

Background: It is unknown how the loss of bronchial asthma (BA) control effects on the control of breathing.

Aim: To study relationship between the level of BA control and pattern of breathing and respiratory rhythm variability.

Methods: 97 BA patients and 21 healthy people were examined. BA patients were divided on two groups: 15 patients with controlled BA (CBA) and 82 patients with uncontrolled BA (UBA). The pattern of quiet breathing and respiratory rhythm variability were studied by spirometry. Quiet breathing was registered through the month during 15 minutes.

Results: In the group of healthy people compared with the asthmatics the inspiratory time (1.76±0.1 and 1.54±0.03 sec., respectively, p=0.04) and the effective inspiratory time (0.40±0.009 and 0.38±0.004, p=0.029) were significantly longer and the effective expiratory time (0.60±0.009 and 0.62±0.005, p=0.036) was shorter. In the UBA group in comparison with the CBA group there were shorter...

Anamnestic and clinical peculiarities of severe bronchial asthma in children
Oleks Tsyvun, Svetlana Smirnova, Natal'ya Iliienkova. Siberian Branch under the Russian Academy of Medical Sciences, Scientific Research Institute for Medical Problems of the North, Krasnoyarsk, Russian Federation Medicine, Krasnoyarsk State Medical University, Krasnoyarsk, Russian Federation

Aim: To study anamnesis and clinical data on severe/moderate severe atopic bronchial asthma with different level of control, determine the main risk factors of the formation of BA non-controlled course in infants.

Materials and methods: We have examined 100 infants, severe/moderate severe atopic BA patients, inhabitants of Krasnoyarsk territory in average ages of 10.9±1.1. We have studied allergy anamnesis, carried out physical and specific allergy examination, estimated the results of instrumental research. In order to determine the level of controlling the disease we had estimated the results of “Test on controlling asthma”. We have formed 2 groups: with controlled BA (n=50) and non-controlled BA (n=50).

Results: Living under unfavorable living conditions (wooden homes with damp, mould, stove heating, overcrowding) had been marked in 34% cases in group with non-controlled BA course and in 26% in group with controlled BA (p=0.012). One or two smoking parents had been marked in 36% cases in controlled BA course and in 48% in non-controlled BA (p=0.007). Analysis of family structure revealed that 48% children of group of good control and 74% of group of absence of control live in sole-parent families (p<0.001).

Conclusions: We have determined anamnesis predictors of non-controlled BA course in children: living in home with stove heating with damp in living area, smoking inside and presence of domestic animals. When estimating social status of the families in BA children with non-controlled course we have stated frequent occurrence of sole-parent families with low income.

P518
Complementary and alternative therapy in bronchial asthma – A study from India
Kunigalavj Venugopal, P.R. Sreelatha, R.S. Nisha. Healthservices, Govt General Hospital, Alappuza, Kerala, India medical Education, Medical College, Alappuza, Kerala, India medical Education, Medical College, Alappuza, Kerala, India

Introduction: Various complementary and alternative therapies (CAT) are being studied in Asthma management, with reports of varying effects. CAT includes a variety of breathing and relaxation exercises including Yoga, diaphragmatic breathing, progressive relaxation etc. If these can facilitate easy disease control, they can be utilized in bringing down the cost of Asthma treatment, a major issue in resource limited countries like ours.

Aim: 1. Compare the effect of 2 CATs i.e. Butyryko Breathing Technique (BBT) and Diaphragmatic Breathing Exercises (DBE) in asthma treatment
2. Compare the effect of each to conventional treatment alone.

Materials & methods: Prospective, case-control study conducted in an asthma clinic at Alappuza. Patients with persistent asthma aged 25-65 years were randomly grouped into 3.

- Receiving conventional therapy alone
- Above+BET
- Above+DBE

Disease control assessed by spirometry, Mini Asthma Quality of Life Questionnaire (MAQOL), Asthma Control Test and %age use during first week of study and end of third month.

Statistical analysis by 2 way ANOVA technique

Result: Total of 30 patients, 10 in each group studied. No significant difference in FEV1 among 3 groups; statistically significant improvement in quality of life (QOL) among groups B & C, with reduction in % age use.

Conclusion: CAT can be useful in improving QOL among asthmatics.

P519
Depressive symptoms in asthma patients
Evelyn Mekeu1, Penka Nikolova2, Petra Marinova2. 1First Therapeutic Clinic, SHAFTPD “St. Sofia”, Sofia, Bulgaria; 2Second Psychiatric Clinic, UMBIATNP “St. Sofia”, Sofia, Bulgaria

Background: Asthma is a chronic disease with worldwide prevalence of 1-1.8%.

Co-morbid depression (prevalence of around 10%) in patients with asthma affects quality of life and treatment outcomes.

Objective: To examine the prevalence of depression and its association with asthma control in patients with asthma versus healthy controls.

Methods: Two groups of subjects were recruited: 1) patients with asthma and no other chronic condition (n = 114) - all of them performed spirometry and answered two questionnaires: ACQ and CES-D20; 2) healthy controls (matched for age, sex, BMI, education and smoking history) (n = 288) without asthma or other chronic disease - they answered only the CES-D20 questionnaire.

Results: The difference between the mean Total CES-D group scores is not significant (p=0.073). 51.9% of the control group had >15p, while 30.7% of the asthmatics had the same result. In the asthma group, 10.5% had major depression, but 58.8% had mild-moderate depression. Total CES-D score correlates well with smoking status (r = -0.574, p<.0001). Total CES-D score did not correlate with mean ACQ score, FEVI, education and sex. The mean ACQ score correlates well with CES-D question11 (r = 0.431, p<.0001). There is statistically significant difference between mean ACQ score in asthmatics with major depression and the rest of the asthmatics.

Conclusions: In this study healthy people tend to have major depression or no depression at all, while asthmatic patients have predominantly mild-moderate depression. Asthmatics with major depression have worse asthma control. This study confirms earlier results concerning prevalence of depression in asthma patients, but questions the higher prevalence in asthma patients compared to healthy controls.

82. COPD comorbidities I

P520
Chronic obstructive pulmonary disease (COPD) as co morbidity (CO) in different patient categories in a university hospital setting. A cross sectional study
Helene Moeller Nielsen1, Pernille Roedgaard2, Ulla Weinreich3. 1Aalborg University Hospital, Pulmonary Medicine, Aalborg, Denmark; 2Aalborg University Hospital, Pulmonary Medicine, Aalborg, Denmark; 3Aalborg University Hospital, Pulmonary Medicine, Aalborg, Denmark

20% of the Danish adults suffers from COPD[1]. 50% of the patients are undiagnosed[1]. COPD patients have multiple CO[2]. To elucidate the frequency of COPD as CO among hospitalized patients. To investigate in which patient categories COPD is a frequent CO. Aalborg University Hospital covers all medical and surgical specialties. A one cross-sectional study was performed on 666 patients. A spirometry was performed. Smoking habits, prior lung function, prescribed lung medicine were recorded. Co-existing diagnoses were registered from case records. Of 583 possible participants 194 couldn't/didn't wish to participate. 111 weren’t present.12 were excluded. 215 participated, 28% (61/215) suffered from COPD (PC), 41% (25/61) of PC had 3 or more COs and 29% (45/153) patients without COPD (PwC) had 3 or more COs (p=0.05).

Table 1. Disease entities in which COPD was a frequent CO. Diagnoses found significantly more often in PC diagnosed at this examination than in general.

P521
Nutritional status and lipid parameters in COPD patients
Barbara Koznar-Kaminska1, Marcin Grabics1, Beata Brajer-Luflmann2, Halina Butera-Gabayda3. 1Department of Pulmonology, Allergology and Respiratory Oncology, Poznan University of Medical Sciences, Poznan, Poland; 2Department of Pulmonology, Allergology and Respiratory Oncology, Poznan University of Medical Sciences, Poznań, Poland; 3Department of Pulmonology, Allergology and Respiratory Oncology, Poznan University of Medical Sciences, Poznan, Poland

Aim of study was evaluation of nutritional status and lipid parameters in COPD patients and assessment the dependence between above. 114 COPD patients - 69 males (60.5%) and 45 females (39.5%) mean age 65.82, in different stages of the disease participated in the study. It was assessed nutritional status using bioimpedance method (Akern BIA 101) and concentrations of lipid...
parameters in blood serum. Malnutrition was confirmed in 17 (14.91%) patients, more frequent among women than men (58.8% vs 41.2%). Between patients with decreased FFM normal BMI was confirmed in 9 individuals. Deviations in the level of serum lipids was found in 43 participants (37.7%) and it was the most often hypercholesterolemia (33.3%) - in 6 (5.26%) patients hypercholesterolemia with hypertriglyceridemia and 5 cases (4.38%) of hypertriglyceridemia only. PM (fast mass index) didn’t correlate with cholesterol serum level, as well as LDL and TAG levels; unlike the BMI, where weak correlation with cholesterol was noted (p<0.02). FFMI correlated strongly with HDL cholesterol (p=0.004).

Deviations in lipid profile in COPD patients are not exclusively connected with fat contents but may be the consequence of systemic disease.

A total 77 patients with COPD (mean age 54.93±0.63 yrs) was monitored over 5 years in our study. COPD was diagnosed according GOLD criteria. During follow-up 18 patients (23.4%) died. 17 patients due to respiratory insufficiency and/or heart failure and 1 pts due to cancer. Died patients with COPD had higher CCI than alive (4.50±0.46 and 2.44±0.17, p<0.001). Died patients with COPD had CCI 3 score more frequently than alive patients. We noted correlations between baseline CCI and time before patients died (r=0.54, p<0.05).

The Charlson Comorbidity Index has demonstrated good predictive validity in our study. In our opinion, the CCI represents the optimal balance between ease of use and prognostic ability. CCI> score was associated was poor prognoses in patients with COPD.

PS25
Phenotypic characteristics of patients with arterial hypertension and chronic obstructive pulmonary disease

Patients with combination of COPD with arterial hypertension (AH) have a worse clinical course, higher risk of cardiovascular events (CE) than AH without COPD. However, the specific phenotypic characteristics of such comorbidity is still unclear.

Objective: To reveal clinical features, risk of CE in patients AH with and without COPD included in clinical trials.

Methods: A retrospective analysis of five clinical trials conducted in Russia from 2005 to 2010. The analysis included 3409 patients from 40 to 80 years with essential or isolated systolic AH. Age, sex, risk factors (RF), target organ damage (TOD), the presence of associated clinical conditions (ACC) were evaluated.

Results: 2936 from 3409 patients had AH, 385 patients had AH with COPD. In COPD with AH patients had lower age than without COPD (55.4±6.8 and 57.9±6.1, p<0.001, respectively), among them were more males (51.9% and 30.6%, p<0.001), more frequent smoking history (89.1% and 17.9%, p<0.001), higher SBP and DBP (164.6±11.1 and 160.3±12.8 p<0.001; 98.7±7.9 and 96.1±8.1 p<0.001), more HR (76.6±9.6 and 75.0±8.8 p<0.001). In COPD group there were more patients with 3 or more RF (91.4% and 76.1%, p<0.001) more often TOD (90.4% and 77.3%, p<0.001). Differences in ACC were not observed.

Conclusion: Patients COPD with AH phenotypically have lower age, more severe condition and have higher risk of CE. Differences in age are possibly due to the fact that patients with COPD have a worse clinical course and older patients are not included in clinical trials in the criteria of inclusion/exclusion, which may affect the representativeness of the results with respect to AH with COPD subgroup of patients.

PS26
Platelets count in chronic obstructive pulmonary disease

Emesto Crisafulli,1 Marco Marietta,2 Elena Venturelli1,2/MIhai Roca,3 Bianca Beghe,2 Monica Borrillonti2, Alessia Verderi2, Mario Malerba4, Michele Malagola4, Leonardo Fabbri, Enrico Clini1,2,1Pulmonary Rehabilitation, Ospedale Villa Pineda, Paravolo - Modena, Italy; 2 DM Oncology, Haematology and Pneumology, University of Modena, Italy; 3 Dept of Pneumology, University of Iasi, Romania; 4 Dpt Internal Medicine, University of Brescia, Italy; 4 Dpt. Haematology, University of Brescia, Italy

Platelets count (PTL) and activity in complex COPD is still a matter of debate in recent years. We have therefore undertaken a preliminary retrospective analysis in

P524
Prognostic value of the Charlson Comorbidity Index in patients with COPD

Nina Kurelic, Andrey Rebrov. Hospital Therapy, Saratov State Medical University, Saratov, Russian Federation

Few studies show patient outcomes over time in chronic obstructive pulmonary disease (COPD). The traditional pulmonary function test assessed by tge FEV1 is known to correlate poorly with dyspnea, health status and exercise intolerance.

In the present study we evaluated by Charlson Comorbidity Index (CCI) as a predictive marker of death in patients with COPD.
Background: Several studies have suggested that a low percentage of peripheral lymphocytes (LYM%) is associated with malnutrition, inflammation, and mortality in diseases such as cancer and chronic kidney disease. In COPD cases, malnutrition is very common, and its prevalence increases with disease severity.

Objectives: We evaluated whether the LYM% is associated with disease severity and nutritional status in patients with COPD.

Methods: We recruited clinically stable male outpatients with COPD for a cross-sectional study. We conducted the following examinations: blood tests, pulmonary function tests, computed tomography image analyses, anthropometric measurements, the 6-minute walk test (6MWT), and dyspnea evaluation. We examined the correlations between the LYM% and the clinical variables.

Results: We evaluated 72 patients (mean age, 70.6 years). The LYM% was significantly correlated with FEV1% predicted (Pearson’s coefficient, r = 0.496; p < 0.005), percentage of low attenuation area (r = −0.306; p = 0.015), body mass index (r = 0.252; p = 0.034), fat-free mass index (r = 0.404; p < 0.0005), distance covered during the 6MWT (Spearman’s rank correlation coefficient, ρ = 0.491; p < 0.0005), and the modified Medical Research Council (MMRC) dyspnea score (r = −0.439; p < 0.0005). Stepwise multiple regression analysis showed that FEV1% predicted significantly correlated with the LYM% (R² = 0.252).

Conclusions: A low LYM% is associated with impaired nutritional status, exercise capacity, and pulmonary function. The LYM% may serve as a clinically convenient and useful biomarker for predicting disease severity in patients with COPD.

P530 Relevance of respiratory muscle strength in chronic obstructive pulmonary disease

Chung Ju, Rongchang Chen. State Key Lab of the Respiratory Disease, Guangzhou Institute of Respiratory Disease, Guangzhou, Guangdong, China State Key Lab of the Respiratory Disease, Guangzhou Institute of Respiratory Disease, Guangzhou, Guangdong, China

Backgrounds: Respiratory muscle strength is recognized to be impaired in patients with COPD, while its severity in Chinese COPD patients and the related factors contributing to this clinical situation is not clearly established. Respiratory muscle stimulation is a non-volitional technique to measure respiratory muscle strength. Thus, the present study was aimed to quantify the severity of respiratory muscle weakness at different stages of COPD, and to investigate the potential factors related to TwPM in COPD.

Methods: Seventy-five patients with COPD and sixty-three age-matched controls participated in the study. Pulmonary function was tested for each participant. Respiratory muscle strength was assessed with measurement of both TwPM and non-volitional static mouth pressures. A score of physical activity (PA score) was obtained using an adapted physical activity questionnaire for the elderly, and nutritional status was evaluated with a multiple-nutritional index. Multiple regression models were developed by stepwise method to determine factors independently contributing to TwPM in COPD.

Results: TwPM (cmH2O) was significantly lower in COPD patients (COPD II (12.42±2.19); COPD III (10.85±1.82); COPD IV (8.58±1.46) vs controls (13.95±3.28); P<0.005). Regression correlation analysis showed that FEV1% predicted, PA score, malnutrition index and gender were the independent factors responsible for TwPM, with R² of 58% (P<0.001).

Conclusion: We conclude that respiratory muscle strength decreases with increasing severity of COPD. Respiratory muscle strength in COPD is comprised by multiple factors such as airflow limitation, physical inactivity and malnutrition, with airflow limitation being the most significant one.

P531 Comorbidity and some markers of cardiovascular disorders in disabled COPD patients

Svitalina Panina1, Nataliya Samina1, Nataliya Gondulenko1, Khizhnayk Galyna2, Tetyana Igunova1. 1Department of Therapy, SI “Ukrainian State Institute of Medical and Social Problems of Disability of MoPh of Ukraine”, Dnipropetrovsk, Ukraine; 2Ukrainian State Institute of Medical and Social Problems of Disability of MoPh of Ukraine”, Dnipropetrovsk, Ukraine

Aim: To assess the comorbidity level and its correlations with markers of cardiovascular disorders in disabled COPD patients.

Methods: A retrospective analysis of 53 disabled patients’ medical documentation with COPD II and III stages was performed (age 55.6±1.8, 40 male). The complex assessment of comorbidity level was performed by Charlson index (CI) and BODE-index.

Results: Most of patients (70.5%) had comorbidity level of 2-3 points by CI, so their 10-year prognostic survival diminished to 10-23% compared with healthy
individuals. 11.8% of patients had a CI value equal to 5 points, and 5.9% - equal to 8 points, which is extremely high. One-point comorbidity was recorded in only 5.9% of patients. The CI was significantly correlated with Kelle’s index (r = 0.87, p < 0.05), the level of total cholesterol (r = 0.71, p < 0.05), plasma β-globulins level (r = -0.71, p < 0.05), 6-minute walk distance (r = -0.72, p < 0.05), and the size of the left atrium of the heart (r = 0.70, p < 0.05). As for the BODE-index, 38.9% of patients had its value laying in the range of 47.4 points, indicating a progressive decrease in survival of these patients by 40% or more compared with healthy individuals. The correlation analysis showed a direct reliable link of BODE-index and CI (r = 0.76, p < 0.05).

Thus, patients with COPD have a high level of comorbidity, which is closely related to some markers of cardiovascular diseases, protein metabolism disorders, and physical exercise tolerance. The received data suggest that in rehabilitation of COPD patients we should focus on treatment of comorbid conditions in order to increase the life expectancy of patients and reduce the risk of their mortality.

P532
Prevalence of anxiety and depression in 196 patients with chronic obstructive pulmonary disease (COPD)
Karen Haslen1, Usman Butt1, Alan Anderson1, Chris Stenton1, Julia Newton2, Debbie Carrick-Sen1, Christine Baker4, Graham Burns1, Anthony De Soyza3, 1Chest Clinic, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle, Tyne & Wear, United Kingdom; 2Institute of Ageing and Health, Newcastle University, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 3Postgraduate School, Newcastle University, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 4Psychology Department, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, Tyne & Wear, United Kingdom;

Introduction: Anxiety and depression are common co-morbidities associated with COPD. A systematic review and meta-analysis reported prevalence 36% for anxiety and 40% for depression (1).

Aims and objectives: This prospective study aimed to identify the prevalence of anxiety and depression symptoms in COPD patients attending out-patient respiratory clinics within a UK NHS Trust.

Methods: Patients with COPD were screened in Clinic in 2011 by completing the Hospital Anxiety & Depression Scale (HADS) (2). Data from 196 patients were analysed.

Results: The mean age was 65.3 years (range 31 - 97) and 88 (45%) male. Using NICE 2010 airflow severity criteria 28 had mild obstruction; 69 moderate; 59 severe and 42 very severe. Significant rates of anxiety were seen: 78% of patients had HADS-anxiety (HADS-A) scores 8 or over and 55% had HADS-depression (HADS-D) scores 8 or over. Both the HADS anxiety & depression scores decreased with increasing age (r=0.28, p<0.01 for HADS-A; r=0.29, p<0.01 for HADS-D).

Conclusion: The prevalence of anxiety and depression is higher in this population than in prior studies. Symptoms of anxiety and depression appear commoner in younger patients and are unrelated to COPD airflow severity. There were no significant associations with COPD NICE severity stage or gender. It is important to screen for both in COPD patients and consider appropriate treatment.

P533
Degree of LVEF with respect to severity of COPD
J. K. Samaria1, Kapil Sharma2, Henmant Kumar3, 1Dept. of Chest Diseases, Instt of Medical Sciences, Banaras Hindu University, Varanasi, UP, India; 2Dept. of Chest Diseases, Instt of Medical Sciences, Banaras Hindu University, Varanasi, UP, India; 3Dept. of Chest Diseases, Instt of Medical Sciences, Banaras Hindu University, Varanasi, UP, India

Background: Cardiovascular diseases are important co-morbidities in patients with COPD. Detection of the presence of Heart Failure with respect to severity of COPD provides valuable information regarding necessary therapeutics.

Aim of study: The primary aim of this study was to determine the quantum of LVEF, which is an indicator of left ventricular function, in relation with the severity of the COPD as measured by the FEV1.

Methods: The study included 112 patients of COPD admitted in the Chest Unit of the hospital, which is a tertiary care centre. All the patients were subjected to thorough history, clinical examination, investigations- ECG, 2-D ECHO of heart, ABG, RFT, LFT, CBC, RBC etc. were done and data were analysed.

Results: Most patients were elderly with mean age of 62.77 years. 53.6% (60/112) of patients categorized in GOLD STAGE 1,2 had mean LVEF 59.07 (SD-10.52,SEM-1.552),while 46.5% (52/112) of those in GOLD STAGE 3,4 had mean LVEF 53.55 (SD-8.4,SEM-1.330). This difference between both groups was significant statistically T test (P=0.009) (CI= -9.643 – -1.388)(Pearson correlation coefficient 0.363 (p=0.001).

Conclusion: The study clearly indicate that severity of the COPD as measured by FEV1 is directly related to the severity of the left ventricular function as measured by LVEF.

P534
COPD and depression
Ivan Cekerevac, Zorica Lazic, Marina Petrovic, Ljiljana Norkovic. Center for Pulmonary Disease, Clinical Center, Krupanj, Serbia

Background: Patients with chronic obstructive pulmonary disease (COPD) have been characterised as a population of chronically ill patients with a higher than normal prevalence of depression.

Objective: To reveal associations of depression with severity, health-related quality of life and mortality of COPD patients.

Methods: A group of 39 COPD patients was analysed during one year. St George’s Respiratory Questionnaire [SGRQ] and mMRC scale was done in order to assess quality of life and dyspnoea level. We used the Hospital Anxiety and Depression Scale [HADS] and Geriatric depression score [GDS] for depression assessment.

Results: The highest value of depression score were in patients with very severe COPD.

Severity of COPD and depression

<table>
<thead>
<tr>
<th>Mild and moderate COPD</th>

</tr>
</tbody>
</table>

Statistical significant correlation was between dyspnoea level and depression score [HADS] [r=0.437, p=0.01]. Also, we found positive correlation between health-related quality of life [SGRQ] and depression score [HADS]: symptoms- depression [r=0.654, p=0.000], activity- depression [r=0.624, p=0.000], impact - depression [r=0.556, p=0.000], total score - depression [r=0.634, p=0.000]. We found statistical significant higher value of initial depression score [HADS] in patients who have been died [n=6] during this study [t test, p<0.05].

Conclusions: These data suggest that depressive symptoms in COPD are related to severity of disease. Depression is also associated with dyspnoea level and quality of life. The data suggest that assessment for depression should be considered for all COPD patients, particularly in those with more severe clinical levels of disease.

P535
Gastroscopic findings in COPD patients
Abdalla Khoury1, Adnan Koorid2, Shoukri Moubaid3, Bashir Moubaid2, 1Internal Medicine, Aleppo University Hospital, Aleppo, Syrian Arab Republic; 2Pulmonology, Faculty of Medicine, Aleppo, Syrian Arab Republic

Introduction: The aim of this study was to determine the prevalence of GERD symptoms and esophagitis in COPD patients and their effect on the number of exacerbations of COPD.

Materials and methods: This study included 106 COPD patients 55of them (51.88) with moderate COPD and15of them (31.91) with severe COPD and7of them (14.89) with very severe COPD. All groups were subjected to history taking, full clinical examination, investigations- ECG, 2-D ECHO of heart, gastroscopy and spirometry.

Results: Revealed that the prevalence of GERD symptoms in COPD patients was 45.5% in the moderate group,54.8% in the severe group and 57.9% in the very severe group (total=52.73%), and prevalence of esophagitis in COPD patients by endoscopy was 32% in the moderate group, 26.7% in the severe group and 42.9% in the very severe group (total=33.86%). GERD symptoms and esophagitis increase with increase in the smoking (pack/year) both in moderate & in the severe groups. Moreover, there were increase in the frequency of exacerbations of COPD in positive GERD symptoms patients both in moderate & in the severe groups. Presence of esophagitis increases the frequency of emergency visits and hospitalization of COPD patients.

Discussion: GERD is common in COPD patients being more among severe group,also GERD increases the number of exacerbations.

Effect of antidepressants on respiration with chronic physical disease
Ki-Suck Jang1, Yong Il Hwang2, Hee Soon Chang3, Wang-Youn Won1, Yoon-Mok Oh4, Sang-Doo Lee5 1Pulmonary, Allergy and Critical Care Medicine, Hallym University Medical Center, College of Medicine, Hallym University, Seoul, Republic of Korea; 2Pulmonary and Critical Care Medicine, Seoul National University Bumae Hospital, Seoul National University College of Medicine, Seoul, Republic of Korea; 3Psychiatry, St. Paul Hospital, Catholic University, Seoul, Republic of Korea; 4Pulmonary and Critical Care Medicine, Asian Medical Center, University of Ulm, College of Medicine, Seoul, Republic of Korea

Physical illness is strongly associated with depression. In Korea, 23.8% of COPD patients suffer from depression. Aside from being an unpleasant condition in its own right, depression is a risk factor for poor progression of physical diseases. Therefore, it has been emphasized that management of depression in patients with physical illness. Antidepressives such as diazepam is well known to have respiratory suppression. But little is known for the anti-depressant to have such effects. The aim of this study was to evaluate the effects of anti-depressants on respiration in patients with chronic physical illness. We performed systematic review of randomized controlled trial. A literature search was conducted for key words “depressive disorder, pharmacological therapy and chronic illness” using Medline, pubmed, Embase, Cochrane library, and National Guideline Clearinghouse (NGC). A total 69 studies were retrieved. Of these, nine studies were included for final analysis (six studies for COPD, three studies reporting dyspnea as an adverse event). Anti-depressants didn’t worsen the respiratory symptoms nor cause respiratory suppression in patients with COPD. Anti-depressants had no effects on pulmonary function, exercise capacity and the results of blood gas analysis in COPD patients. In patients with chronic illness other than COPD, antidepressants caused less dyspnea compared to placebo (13% vs. 17.6%; p<0.0001) and did not develop the respiratory suppression. In conclusion, anti-depressants did not aggravate dyspnea in patients with chronic physical illness including COPD. However, it is not sufficient to conclude that anti-depressants are safe in physically ill patients. A large prospective study is warranted.

P537

Assessment of the BODE index, arterial stiffness and endothelial dysfunction in patients with chronic obstructive pulmonary disease
Gokhan Tirci1, A. Fusun Kalpaklioglu2 1Department of Pulmonary Diseases, State Hospital of Goksu, Maras, Turkey; 2Department of Pulmonary Diseases, Kirikkale University Faculty of Medicine, Kirikkale, Turkey

Purpose: COPD is a respiratory disorder, but also having systemic effects. Cardiovascular diseases are leading cause of mortality in patients with COPD and have an association with the increased risk of cardiovascular disease. Aim of this study was to evaluate the effects of anti-depressants on respiration in patients with chronic physical illness. We performed systematic review of randomized controlled trial. A literature search was conducted for key words “depressive disorder, pharmacological therapy and chronic illness” using Medline, pubmed, Embase, Cochrane library, and National Guideline Clearinghouse (NGC). A total 69 studies were retrieved. Of these, nine studies were included for final analysis (six studies for COPD, three studies reporting dyspnea as an adverse event). Anti-depressants didn’t worsen the respiratory symptoms nor cause respiratory suppression in patients with COPD. Anti-depressants had no effects on pulmonary function, exercise capacity and the results of blood gas analysis in COPD patients. In patients with chronic illness other than COPD, antidepressants caused less dyspnea compared to placebo (13% vs. 17.6%; p<0.0001) and did not develop the respiratory suppression. In conclusion, anti-depressants did not aggravate dyspnea in patients with chronic physical illness including COPD. However, it is not sufficient to conclude that anti-depressants are safe in physically ill patients. A large prospective study is warranted.

Variability in systemic inflammatory response, nutritional profile, and quality of life in stable COPD due to tobacco and non-tobacco etiology
Janan Mahboob1, Amin Murad1, Shree Arora2, Rajkamal Borah3, R.M. Pandey3 1Pulmonology and Respiratory Medicine, Fac. of Med Univ. of Indonesia/Persahabatan Hospital, Jakarta, Indonesia; 2Department of Community Medicine, Faculty of Medicine University of Indonesia, Jakarta, Indonesia

Anemia is frequently associated with many chronic diseases and can be responsible for weakness, fatigue, impaired mood, deficits in cognitive function and decreased quality of life. Anemia is also common in COPD and is associated with increased comorbidity, mortality, and costs of care, its prevalence in COPD patients is estimated at 13 to 23%. The aim of our study was to evaluate the presence of anemia in COPD patients and analyze its relationship with functional status. Methods: Study group consisted of 132 patients (37% F), at mean age 68.2±9 years with post-bronchodilator FEV1 57.1±19.2% of predicted. Anemia was defined by hemoglobin concentration <13.5 g/dL in male and <12 mg/dL in female patients. Biochemical analysis included measurement of serum C-reactive protein, iron, transferrin, and soluble transferrin receptor. Pulmonary assessment comprised spirometry, plethysmography and 6 minute walk test (6MWT). Results: Anemia was diagnosed in 24 (18.2%) patients: 4 female and 20 male patients (p<0.05). There were no differences in the distribution of anemia depending on the severity of COPD (according to the GOLD staging system or BODE index). Patients with anemia were older (66.7±8.9 vs 74.5±5.6 years; p<0.05), had higher serum creatinine level (0.9±0.2 vs 1.0±0.2 mg/dL; p<0.05) and lower 6MWT distance (365.5±123 vs 439.5±115.4 m; p<0.05). Patients with anemia were also characterized by lower serum iron (90.2±30.7 vs 113±41.2 µg/dL; p<0.05) and higher serum transferrin receptor (3.7±1.2 vs 3.1±0.9 mg/L; p<0.05). Conclusions: Anemia in COPD is more prevalent in males and can affect up to 20% of patients. It does not seem to depend on the severity of disease, however, it significantly reduces exercise capacity of patients.

P539

Anemia in chronic obstructive pulmonary disease
Tuduzo Dzvyalowska, Renata Rubinsztein, Krzysztof Karw, Marta Maskey-Warzechow, Ryszard Chazan, Department of Medicine, Pneumonology and Allergology, Warsaw Medical University, Warsaw, Poland

The presence of COPD is associated with increased systemic inflammatory response, muscle wasting, lower exercise capacity and poorer QOL. The etiological agent of COPD, however, does not seem to be an important factor in affecting the above parameters.

83. COPD comorbidities II

P540

The role of modification of CURB-65 score as predictor factor for one year survival in acute exacerbation of COPD
Wiwien Heru Wiyono1, Widyah Sri Hastuti1, Ramawati2, Iwang Gunawij2, Toodo Prihartono3 1Pulmonology and Respiratory Medicine, Fac. of Med Univ. of Indonesia/Persahabatan Hospital, Jakarta, Indonesia; 2Department of Community Medicine, Faculty of Medicine University of Indonesia, Jakarta, Indonesia

Introduction: Acute exacerbation of COPD (AECOPD) is associated with a high risk of mortality. A risk-prediction model using information easily obtained on admission could help to identify high-risk individuals. The CURB-65 score was developed to predict mortality risk in community acquired pneumonia. A retrospective study found that this score was also associated with mortality in AECOPD patients. Methods: Consecutive patients with physician diagnosed AECOPD admitted to a public hospital during a 1-year period were studied prospectively. The modification of CURB-65 Score were calculated from information obtained at initial hospital presentation. The modification of CURB-65 Score are one point each for Confusion, Age >79 mmol/L, Respiratory rate ≥30/min, Systolic Blood pressure <90 mmHg, Severe diabetic or blood pressure >160 mmHg, age ≥65 years and present of cardiovascular disease. Remeasure will be done every three month and looking for the correlation between both using McNemar test. After complete one year of evaluation, the relation between modification of CURB-65 score and risk of mortality was analyzed using Chi Square test. Results: Research is still proceeding and 92 patients have been collected. 30-day
mortality data were available for 92 of 92 patients. The 30-day mortality by score groups were: low risk (scores 0–1) 1.16% (2/178) and high risk (scores 2–6) 11.36% (5/44). There was significant correlation between modification of CURB-65 score and mortality, with relative risk 2.73. The investigation is ongoing, and not all questions have been answered.

**CONCLUSION:**

The frequency of osteoporosis was assessed in the whole group and separately for each stage of COPD. **RESULTS:** In the whole group was most impressed by osteoporosis, lumbar spine - in 37.2% of cases, osteoporosis of the femoral neck - in 19.7% of cases. The lowest BMD were observed in patients with stage 4 COPD (<0.05). Osteoporosis of the femoral neck was detected in 5.4% of patients with COPD stage 2, with 23.68% of patients with COPD stage 3, the maximum percentage of osteoporotic changes in the femoral neck was observed in patients with COPD stage 4 - 54.5%. A significant correlation values of bone mineral density with BMI (r=0.44, <0.05), with the CO (r=0.43, <0.05), with the DLCO (r=0.43, <0.05).

**Conclusion:** Densitometry is an important method of diagnostics of osteoporosis and should be applied in full in COPD patients.

**P542**

Is COPD a risk factor for diabetes?

**Laura Ciobanu** 1, Eva López González 2, Silvia Rey 1, Ekaterina Kochetova 1

**Chair of Internal Medicine, Petrozavodsk, Karelia, Russian Federation**

**Introduction:** Diabetes mellitus is one of the multiple endocrinological disorders induced by COPD through systemic inflammatory, oxidative stress, smoking and administration of glucocorticoids.

**Aims and objectives:** To investigate if COPD is a risk factor for diabetes mellitus DM and which factors are some other contributing factors.

**Methods:** 2 groups of pts were assessed for age, gender, body mass index (BMI), smoking, alcohol intake, diabetes and dyslipidemia. First group was compound of non-COPD pts (n 272, male:22.8, female: 210, mean age 60.67, SD 13.75) and the second one of COPD pts (n 178, 103 M:57.9, 75 F:42.1%, mean age 64.79, SD 10.78). COPD pts were staged according to GOLD criteria in stage I 122/2171 pts, stage II 206/2% pts, stage III 224/9% and stage IV 61/3%.

**Results:** The relative risk of DM in COPD pts is 3.380 (95% CI 1.380–8.906). COPD stage 1, 2.52 (95% CI 0.904–7.335) in stage II and 2.04 (95% CI 0.863–4.930) in unified stages III and IV. There is a correlation coefficient of 0.154 between COPD and DM, 0.256 for COPD, BMI and DM and respectively 0.293 for COPD, BMI, dyslipidemia and DM.

**Conclusions:** There is a small risk for DM to appear in the whole group of COPD pts, but RR increases while advancing the severity of disease. Being mild in stages I and II, RR become moderate in the unified group of pts staged III and IV, considered together due to the low number for each separate stage. Correlation between DM and COPD is weak, but it is moderate and relevant when adding BMI and dyslipidemia. The risk to develop DM in COPD increases with the severity of disease, and the presence of two other important factors, BMI and dyslipidemia.

**P543**

Is COPD a risk factor for diabetes?

**Laura Ciobanu** 1, EvAlina Grigorescu 1, Gabriela Grigorescu 1, Internal Medicine, University of Medicine and Pharmacy "Gr T Popa", Iasi, Romania; 2Scientific Research and Development, University Hospital and Faculty of Medicine, Iasi, Romania; 3Clinical Section of Pulmonary Rehabilitation, Clinical Hospital of Rehabilitation, Iasi, Romania

**Aims and objectives:** To investigate if COPD is a risk factor for diabetes mellitus DM and what stage is more risky; also, if there are some other contributing factors.

**Methods:** 2 groups of pts were assessed for age, gender, body mass index (BMI), smoking, alcohol intake, diabetes and dyslipidemia. First group was compound of non-COPD pts (n 272, male:22.8, female: 210, mean age 60.67, SD 13.75) and the second one of COPD pts (n 178, 103 M:57.9, 75 F:42.1%, mean age 64.79, SD 10.78). COPD pts were staged according to GOLD criteria in stage I 122/2171 pts, stage II 206/2% pts, stage III 224/9% and stage IV 61/3%.

**Results:** The relative risk of DM in COPD pts is 3.380 (95% CI 1.380–8.906). COPD stage 1, 2.52 (95% CI 0.904–7.335) in stage II and 2.04 (95% CI 0.863–4.930) in unified stages III and IV. Bronchitic and non-bronchitic phenotypes of COPD differ in the prevalence of depressive symptoms

**Vladimir Košteřek** 1, Sanka Pracharova 1, Miloslav Hroněcký 2, Miroslav Kovarík 2

1Pulmonary Department, University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic; 2Department of Research and Development, University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic

**Background:** Psychological sequelae of COPD may influence functional status independent of disease severity. Presence of depression among several phenotypes of COPD is not clearly understood.

**Aim:** We wanted to find out the real occurrence of depression in both basic clinical phenotypes of COPD.

**Methods and material:** Multicomponent assessment of 38 consecutive patients (6 female, 32 male; age 62.7±6.3 years) with stable COPD GOLD categories A 1, B 21, C 1, D 61 in the out-patient clinic of university hospital (within non-interventional cross-sectional Complexity of COPD Study).

**Results:** 27 patients had bronchitic and 11 subjects suffered from non-bronchitic phenotype of COPD (post- ipratropium and salbutamol FEV1 57.7%). Bronchitic variant was associated with lower level of depressive symptoms (Beck scale 5.1±3, Zung scale 50.2±10.9) than that found in non-bronchitic subtype of COPD (Beck scale 8.3±3.4, Zung scale 57.5±7.4). Although this difference reached statistical significance only in Beck questionnaire p<0.013 (Mann Whitney test). In all other parameters (BMI, FFMI, education level, inhalation risk, 6MWD, exercise desaturation, nMBR dyspnea, Celi’s BODE, Pahan’s BODE, ADD, CAT, all domains of SGRQ, arterial blood GEs, ECG heart rate) were no differences between these two basic phenotypes.

**Conclusion:** Non-bronchitic phenotype of COPD was associated with more depression complaints than bronchitic scenario. This difference was not apparent in terms of quality of life, prognostic indices and number of other variables describing course of COPD.
PS46 The influence of metabolic syndrome in mortality rate of COPD patients:
A five years follow up study
Karime Schelini, Suzana Tanti, Amanda Zamaner, Liana Coelho, Simone Vale,
Renata Ferrari, Laura Caram, Ilda Godoy, Sergio Paiva, Irma Godoy.
Pulmonary Division of Internal Medicine, Botucatu Medical School - UNESP,
Botucatu, SP, Brazil.
Background: Patients with chronic obstructive pulmonary disease (COPD) or metabolic syndrome (MS) present systemic inflammation and the association between diseases can increase risk of cardiovascular events. However, the influence of MS in survival of COPD patients is still unclear.
Methods: We followed 115 COPD patients (age: 64.5±1.21 years, FEV1: 58.7±2.75% during five years and causes of death were noted. At baseline, patients' clinical history and physical examination were assessed, and anthropometric (weight, height, body mass index and waist circumference), spirometry, 6-minute walking distance (6MWd), dyspnea perception by the modified medical research council (MMRC), serum lipid profile and triglycerides measurements were performed. The diagnosis of MS was established by harmonization MS criteria. The Cox proportional hazard analysis was used to evaluate the influence of MS in the survival time, adjusted for potential confounders (age, gender and BODE index).
Results: MS was present in 35.6% of patients and hypertension (47.4%) was the MS component more prevalent. More than 80% of the patients presented at least one diagnostic component of MS. During the period of study, 17.0% died. We did not observe statistical difference in mortality between groups with and without MS (HR: 1.30, 95%CI: 0.32-5.20).
Conclusion: Patients with COPD have intermediate prevalence of MS; however, no association between MS and mortality was found in these patients.

PS47 COPD: Different psychosocial status (PS) in patients with different cardiac co-morbidities rate
Kateryna Gashynova, Internal Medicine, DMA, Dnipropetrovsk, Ukraine.
Aim: To evaluate whether and in which extent cardiac co-morbidity have influence on the PS in patients with COPD.
Study population: 78 outpatient with COPD made the study sample. Exclusion criteria were 1) mental diseases.
Methods: For the evaluation of the PS the depression (by Zung scale), the anxiety (by Ch.D. Spilberger questionnaire) and the vegetative lability (by VELA test) were studied in all patients. Cardiac co-morbidity rate was established by original analysis of patient's medical documentation.
Results: In accordance with cardiac co-morbidity rate all patients were divided on two groups (GR): GR I (n=17; 21.8%) without any and GR II (n=61; 78.2%) – with cardiac co-morbid conditions. Both groups were similar regarding to age, sex and smoking status. The data of psychological tests are performed in the table 1.

*p<0.005; Δp=0.05, ^p<0.05

Conclusions: 1. 78.2% of outpatients with COPD had cardiac co-morbidity.
2. Cardiac co-morbid conditions significantly impair psychology status in patients with COPD, and the most significant changes concerns depression and vegetative lability level.

PS48 Pulmonary hypertension in COPD: Prevalence and characteristics
Daniela Gologanu.
Pulmonary hypertension in COPD: Prevalence and characteristics
Daniela Gologanu
Aim: To evaluate the prevalence of PH in COPD patients (pts) and define the characteristics of this group.
Methods: Retrospective study including 66 consecutive COPD pts hospitalised in our department, right heart catheterization, echocardiography, graphy, history of exacerbations and comorbidities were obtained from patients records. PH was defined as systolic pulmonary arterial pressure (SPAP) greater than 35 mmHg.
Results: Among 66 COPD pts studied, mean age was 67 years and GOLD stages were II - 26 pts, III - 15 pts, IV - 22 pts. Only 53 pts had undergone echocardiography. Among them, mean age was 68, GOLD stages were II - 11 pts, III - 7 pts, IV - 15 pts. PH was found in 12 pts (36,4%). Mean FEV1 was 46,4% in COPD pts without PH and 36,9% in pts with PH (p=0.07). PH resulted in right ventricular (RV) enlargement in 9 out of 12 pts, these particular COPD pts had lower mean FEV1 (37,6%) than pts with PH without RV enlargement (56%) (p = 0.02). More severe PH was found in 7 pts; the mean FEV1 was 37,2% versus 36,7% in pts with moderate versus mild PH. No significant association between PH and GOLD stage, FEV1, polyglobulia, COPD exacerbation or basal SpO2 were found.
Conclusions: The prevalence of PH in our COPD pts was 36,4%, probably underestimated, as echocardiography was performed mostly in pts with higher GOLD stage. No significant associations between PH and GOLD stage, FEV1, polyglobulia, COPD exacerbation or basal SpO2 were found. RV involvement due to PH seems to occur mostly in pts with more severe obstructive disease.

PS49 Cognitive function of patients with COPD after virtual admission – A randomized clinical trial
Lone Schol1, Birte Østergaard2, Lars Rasmussen1, Susan Rydahl-Hansen3, Amanda Svaare Jakobsen1, Christina Emmel2, Klaus Phanare1, 1Telemedicine Research Unit, Fredriksberg University Hospital, Copenhagen, Denmark; 2Research Unit of Nursing, Institute of Clinical Research, University of Southern Denmark, Odense, Denmark; 3Department of Anaesthesia, Center of Head and Orthopaedics, Rigshospitalet, University Hospital of Copenhagen, Copenhagen, Denmark; 4Research Unit of Clinical Nursing, Bispebjerg and Frederiksberg University Hospital, Copenhagen, Denmark.
Background: Substantial healthcare resources are spent on Chronic Obstructive Pulmonary Disease (COPD). As a result, the involvement of patients in monitoring of their condition has been suggested. However, the level of cognitive functioning must be taken into consideration before self-care strategies can be adopted.
Aim: We hypothesized that cognitive performance would be better in COPD patients allocated to virtual admission - using a telemedicine solution - compared to patients admitted to conventional hospitalization after exacerbation.
Methods: This study was a Randomized Clinical Trial. The primary outcome was cognitive function evaluated at discharge and after six weeks using a neuropsychological test battery comprising 4 tests and 7 variables. Secondary outcomes included self-reported cognitive function (SCF), activities of daily living (IADL), and anxiety and depression (HADS).
Results: We included 44 patients consecutively. Baseline data were: Mean age 70 years (SD 10); forced expiratory volume in one second (FEV1) 1.0 L (SD 0.55); Oxygen saturation 94.5 (SD 2.5); and a Mini Mental State Examination score of 27.5 points (SD 1.6). The performance in all seven neuropsychological test variables tended to be better in the group allocated to virtual admission, but the difference was only statistically significant in the time for the Stroop Color Word test, (p=0.05). The pattern was the same at follow-up after six weeks but the differences were less pronounced. There were no significant differences in SCF, IADL, and HADS at discharge or after 6 weeks.
Conclusion: Cognitive function may be better preserved in COPD patients treated for exacerbation during virtual admission at home.

PS50 Longitudinal changes in detrended fluctuation analysis “alpha” of PEF in COPD
The full abstract can be found on page 890.

PS51 Anxiety and dyspnea relation in early stage COPD patients
Levila Yilmaz Aydin1, Tarkan Or泽m2, Sinem Berk3, 1Chest Disease, Duzce University Medical Faculty, Duzce, Turkey; 2Chest Disease, Corum Chest Disease Hospital, Corum, Turkey.
Introduction: Anxiety is a co-morbid diseases in COPD. Anxiety prevalence in COPD patients is higher than general population. Although the relationship between anxiety and COPD can not be revealed yet, increased anxiety prevalence was associated with increased dyspnea level.
Aim: To determine the rate of anxiety and relationship of anxiety and dyspnea in early stage COPD patients who do not have advanced functional restriction.
Method: COPD patients that volunteered to participate the study who admitted to hospital with a reason other than COPD exacerbation was included to this cross-sectional/descriptive study consecutively. Beck anxiety inventory, medical research council (MRC) dyspnea scale applied.
Results: 134 patients with GOLD1-2 COPD included. Mean age was 58.1±10.53, 92.5% of them were male. Active smokers and former smokers were 61.9% and 38.1%, respectively. 64.9% did not have co-morbid diseases. According to MRC dyspnea scale 33.6% of the patients were in grade 1 and 55.2% were in grade 2. 34,1% of the patients that answered the question “Do you have shortness of breath?” answered as “No” were having MRC grade 2 and 3 dyspnea. 11.2% of 134 participants had mild and 9% had moderate anxiety. In patients with anxiety 89% were having MRC grade≥2.Although there was not statistically significant relationship between shortness of breath and level of anxiety, there was a significant relationship between MRC grade and level of anxiety (p=0,529 and p=0,004, respectively).
Conclusion: MRC scale can be more effective in detection of dyspnea in early stage COPD. All COPD patients with MRC score ≥ 2 should investigate for anxiety.
Acute pulmonary embolism in COPD patients

Daniele A. Rodriguez1, Mauricio Orozco-Levi2, Anna Herranz3, Niki Fens1, Mauricio Orozco-Levi1,2, Anna Herranz1,2, Ana Rubio-Muniz1,2, Annamaria Penza2, Anna Rubio-Muniz1,2, Nuriya Bas Costs1, Juea Tinaz-llerrenos1, Jordi Bruguera1, Joaquim Gea1, Luis Molina1, Carlos Molina1, Ana Herranz1,2, Niki Fens1

COPD is an established cause of worse evolution during acute pulmonary embolism (PE). The aim of our study was to evaluate the profile of COPD patients admitted for PE. We conducted a retrospective cohort study in consecutive patients (n=225) diagnosed with PE between January 2009 and December 2010. Of 225 subjects included (mean ± SD: 72 ± 15 years), 27 (12%) had COPD (71 ± 10 years). The total number of deaths during hospitalization was 38 (17%) in patients without COPD, and 7 (25%) in COPD patients (p<0.05). COPD Patients (78% males) showed severe disease (FEV1 < 46.1 ± 12%) previously. Previous venous thromboembolic disease (VTD) (37%) or surgery (3%), cancer (26%) or immobility (18%) were detected. Obesity was the most frequent co morbidity (50%). Non-survivors COPD showed statistically significant increase of NTpro-BNP (2500 ± 530 pg/ml) and CRP (8.6 ± 7.5 mg/l) than COPD survivors patients (850 ± 140 pg/ml and 2 ± 1 mg/l, respectively). Severity disease was similar in both groups (FEV1 < 45% vs 47%, respectively). Previous VTD (relative risk RR, 1.1; 95% CI, 1.0–2.0), obesity (RR, 2.1; 95% CI, 1.0–5.0), cancer (RR, 2.6; 95% CI, 1.3–5.1) and elevated CRP (RR, 3.3; 95% CI, 1.4–6.6) were significantly associated with PE-related death, with heart failure or prolonged hospital stay. The number of COPD patients diagnosed for acute PE was slightly higher than previously reported. In addition, COPD patients might be an under recognized group with increased mortality.

COPD subphenotypes in a population-based survey by factor and cluster analysis

Fikri Ferni1, Annelot J.G. van Rossum1, Pietert Zanen1, Bram van Gennip12, Rolf J. van Klaveren3, Gero H. Zwinderman1, Petrus van der Velden1, Respiratory Medicine, Academic Medical Centre, University of Amsterdam, Netherlands;
2Respiratory Medicine, University Medical Center Utrecht, Utrecht, Netherlands;
3Radiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands;
4Respiratory Medicine, Erasmus Medical Centre, University of Rotterdam, Rotterdam, Netherlands;
5Clinical Epidemiology and Biostatistics, Academic Medical Centre, University of Amsterdam, Netherlands

Background: Classification of COPD is currently based on symptoms, airways obstruction and exacerbations. However, this may not fully reflect the phenotypic heterogeneity of COPD in the (ex-) smoking community. We hypothesized that factor analysis followed by cluster analysis of functional, clinical, radiological and exhaled breath metabolic features identifies subphenotypes of COPD in a community-based population of heavy (ex-)smokers.

Methods: Adults (50-75 yrs) with ≥15 packyears derived from a random population-based survey underwent pulmonary function testing, chest CT scanning, questionnaires and exhaled breath molecular profiling using an electronic nose. Factor analysis followed by K-means cluster analysis was performed on subjects fulfilling the GOLD criteria for COPD with post-BD FEV1/FVC <70%. Factor analysis revealed 12 factors representing different domains of COPD including lung function, radiologic features, exhaled breath metabolomics, symptoms and quality of life. Four clusters were identified: cluster 1 (n=35, 22%): mild airways obstruction and no emphysema; cluster 2 (n=48, 31%): severe airways obstruction with emphysema and low diffusion capacity, chronic bronchitis, low quality of life and a distinct breath profile; cluster 3 (n=60, 38%): mild COPD with a close to normal lung function, but with radiologic signs of emphysema and a distinct breath profile; cluster 4 (n=14, 9%): highly symptomatic males with dyspnea and low quality of life with moderately impaired lung function.

Conclusions: This unbiased taxonomy for COPD confirms and extends clusters found in previous studies and allows better phenotyping of COPD.
P557
The association between pulmonary arterial hypertension secondary to chronic lung disease and serum asymmetric dimethylarginine levels
Baris Acikelce, Gönür Çansaray, Aygün Gür, Nur Dilek Bakanc
Gülçihan Örkan, Pınar Güven. Chest Disease, Yedikule Teaching Hospital for Chest Disease and Thoracic Surgery, Istanbul, Zeytinburna, Turkey
Asymmetric dimethylarginin (ADMA) is an endogenous molecule that prevents nitric oxide synthesis enzyme inhibition. It has been shown that serum ADMA levels increase in COPD patients as well as idiopathic pulmonary hypertension patients. In this study, association between serum ADMA levels and pulmonary hypertension secondary to COPD and interstitial lung disease (ILD) was evaluated. Fifty-five to 95% of COPD patients and ILD patients were included into the study. Echocardiography was used to evaluate pulmonary arterial pressure (PAP). Serum ADMA levels were measured by ELISA. Association between OPAP and serum ADMA levels were evaluated by Pearson correlation test. Mean ADMA levels of patients have normal and high OPAP were compared by student-test. Mean serum ADMA levels of patients have increased OPAP was found significantly higher than that of patients that have normal OPAP (p=0.05). A positive correlation (Pearson r=0.6, p<0.01) was found between serum ADMA levels and OPAP. Evaluation of COPD and ILD patients separately showed that significantly higher ADMA levels were found in pulmonary hypertension secondary to COPD (p<0.05) in both groups. COPD and ILD groups showed correlation between serum ADMA levels and OPAP (COPD and ILD Pearson r=0.47 and 0.72 consequently) also exist. ROC analysis was used to evaluate the value of serum ADMA levels measuring in diagnosis of pulmonary hypertension. Area under curve was found 0.7.
Conclusion: Serum ADMA levels measurement may be an indicator for PH secondary to COPD.Area under curve was found 0.7.

P558
Pneumothorax secondary to chronic obstructive pulmonary disease
Nadia Fetta, Abdessemed Taleb. Pulmonary, University Hospital, Sidi Bel Abbes, Algeria
Spontaneous pneumothorax is defined by the presence of air in the pleural cavity without history of trauma. This is a significant clinical problem. COPD is a common cause of pneumothorax. The risk of recurrence of spontaneous pneumothorax secondary to COPD is high and various studies have quoted values 20-60%.
Methods: Retrospective cohort study of all patients COPD admitted with pneumothorax to the pulmonary department between January 2004 and September 2011. The aim: to assess the frequency of pneumothorax in the COPD and describe its clinical profile and scable.
Results: In a study period of 6 years, 248 cases with a diagnosis of pneumothorax were observed at the pulmonary department secondary to COPD was 67% (80 patients COPD developed 167 pneumothorax). Our series is composed mainly of men, mean age 59.6 years. The notion of smoking was found in 100%; ex-smokers 67% and active smokers 33%. The most frequent initial symptom was dyspnea 100% with pleuritic chest pain 42% The episode of pneumothorax revealed the disease COPD in 32% and was responsible of exacerbation of COPD in 68% According to GOLD classification, Fifty five (68%) had moderate COPD and twenty five (31%) had severe COPD. All patients received tube chest drainage and hospital stay mean was 12 days range (6-23 days). Twenty eight patients (52%) had recurrence of pneumothorax. Forty two patients (52%) had emphysema. Four patients developed empyema, six had emphysema subcutaneous and two had pneumonia after chest operation. The evolution of the study was favorable in 74 cases and 6 patients died in an array of acute respiratory failure.
Conclusion: Pneumothorax represents a factor of mortality for patients suffering of COPD and the surgical treatment is needed to prevent recurrence.

P559
Endocrinopathies and related with COPD exacerbation
Tugba Körlü1, Mehsem Nuruzuml1, Sakine Naz1, Nurdan Köktürk1
1Pulmonary Medicine, Gazi University School of Medicine, Ankara, Beştevi, Turkey; 2Family Medicine, Ankara Numune Research and Training Hospital, Ankara, Turkey
Osteoporosis, metabolic syndrome, thyroid dysfunction are common in COPD. Results related with Vit D Deficiency associated with COPD exacerbation are common and controversial.
This study is planned to investigate the levels of Vit D, thyroid hormones and bone densitn COPD in related exacerbation numbers, hospitalization duration related with exacerbation, and the number of antibiotics for exacerbations.
70 subjects with the mean age of 69.1±10.02 years (57.5% of the patients) and the mean FEV1/1.38.75±16.91 were included in the study. Diabetes Mellitus (DM) has found in 13 and hyperlipidemia has found in 9 patients. Vit D Levels was reduced in 90% and thyroid hormones abnormalities were seen in 50% (1 hypothyroidi, 34 subclinic hypertyroidi) of the patients. Bone mineral density was normal in 21 (30%) and osteopenic in 24 (34.3%) and osteoporotic in 25 (35.7%) of the patients. These abnormalities did not relate with FEV1, exacerbation numbers in the last year, ICU admission rate and the duration of hospitalisation.
Endocrinopathies in COPD have been encountered frequently however the impact of these abnormalities of disease outcomes have not elucidated thoroughly. This study has not showed any relation of endocrin abnormalities with parameters of exacerbations.

Prognostic biomarkers in severe community-acquired pneumonia (SCAP) patients, requiring intensive care unit (ICU) admission
Öksana Onyshlayenko1, Alexander Makarevich1, Paulina Jagus2, Joanna Chorostowska-Wymisk1, Tatjana Rybina1, Elena Amelchenko1,2 1st Department of Internal Diseases, Belarussian State Medical University, Minsk, Belarus; 2Laboratory of Molecular Diagnostics and Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; 2Clinical Laboratories of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus
Background and aim: Measurement of prohormones representing different pathophysiological pathways could enhance risk stratification in SCAP pts. The aim of the study was to investigate procalcitonin (PCT), adrenomedullin (AMD), copeptin (CP), B-type natriuretic peptide (BNP-32) levels in ICU SCAP pts and their relationship with in-hospital outcomes (in-hospital mortality (BIM), length of in-hospital stay (LOS),duration of ICU stay,disease specific complications,need for invasive mechanical ventilation (IMV) and vasopressor support (VS)).
Methods: 20 ICU pts with proven SCAP CURB-65 class 3.4 were enrolled to the study. Serum PCT, AMD, CP, BNP-32 values were measured within the 24 hours after admission.
Results: Increasing CAP severity was associated with increased PCT values (p=0.04; p=0.05). PCT in CURB-65 3 and 4 class pts was [median] 0.73 vs 5.94 ng/ml, respectively (p=0.03). CP levels on admission appeared to be higher in CURB-65 4th class pts vs the 3rd class pts -74.8 vs 47.6 pg/ml, respectively (p=0.03). PCT values demonstrated statistically significant correlation with BIM (p=0.74; p=0.005), were higher in non-survivors than those in survivors [5.94 vs 0.73 ng/ml, p=0.01]. PCT and CP values correlated with need for VS (p=0.74; p=0.005 and r=0.54; p=0.02) and showed higher concentrations in pts requiring VS compared with those with stable haemodynamics [102 vs 0.73 ng/ml, p=0.01] and [74.8 vs 47.6 pg/ml, p=0.03]. AMD levels on ICU admission were associated with need for IMV (p=0.47; p=0.04). BNP-32 values correlated with LOS (p=0.56; p=0.02), PCT - with duration of ICU stay (p=0.81; p=0.001).
Conclusion: PCT and CP appeared to be the most reliable prognostic biomarkers in ICU pts with SCAP.

P561
Cat-scratch disease mimicking lymph node tuberculosis about four cases
Jean-Baptiste Obstler, Elodie Verger, Elodie Barra, Caroline Claret, Olivier Lelou. Pneumology, CH Abbeville, Abbeville, France
Cat-scratch disease (CSD) is a bacterial infection due to Bartonella henselae. It’s usually present as isolated lymphadenopathy. Lymphadenopathy histological examination is often non specific. It can be revealed an epithelioid necrotizing granuloma just like lymph node tuberculosis. We report four cases referred in our institution for tubercular lymphadenitis suspicion, which were in fact CSD. Patients were aged between 15 and 61 years old, healthy, without biologic inflam mation. Regional lymphadenopathy without any other lesions was confirmed by CT scans. Biopsy were realized for all patients. Histological analysis was necrotizing epithelioid granuloma and giant cell. Zielh-Neelsen method and quantiFERON-TB GOLD test were negative whereas serologic tests for Bartonella henselae were positive. One patient does not remember contact with cat. Two patients were treated by antibiotic. Outcome of all cases was favorable.
Cat-scratch disease stays a difficult diagnostic. Clinicians must keep this diagnosis possibility in mind when lymph node presents an necrotizing epithelioid granuloma with giant cells. A systematic clinical and laboratory testing approach is necessary. Serology is the best initial test and can be performed by immunoperoxidase assay. Moreover polymerase chain reaction can be useful. Indication of antibiotic treatment is reserved to complicated CSD.
P562
Serotyping, multilocus sequence typing and antibiotic resistance of Streptococcus pneumoniae isolates in China
Yujie Chen1, Dongyan Chen2, Yanli Fan1, Zhanwei Wang1, Daozhuang Li4, Daxuan Wang2, Ying Wang2, Rongrong Fu1, Zhenchao Gao3, 1Department of Respiratory and Critical Care Medicine, Peking University People's Hospital, Beijing, China; 2Department of Respiratory Medicine, Fujian Provincial Hospital, Fuzhou, China; 3Department of Clinical Laboratory, Peking University People's Hospital, Beijing, China; 4National Institute for Communicable Disease Control and Prevention, Chinese Center for Disease Control and Prevention, Beijing, China

Introduction: Streptococcus pneumoniae is a major causative agent of severe infections, which has become a major public health concern.

Objectives: A prospective study was performed to investigate the serotype distribution, genetic relationship and antimicrobial resistance in Streptococcus pneumoniae (S. pneumoniae) isolates from patients in China.

Methods: 21 Blood/cerebrospinal fluid (CSF) isolates and 18 sputum isolates were collected from patients admitted to the Peking University People's Hospital and Fujian Provincial Hospital were analyzed for investigating the serotypes, the multilocus sequence typing (MLST), and their susceptibilities to antibiotics.

Results: The most frequent serotypes of blood/CSF isolates were 14 (38.1%), 19A (14.3%), 23F (9.5%), 18C (9.5%), and in the sputum isolates the most frequent serotypes were 19F (33.3%), 23F (16.7%), 19A (11.1%), 3 (11.1%). The coverage rates of the blood/CSF and sputum isolates for the 7-valent pneumococcal conjugate vaccine (PCV7) were 66.7% and 61.1%, respectively. 4 of 5 isolates determined as 19A were collected from patients <5 years old. The MLST analysis showed that all the 5 isolates were ST320. All the 21 blood/CSF isolates, the resistance rates of erythromycin and penicillin were 83.3% and 61.1%. Of the 18 sputum isolates, the resistance rates of erythromycin and penicillin were 83.3% and 66.7%. All of the isolates of serotype 19A were resistant to both penicillin and erythromycin.

Conclusions: The introduction of PCV13, in which the 19A conjugate is included, will be necessary in China because of the high rates and severe antibiotic resistance of 19A.

P563
Pulmonary manifestation of lassa fever and the impact on mortality
Peter Okohore: Johnson Unbes embargo, Cyril Erameh. Medicine, Irrua Specialist Teaching Hospital, Irrua, Edo, Nigeria

Background: Lassa fever is associated with multi-systemic clinical disease in severe cases, with consequent increase in mortality. The respiratory system has been shown, both clinically and pathologically, to be involved. However, there is little information on the impact of this on mortality. This study aims to determine the impact of pulmonary involvement on mortality.

Materials and methods: The medical records of 65 RT-PCR confirmed cases of Lassa fever patients with respiratory symptoms (cough and/or breathlessness) admitted to the medical wards of our hospital between January 2009 and February 2011 were reviewed. There were 34 males and 31 females. Of the 65 patients, 10 had both physical and chest x-ray features of pulmonary involvement. Case fatality rates (CFR) were compared between the sub-groups of patients with and those without pulmonary involvement. Significance level was set at P value < 0.05.

Results: The pulmonary features were pneumonia (5); pneumonia with pleural effusion (3); ARDS (2). Among the 10 patients with pulmonary involvement, 7 died, giving a CFR of 70%, while with the group without pulmonary involvement 21 died out of 55, with a CFR of 38.2% (p=0.06; Odds ratio 0.26; 0.04-1.34 (2-tailed Fisher exact)). Over all CFR was 44.6% (2005).

Conclusions: Lassa fever with respiratory features is associated with high CFR especially when the lungs and pleura are involved.

P564
Obesity as the most considerable risk factor for death due to influenza A(H1N1)-09 viral infection
Natasa Lezaja, Elena Luzina. Department of Internal Medicine, Chita State Medical Academy, Chita, Russian Federation

Objective: The aim of this study was to assess the complications of A/H1N1-09 viral infection in died patients in dependents of body mass.

Methods: We reviewed medical records and postmortem examination reports of 33 pts who died in 2009 in Zabavsky region of RF. A/H1N1-09 viral infection was confirmed by transcription- polymerase chain reaction method.

Results: 14 men and 19 women (average age 39.8±12.5 years) were included. All patients were divided into 2 groups: 22 patients with BMI 32.3±4.185 (the 1st group) and 11 patients with BMI< 25 (the 2nd group). There was no difference between the groups in age and gender structure. Causes of death were pneumonia and progressive respiratory failure. Pneumonia developed more rapidly in the 1st group (5,3±1.75 vs 4,09±1.13 days, p=0,049). The rate of acute respiratory distress syndrome was similar in both groups. Thrombosis of various locations was seen more often in obese patients (31,7% vs 0%, p=0,037). A tendency was found to a higher rate of rhabdomyolysis, acute canalicular necrosis and intravascular blood coagulation syndrome in obese patients. Additional risk factors were determined in 77,3% pts of the 1st group (diabetes mellitus, pancreatitis and arterial hypertension). We suppose that possible reasons of severe course of influenza A/H1N1-09 viral infection in obese people were alveolar hypventilation, production of proinflammatory cytokines by the fat tissue resulting in poor immune response.

Conclusions: Thus, obesity was the most considerable risk factor for death during influenza A/H1N1-09 virus infection in Zabavsky region due to aggravation of underlying metabolic disorders by specific effects of A/H1N1-09 virus strain.

P565
Seasonal variation of viral lower respiratory tract infections in immunocompromised patients undergoing diagnosis bronchoscopy
Kathleen Jahn1, Lilian Junke2, Jorg Halter2, Daisia Stolz1, Michael Tammi3, 1Clinic for Pneumology, University Hospital, Basel, Switzerland; 2Clinic for Haematology, University Hospital, Basel, Switzerland; 3Clinic for Pneumology, Hospital Thun, Thun, Switzerland

Pulmonary infections and non-infectious complications are frequent in immunocompromised patients. Multiplex PCR allows to detect a broader spectrum of viral infections in immunocompromised patients suffering from respiratory symptoms. We analysed the types of viral infection in a large cohort of patients undergoing diagnostic bronchoscopy for symptoms of LRT infection. Multiplex PCR for respiratory viral infection consisted of 13 viruses. 670 patients underwent a bronchoscopy with BAL from October 2009 to January 2012. 351 of the patients suffered from haematologic disorders, 157 underwent solid organ transplantation (including 137 lung transplantation, 10 kidney transplantation, 5 heart transplantation and 5 liver transplantation) and 174 were immunocompromised for other reasons (HIV, rheumatological diseases, interstitial lung disease). Overall respiratory viral infection could be documented in 212 cases (31.6%). The most frequent viruses were rhinovirus in 109 samples. A single viral infection was found in 196 cases (29.3%) whereas at least two viruses were detected in 16 patients (2.4%). Rhinovirus was found throughout the whole year. Coronaviruses, parainfluenza, RSV and IMPV were documented from November to April. There were only nine cases of adenovirus and eight cases of influenza respectively. H1N1 was only present in the winter of 2009.

Summary and conclusion: Multiplex PCR in BAL allows to diagnose rapidly viral infection in a high percentage of immunocompromised patients suffering from respiratory tract infection. Except for rhinovirus most viruses show seasonal pattern. However the “winter” period lasts for at least 6 months.

P566
Risk factors for tuberculosis in patients with early gastric cancer: Is gastrectomy a significant risk factor for tuberculosis?
Hoe Seok Lee1, Sung Jin Na1, Young Moo Kim2, Ji Ju Choi1, Bin Hwangbo1, 1Division of Pulmonary and Critical Care Medicine, Peking University People's Hospital, Beijing, China; 2-department of Respiratory Medicine, Peking University People's Hospital, Beijing, China

Since 1940s, many studies suggested the strong relationship between gastrectomy and the development of TB. But there is no study about the association between TB development and gastrectomy in patients with early gastric cancer (EGC). We used our EGC cohort confirmed pathologically by gastrectomy (pT1N0M0) or endoscopic mucosal resection (EMR) (pT1) between Jun 2001 and Dec 2008 and followed (2). We searched an active TB case developed at least 3months after gastrectomy and EMR in EGC cohort retrospectively. Of total 1395 patients with EGC, 1495 patients were classified as gastrectomy cohort and 440 patients as EMR cohort. While one patient (0.2%) was diagnosed as active TB in EMR cohort, 26 (1.7%) were diagnosed in gastrectomy cohort during the follow-up period. TB cumulative incidence showed significant difference between the two cohort (Log-Rank test p=0.030). Cox proportional multivariate analysis after adjustment with age, sex, and BMI group in EGC cohort showed hazard ratio of old TB lesion was 4.911 (95% CI 2.213-10.901) and that of gastrectomy was 8.599 (95% CI 1.155-64.000). In subgroup analysis using gastrectomy cohort, Cox proportional multivariate analysis after adjustment with age and sex showed hazard ratio of old TB lesion was 4.570 (95% CI 2.041-10.231) and postoperative weight reduction (per 10% compared with weight before gastrectomy) was 2.240 (95% CI 1.452-3.486).

Gastrectomy and old TB lesion on chest radiograph were significant risk factor for TB development in EGC cohort and old TB lesion on chest radiograph and body weight loss after gastrectomy were too in gastrectomy cohort.

P567
Identification of bacterial pulmonary infection by a PCR based rapid molecular diagnostic assay in bronchoalveolar lavage
Kathleen Jahn1, Michael Tammi3, Minna Maki2, Marko Kuusima2, Daisia Stolz1, 1Clinic for Pneumology, University Hospital, Basel, Switzerland; 2Mobidag Ltd, Tukholmankatu 8/Bismedicum 2U, Helsinki, Finland

Rapid PCR based diagnostic tools have been developed to diagnose early bacterial respiratory tract infections. If there is a suspicion of pneumonia patients are usually empirically treated. Bronchoscopy with BAL is advocated in patients with nonresolving pneumonia.
Bacterial PCR might allow to find bacterial pathogens in patients with nonresolving pneumonia under current treatment. In a pilot-study we analysed the diagnostic yield of a new PCR and microarray-based rapid molecular diagnostic assay (Prove it 41 with 35 samples at BAL-fluid including patients with non-resolving pneumonia.

Most of the patients are already pretreated before a sampling with BAL could be done. We included 22 patients (group A) undergoing bronchoscopy with BAL with a strong clinical suggestion of bacterial infection (purulent bronchial secretions) and 13 patients (group B) with no evidence of bacterial infection and no inflammatory signs in the peripheral blood. A were under antibiotic treatment as compared to 15% in group B. Conventional microbiological cultures showed no growth in group B. In group A there were bacteria grown from 10 samples (43%). The Prove it assay identified additional bacteria in 7 BALs of group A with negative culture results (mainly haemophilus influenzae). 3 cases were cultural positive (pseudomonas aeruginosa, klebsiella oxytoca, enterobacter) without detection in Prove it assay. On the other hand bacteria were identified by Prove it in 6 cases of group B.

Conclusion: Bacterial Multiplex PCR (Prove it) might be an interesting tool to diagnose bacterial infection in the BAL of patients with nonresolving pneumonia under current treatment with antibiotics.

P568 Early diagnosis and causal treatment of pneumonia associated with pandemic influenza A (H1N1) virus

1Department of Internal Diseases, Chita State Medical Academy, Chita, Russian Federation; 2Clinical of Internal Diseases, Railroad Clinical Hospital, Chita, Russian Federation

Introduction: In the conditions of epidemic of highly pathogenic virus a special role is taken away to early aetiologic diagnosis of the disease. Meanwhile, expectation or absence of the result of RT-PCR can’t be the reason for a delay of appointment of the antiviral therapy.

Aim: The aim of the study was to investigate early diagnostic features of pneumonia associated with influenza A (H1N1) and the role of antiviral therapy.

Methods: Retrospective analysis of the medical records of 135 patients with pneumonia associated with influenza A (H1N1) during October-December 2009 in Chita, RF. In all patients high resolution CT was developed. Antiviral therapy consisted of oseltamivir 150-300 mg or zanamivir 20 mg per day.

Results: The greatest diagnostic value in laboratory confirmed cases of pneumonia associated with influenza A (H1N1) possessed following indicators: myalgia, leukopenia (4.0 or less), and a symptom of “matte glass”

Diagnostic value of indicators of pneumonia associated with influenza A (H1N1)

</table>

Antiviral therapy in the first 48 hours received 25 pts (18.5%). Duration of hospitalization in those patients was shorter - 8 [6; 11] in comparison of patients not receiving early antiviral therapy - 12 [9; 14.5] (p<0.05). An early initiation of oseltamivir reduced the risk of lethal outcome in 3 times, zanamivir - in 3.2 times (p<0.03).

Conclusion: The greatest sensitivity and specificity in early diagnostic of influenza A (H1N1) is a symptom of “matte glass”. Antiviral medications, prescribed in due time can reduce risk of lethal outcome.

P569 Biomarkers in community-acquired pneumonia (CAP)

Regina Hao1, Anya Buto, Perli Kapsyzy, Hasan Hatiz, Silvia Bala, Redha Haddad, Dhimiter Argiri, Milda Nanushi, Jolanda Nnikolla, Olvis Petre, Aldi Shehu, Elii Petrella, Jul Bushati. Pulmonary Disease, University Hospital "Sheqet Ndroqi", Tirana, Albania Laboratory of Clinical Chemistry and Hematology, UHC "Mother Theresa", Tirana, Albania Radiologic Department, Hygea Hospital, Tirana, Albania

Introduction: Many investigators have tried to identify a simple blood test or predicting rules that can help physicians to make more rational decisions to identify patients who are at risk for adverse outcomes or death.

Aim: The aim of this study was to investigate the prognostic value of plasma D-dimer, CRP and some other biomarkers levels in patients with CAP.

Materials and methods: In this study were enrolled 72 patients admitted on Sept - Dec 2011 with clinical and radiological evidence of CAP. Within 24 hours after admission and on the 4-th day blood samples were taken for analysis. CURB-65 and PSI severity scores were calculated at admission. Statistical analysis is made with SPSS 19.0.

Results: Mean age 62.7±16.6 years (range 25-92). Mean D-dimer on the first day resulted 2621ng/ml (range 206-9000), on the 4-th day 2585 ng/ml (range 120-9000). Mean CRP on the first day resulted 198 mg/l (range 0.76 - 743), on the 4-th day 72 mg/l (range 0.10 - 316). On admission mean value of fibrinogen was 811mg/dl and on the 4-th day resulted 2621ng/ml (range 296-9000), on the 4-th day 2585 ng/ml (range120-9000).

Conclusion: Even though mean values of D-dimer and CRP are higher, no significant correlations resulted between them and CURB-65 and PSI score. Significantly mean values of D-dimer and CRP are higher on groups of patients with complicated CAP (p < 0.004).

P570 Tuberculosis in Esbjerg. High risk group of persons from Greenland

Paul Gade Sørensen. Department of Respiratory Diseases, SVS, Esbjerg, Denmark

Introduction: Tuberculosis among immigrants in Denmark decreased with 50% as the immigration decreased. However, tuberculosis among persons from Greenland is increasing and in the period 2006 to 2010 an increased number of persons from Greenland immigrated to Denmark.

Material and method: In the period of two years from january 2009 to december 2010, 24 patients were treated for active tuberculosis, 32 treated for latent tuberculosis as new positive and four before treatment with TNF-alpha-inhibitor: M.Brimon (2),SA (1), Pfortasi (1). Sexratio M/F 2.0, mean age 43 years, range 7-80 years in the group with active tuberculosis. Sexratio 0.4, mean age 16 year, range 10-43 years in the group with latent tuberculosis. Nationality noted.

Results: In the group treated for active tuberculosis patients were born in Greenland (5), Somalia (2), India (1), Vietnam (1), Burma (1) and Denmark (13) In the group with latent disease as new positive patients were born in Greenland (5), Somalia (2), Venezuela (1) and Denmark (24).Only 1 of 4 treated with TNF- inhibitor and latent disease was born in Denmark. Discussion.Uptake area for the hospital in Esbjerg include 210.000 persons. In the town 400 persons are born in Greenland. About 75 persons of them have social problems with abuse of alcohol and drug. The number of persons from Greenland is increasing in Denmark and the frequency in Esbjerg. The frequency of active disease and latent disease of tuberculosis in 2009-2010 was 20.8% and 15.6%.

Conclusion: Tuberculosis in Denmark an increasing problem for persons born in Greenland as the uptake area of the hospital include 210.000 persons. In Esbjerg 60 patients through a 2 year period 2009-2010 were treated for active disease and latent disease. 16.6% of the patients from Greenland.

P571 A case of HIV-associated multicentric Castleman disease with pulmonary involvement

Sophie Lemay1, Philippe Lachapelle2, Bernard Lemiess3, Claude Porier4. Internal Medicine, CHUM, Montreal, QC, Canada; 1Internal Medicine, CHUM, Montreal, QC, Canada; 2Hematology-Oncology, CHUM, Montreal, QC, Canada; 3Pneumology, CHUM, Montreal, QC, Canada

Multicentric Castleman disease (MCD) is a rare lymphoproliferative disorder that is increasingly diagnosed in patients with HIV infection. The course of the disease is unpredictable, ranging from a rapidly progressive form that can be fatal within weeks to a long course of a remitting and relapsing disease. Its principal manifestations are diverse but are almost always include fever, malaise, lymphadenopathy and hepatosplenomegaly. Pulmonary complications are rare.

We report a case of HIV-associated MCD that relapsed after being on remission for 30 years. The patient presented with recurrent "attacks" of classical symptoms (fever, night sweats, polyadenopathy), accompanied by thorarica, shortness of breath and cough. A diffuse interstitial pneumonitis was found on CT-scan of the chest, described as a ground-glass infiltrate with peribronchial micronodules and interlobular thickening that affected mostly the inferior third of both lungs. A slight bilateral pleural effusion was also noted. Lung function tests were normal. Final diagnosis of MCD was made on lymph node biopsy. We first treated this patient with Rituximab alone which led to a rapid relief of his symptoms and radiologic improvement. However, as he relapsed twice following this treatment, each time with systemic symptoms accompanied by a radiologic progression of the diffuse interstitial pneumonitis, we opted for a combined regimen of Rituximab and chemotherapy (CHOP). He is still on remission (6 months) and a follow-up CT-scan shows an almost complete regression of the pulmonary interstitial anomalies. The long term management of MCD presenting with pulmonary involvement has yet to be defined, as long term prognosis.

P572 The resistance rates of Acinetobacter baumannii at endotracheal aspirate cultures

Sibel Deniz1, Deniz Celik1, Galgun Yenisehirli2, Handan InomuKosegolu1, 1Department of Chest Disease, Gaziosmanpasa University, Tokat, Turkey; 2Microbiology, Gaziosmanpasa University, Tokat, Turkey.

Introduction: The long term management of MCD presenting with pulmonary involvement

AIM: We aimed to determine the rate of Acinetobacter baumannii resistance in intensive care unit (ICU).

Method: We analyzed 34 cases’ (30 entubated and 4 nentubated) files who had positive cultures for Acinetobacter baumannii at endotracheal aspirate.

Results: The mean age of patients was 65.5, 73.5% (n=25) was male. The most hospitalization 9.65 days (range 0-35).Mean values of D-dimer and CRP resulted in correlation with complications events. Even though mean values of D-dimer and CRP are higher, no significant correlations resulted between them and CURB-65 and PSI score. Significantly mean values of D-dimer and CRP are higher on groups of patients with complicated CAP (p < 0.004).

Conclusion: D-dimer and CRP level cannot replace CURB-65 or PSI scoring for assessment in CAP patients, but are useful to predict clinical outcome, especially complications in patients with CAP.
common comorbidities were COPD and CVD. In 27 patients, blood culture was taken concurrent with endotracheal aspirate culture and 22.2% (n:6) was positive with same agent. 52.9% (n:18) of patients were dead. The rate of Acinetobacter baumannii resistance and MICs presented in Table 1 and 2.

Conclusion: Higher resistance rates for broad spectrum antibiotics in Acinetobacter baumannii infections explains higher mortality rates in these patients. Higher resistance rates for carbapenems seems to limit of these antibiotics usage for ICU patients in time.

Conclusion: Although ESRD patients suffered from pneumonia caused by multi-resistant pathogens compared with previous CAP studies, including S. aureus, drug resistant organisms were the most common pathogens. The prevalence of pulmonary hypertension and the related factors in hemodialysis patients

Methods: In this study, 76 chronic hemodialysis patients with pleural effusion admitted in hospital between June 2005 and May 2011, and evaluated for the etiology of pleural effusion and associated clinicopathological findings. Statistical tests of Chi square, ANOVA and Kruskal Wallis were used to compare patient’s data with the most common etiologies of pleural effusion.

Results: Parapneumonic effusion (23.7%), urticarial pleuritis (23.7%) CHF (19.7%) volume overload (6.6%) tuberculosis (6.6%) and malignancy (5.4%) were the most common causes of pleural effusion. There was not any significant difference in the frequency of presenting symptoms such as: Dyspnea, cough, weight loss, anorexia, chest pain and fever, in patients with CHF and urticarial pleuritis. Moreover, pleural Adenosine Deaminase levels were not different in patients with tuberculosis, bronchitis, parapneumonic effusion and CHF.

Conclusion: Infectious disease including parapneumonic effusion and tuberculosis can be the most common causes of pleural effusion in hemodialysis patients. This study showed that some inflammatory pleural reactions such as increase in pleural leukocyte count and ADA may be attenuated in hemodialysis patients.

85. Respiratory manifestations of systemic disease: a holistic approach

P577 Pulmonary brucellosis detected during treatment of active tuberculosis in a patient with operated lung cancer (Case report)

Fatma Erboy1, Fatma Erboy1, 2, chest Disease, Bezmi Alem Vakif University Medical Faculty, Istanbul, Turkey; 3, Infectious Diseases, Bezmi Alem Vakif University Medical Faculty, Istanbul, Turkey; 4, Infectious Diseases, Abant Izzet Baysal University, Bolu, Turkey; 5, Chest Disease, Bilisil Public Hospital, Bilisil, Turkey

P578 Copetin application in severe community-acquired pneumonia (SCAP) severity assessment and outcomes

Joanna Chorostowska-Wynimko1, Tatyana Rybina3, Elena Amelchenko3, 1, 1st Department of Internal Diseases, Belarusian State Medical University, Minsk, Belarus; 2, Laboratory of Molecular Diagnostics and Immunology, National Institute of Tuberculosis and Lung Diseases, Warszaw, Poland; 3, Clinical Laboratory of Occupational Diseases, Republican Scientific and Practical Center of Hygiene, Minsk, Belarus

Background: Appropriate early prognostic assessment is crucial for SCAP patients management.

Aim: We aimed to investigate copeptin levels in SCAP patients and their relationship with in-hospital outcomes (in-hospital mortality (IHM), length of in-hospital stay (LOS), duration of ICU stay), disease specific complications, need for invasive mechanical ventilation (IMV) and vasopressor support (VS).

Methods: 20 ICU patients with proven SCAP CURB-65 class 3, 4 were enrolled to the study. Serum CP values were measured within the first 24 hours after the hospitalization.

Results: Increasing CAP severity was associated with increased CP values (r=0.53; p<0.02). CP levels on admission appeared to be higher in CURB-65 scores 4 vs 0-3 (p<0.03), CP values on ICU admission correlated with need for VS (r=0.54; p=0.02 respectively) and showed higher concentrations in patients requiring VS compared with those with stable haemodynamics (74.8 vs 47.6 pg/mL, p=0.03) respectively. CP correlated with duration of ICU stay (r=0.43; p<0.005).

Conclusion: CP could add prognostic information in SCAP patients.

P579 Neuropsychiatric side effects of tuberculosis

L. Fekih, W. Ben hammad, D. Greb, H. Abdeghaffar, H. Hassene, Mahamed Lamine Megdiche. JNB NAFIS, Abderrahmen Mami Hospital, Ariana, Tunisia

Accur e knowledge of microbiological or psychiatric complications secondary to the administration of antituberculosis may be of the origin of diagnosis and therapeutic problems. This work aims at studying the frequency of these manifestations, their clinical presentations and their therapeutic approach.

P580 Pleural effusion in hemodialysis patients with chronic kidney disease

Giunti Prząkówki1, Farm Rashid Farokhi2, 1, Chronic Respiratory Disease Research Center, NRITLD, Mashh School Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; 2, Department of Nephrology, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

Background: Uremic patients are susceptible to many causes of pleural effusions. Moreover, uremia directly creates a kind of exudative pleural effusion. Uremic pleuritis has been introduced as a clinicopathologic entity for the past few decades. However, knowledge of pathogenesis, clinical course and management of this complication is still limited.

Materials and methods: In this study, 76 chronic hemodialysis patients with pleural effusion admitted in hospital between June 1996 and May 2011, and evaluated for the etiology of pleural effusion and associated clinicopathological findings. Statistical tests of Chi square, ANOVA and Kruskal Wallis were used to compare patient’s data with the most common etiologies of pleural effusion.

Results: Parapneumonic effusion (23.7%), urticarial pleuritis (23.7%) CHF (19.7%) volume overload (6.6%) tuberculosis (6.6%) and malignancy (5.4%) were the most common causes of pleural effusion. There was not any significant difference in the frequency of presenting symptoms such as: Dyspnea, cough, weight loss, anorexia, chest pain and fever, in patients with CHF and urticarial pleuritis. Moreover, pleural Adenosine Deaminase levels were not different in patients with tuberculosis, bronchitis, parapneumonic effusion and CHF.

Conclusion: Infectious disease including parapneumonic effusion and tuberculosis can be the most common causes of pleural effusion in hemodialysis patients. This study showed that some inflammatory pleural reactions such as increase in pleural leukocyte count and ADA may be attenuated in hemodialysis patients.

P581 The prevalence of pulmonary hypertension and the related factors in hemodialysis patients

Ali Sharifpour, Omid Sedighi, Samad Golshani, Fatemeh Mahjoob. Pulmonary, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Islamic Republic of Iran Nephrology, NRITLD, Mashh School Hospital, Shahid Beheshti University of Medical Sciences, Sari, Islamic Republic of Iran Cardiology, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Islamic Republic of Iran Internal Medicine, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Islamic Republic of Iran

Background and purpose: Pulmonary hypertension (PH) has been reported in hemodialysis patients, but there are scant studies about its prevalence and mechanisms. The aim of this study was to determine the prevalence of pulmonary hypertension in hemodialysis patients and to study some of its possible etiologic factors.

Materials and methods: In this cross-sectional study, the prevalence of pulmonary hypertension was determined by Doppler echocardiogram in 100 patients on hemodialysis via arteriovenous fistula at least for 6 months. All the patients underwent a thorough clinical evaluation. The laboratory findings including mean of three-month hemoglobin and serum level of calcium, phosphorus, albumin, alkaline phosphatase, parathormone (PTH), triglyceride and cholesterol were all recorded.

Pulmonary hypertension was defined as systolic pulmonary artery pressure higher than 35 mmHg.

Results: Pulmonary hypertension was detected in 44 patients (44%) with a mean
systolic pulmonary artery pressure of 52.09±7.33 mmHg. No significant differences were found between those with and without pulmonary hypertension with regard to age, gender, duration of hemodialysis and all the biological parameters.

**PS84 Predictors of pulmonary artery hypertension in patients with systemic sclerosis**

M.C. Sabir, Shahjahan P. Sulaiman, Davis Paul Chelangara, Nikhula K. Govind, Aneesh C. Retheditram, Raghunath D. Vijayan. Pulmonary Medicine, Medical College, Kottayam, Kerala, India

**Introduction:** Pulmonary Arterial Hypertension (PAH) is the leading cause of death in patients with systemic sclerosis1. Newer treatment modalities have improved the outcome; hence the early identification of this complication is important.

**Aim:** To study the predictors of PAH in patients with Systemic Sclerosis who attended the out patient service of Pulmonary Medicine, Medical College, Kottayam.

**Methods:** We studied 28 cases of systemic sclerosis patients who had diffuse form. All of them had PAH.

**Results:** Among patients with PAH (diffuse and overlap form), 7 had ILD (63%) and 3 had PAH (38%).

No patient with limited form had PAH but, all the two had PAH (100%).

**Conclusions:** Prevalence of PAH was observed in patients with limited variety when compared with diffuse form and overlap syndrome.

In diffuse form PAH was associated with ILD and no such association was found in overlap syndrome.

A decreasing DLCO is an excellent predictor of the development of PAH in diffuse systemic sclerosis2.

**PS85 Respiratory problems in late onset Pompe disease**

Mehtup Ertas, Zuleyha Bingol, Guler Okumus, Piraye Serdaroglu, Esgen Kiyani. Pulmonary Department, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey; Neurology Department, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey

**Introduction:** Pompe disease (glycogen storage disorder type II) is associated with functional deficiencies in skeletal, heart and respiratory muscles due to glycogen deposition. While progression and mortality rates are fast in early onset (first year) Pompe disease, late onset (adult) Pompe disease is related with slow progression and proximal myopathy. In this disease respiratory muscle involvement is independent from severity of skeletal muscle weakness. Here, we present the respiratory evaluation of 10 patients with Pompe disease who are followed up in our clinic.

**Table 1. Characteristics of the patients**

**Conclusion:** Respiratory muscle involvement especially diaphragm muscle dysfunction and respiratory disorders in sleep are common in late onset Pompe disease even the respiratory symptoms are recessive.

**PS86 Ankylosing spondylitis: Pulmonary manifestations**

Fıratufar Karakus1, Aylin Rezvani2, Muhammet Emin Akköyulu1, Mehmet Bayram1, Fatih Kothyab Ozczyel1, Murat Sezer1, Levent Kari1. 1Department of Chest Disease, Bezmiuml Vakif University Medical School, Istanbul, Turkey; 2Department of Physical Therapy and Rehabilitation, Bezmiuml Vakif University Medical School, Istanbul, Turkey.

In present study we aimed to assess the spirometric and pulmonary radiological findings of the patients with ankylosing spondylitis.
Methods: 35 outpatients with ankylosing spondylitis were evaluated in terms of demographic characteristics, smoking status, tuberculosis history, respiratory symptoms, HLA B27 status, activity of illness. X-ray, HRCT, spirometry, body plethysmography and DLCO tests were evaluated. 

Results: The characteristics of all the subjects are shown in Table 1.

Lung Volumes were normal at 20 (%57.1) patients, abnormal at 3 (%8.6) patients. DLCO were normal at 16 (%45.7) patients, abnormal at 10 (%28.6) patients. PI max and PE max were normal at 17 (%48.6) patients, abnormal 13 (%33.7) patients.

Conclusion: Disease activity determined by BASDAI Index has no significant correlation with Chest Expansion and value of PI max-PE max (p=0.388). There is no significant correlations between chest expansion and normal or reduced intrathoracic pressures (p= 0.509).

PS87 Diffuse aspiration bronchiolitis diagnosed on transbronchial lung biopsy in a case of thymoma with dysphagia

Vikas Mittal1, Nevin Kishore1, Andleeb Abrari1, Amit Kumar1, 1Department of Respiratory Medicine, Max Super Specialty Hospital, New Delhi, India;
2Department of Histopathology, Max Super Specialty Hospital, New Delhi, India; 3Department of Radiology, Max Super Specialty Hospital, New Delhi, India.

Background: Diffuse aspiration bronchiolitis (DAB) is a form of aspiration related lung disease and has unique clinicoro-radio-pathologic features. It has heretofore been reported on autopsies or surgical biopsies. We report a case of DAB diagnosed on trans-bronchial lung biopsy (TBLB).

Case: A 72 year old previously healthy male, smoker (150 pack-years) presented with hoarseness of voice and vertigo for 4 months, dyspnea and swelling in the neck for 1 month. Examination revealed a firm, non tender swelling in the right side of the neck, extending into the superior mediastinum, encasing the trachea, abutting and displacing the esophagus to the left and normal lung parenchyma. A CT-guided transbronchic percutaneous biopsy of the mass revealed an immature lymphocyte rich thymoma. Patient developed sudden breathlessness, after 3 weeks from the start of radiotherapy. A CT-pulmonary angiography was negative for pulmonary embolism. HRCT showed bilateral disseminated centrilobular nodules with ‘tree-in-bud’ appearance suggestive of diffuse bronchiolitis. A TBLB revealed necrotising alveolitis with foreign body giant cells containing refractile material, suggestive of aspiration. A final diagnosis of DAB/aspiration alveolitis secondary to occult chronic aspiration was made. Patient improved on nasogastric feed and treatment with clidamycin. A repeat CT-thorax after 2 months showed normal lung parenchyma.

Conclusion: DAB is an underrecognised, yet an important differential diagnosis, which should be considered in any patient having risk of aspiration and a HRCT showing diffuse bronchiolitis.

PS88 Evaluation of pulmonary function and functional capacity in patients with liver cirrhosis

Olga Corlateanu, Eugen Tcaciuc, Alexandru Corlateanu

Internal Medicine, State Medical and Pharmaceutical University "Nicolae Testemitanu", Chisinau, Republic of Moldova

Background: Various changes can be detected by pulmonary function tests in patients diagnosed with chronic hepatic diseases. These changes characterize the hepatopulmonary syndrome result in hypoxemia and affect one-third of all patients diagnosed with cirrhosis.

The aim of this study was to evaluate and compare the pulmonary function and functional capacity in patients with liver cirrhosis according to the Child-Pugh score and to correlate these variables within each group.

Methods: 40 patients with liver cirrhosis were enrolled into the study. Spirometry (FEV1, FVC, FEV1/FVC), hemoglobin levels, dyspnea by BORG scale, exercise capacity by 6 min walking test (6MWT), blood gas analysis were evaluated. Blood gases were measured in supine and sitting positions.

Results: The patients were classified into three groups, according to cirrhotic severity, using Childs-Pugh classification (A - 7 patients; B - 24 patients; C - 9 patients). There were significant differences (p<0.01, ANOVA) in FEV1 between 3 groups: there was observed a decrease of pulmonary function with progression of cirrhosis from 107±13.1% in group Childs-Pugh A to 89±17.4% in group Childs-Pugh C. Also there was detected a diminution of PaO2 in supine and sitting positions with progression of cirrhosis. The longest 6MWD was 435±17.8 m by group A; then group B (352±43.4 m) and group C (310±63.6 m). There was a strong negative correlation between 6MWD and Child-Pugh classification (r=-0.55, p<0.01).

Conclusion: The progress of liver disease contributes to the onset of several complications which together appear to contribute to the reduction of pulmonary function and functional capacity of patients.

PS89 Assessment of dyspnoea in patients with liver cirrhosis

Olga Corlateanu1, Eugen Tcaciuc, Alexandru Corlateanu, Angela Tcaciuc.

Internal Medicine, State Medical and Pharmaceutical University "Nicolae Testemitanu", Chisinau, Republic of Moldova

Background: Pulmonary involvement is a common complication of liver cirrhosis, mainly owing to a decreased hepatic clearance of toxins or increased hepatic production of circulating inflammatory mediators. The connection between the severity of lung manifestations and liver impairment is not well characterized.

The aim of this study was to evaluate and detect predictors of dyspnoea in patients with liver cirrhosis according to the Child-Pugh score.

Methods: 40 patients with liver cirrhosis were enrolled into the study. Spirometry (FEV1, FVC, FEV1/FVC), hemoglobin levels, dyspnea by BORG scale, exercise capacity by 6-min walking test (6MWT), blood gas analysis were evaluated.

Results: The patients were classified into three groups, according to cirrhotic severity, using Childs-Pugh classification: A - 7 patients; B - 24 patients; C - 9 patients. There were significant differences (p<0.01, ANOVA) in dyspnoea assessed by BORG scale between 3 groups: there was the demonstrated the increase of dyspnoea with progression of cirrhosis from 0.7±1.9 points in group Childs-Pugh A to 2.4±4.9 points in group Childs-Pugh C. Dyspnoea correlated better with 6-minute walking distance (r = 0.67, p = 0.001) in cirrhotic patients. Also a significant positive correlation between dyspnoea and Child’s-Pugh classification (r = 0.60, p = 0.01) was demonstrated. The forward stepwise regression analysis shows that the stage of cirrhosis and level of hemoglobin are important predictors of dyspnoea in patients with liver cirrhosis which explains 60% of the dyspnoea.

Conclusion: The Child’s-Pugh stage of cirrhosis and level of hemoglobin in patients with liver cirrhosis are independent risk factors for worsening of dyspnoea.

PS90 Evaluating airway obstruction in patients admitted to general medicine wards by bedside spirometry

Pavan Yadav1, 1, J.K. Samarai2, Moosa Hussain3.

1Dept. of Chest Diseases, Instrt of Medical Sciences, Banaras Hindu University, Varanasi, UP, India; 2Dept. of Chest Diseases, Instrt of Medical Sciences, Banaras Hindu University, Varanasi, UP, India; 3Dept. of Chest Diseases, Instrt of Medical Sciences, Banaras Hindu University, Varanasi, UP, India

Study objectives: Airway obstruction is found to coexist with other medical conditions. This study attempts to assess airway obstruction in patients admitted in general medicine wards.

Methods: A cross-sectional study of 52 patients admitted to medicine ward of a tertiary hospital was carried out. Bed-side spirometry was performed in each of these patients after taking consent and recording a detailed history.

Results: A remarkable 52% of the patients were found to have airway obstruction (FEV1/FVC<70%) on performing spirometry, including 11.5% with very severe (FEV1<30% predicted), 17.3% with severe (FEV1 30%-49%), 11.5% with moderate (FEV1 50%-69%) and 9.6% with mild (FEV1>70%) obstruction respectively. A diagnosis of obstructive airway disease was present only in 28% of these patients at the time of admission. A considerably higher prevalence of airway obstruction than average was observed in patients admitted for respiratory (70%), cardiac (62.5%) and neurological (58.8%) disorders, while a lower prevalence was seen in those with nephrological (40%), haematological (0%) or other (22%) conditions. No patient was additionally diagnosed with airway obstruction during the hospital stay and only 26% of patients with airway obstruction received bronchodilator therapy.

Conclusions: Airway obstruction co-existing with other medical conditions is grossly under-diagnosed. A routine bedside spirometry performed on hospitalized patients could be a useful tool for detecting and treating airway obstruction.

**PS91**

Is it GER? Different diagnostic approaches for detection of gastroesophageal reflux in patients with chronic cough

Elzbieta Madalena Grabow1, Anna Domeracka-Kolodziej2, Marta Dabrowska1, Ratal Krenke1, Ryszard Chazan1. 1Department of Internal Medicine, Pneumonology and Allergology, Medical University of Warsaw, Poland; 2Department of Otolaryngology, Medical University of Warsaw, Poland

**Background:** Gastroesophageal reflux (GER) is a common cause of chronic cough. Different methods can be used to detect it. The limited accessibility of some devices or difficulties in assessment of relationship between GER and cough may influence their practical usefulness.

**Objectives:** To assess the utility of different methods in the diagnosis of GER in patients with chronic cough.

**Methods:** We included 60 consent, nonsmoking, adult patients, with history of cough longer than 8 weeks, with normal chest radiograph. We used the Carls-

son questionnaire (CQ), assessment of abnormalities in larynx mucosa (Belafsky reflux finding score, RFS), upper gastrointestinal tract radiography, 24-hour-pH monitoring and multichannel impedance (MI) of esophagus.

**Results:** Sixty patients were included (M/F = 1:1.86), mean age 48.8 yrs, mean cough duration 260 weeks (range 16-1440). Sixteen subjects were excluded from further studies due to consent withdrawal or technical problems with pH probe insertion. Positive results of CQ and RFS were observed in 13 and 50/54 cases respectively. Mean calculated RFS was 11.7 points. Exophagasemia herina or reflux during radiography was shown in 6 and 7/54 pts, respectively. Increased esophagus exposure to acid reflux was diagnosed in 43/58 pts using pH monitoring alone, and in 37/54 on the basis of MI. Time-relationship between GER and cough was found in 23 and 21 cases, respectively. MI probe was slightly worse tolerated.

**Conclusions:** Diagnosis of GER was most frequent on the basis of RFS and MI. Combination of few methods allows to recognize GER more precisely. The time relationship between GER and cough, can be assessed by not all used devices by us.

---

**PS92**

Platypnea-orthodeoxia syndrome precipitated by kypho-scoliosis: An unusual case of refractory hypoxia

Arun Khanna, David Reed, Gillian Lowrey, Chris Whale. Respiratory Medicine, Derby Hospital NHS Trust, Derby, United Kingdom

**Introduction:** Platypnea-Orthodeoxia syndrome is caused by intra-cardiac, pulmo-

nary artery-right or pulmonary parenchymal shunt. It’s first clinical manifestation in

an elderly lady as a result of a ‘masking’ of a patent foramen ovale (PFO) attributable to her worsening kypho-scoliosis is a novel and poorly understood presentation.

**Case Summary:** An 85 year old lady presented with breathlessness and hypoxia (PaO25.6kPa, PaCO25.2kPa, pH7.4). Clinical examination was normal apart from

marked kypho-scoliosis. Her ECG, chest X-ray, High resolution chest CT, CT pul-

monary Angiogram, Ventilation/Perfusion scans and Trans-thoracic ECHO were all

normal. In particular, she had normal pulmonary pressures. Her lung functions demonstrated a restrictive defect with a normal single-breath diffusion capacity of carbon monoxide. She subsequently exhibited orthodeoxia prompting a ‘bubble’ ECHO study. This revealed a large PFO with a prominent ‘right to left’ shunt, confirmed on Trans-oesophageal ECHO. Percutaneous transcatheater closure of the PFO reduced her oxygen saturation to within normal limits enabling rehabilitation.

**Discussion:** Symptomatic Platypnea-Orthodeoxia syndrome without pulmonary hypertension can be caused by altered intra-thoracic anatomy and physiology. It is postulated that kyphoscoliosis resulting in right atrial compression and alterations to caval flow may result in ‘right to left’ shunt unmasking a ‘silent’ PFO. PFO’s, reported at the time of discharge. The analysis covered the period from 01’2008 to 10’2011.

**Conclusions:** TO present frequently with chronic or acute non specific respiratory symptoms, but with pathognomonic characteristic features in FBS. Thoracic CT scanner is a non invasive diagnostic method. The treatment is symptomatic.

---

**PS93**

Pulmonary complications in patients with hematologic diseases

Hiroshi Ohboshi, Kazuo Togitani, Miru Sukai, Ayako Taniguchi, Takayuki Bezoe, Tetsuya Kubota, Akihito Yokoyama. Department of Hematology and Respiratory Medicine, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan

**Patients with hematologic diseases may complicate with various respiratory dis-

ases, such as infections, lung involvement of hematologic diseases, alveolar hemoptoe, and drug-induced pneumonitis. The aim of this study is to clarify the recent incidence and the risk factor for pulmonary complications in patients with hematologic diseases. Medical records and chest computed tomography of patients with hematologic diseases, who were treated in our university hospital during 2010-2011, were reviewed and analyzed retrospectively by hematologists and pulmonologists. Diagnosis of respiratory complications was confirmed by pulmonologists. One hundred sixty six patients with hematologic diseases were admitted mainly for chemotherapy of malignant lymphoma (51.2%), multiple myeloma (17.5%), and leukemia (15.7%). Forty six patients (27.7%) suffered from pneumonia (27 cases, 51.9%), pleural effusion (8 cases, 15.4%), drug-induced pneumonitis (3 cases, 5.7%), acute respiratory distress syndrome (ARDS, 2 cases, 3.8%), alveolar hemorrhage (2 cases, 3.8%), and/or others (10 cases, 19.2%). Six patients (3.6%) were deceased because of respiratory complications (3 cases with pneumonia, 2 cases with ARDS, and a case with alveolar hemorrhage). Pulmonary complications developed significantly higher in current or recent smokers than never smokers. Pulmonary complications in hematologic diseases may be de-

creased by recent introduction of prophylaxis for infections, but are still important in the management of hematologic diseases. Smoking status may be related to the development of pulmonary complications during treatment of hematologic diseases.

**Conclusions:** TO present frequently with chronic or acute non specific respiratory symptoms, but with pathognomonic characteristic features in FBS. Thoracic CT scanner is a non invasive diagnostic method. The treatment is symptomatic.

---

**PS94**

Tracheobronchopathia osteochondroplastica – Analysis of 10 years period

Mitsi Nomoto, Jolanda Nikolla, Hasan Hatira. Internal Medicine, University Hospital of Respiratory Diseases “Sh. Ndroqi”. Tirana, Albania

**Background:** Tracheobronchopathia osteochondroplastica (TO) is a pulmonary orphan disease and consists at the presence of multiple osseseous or cartilaginous nodules localized in the submucosa of the tracheobronchial wall. These nodules protrude into the lumen of the trachea and the large bronchi, leading to the airway obstruction. The disease does not involve other organs.

**Method:** We studied in retrospective all cases of TO diagnosed with fiberoptic bronchoscopy for the period 2001 - 2011. In our hospital we realise approximately 1200 bronchoscopies per year.

**Results:** We found 17 cases, 52% were female and 48% male. The average age was 40.6 years, 42% were smokers (~40 UPA) without family history for TO. The duration of symptoms till the diagnostic was 2.3 years. The most frequent symptoms were: cough 100%, sputum 64%, dyspnea 41%, haemoptisis 5%, and erythema nodosa 5%. The laboratory findings demonstrate an increase of sedi-

ment in 58% of cases, 11% leukocytosis and all the others were normal. Proteus mirabilis was the most frequent microbiological strain (17%). Functional respira-
tory tests resulted: 35% obstruction, 11% restriction, 5% mixed and 17% normal.

**Conclusions:** TO present frequently with chronic or acute non specific respiratory symptoms, but with pathognomonic characteristic features in FBS. Thoracic CT scanner is a non invasive diagnostic method. The treatment is symptomatic.
Results: 1779 sarcoidosis patients were hospitalized during almost four years. Majority (79.2%) were diagnosed as pulmonary and/or lymph node sarcoidosis (D86.0, D86.1, D86.2). Sarcoidosis of other and combined sites (D86.8) were diagnosed in 15.8% and unspecified sarcoidosis (D86.9) in 5.0% of patients. At least one comorbidity was noted in 54% of patients. The most frequent reported comorbidities are presented in figure below.

Using linear regression models the association between the number of comorbidities and age and extent of the disease were found (p < 0.001).

Conclusion: Comorbidities in sarcoidosis patients are more frequent in multiorgan disease.

P596 Pulmonary alveolar proteinosis due to mycopnehalone and cyclocoprine combination therapy in a renal transplant recipient
Ashfaq Hasan, T.L.N. Swamy, Raja Ram. Department of Respiratory Medicine, Oasis Hospital and Research Centre, Hyderabad, AP, India Department of Pulmonary Medicine, Care Hospital, Hyderabad, AP, India Department of Nephrology, Deccan College of Medical Sciences, Hyderabad, AP, India

Since the first case of Pulmonary Alveolar Proteinosis (PAP) was described in 1858 about 500 cases have been reported. We describe a case of PAP occurring in a renal transplant recipient due to mycopnehalone and cyclocoprine combination therapy.

Five years ago, a diagnosis of acute-on-chronic kidney disease was made in a 36 year old woman who eventually underwent renal transplantation then triple-drug immunosuppression. Subsequently she was in maintenance regimen with mycopnehalone and cyclocoprine. Several years ago, she had been treated for tuberculosis of the cervical lymph nodes. Chest X-ray showed a bilateral perihilar infiltrate sparing the costophrenic angles (Figure 1). CT-scan showed bilateral diffuse ground-glass haziness with superimposed interlobular septal thickening, predominantly in the perihilar areas (Figure 2).

Transbronchial lung biopsies showed dilated alveoli filled with PAS-positive granular eosinophilic material with deeply eosinophilic structures, resistant to de-colorization with diastase, consistent with alveolar proteinosis. The appearance of the symptoms after a few months of the commencement of immunotherapy suggested causality.

Immunosuppressive agents are capable of decreasing macrophage numbers and use of these agents in the post renal-transplant patient has been known to produce PAP. This patient was described a combination of mycopnehalone and cyclocoprine.

P597 Effect of respiratory pathology on the quality of life for patients, suffering from rheumatoid arthritis
Tatyana Pertseva, Lyutsa Botvinikova, Yulia Guba. Internal Medicine Department, Dnepropetrovsk Medical Academy, Dnepropetrovsk, Ukraine

Aim: To study the influence of pulmonary pathology on the quality of life (QoL) in patients suffering from rheumatoid arthritis (RA).

Methods: 58 patients with RA (42 women, middle age 57,1±3,17) were investigated by routine, clinical, functional tests and were divided into 2 groups: 1'st – 31 patients who had the respiratory discomfort (breathlessness, cough) and 27 patients without respiratory symptoms (and any disturbances of the function of mycopnehalone and cyclocoprine).

Tests were: unencumbered room air, NIOV+air, NIOV+O2, or O2 via standard nasal cannula. Data collected included exercise time, SpO2 and transcutaneous (Tc) PCO2.

Results: Significant decreasing of the QoL for patients with RA in comparison with patients of the control group and the general population: the low level of QoL was registered in all scales in the patients of the 1-st group – (Symptoms 68,5±4,41, Activity 60,2±1,34, Consequences 63,4±2,11, total score was correspondently decreased: 49,5±2,12, Primary reason of lowering indexes of the SGRQ in patients with RA was a dyspnea. Established multifactor origin of dyspnea in patients with RA upon significant role of lung pathology, which registered in RA-patients.

Conclusions: Pulmonary pathology shows unpleasant effect on QoL, and level of general health of patient with RA, significantly decreased them. The perspective direction for increasing the QoL for patients with RA with pulmonary pathology depends on saving the respiratory function of lungs, adequate control of the activity of the RA, correction of violations of psychosomatic disorders and depressive level of patients.

P598 Venous thromboembolic disease and bronchial cancer

Venous thromboembolic disease (VTE), defined by the occurrence of a deep thrombosis and/or lung embolism. It is a frequent complication of cancer, particularly during chemotherapy. On average, it occurs with 15 to 20% of the patients, and is one of the main causes of death (one hospitalized cancer patient out of seven). We have retrospectively evaluated the occurrence of VTE in 139 bronchial cancer patients treated at the pneumology service of CHU Bab El Oued over a twelve-month duration. The incidence was of 8.6% (twelve cases out of 139), 50% of the VTE were present at the time of diagnosis and 90% appeared during the three following months. Among the twelve VTE diagnosed cases (three women and nine men), we found a predominance of the adenocarcinoma type (41.66%). All cases were stage III and IV and had received chemotherapy, with complementary surgical treatment for two patients. The twelve VTE cases had received an anticoagulant treatment with six deaths occurring after six months of treatment, three recoveries and three patients still under anticoagulants in continuation.

Conclusions: bronchial cancer predisposes the occurrence of a venous thromboembolic event which, once associated to neoplasia, is a factor of high mortality risk. VTE is more frequent with advanced stages, bronchial cancer patients, in adenocarcinoma and with patients under chemotherapy. Response to anticoagulant treatment is uncertain and death can occur after stopping the treatment, which justifies discussing the continuation of anticoagulants, and sometimes even their prescription as preventive treatment.

P599 Nutritional status in patients with bronchiectasis
Leila Boussofara, Nadia Bouadara, Imen Touil, Mounia Ben Khelifa, Mourita Sakka, Zaed Khnani. Pneumology Department, Tahar Sfar Hospital, Mahdia, Tunisia

Introduction: The association between nutritional depletion and chronic respiratory diseases has been recognised for years and mainly documented in chronic obstructive pulmonary disease. However little information is available regarding nutritional depletion in patients with bronchiectasis.

Aims of the study: This study was carried out to determine the nutritional status in patients with bronchiectasis and the relationship between the extent of these bronchiectasis on the C-T scan and nutritional depletion.

Methods: In 45 patients with bronchiectasis, body mass index (BMI), serum albumin, C-reactive protein and spirographic indexes were studied.

Results: BMI was <20 kg/m2 in 17% of patients and serum albumin was <35 g/l in 15% of patients. C-reactive protein was >5 mg/l in 80% and were higher essentially in patients who had more than one pulmonary lobe affected by bronchiectasis. BMI was not correlated to the extent of bronchiectasis, but serum albumin was correlated with p=0.02. BMI and serum albumin were not correlated with Post-bronchodilator FEV1 and long-term oxygen therapy.

Conclusion: Malnutrition is coming to be highly prevalent in patients with bronchiectasis. Assessing this nutritional depletion may be offers benefits to patients with bronchiectasis.

86. The latest insights in chronic care

P600 Effects of a novel noninvasive open ventilation system during constant work rate exercise in COPD
Janos Povaza1, Robert Cao1, Richard Morishige 2, Richard Casaburi1
1Rehabilitation, Clinical Trials Center, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States; 2Clinical Affairs, Breathe Technologies, Irvine, CA, United States

Exercise intolerance limits daily activities of COPD patients. Noninvasive ventilation improves exercise capacity in severe COPD, but previous systems are impractical for ambulatory use. This study evaluated a 0.45 kg noninvasive open ventilation (NIOV) system (Breathe Technologies), designed for nasal delivery of compressed O2 with each inhalation. This was a randomized single-blinded study of 10 men with severe-to-very severe COPD and exercise desaturation. Following a test day in which a cycle ergometer constant work rate (CWR) was established, subjects completed 3 additional days in which 2-3 CWR tests (separated by 1.5 hrs) were performed in random order. Tests were: unencumbered room air, NIOV+sair, NIOV+sO2, or O2 vs standard nasal cannula. Data collected included exercise time, SpO2 and transcutaneous (Tc) PCO2.
Subjects ages were 67±9y, with FEV1/FVC20±6% and FEV1=30±12% pred.

Responses to CWR exercise

Mean (SD). One-way, repeated-measures ANOVA. **Time**.

Exercise endurance was dramatically enhanced using the NIO2 system+O2. These data suggest that this system is a practical means to improve tolerance of everyday activities in oxygen-dependent severe COPD.

P601

The minimal clinically important difference (MCID) for the 6 minute walk (6MW) test in COPD in relation to death

Michael Polkey1, Martijn Spruit2, Lisa Edwards3, Michael Watkins1, Vincent Pinto-Plana1, Jorgen Vestbo3, Peter Calverley3, Ruth Tal-Singer2, Alvar Agusti4, 5, Per Jakobsen5, Harvey Coxson3, David Lomas1, William MacNee6, 7, Steven Rennard8, Edwin Silverman9, 10, Bruce Miller11, Courtney Crim12, Julie Yates12, Emiel Wouters1, Bartloome Celis1, 12, Consultant Physician, Royal Brompton Hospital, London, United Kingdom; 2Program Development Centre, CIBRO, a Centre of Expertise for Chronic Organ Failure, Horn, Netherlands; 3GSK, GlaxoSmithKlineC, Research Triangle Park, NC, United States; 4Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, United States; 5Department of Respiratory Medicine, University of Manchester, United Kingdom; 6Department of Respiratory Medicine, School of Clinical Sciences, University of Leeds, Leeds, United Kingdom; 7Galaxy Initiative, GlaxoSmithKline, Boston, MA, United States; 8Institute of Respiratory Medicine, University of Manchester, United Kingdom; 9Department of Respiratory Medicine, School of Clinical Science, University of Leeds; 10randomly selected, GlaxoSmithKline, King of Prussia, PA, United States; 11Institut del Tòrax, Hospital Clinic, IDIAPRS, CIBER Enfermedades Respiratorias and Fundación Caubet-Cimera, Barcelona, Spain; 12Institute of Medicine, University of Bergen, Norway; 13Department of Radiology, Vancouver General Hospital, University of British Columbia, Vancouver, BC, Canada; 14Department of Medicine, Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom; 15ELEG5 Colt Research Unit, University of Edinburgh/MRC Centre for Inflammation Research, The Queen’s Medical Research Institute, Edinburgh, United Kingdom; 16Division of Pulmonary, Critical Care, Allergy and Sleep Medicine, University of Nebraska Medical Center, Omaha, NE, United States; 17Channing Laboratory, Brigham & Women’s Hospital, Boston, MA, United States

Introduction:
The 6MW is used to assess interventions in COPD but existing esti-
mates of the MCID for this test have been derived from narrow cohorts where a non-blinded
intervention, for example pulmonary rehabilitation, has been applied.

Objective:
To define the MCID for 6MW distance in an unselected population.

Methods:
Data from the ECLIPSE cohort were used. Briefly 2112 patients were
prospectively followed for 3 years in a multicentre study. We defined an index
event as death or first hospitalisation and calculated the change in 6MW (Δ6MW)
in the last 12 month period before the event occurred. If a patient did not have an
event as death or first hospitalisation and calculated the change in 6MW (Δ6MW)
requiring hospitalisation in the EB group (mean difference -0.5, 95% CI -0.8 to -0.2, p=0.003) but not the B group (mean difference
were recorded as outcomes. Exacerbations were defined by changes in the 14-item,
Exacerbations of Chronic Pulmonary Disease Tool (EXACT), which was filled
by patients who were discharged with the EDS-AA service. There was a significant reduction in
the 12 month exacerbation rate requiring hospitalisation in the EB group (mean
difference -0.5, 95% CI 0.8 to -0.2, p=0.003) but not the B group (mean difference
0.0, 95%CI -0.4 to 0.3, p=0.865). Mortality was not different in patients on the
EDS-AA service compared to those that were not (13% vs. 9%, p=0.43)

Conclusion:
The institution of a specialised EDS-AA service at our hospital was
associated with reductions in COPD exacerbations requiring hospitalisation & has
significant cost implications.

P603

Doctors’ awareness of the Gold standard framework (GSF) for palliation in chronic obstructive pulmonary disease (COPD)

NSAugsdorff1, N. Gamers2, M. Gaunt3, D.C. Lee1, H. Burhan2, J. F. Reilly1.
1Aintree Chest Centre, University Hospital Aintree, Liverpool, Merseyside, United Kingdom; 2Respiratory Department, Royal Liverpool University Hospital, Liverpool, Merseyside, United Kingdom

Background:
The GSF aims to improve the quality of patient care in the final
year of life, to reduce hospitalisation by reducing length of stay, to facilitate rapid
discharge and admission avoidance thereby reduce costs and improving
cost effectiveness.

Aims:
To assess the awareness of the GSF programme in COPD amongst the
doctors and nurses working in various grades from February 2011 to February 2012 in two University hospitals.

Methods:
An anonymous questionnaire was administered to doctors and nurses who had EXACT-defined COPD exacerbations (mean change = 15 units) over 1200+
total patient-days of observation. Exacerbation durations ranged from 1 to 11 days.

Mean daily physical activity on exacerbation days tended to be lower than on
non-exacerbation days: moderate activity, 70±12 vs. 74±10 minutes (p=0.01); and very vigorous
activity, 6±4 vs 1±3.3 minutes (p = 0.07). in summary, this longitudinal study suggests that physical activity decreases during COPD exacerbations.

P604

Early discharge COPD experience: Reduction of severe exacerbations requiring hospitalisation

Joanne King, Rachel Arnold, Richard Russell, Mona Rafaetheus, Respiratory Medicine, Heatherwood & Wexham Park Hospital NHS Foundation Trust, Slough, Berkshire, United Kingdom

Introduction:
Hospital at home schemes for COPD exacerbations are used but
evidence to support them with reductions in exacerbations or mortality has not
been well validated

Method:
Data 12 months pre & post instigation of an early discharge with admis-
sion avoidance service (EDS-AA) was available to COPD exacerbation patients
hospitalised at our hospital, providing care to a population of 450000, covering
the Bucks (B) & East Berks (EB) area. Currently only patients from EB qualify
for care with the EDS-AA team. The EDS-AA team takes patients home within 5
days of admission & offer support for 10 days after. Subsequent to this, patients
are offered direct EDS-AA team access, including home visits,telephone advice &
self-management strategies

Result:
Data was available in 95 COPD patients hospitalised with a severe COPD
exacerbation. The mean (range) age was 75 (48-99) years & severity of COPD was
classified as GOLD I, II, III & IV in 5%, 33%, 31% & 31% of patients. The
mean (range) exacerbation frequency prior to the EDS-AA service was 1 (0-4)
in all patients. 64% of exacerbations occurred in patients from the EB group &
were discharged with the EDS-AA service. There was a significant reduction in
the 12 month exacerbation rate requiring hospitalisation in the EB group (mean
difference -0.5, 95% CI 0.8 to -0.2, p=0.003) but not the B group (mean difference
0.0, 95%CI -0.4 to 0.3, p=0.865). Mortality was not different in patients on the
EDS-AA service compared to those that were not (13% vs. 9%, p=0.43)

Conclusion:
The institution of a specialised EDS-AA service at our hospital was
associated with reductions in COPD exacerbations requiring hospitalisation & has
significant cost implications.
P605 Factors affecting physical activity in patients with air pollution-related illness compared to patients with COPD

Nanna Miyamoto1, Naoto Kikukawa2, Chika Kitagawa3, Hideoe Senju1.
1Medical Science, Nagasaki University Graduate School of Biomedical Science, Nagasaki, Japan; 2Rehabilitation, Nagasaki Pulmonary Rehabilitation Clinic, Nagasaki, Japan; 3Internal Medicine, Nagasaki Pulmonary Rehabilitation Clinic, Nagasaki, Japan

Background: The survival of chronic obstructive pulmonary disease (COPD) patients has been reported to be associated with physical activity (PA). However, there have been no reports concerning PA in patients with air pollution-related illness (API), who have symptoms of dyspnea similar to COPD patients.

Objective: We investigated the factors affecting PA in patients with API compared to COPD patients.

Methods: The study subjects were 30 patients with API and 38 COPD patients. The MRC dyspnea scale (MRC), pulmonary function, muscle strength, six minute walking test (6MWT), incremental shuttle walking test (ISWT), ADL score, SGRQ, CES-D and PA were measured. PA was assessed using a multisensor accelerometer that records steps and energy expenditure for 7 consecutive days after admission for pulmonary rehabilitation. An analysis was performed to examine the differences between the two groups in order to identify the factors that influence PA in patients with API.

Results: Patients with API had significantly better pulmonary function compared with COPD patients (p<0.001). However, their leg strength, exercise tolerance and QOL were significantly worse (p<0.01), and a higher incidence of depression symptoms were seen in patients with API (p<0.05). On the other hand, the differences of MRC and PA were not significant between the two groups. PA of patients with API was correlated with the MRC, %VC, ISWT and ADL score, while PA of COPD patients was not. PA of patients with COPD did not differ from inactive by gender, age, smoking status, somatic co-morbidities, or BMI. Activity correlated significantly with patients’ reported dyspnea (r=0.32, p<0.001), quality of life (r=-0.25, p<0.001), mobility disability (r=-0.37, p<0.001), and bronchial obstruction (r=0.18, p<0.001). Sensation of dyspnea related to physical inactivity. When COPD patient suffers from dyspnea, actions should be taken to promote physical activity.

P606 Mortality of the COPD, a two years retrospective study

Britt-Marie Sundblad1, Sven-Arne Jansson1, Leonard Nyström2.
1Physical Therapy Department, West University of Timisoara, Physical Education and Sport Faculty, Timisoara, Romania; 2Physical Therapy Department, West University of Timisoara, Physical Education and Sport Faculty, Timisoara, Romania

Results: The survival of chronic obstructive pulmonary disease (COPD) patients, indicate that the diagnosis of COPD is made late. The generally high length of life together with short time with COPD in women is a consequence of COPD.

Aim: To describe the disease and the care of COPD patients during their last two years. The aim was also to find out whether there is gender and/or regional differences with regard to terminal COPD care in Sweden.

Method: Retrospective collection of data from patients records from all patients who died due to COPD in 2003 and 2004, in one urban and one rural area, covering 19% of the Swedish population. A questionnaire was developed for collection of information.

Results: Out of 822 deaths from COPD, sufficient information was found for 729 (89%) records who died in 2003-2004 with COPD as the underlying cause of death. Median disease duration was 6.0 (range 0.36-36 years) with no difference by gender or area and the diagnosis was based on lung function measurement in 47% of the patients.

Median age at death was 78 (range 52.96) years in women and 80 (51.99) in men (corresponding figures for all who died in 2003 in Sweden were, 82.6 and 78.1, respectively). The proportion of current smokers at the time of death was 41% in women and 33% in men (p=0.02).

Most of the patients died at hospital (68%) while 13% died at home. Care days during the two last years were in average 23 days and in 63% of the patients a history of one or more exacerbations were reported.

Conclusions: In Sweden women become 4 years older than men but women with COPD had shorter length of life than had men. This indicates a faster COPD-course in women. The generally high length of life together with short time with COPD diagnosis, indicate that the diagnosis of COPD is made late.

P607 Subjective sensation of dyspnea relates to physical inactivity in COPD

Milla Katunar1, Henna Kuppipaita, Pirita Rantanan, Ari Lindqvist, Heikki Tikkanen, Marita Kilpeläinen, Tarja Laitinen. Clinical Research Unit for Pulmonary Diseases and Division of Pulmonology, Helsinki University Central Hospital, Helsinki, Uusimaa, Finland; Dept of Pulmonary Diseases and Clinical Allergology, Turku University Central Hospital, Turku, Uusimaa-Suomi, Finland; Dept of Sports and Exercise Medicine, Institute of Clinical Medicine Helsinki University and Foundation of Sports and Exercise Medicine, Helsinki, Finland

Background: The importance of physical activity in COPD has been recognised. Physical inactivity relates to exacerbations, hospitalisations and mortality. We don’t know why significant proportion of patients who have severe disease can maintain physical activity, while others turn inactive at early stages of the disease. More information is needed about the factors behind physical activity.

Aim of the study: The aim was to study physical activity in well defined COPD patient cohort. We asked about daily life activity, history in sports and barriers for exercising.

Methods: The study was postal survey of the COPD cohort (N=719) recruited in Helsinki and Turku University Central Hospitals and followed since 2005. Validated questions were chosen to evaluate physical activity, dyspnea, and quality of life.

Results: Fifty percent of the participants exercised >2 times a week throughout the year. Participants showed great variation in activity and sport choices. Active patients did not differ from inactive by gender, age, smoking status, somatic co-morbidities, or BMI. Activity correlated significantly with patients’ reported dyspnea (r=0.32, p<0.001), quality of life (r=-0.25, p<0.001), mobility disability (r=-0.37, p<0.001), and bronchial obstruction (r=0.18, p<0.001). Sensation of dyspnea related to physical inactivity. When COPD patient suffers from dyspnea, actions should be taken to promote physical activity.

P608 Increase motivation and efficiency in cystic fibrosis teenagers using sport activities, respiratory muscle training and airway clearance techniques

Bogdan Altugan Geta1, Claudia Avram2, Alexandra Mihaela Rusu3, Cornelia Olivia Cluci4, Mihaela Gravinan5, Zoran Popa6, Sebastian Gheolohan7.
1Physical Rehabilitation and Sport Department, Polyclinic Timisoara, Romania; 2Physical Therapy Department, West University of Timisoara, Romania; 3Physical Rehabilitation, Victor Babes University of Medicine, Timisoara, Romania; 4Department of Gynecology, Victor Babes University of Medicine, Timisoara, Romania; 5Management in Public Nourishment and tourism, USAVMB, Timisoara, Romania

Purpose: This study is aiming to demonstrate the efficiency of combined physio-therapy techniques: clearance techniques, respiratory muscle training (RMT) and sport activities, in order to improve clinical outcomes and quality of life in cystic fibrosis (CF) teenagers.

Method: This prospective study was conducted in the Romanian Cystic Fibrosis Centre and included a number of 40 patients, aged between 12 and 18 years. We have used classic techniques of clearance in the daily physiotherapy: the active cycle of breathing techniques, autogenic drainage, oscillating PEPP, high frequency chest wall oscillation (5 times a week), sport programmes (2-4 times a week) and RMT (3 times a week using TrainAir computer system). We have evaluated at baseline and after 24 months of intervention the quality of life (using CFQOL questionnaire) and functional respiratory parameters FVC, FEV1, FEV2,75-95. The statistical processing of data was made using a non-parametric test: the Wilcoxon matched pairs test.

Results: On a long term we noticed a substantial improvement in the clinical outcomes (less acute respiratory hospitalization and medication) and CFQOL scores. We also noticed significant statistical difference (p<0.05), from initial vs. final evaluation in de functional respiratory parameters.

Conclusions: All cystic fibrosis patients should be encouraged to combine airway clearance techniques with respiratory muscle training and sport activities for better inclusion and quality of life.

Acknowledgements: This paper was supported by a research grant from UEFIS-CDI Romania, code TE 36.
Mortality has decreased by 12% compared to previous data (Pilcher et al Thorax 2005). Mortality is lowest in the NMD and other neurological conditions groups. Complete ventilator independence was most common in the COPD and post surgery groups. The data indicates improved survival and weaning success in the group admitted to the LPU compared to those accepted but not transferred.

P610
The impact of COPD care bundles on compliance of care in northwest London
Lauren Lennes, Urvashi Sharma, Hannah Musgrave, Medicine, Imperial College, NIHR CLAHRC for Northwest London, London, United Kingdom

Background: Chronic Obstructive Pulmonary Disease (COPD) is one of the most common respiratory diseases in the UK, causing around 25,000 deaths a year and with a large portion of patients not receiving ideal care for COPD exacerbations. Care bundles, a sequence of evidence based interventions, have been identified as a way of delivering consistent patient care.

Aims: National Institute for Health Research (NIHR) Collaboration for Applied Health Research and Care (CLARHC) for Northwest London implemented COPD discharge care bundles across 7 sites over 18 months (beginning in April 2009) to improve compliance to existing evidence based interventions.

Methods: The COPD discharge care bundles initially included smoking cessation, pulmonary rehabilitation, patient information on self-management, inhaler technique training, and follow-up appointment. Each of the sites adapted the bundle according to available resources and local settings. Weekly data on compliance was entered into a web reporting tool.

Results: The results from the data showed that 1052 patients were discharged with the care bundle, 668 of these patients were discharged having received all the elements of the care bundle (63.5% were fully-compliant). The bundle element with the highest overall compliance was smoking cessation with 92.5%, and lowest was recorded with the follow-up appointment at 77.8%. Overtime improvement to overall compliance was seen across all sites.

Conclusions: This study reveals aspects that impact compliance of care with COPD care bundle elements. The findings offer valuable lessons to future sites interested in implementing COPD care bundles and should be considered in order to improve COPD care.

P611 COPD acute exacerbation care self-audit in public hospitals in Catalonia (Spain)
Joan Escarrabill, Elena Torrente, Cristina Esquinas, Carme Hernández, Eduard Monsó, Montserrat Freixas, Pere Almagro, Ricard Tresserras. Evaluation Area & Master Plan for Respiratory Diseases (PDMAR), Catalan Agency for Health Technology Assessment and Research (CAITAS), Barcelona, Catalonia, Spain Evaluation Area & Master Plan for Respiratory Diseases (PDMAR), Catalan Agency for Health Technology Assessment and Research (CAITAS), Barcelona, Catalonia, Spain, Spain Evaluation Area & Master Plan for Respiratory Diseases (PDMAR), Catalan Agency for Health Technology Assessment and Research (CAITAS), Barcelona, Catalonia, Spain, Spain Evaluation Area & Master Plan for Respiratory Diseases (PDMAR), Catalan Agency for Health Technology Assessment and Research (CAITAS), Barcelona, Catalonia, Spain, Spain

Aims: To carry out a self-audit to survey the quality of care provided to patients admitted with Chronic Obstructive Pulmonary Disease (COPD) acute exacerbation.

Methods: All 48 acute hospitals with chest unit in Catalonia were invited to complete a retrospective clinical self-audit comprising up to 40, 30 or 20 consecutively admitted episodes of COPD exacerbation (according to the size of the hospital measured through the annual COPD discharges: >400 (Group 1), 100-400 (Group 2), <100 (Group 3)). Results are presented as median, mean or ± standard deviations. Comparisons between hospitals were performed using one way ANOVA.

Results: Data for 910 episodes from 30 hospitals (62.5%) were received (a sample of >70% of discharges). Age 74.9±9.8, males (83.3%), FEV1 41±15, mean of Charlson index by age 4.5±2. Median previous year respiratory admissions=2, IQ=1.3. Mortality: inpatient (4.4%), 90 days (4.4%). Readmission rate (RR) at 90 days: 23%. Mean length of stay (LOS): 8 days (SD=7). A significant variation was observed between the 3 hospitals groups: 8 (SD=6), 9 (SD=4), 7 (SD=5), (p<0.0001). There were no significant differences in inpatient mortality but there were significant differences in 90 day hospital RR (26% vs 23% vs 16%, p<0.045) and 90 day mortality (4% vs 5% vs 8%, p=0.050). In the discharge report there was information on smoking habit (35%, in smokers’ patients), ABG room air (18%) and lung function (52%).

Conclusion: We observed a considerable variation in the care provided between hospitals with a high variability in LOS, 90 day RR and 90 day mortality. The information in discharge report should be improved.

P612 Effect of cough on health-related quality of life in COPD
Helene Bellas 1,2, Bronwen Connolly 3, Surinder Biring 3, Billie Hurst 2

Physiotherapy Department, King’s College Hospital, London, United Kingdom; 2School of Health Sciences, Queen Margaret University, Edinburgh, United Kingdom; 3National institute of Health Research Comprehensive Biomedical Research Centre, Guy’s and St. Thomas’ NHS Foundation Trust and King’s College, London, United Kingdom;

Background: Current disease-specific health related quality of life (HRQL) measures in COPD focus on symptoms such as breathlessness, fatigue, mastery and social disease aspects. HRQL is known to be affected in idiopathic cough patients and given the reported prevalence of cough in COPD, determining its effect on HRQL is justified.

Aim: Determine the relationship between cough and HRQL in COPD.

Method: Consecutive, unselected participants with COPD were recruited from outpatient clinics. Those who met eligibility criteria completed a set of questionnaires; COPD Assessment Questionnaire (CAT) to determine the presence of cough. The Leicester Cough Questionnaire (LCQ) as a cough-specific, HRQL measure and Cough Visual Analogue Scale (VAS) to indicate self-reported cough severity.

Results: Forty participants were recruited. Baseline demographics showed a mean (±SD) age of 65.2 (±11.9) years, mean (±SD) FEV1% predicted of 49.0% (±18.6), the majority of the sample was of Caucasian background (80%) and the group was well matched in terms of gender (M:F, 22:18). Median (IQR) CAT cough score (5) was shown to be 3 (2-3.5), no participant selected 0 which would indicate ‘no cough at all’. Mean (±SD) VAS score 50.0 (±27.0). Median (IQR) LCQ scores (2/1) were found to be 16 (11.8-18.6), for the group as a whole with the physical domain showing the poorest score of all domains. Median LCQ score decreased with an increasing CAT score. A significant inverse relationship was evident between median LCQ score and VAS (r = 0.70, p<0.0001).

Conclusions: Cough was prevalent in a cohort of stable COPD patients with moderate to severe disease severity. Furthermore, increasing cough severity is associated with greater impairments in HRQL.

P613 Physical activity and sleep duration following hospitalisation with exacerbation of COPD vs. stable COPD & age matched controls
Dilber Yilmaz 1, James Dodd 1, Dinesh Shrikrishna 2, Nick Hopkinson 2

1Clinical Sciences, St. George’s University, London, United Kingdom; 2Muscle Laboratory, Royal Brompton Hospital, London, United Kingdom

Background: Exacerbations are known to reduce physical activity, but little is known about their effect on sleep.

Aim: This study measures physical activity and sleep quantity in participants recovering at home following hospitalisation for a COPD exacerbation and compares them with stable COPD patients and controls.

Methods: We recruited 23 COPD patients immediately following hospital admission for exacerbation (Acute), 34 stable COPD patients (Stable) and 19 age-matched people (Control). Physical activity and sleep duration were measured...
P614 Changes in physical activity and sleep duration following hospitalisation with acute exacerbation of COPD

Dilber Yılmaz1, James Dodd2, Dinesh Shrikrishna3, Nick Hopkinson3.

Objective: To investigate the effects of the past year of a home care based, respiratory therapist centered transition of care program for patients who require home oxygen therapy following hospital admission for an exacerbation.

Methods: To evaluate the effects over the past year of a home care based, respiratory therapist centered transition of care program for patients who require home oxygen therapy following hospital admission for an exacerbation. The 30 day rehospitalization rate (5%) for those patients who required supplemental oxygen on discharge was significantly lower than the historically observed rates (25%) in the Western Pennsylvania area.

Results: 555 patients from 23 different hospitals in the Western Pennsylvania area were enrolled into the program from March 2010 through February 2012. The primary discharge diagnosis was: COPD 69%; CHF 14%; hypoxemia 6%; pneumonia 4%; and other 7%. The overall readmission rate for the entire group was 5%. The 30 day readmission rate for those with COPD was 3% and for those with CHF was 3%.

Conclusions: With the use of this novel respiratory therapist based transition of care program, the 30 day rehospitalization rate (5%) for those patients who required supplemental oxygen on discharge was significantly lower than the historically observed rates (25%) in the Western Pennsylvania area.
at HH can be useful to improve functional capacity and quality of live in these patients. Nevertheless, to assess exercise tolerance at home complexity is complex. The modified Glittre ADL-Test is a measure of functional status that we have adapted to patient’s home.

**Objective:** Analyze the modified Glittre ADL-Test as a tool to measure exercise tolerance during an AECOPD at HH.

**Method:** 17 AECOPD patients, 15 males (median (ICR): 66 (60-84) years, FEV1 38% (29-44) predicted) attended at HH accepted to participate and completed 3 visits (V1: HH discharge, V2: 10 days post discharge, V3: 1 month post discharge). Outcomes: 3) Modified Glittre ADL-Test: laps (m), VO2 and VE; 2) COPD Assessment Test; 3) MMRC and London Chest Activities of Daily Living (LCADI); 4) Modified Baecke (V1 and V3); 5) Handgrip.

**Results:** Modified Glittre ADL-Test laps increased (4 vs 5 l/min, p<0.005), VO2 per lap (242 vs 229 vs 177 mL/min, p<0.03) and VE per lap increased (7 vs 7 vs 5 L/min, p<0.01). CAT (18.5 vs 11.5 vs 12, p<0.01), MMRC (2 vs 1.5 vs 1, p<0.01) and Modified Baecke (4 vs 14, p<0.01) also significantly improved between each assessment. There were no differences in Handgrip or LCADI.

**Conclusion:** Modified Glittre ADL-Test was suitable to measure exercise tolerance following an AECOPD attended at patient’s home.

**P619 Six minute walking test in chronic respiratory failure: Which reflects the patient clinic status, walking distance or %predicted value?**

Zuhal Karakurt, Gökay Güngör

**Aim:** Six minute walking test (6MWT) with limited values are limited for the patients who has been prescribed noninvasive mechanical ventilator due to chronic respiratory failure (CRF).

**Methods:** 6MWT is performed in patients during June–December 2011 who were already using HMW due to CRF and followed in our polyclinic. WD, ideal and lower limit of normal WD according to gender, age, BMI and %predicted of ideal values were calculated. Parameters that recorded during standard 6MWT and %predicted values were compared according to arterial blood gas (ABG), spirometry values and concomitant diseases.

**Results:** Correlation of WD and %predicted values for spirometry and ABG values of 144 patients were shown in Table 1.

**Conclusion:** Predicted % values of 6MWT are better correlated with respiratory functions than WD for patients who use HMV due to CRF.
Objective: To compare functional (torque) and metabolic (deoxygenation) effects of NMES at increasing levels of stimulation in patients with COPD and age- and gender-matched controls.

Methods: Fifteen males with moderate-to-severe COPD (FEV1 = 46.2±18.1% pred) and 10 controls underwent high-frequency (50 Hz) NMES at 20 to 50 mA. Torque was measured by isokinetic dynamometry, muscle deoxygenation (HHb) by near infrared spectroscopy, and muscle mass by DEXA.

Results: Maximal voluntary contraction (MVC) was significantly higher in patients than controls; these differences, however, disappeared after muscle mass correction (p = 0.05). There were progressive increases in torque and HHb with amplitude of stimulation in both groups. Although absolute torque at given level of stimulation was systematically lower in patients, MVC-corrected values were similar (20 ± 50 mN and 57 ± 3±7% and 24.4±8.4% in patients and 64±5±2 and 22.4±10.0% in controls, respectively). Moreover, there were no between-group differences in HHb (% cuff-induced maximal) across the stimulation intensities (p = 0.05).

Conclusions: Our results indicate preserved functional and metabolic responses to NMES in non-depleted patients with moderate to severe COPD. These data suggest that they might derive full physiological benefit from this intervention.

Phyllis Murphie
CREWS – A validation pilot
suggest that they might derive full physiological benefit from this intervention.

Conclusions: We interrogated the Patient Outcomes and Information Service (POINTS) database of participating practices in the UK. The POINTS provided by GlaxoSmithKline UK Ltd as a service to medicine is delivered by Quintiles Data was collected between 2007-08 and 2009-10.

Results: 1265 GP practices had a list size of 7 million with 160000 COPD patients. 911 practices returned total list sizes (1.7% prevalence of COPD) 51,000 (32%) had a COPD review recorded yet 85,000 (53%) had spirometry recorded within 15 months, 124,600 had flu and/or pneumococcal vaccination status recorded (82%) which only 15% had exacerbation frequency recorded. Increases in MRC dyspnoea score (MRCD) recording occurred from 2007 at 28% to 44% in 2009 (p < 0.001). The most common prescription was short acting β agonist SABA in 67%, ICS/LABA combi inhaled in 47%, LAMA in 30%, 24,000 (15%) were prescribed an ICS inhaler (outside of licence and against NICE guidelines). 19000 patients with mild airflow limitation were on ICS-LABA beyond licence (FEV1 60-80%). We found 10,000 potentially misdiagnosed patients with FEV1 < 80%; of these 38% were on ICS-LABA and 20% were on LAMA.

Conclusions: Over-treatment of mild COPD with ICS-LABA or LAMA is frequent. Exacerbations rates were poorly recorded suggesting incomplete COPD reviews which may lead to failure of appropriate management. Exacerbation frequency recording should be incorporated into QOF pay.

P625
Current COPD care in the UK – Data from 160000 patients in the POINTS database
Anthony De Souza1, Kate Best2, June Roberts3, 1Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 2Statistics and Epidemiology, Institute for Health and Society, Newcastle University, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 3Salford Royal NHS Foundation Trust, Salford Royal NHS Foundation Trust, Salford, United Kingdom

Background: COPD is a major UK healthcare cost. Differing standards of care exist e.g. those qualifying for payment. Quality & Outcomes Framework (QOF) vs. patient-focused incentivised NICE guidelines.

Aims: To define a large UK wide COPD cohort and describe their primary care management compared to these standards.

Methods: We interrogated the Patient Outcomes and Information Service (POINTS) database of participating practices in the UK. The POINTS provided by GlaxoSmithKline UK Ltd as a service to medicine is delivered by Quintiles Data was collected between 2007-08 and 2009-10.

Results: 1265 GP practices had a list size of 7 million with 160000 COPD patients. 911 practices returned total list sizes (1.7% prevalence of COPD) 51,000 (32%) had a COPD review recorded yet 85,000 (53%) had spirometry recorded within 15 months, 124,600 had flu and/or pneumococcal vaccination status recorded (82%) which only 15% had exacerbation frequency recorded. Increases in MRC dyspnoea score (MRCD) recording occurred from 2007 at 28% to 44% in 2009 (p < 0.001). The most common prescription was short acting β agonist SABA in 67%, ICS/LABA combi inhaled in 47%, LAMA in 30%, 24,000 (15%) were prescribed an ICS inhaler (outside of licence and against NICE guidelines). 19000 patients with mild airflow limitation were on ICS-LABA beyond licence (FEV1 60-80%). We found 10,000 potentially misdiagnosed patients with FEV1 < 80%; of these 38% were on ICS-LABA and 20% were on LAMA.

Conclusions: Over-treatment of mild COPD with ICS-LABA or LAMA is frequent. Exacerbations rates were poorly recorded suggesting incomplete COPD reviews which may lead to failure of appropriate management. Exacerbation frequency recording should be incorporated into QOF pay.

P626
The need for the integrated care for advanced COPD patients in the northern Poland (Pomerania)
Iwna Dampa-Konstanska1, Lidia Werachowska4, Amelia Szymanowska-Narloch3, Piotr Krzakowski3, Małgorzata Kaczmarsk2, Ewa Jassem1, 1Department of Allergology, Medical University of Gdansk, Poland; 2Department of Pneumonology, Province Hospital, Chojnice, Poland; 3Department of Sociology, and Education, University Nicolaus Copernicus, Torun, Poland; 4Department of Nursing, Medical College, Chojnice, Poland

COPD is one of the most prevalent chronic disease, significantly increasing morbidity and mortality in developed countries. Symptom control and preventing risk of exacerbation is the main goal in the management of COPD. Poor compliance and insufficient self-management, especially in the more advanced patients are recognized causes of increased exacerbation rate. Currently, in the Northern Poland the model of integrated care for advanced COPD patients is to be introduced. However little is known about the need and acceptance for such a care among patients and their relatives. Thus, the aim of this initial study was to assess the QoL (using SGRQ) in 30 consecutive advanced COPD patients living one of the small towns in Pomerania and their acceptance for continuing support (two times a week during one month) delivered in their homes (assessed by specially constructed questionnaire). Home intervention included two-hours meeting (structured as follows: 30 min of education including assessment of the proper use of inhalators and medications intake, 30 min of physical activity, 30 min of small-talk focused on the subject proposed by patient, and 30 min of the assessment of symptoms, palsoximetry and PEF measurement) with medical caregiver. Results demonstrated poor QoL in the study group during the stable period of the disease (total score of SGRQ – mean: 71; range: from 24 to 91) and the full acceptance for the home support (28 patients were very satisfied, 2 were satisfied). These findings confirmed the need for integrated care in Pomerania and chance for realization of the program.
P627 Family care in advanced COPD: Perceived difficulties and expectations of support from services
Ana Pereira1, Daniela Figueiredo1,2, Alda Marques1,2. 1Escola Superior de Saúde, Universidade de Aveiro, Portugal; 2Unidade de Investigação e Informação Sobre Adultos e Idosos, Universidade do Porto, Portugal

Chronic Obstructive Pulmonary Disease (COPD) is an incapacitating, highly prevalent disease which often requires intensive support from patient’s family members. However, knowledge about the difficulties experienced by family members in their caregiving role remains scarce. This study aimed to explore the difficulties experienced by family carers, and their expectations towards social and health support services.

A qualitative, cross-sectional study was conducted with 21 family carers of COPD patients at advanced grades (GOLD 3 and 4). Semi-structured interviews were performed to collect data. Participants were mostly female (n=20), with a mean age of 60.9±12.35 years old, spouses (n=12) and caring for more than 4 years (n=18). All interviews were audiorecorded, transcribed and submitted to content analysis by 2 independent judges.

The major difficulties reported are related to: i) provide support in basic [washing (n=1), dressing (n=2)], and in instrumental activities of daily living [preparing meals (n=4)]; ii) communication with patient (n=2); and iii) restrictions in social activities (n=2). Six carers did not identify any difficulty. Most of participants (n=12) could not identify how formal support services could help them. They lack of information about community resources might explain these results. Strategies towards effective flow of information must be addressed in order to prevent caregivers’ burden.

P628 Rehospitalization rates for patients with pneumonia who require supplemental oxygen therapy following hospital discharge
Brian Carlin1, Kim Wiles2, Dan Esleby1. 1Pulmonary and Critical Care Medicine, Allegheny General Hospital, Pittsburgh, PA, United States; 2Medicine, Klingensmith HealthCare, Ford City, PA, United States

Objective: To compare the hospital readmission rates for patients with pneumonia who require supplemental oxygen therapy following an exacerbation who are entered into a home-care based, respiratory therapist centered transition of care program.

Method: Patients with a diagnosis of pneumonia who required supplemental oxygen therapy on hospital discharge were entered into a post hospitalization transition of care program (Discharge, Assessment and Summary @ Home (D.A.S.H., Klingensmith HealthCare, Ford City, PA)). Patients with a diagnosis of COPD were excluded from this analysis. The program consists of face to face visits by a respiratory therapist with the patient on days 2, 7, and 30 following hospital discharge. Education, behavior modification, skills training, oxygen titration during performance of activities of daily living, clinical assessment, and adherence data collection are components of the program. The 30 day readmission rates following discharge for those patients entered into the program over a twenty four month period were evaluated.

Results: 22 consecutive patients with pneumonia from 23 different hospitals were enrolled into the program over the two year period. None (0%) of the patients were rehospitalized within the first thirty days following hospital discharge.

Conclusions: The use of a multiple visit respiratory therapist based patient centered management program resulted in a significant decrease in the 30 day readmission rates for those patients who were discharged following a hospitalization for pneumonia.

P629 Psychological distress in asthma and COPD
Bransilava Milenevkov1,2, Aleksandra Ilic1,2, Sanja Dunic-Ianic1,2. 1Faculty of Medicine, University of Belgrade, Serbia; 2Clinic for Pulmonary Diseases, Clinical Center of Serbia, Belgrade, Serbia

Background: The effective control of asthma requires a treatment regimen that may be compromised by psychological factors, such as anxiety and depression.

The aim of our study is to estimate the prevalence of anxiety and depression among adults with stable persistent asthma.

Methods: We analyzed the data from 50 adult patients with persistent asthma (group A). Fifty patients with COPD (GOLD II-IV) were the control group (group B). The pulmonary function test was performed by spirometry. Depression and anxiety scores were assessed by Hospital Anxiety and Depression Scale. The prevalence of anxiety and depression was calculated in both groups and the difference between groups was estimated. The correlation between pulmonary function parameters and psychological distress was calculated.

Results: The anxiety score in Group A was 6.2±2.3 and in Group B 7.87±2.35. The depression score in Group A was 4.9±2.4 and in Group B 7.97±4.04. The difference between groups was significant for both anxiety and depression (p<0.05).

There was no correlation between psychological status and pulmonary function tests in group A (p>0.05) and in group B (p>0.05).

Conclusion: This research suggests the importance of psychological distress screening for patients with persistent asthma, as COPD also. Further studies are needed to examine the correlations between the severity of the respiratory disease and mental status and to target the psychological factors that contribute worsening asthma and COPD.

P630 Influence of anthropometric characteristics in respiratory reserve volume of morbidly obese subjects
Eli Maria Pazzianoto-Forti1, Fabiana Peixoto-Souza1, Camila Picioni-Mendes1, Letícia Baltieri1, Marcela Barbalho-Moulin2, Ireneu Rasera-Junior1, Elisane Pessotti2, Dircet Costa3. 1Physical Therapy, Methodist University of Piracicaba, Piracicaba, SP, Brazil; 2Physical Therapy, Federal University of São Carlos, SP, Brazil; 3Gastroenterology Center and Obesity Surgery, Bariatric Clinic, Piracicaba, SP, Brazil

Introduction: The reduction of the respiratory reserve volume (ERV) is considered the most consistent finding for changes in lung function in morbid obesity. The importance of decreased ERV in morbid obesity is attributed to the known association between these volumes with the closure of small airways, which causes hypoxemia.

Objective: To correlate ERV with anthropometric characteristics of morbid obese women.

Methods: Cross-sectional study with morbidly obese (BMI=40kg/m2) and control (BMI between 18.5 and 24.9 kg/m2), both with normal lung function. The body mass index (BMI), waist circumference (WC), waist-hip ratio (WHR), and neck circumference (NC) were measured. Subsequently, pulmonary function test were performed.

Results: A total of 30 morbidly obese (BMI 44.1±14.1 kg/m2) and 30 lean women (BMI 22.1±1.18 kg/m2) were evaluated. ERV was significantly lower in obese [0.28 (0.14-0.60 L) when compared to lean women [0.74 (0.51-1.08 L)]. The percent-age of predicted values of forced expiratory volume in one second (FEV1) were significantly lower in morbidly obese (88.31±4.31L/min) when compared to lean women (102.75±13.2L/min). There were no differences in forced vital capacity (FVC), the ratio FEV1/FVC. There was negative correlation between body mass index, BMI, waist circumference (WC), waist-to-hip ratio (WHR) and neck circumference (NC) with ERV, respectively (r= -0.3757, -0.4112, -0.4711, -0.3456, -0.5145).

Conclusions: The ERV is influenced by body mass, BMI, WC, WHR and NC.

P631 Association between the mini nutritional assessment and the COPD assessment test
Ruiko Funatsu1, Takeo ibii1,2, Takashi Motei1,2, Kouichi Yamada1,2. 1Respiratory Care Clinic, 2Division of Pulmonary Medicine, Infectious Diseases, and Oncology, Dept. of Internal Medicine, Nippon Medical School, Tokyo, Japan

Background: The Mini Nutritional Assessment® (MNA) has not been studied extensively in COPD patients.

Objectives: We evaluated whether COPD patients with impaired health status as determined by the COPD Assessment Test (CAT) have poor nutritional status according to the MNA.

Methods: We recruited clinically stable male COPD outpatients (age, ≥65 years) as a cross-sectional study. We conducted the following examinations: pulmonary function tests, nutritional assessment using the MNA questionnaire (high scores indicate good nutritional status), the CAT, and dyspnea evaluation. The patients were divided into 2 groups: (A) those with CAT scores ≥10 and (B) those with CAT scores <10. We also calculated 4 scores exploring the domains of the nutritional status from the MNA questionnaire: anthropometric, general, dietary, and subjective scores.

Results: The study included 68 patients (mean age, 75.4± years). The total score was significantly correlated with FEV1% predicted, BMI, the modified Medical Research Council dyspnea score, and the CAT score (Spearman’s rank correlation coefficient, ρ = 0.298, p = 0.013; ρ = 0.701, p < 0.0005; ρ = −0.373, p = 0.002; and ρ = −0.363, p = 0.002; respectively). Group (A) (n = 47) had significantly lower total, general, dietary, and subjective scores than group (B) (n = 21) (p = 0.003; p = 0.029, p = 0.045, and p = 0.014, respectively, Mann Whitney U-test).

Conclusions: The nutritional status as determined by the MNA was associated with pulmonary function, dyspnea, and the COPD-related health status. In addition, the nutritional status as determined by the MNA was significantly lower in COPD patients with CAT scores ≥10 than in those with CAT scores <10.

P632 Usability of digital media in patients with COPD: A pilot study
Amy Cheung1, Anton Janssen1, Oliver Amft2, Emiel Wouters3, Martijn Spruit3. 1Pulmonary Care Solutions, Philips Research, Eindhoven, Netherlands; 2Signal Processing Systems, Technical University, Eindhoven, Netherlands; 3Program Development Centre, CIRO+, Centre of Expertise for Chronic Organ Failure, Horn, Netherlands

Digital media can serve as the main interface between the patient and the care-
Long-term oxygen therapy (LTOT):Retrospective audit on ten years prescriptive appropriateness

Lucia Bajerini, Marzia Sononi, Lucia Ricorutro, Carlo Barbetta, Marco Piattella, Franco Zabini, Stefano Puttini, Alfredo Potena. Respiratory Physiol-Pathology Unit, Hospital-University S.Anna, Ferrara, Italy

Background: Guidelines focus on three key issues for appropriate prescription of LTOT: patients should be nonsmokers, in a stable condition, and they should use oxygen for at least 15 h/day.

Aim: To evaluate prescriptive appropriateness in a group of patients with Chronic Respiratory Failure during a period of ten years.

Methods: 702 patients (mean age 74.1±11, 56% males) were prescribed with LTOT between 2002 and 2011. Prescriptive appropriateness based on PaO2 or non invasive SaO2, as indicated by the ERS guidelines.

Results: O2 source: 84.1% liquid, 13.5% concentrator, and 2.3% gas. Main reason for prescription was pulmonary: 88.4%, 69.1% for COPD. Among patients with PaO2 and SaO2 traceable values (n=60), the prescription resulted appropriate for 240 (39.4%). Pneumologists showed higher prevalence of LTOT inappropriate than other prescribers: difference not significant. We noted low appropriateness in the first third of the study, followed by a constant improvement: at that time we performed an educational program for all prescribers. On 2011 we noted a new drop in appropriateness.

Conclusion: The results confirm that a considerable amount of patients are inappropriately prescribed. Efforts need to improve the adherence to the published international guidelines for LTOT prescription through continuous educational programs aimed to all prescribers.
short burst, 53% ambulatory, 47% long term). The oxygen was prescribed mainly by Respiratory Nurses (40%) and General Practitioners (31%).

Methods: We enrolled 138 consecutive patients with chronic lung diseases who underwent a PR in a monocenter, prospective study (CEPRO 2011-036). The global score of the VSRQ (scored from 0 to 80 with 8 questions), SGRQ (scored from 0 to 100 with 8 parts) and HAD (scored from 0 to 42 with 7 questions for anxiety evaluation and 7 for the depression) were measured at the beginning and the end of a six week outpatient PR. HRQL improvement was measured by the increase of the VSRQ score and the decrease of the SGRQ and HAD scores.

Results: The VSRQ correlated with the SGRQ (r=-0.49, p<0.01) and the HAD (r=-0.47, p=0.01). After PR, there was a significant improvement of the VSRQ (46 vs 39, p<0.001), SGRQ (38.3 vs 42.3, p=0.019) and HAD (14 vs 15.1, NS). The VSRQ increase correlated with the SGRQ decrease (r=-0.39, p<0.01).

Conclusions: The VSRQ score correlates with the SGRQ and HAD scores. Our data demonstrate the clinical interest of this simplified test to evaluate the HRQL in PR.

88. Standard of care, incidental findings, image acquisition
In this study, we have successfully validated relative alveolar sizes as measured with the use of predictive correction factors. Lung tissue, the experimentally obtained OFDI measurements could be re-scaled on average. We discovered that the relative change in size between alveoli was extremely on potential refraction effects that are not visible in micro-CT images. Therefore, we compared the cross-sectional area, perimeter, volume, and surface area of matched subpleural alveoli from micro-CT and OFDI images. Furthermore, we developed a ray-tracing model that approximates the reconstructed alveolar size within OFDI images based on fast imaging speed (>10fps). In order to enable quantitative comparisons about alveolar behavior under various ventilation strategies or pathologies, it was crucial to investigate the validity of alveolar size measurements obtained from OFDI images. Therefore, we compared the cross-sectional area, perimeter, volume, and surface area of matched subpleural alveoli from micro-CT and OFDI images. We fixed air-filled swine samples. Furthermore, we developed a ray-tracing model that approximates the reconstructed alveolar size within OFDI images based on potential refraction effects that are not visible in micro-CT images. We observed that the relative change in size between alveoli was extremely well correlated between the two imaging techniques (r=0.9, p<0.0001), but OFDI images underestimated absolute sizes compared to micro-CT images by 27% (area), 5% (perimeter), 46% (volume), and 25% (surface area) on average. Using our model and OFDI measurements of the refractive index for fixed and fresh lung tissue, the experimentally obtained OFDI measurements could be re-scaled to approximate the micro-CT measurements with dramatically reduced error (<10% for all size parameters). In summary, we have successfully validated relative alveolar sizes as measured within OFDI images and show the potential to obtain absolute size measurements with the use of predictive correction factors.

Efficacy of chest CT in establishing the cause of primary spontaneous pneumothorax
Eline Aron-Shelton 1, Anna Chernihovski 1, Norman Loberant 1

Background: The cause of primary spontaneous pneumothorax (PSP) is thought to be a rupture of a subpleural bleb or bulla (BB). Thoracoscopy is considered the gold standard in determining the presence of BB, but this is an invasive procedure that has limitations. Recent studies have shown CT to be almost as sensitive for detecting subpleural blebs and bullae as thoracoscopy. We found CT to be a very sensitive method of diagnosing PSP in patients who underwent preoperative non-contrast chest CT followed by wedge pulmonary resection and pleurodesis through mini-thoracotomy. Results of CT, surgery, and pathological study of resected tissue were compared.

Methods: The study included 42 patients with PSP who underwent preoperative non-contrast chest CT followed by wedge pulmonary resection and pleurodesis through mini-thoracotomy. Results of CT, surgery and pathological study of resected tissue were compared.

Results: The sensitivity and specificity of CT was 96.4% and 76.5% respectively. Correlation was also found comparing the size of BB measured on CT and the pathological study. In 14 cases (30%) no BB were found on CT, during surgery or pathological examination. In all of these cases a finding known as “apical lines” (AL) was demonstrated on CT. The pathological examination of the resected lung specimens showed fibrosis and emphysema.

Conclusions: We found CT to be a very sensitive method of diagnosing BB in PSP patients. The study also demonstrated the presence of AL in PSP patients which were the radiological manifestation of limited fibrotic and emphysematous changes in the apex which may be the cause of PSP in our series of patients. Preoperative diagnosis of the cause of PSP helped to employ the proper surgical technique and to prevent recurrence of PSP.

Assessing the standard and accuracy of chest x-ray reporting by medical physicians in an acute medical take
Imran Sarita 1, Raawama Ahmed 1, Farzad Zaman 1, Stuart Mellore 2

Introduction: The reporting of CXRs for medical patients admitted to hospital was across Europe. Comparison between physicians and radiology reporting has suggested radiologists provide improved quality (1) and accuracy (2) of reporting. In our trust the radiologist report on all the admission CXRs but this may not be available at the time of physician review.

Aim: To assess if disagreement in reporting between general physicians and a radiologist would have an impact on the medical management of a patient.

Method: We retrospectively compared the reporting of 50 CXRs by the medical physician with that of a radiologist.

Results: The overall concordance of reporting was 78%. There were 21/50 normal CXRs of which the physician correctly reported 20/21 (95%) as normal. The remaining were either acute changes (somewhat severe change) or chronic changes (15/50, 30%). Only 6/14 (43%) acutely abnormal CXRs were reported correctly and 11/15 (73%) reported on chronic changes by the physician.

Conclusion: Correctly identifying an acute diagnosis was less than 50%, particularly differentiating between pneumonia and heart failure, yet many trusts require the physician to report on CXRs. Undergraduate and post-graduate training in internal medicine does not formally train or examine in radiology and given these findings more training and service development needs addressing for patient safety.

X-ray interpretation: A self-assessment survey
Manish Pagaria, Premnath Balakrishnan, Arun Dev Vellori, Respiratory and General Medicine, Heart of England NHS Foundation Trust, Birmingham, United Kingdom General Medicine, Heart of England NHS Foundation Trust, Birmingham, United Kingdom; 1United Kingdom; 2Department of Chest Medicine, East Lancashire NHS Hospitals Trust, Blackburn, United Kingdom; 3Department of Radiology, East Lancashire NHS Hospitals Trust, Blackburn, United Kingdom

Aim: To assess the confidence of hospital based doctors in reviewing plain radiographs.

Methods: An online e-survey tool collected responses from 600 doctors from the West Midlands area, UK. They were asked to rate their confidence as: not confident, will always need senior help; somewhat confident in interpreting some conditions; confident of routine and common conditions; very confident, seek radiology advice occasionally; highly confident, almost never seek radiology advice. We also asked them to self assess their confidence in identifying some common findings on x-rays; and collected data on any formal or informal training they had received.

Results: 241 (40%) responses were received; of these 165 were from medical and 76 from non-medical specialties. The level of confidence expressed by medical doctors in interpreting chest x-rays (48.5%) was significantly higher than abdominal (17.4%) and skeletal x-rays (6.2%). Doctors in non-medical specialties were better with skeletal x-rays (22.5%). Of the 241, 70 had been to a radiology course, 127 had some form of formal and 57 had informal training. 11 (9 medical trainees) did not have any form of training. 17/241 felt that there should be radiology training for all doctors, and it should be a compulsory part of the training portfolio.

Conclusion: There was variability in confidence amongst hospital doctors in interpreting x-rays across training grades and clinician groups. Basic radiology training as a separate competency may need to be considered in the training programmes and e-portfolio of hospital doctors. Training in chest radiograph interpretation should merit focused attention in the respiratory specialty training as well as the HERMES curriculum.

Lung ultrasound as an ambulatory investigation tool in respiratory medicine: An audit of clinical practice
Giuseppe Francesco Sferrazza Papa, Giulia Michela Pellegrino, Paolo Carlucci, Michele Mondoni, Elena Parazzini, Fabiano Di Marco, Francesca Reali, Paola Fraccasso, Massimo Verga, Sara Job, Marco Grattieri, Stefano Centanni.

Clinical di Malattie dell’Apparato Respiratorio, Ospedale San Paolo, Università degli Studi di Milano, Milan, Italy

Introduction: Lung ultrasound is an imaging tool which is increasingly used by nonradiologists physicians in the intensive care unit and the emergency department. However, there is a lack of data concerning lung ultrasound directly provided by the pulmonologist during ambulatory investigations.

Methods: The study is an audit of clinical practice of the respiratory diseases ambulatory of a tertiary care university hospital. Consecutive lung ultrasounds, performed by pulmonologists, were prospectively recorded from April 2011 to...
February 2012. The main indication, methods and clinical consequences were registered on a web-database.

**Results:** 8 experienced operators performed 112 exams on 92 patients (aged 66.4 years, mean ± 49 females). The mean duration of the exam was 8.2 minutes. B-mode was used in all patients, while functions such as M-mode and Color-Doppler were needed in 10% and 4%, respectively. Convex probe was the most used as a single transducer (82% of the cases); linear probe was used in association with the convex or as a unique probe in 22% of the exams. The main indications were: pleural effusion (32%), chronic obstructive pulmonary disease (12%), pneumothorax (10%), chest pain (8%), acute exacerbation of COPD (6%), heart failure (4%), and epigastria dysplasia (2%). The pneumologist who executed the exam reported that in 72% of the cases lung ultrasound had a clinical impact, even if minor, on patient management.

**Conclusions:** The execution of lung ultrasound is a rapid and feasible imaging tool which may often provide clinically relevant data during ambulatory consultations. Further studies will be needed to evaluate the impact of lung ultrasound on the patients’ management.

One year’s experience of mobile bedside chest ultrasound service for pleural diseases in a district general hospital

Ali Al-Ameri, Jan Drost, Franco Guarasci, Clare Smart, Jawad Azim. General Medicine, Airedale General Hospital, Sheeton, West Yorkshire, United Kingdom

**Introduction/Objectives:** The role of chest ultrasound for the management of pleural diseases has evolved rapidly over the last few years. The National Patient Safety Agency’s rapid response report and the latest British Thoracic Society guidelines have recommended the use of chest ultrasound prior to intervention in pleural effusion. We describe our experience with using mobile bedside chest ultrasound including complication rates, impact on waiting time and length of hospital stay.

**Methods:** Prospective data from all patients receiving mobile chest ultrasound over a 12 month period in 2011 was collected. Scans were performed by an acute medicine physician and respiratory registrars with level 1 competency in chest ultrasound as classified by the Royal College of Radiology. Case notes, coding and radiology data were assessed, and comparisons made to waiting time and length of hospital stay for those receiving chest ultrasound in the radiology department.

**Results:** Overall 126 scans were evaluated with 123 performed the same day as requested and 3 the next day. Of those, 24 were followed by chest drain insertion, 56 by pleural aspiration and 46 with no intervention. Two patients had small pneumothoraces post aspiration (3.8%) whilst 1 chest drain insertion and 2 pleural aspirations failed. Average hospital stay was 13.3 days compared to 18.6 days for those having scans in the radiology department.

An average time of 21 minutes which included scanning duration, collecting and returning the device was documented in 71 patients.

**Conclusion:** Mobile bedside chest ultrasound when performed by level 1 competent physicians appears to be safe and considerably reduces length of hospital stay.

**P647**

Incidental findings on CTPA at a district general hospital

Jennifer Stephens, Victoria Foy, Fernando Chang, Steve Owen. Respiratory Medicine, Warrington General Hospital, Warrington, United Kingdom

**Background:** CT Pulmonary Angiogram (CTPA) is the gold standard investigation for Pulmonary Embolism (PE) in the UK.

**Aims:** Due to the quality of CTPA imaging, incidental findings are often identified. We investigated the incidence of these findings on CTPA studies done at a large district general hospital.

**Methods:** CTPA reports over a 12 month period in 2011 were reviewed retrospectively. Data was collected regarding PE, incidental findings and chest x-ray (CXR) reports at time of CTPA.

**Results:** A total of 216 CTPA reports were analysed. Results are seen in Table 1. Of the patients who had consolidation on CTPA, 9 (17%) had no consolidation seen on CXR. In those with a pleural effusion on CTPA, 42 (67%) had no effusion on CXR and of the patients who had a malignancy, 21 (75%) had not had this detected on CTPA.

**Discussion:** Out of 216 patients, 15 (6.9%) had no CXR prior to CTPA and 13 (6%) had no formal CXR report.

**Conclusion:** At our centre, CTPA yielded 11% diagnosis rate for PE. A sizeable number of incidental findings were detected resulting in further investigations and treatments of patients. The sensitivity of CXR is not sufficient to rule out consolidation in this set of patients. This study emphasises that CTPA is important in the diagnosis of PE, but also in identifying alternative pathologies not seen on routine CXR.

Evaluation of incidental findings other than PE on CT pulmonary angiogram

Urvi Shah, Freya Shah, Kabali Nandakumar. Respiratory Medicine, Queens Hospital, Burton-on-Trent, Staffordshire, United Kingdom

**Background:** PE is a common cause of admission to hospital, with CTPA increasingly being used to make this diagnosis. However, incidental findings other than PE are frequently noted. Our objective was to investigate the incidence of these, and the implications in patient management.

**Method:** This was a retrospective study which involved all inpatients who had undergone CTPA from June until November 2009. Data was obtained from PACS and electronic records. Abnormalities other than PE was identified and new lesions were differentiated from old.

**Results:** A total of 112 patients were identified with the majority being male (67%). The mean age was 61 years (range 23 to 97). SOB was the most prevalent presenting symptom in 62 (55.3%) followed by chest pain 37 (33%). Chest radiographs were performed in 110 (98.2%) patients, of 52.7% were normal. PE was found in 28 (25%) patients. Incidental findings were seen in 56 (50%) patients, 40 (71.4%) of these were new of which 28 (70%) of them needed further interventions. The most prevalent findings were pneumonia 22 (39%) followed by fibrosis 12 (5.5%), effusions 5 (8.9%) and lung masses 4 (7%). 10 patients had both PE and incidental findings.

The average length of stay was 7.3 days. Patients with additional pathology stayed a day longer (7.5 days) than those without (6.9 days).

**Conclusion:** In patients with suspected PE, CTPA has become a routine investigation with a yield of 25% in our study. Incidental pathology was evident in 50% of scans, which is in keeping with other studies. The addition of these findings on CTPA impacts on the length of stay of patients in hospital by one day, and has important implications for the acute clinical management of these patients.

Audit of the investigation of suspected pulmonary embolism in pregnancy

Jonathan Myers, 1 Kali Potiszil 1, Marie Raine. 1Respiratory and General Internal Medicine, Royal Cornwall Hospital, Truro, Cornwall, United Kingdom; 2Obstetrics and Gynaecology, Royal Cornwall Hospital, Truro, Cornwall, United Kingdom

**Introduction:** The diagnosis of pulmonary embolism (PE) in pregnancy relies upon criteria based clinical assessment supported by the use of appropriate imaging modalities. There is wide discrepancy between clinicians in the way the condition is investigated and this may have profound implications for diagnosis, resource allocation and radiation dose delivered to the mother and foetus.

**Methods:** Using the radiology database, all pregnant women who were investigated for PE were reviewed retrospectively. Data was collected regarding PE, incidental findings and chest x-ray (CXR) reports at time of CTPA.

**Results:** A total of 216 CTPA reports were analysed. Results are seen in Table 1. Of the patients who had consolidation on CTPA, 9 (17%) had no consolidation seen on CXR. In those with a pleural effusion on CTPA, 42 (67%) had no effusion on CXR and of the patients who had a malignancy, 21 (75%) had not had this detected on CTPA.

**Discussion:** Out of 216 patients, 15 (6.9%) had no CXR prior to CTPA and 13 (6%) had no formal CXR report.

**Conclusion:** The audit shows that there is a lack of standardisation pathway for suspected PE in pregnancy and the choice of investigative modality was clinician dependent. There is a need for the international medical community to develop robust guidelines to all standardised care, effective use of resources and minimize maternal and foetal radiation exposure.

**P650**

MDCT in tracheal stenosis assessment

**Purpose:** MDCT assessment of the degree and extent of tracheal cicatricial stenosis (CTS) in comparison to the results of endoscopic examination and intraoperative data.
P651 The difference in upper airway morphology between supine and upright posture
Cedric Van Holbeke1, Wim Von1, Samir Vinchurkar1, Jan De Backer1,
Oswald Peters, Nasier Nadim1, Wilfried De Backer2, 1Respiratory, FluidDA nv, Konstz, Belgium; 2Respiratory Medicine, University Hospital Antwerp, Edegem, Belgium; 3Maxillofacial Surgery, A.Z. Monica, Antwerp, Belgium
Introduction: The effect of upper airway (UA) morphology and especially the effect of the minimal cross sectional area (CSA) on lung deposition of inhaled medication (IM) is significant. However since IM is used when a patient is upright, conventional computed tomography (CT) data may not provide accurate information on the influence of the UA on lung deposition. The objective of this study is to evaluate variability in UA morphology for supine posture using CT vs. upright posture using cone beam CT (CBCT).
Materials and methods: A total of 20 normal subjects were included. 15 valid CBCT scans could be included as the rotating gantry of the CBCT touched the shoulders of the broad-shouldered subjects, causing motion artifacts. The UA CT scans were performed using the GE VCT LightSpeed scanner and the CBCT scans were performed using the SIEM i-CAT scanner.
Results: The UA CSA in the CT scan was characterized by lower CSAs as compared to CBCT (Minimal CSA, p = 0.036, Average CSA, p = 0.006). The minimal CSA in the CT scan could accurately predict the difference in minimal CSA between CBCT and CBCT as indicated in the figure.

Conclusions: It can be concluded that the UA morphology is different between supine and upright position. From the supine CT image, it can be predicted how large the minimal CSA will be when the subject is in an upright position. This function can be used to generate a correction factor for assessing lung deposition of IM.

P652 The relationship between NT proBNP and CT lung density in long term smokers
Laura H. Thomsen1, Saher B. Shaker1, Hasem Ashraf1, Thomas Rasmussen2, Pechin Lo3, Marleen de Bruijne3, Jesper H. Pedersen3,4
1Respiratory Medicine, Gentofte University Hospital, Helle program, Denmark; 2Cardiology, Rigshospitalet, 3Computer Science, 4Thorasic Surgery, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark
Introduction: Cardiovascular conditions are reported to be the most frequent cause of death in COPD.

Aims and objectives: The relationship between NT-terminal prohormone of brain natriuretic peptide (NT-proBNP) as a surrogate marker of congestive heart failure (CHF) and CT lung density remains unclear. Pulmonary oedema leads to increased CT lung density. Little is known about milder CHF and CT lung density. Lung cancer screening provides an opportunity to study this relationship.

Methods: 500 long-term smokers were selected from the Danish Lung Cancer Screening Trial (DLCST). Smoking habits were recorded and spirometry was performed. CT lung density was measured automatically by in-house developed computer software and expressed as the volume adjusted 15th percentile density (V15). NT proBNP with p<0.05 as part of a panel of biomarkers. The 194 persons, who had the CT scan and the blood sample performed the exact same day, were included in a multiple regression model. The model included gender, pack years, number of cigarettes a day during the last month, COPD severity, and NT proBNP with PD15 as outcome variable.

Results: Female sex (+0.5 g/l, SE 1.9, p<0.001), high number of cigarettes a day (+0.6 g/l, SE 1.1, p<0.001) and no or mild COPD (+0.2, SE 0.1, p<0.001) were associated with a higher PD15, but there was no correlation with NT proBNP (+0.001, SE 0.002, p=0.959).

Conclusions: PD15 was not correlated to NT proBNP. Therefore milder degrees of CHF seem to have little influence on CT lung density. Lung density is higher in females, in people without COPD and in heavy current smokers.

P653 Pulmonary emphysema: Qualitative assessment at CT of presence and subtypes
Jennifer Smith1,2, John Austin1, John Newell1, Belinda D’Souza1,
Anna Rozenstein1, Eric Hoffman3, Firas Ahmed1, R. Graham Barr1,5
1Medicine, Columbia University, New York, NY, United States; 2Medicine, McGill University, Montreal, QC, Canada; 3Radiology, Columbia University, New York, NY, United States; 4Radiology, University of Iowa Carver College of Medicine, Iowa City, IA, United States; 5Epidemiology, Columbia University Mailman School of Public Health, New York, NY, United States

Pulmonary emphysema is defined by morphology and is a heterogeneous disease with variably defined subtypes. We hypothesized that reliable detection of the presence of emphysema and its subtypes by visual CT assessment could be achieved by application and training on standard definitions of subtypes and severity. CT scans from 40 participants were selected randomly from a population-based cohort of participants ages 60-80 years with ≥10 pack-year smoking history. Non-contrast CT scans (120 kVp, 100 mAs, 0.75 mm) were performed at full inspiration and sharp filter reconstruction. Standard definitions of centrilobular (CLE), paraseptal (PSE) and panlobular (PLE) emphysema subtypes and severity were developed and three readers (2 chest radiologists, 1 pulmonologist) trained. The three readers independently assessed the 40 scans plus 10 replicates. Intra- and inter-reader agreement were assessed using unweighted Cohen’s κ and intraclass correlation coefficient (ICC), respectively.

Results: The 40 participants had a mean age 68±5 years, 40% were current smokers, and 55% had chronic obstructive pulmonary disease. The κ statistic was 0.57-0.84; inter-reader agreement was good for CLE (κ = 0.67), moderate for PSE (κ = 0.32) and absent for PLE (κ = 0.06).

Conclusions: This protocol for the visual assessment of chest CT can reliably detect the presence and extent of emphysema, in addition to selected emphysema subtypes.

P654 MDCT and MRI DWI early signs of COPD
Tamara Milosavljevic1, Aleksandar Ivkovic2, 1Radiology, ZC Vranje, Serbia; 2Center of Radiology, KC Nis, Serbia

Cigarette smoking is the leading cause of COPD. Most people who have COPD smoke or used to smoke some form of tobacco. But nonsmokers can develop COPD also.

Purpose: The main aim is to find early MDCT or MRI signs of COPD in young population of smokers, before developing the first clinical symptoms.

Material and methods: We examined 5863 patients from 18 to 35 years old. 3101 were male, 2762 female. All patients were examined on 16 or 64 MDCT using all advanced methods like virtual bronchoscopy, emphysema software we created, histogram, huge variation of filters and MDCT pulmonary angiography and MDCT perfusion. Patients with signs of COPD were examined by 1.5 T MRI with DWI.

Results: Patients were examined by MDCT because of different reasons, some of them because of acute respiratory symptoms and some also groups of patients voluntarily screened for lung cancer. We find signs of early COPD in 603 (10.28%) patients. All patients with signs of any other chronic disease or lung cancer were not matter of this study. Also we did not use patients with history of hemoptysis, even small one. In patients we find signs suspect for COPD we performed MDCT pulmonary angiography to find any signs of vascular abnormalities which could mislead us. MRI with DWI was performed to determine small vessels. In all patients we find areas of lower density then lung parenchyma. All areas were in peripheral parts of the lung, on left side of the lung in 61%. We
also had control examination after two years in 6 patients, in all patient areas of emphysema were bigger.

Conclusion: Signs of COPD can be found earlier than first symptoms are visible. MDCT with variety of tools and MRI with DWI are very useful for early diagnosis.

P655 A functional and radiological multiparametric approach to the study of parenchymal features of chronic obstructive pulmonary disease Riccardo Battistelli1, Andrea Sinisgalli1, Giulia Patricelli1, Giuseppe Macio2, Anna Rita Larcì1, Michele Amato1, Salvatore Valente1, Giuseppe Battistelli1, Monica Nona Duma1, Florent Baty1, Michal Devecka3, Giuseppe Macio2, Anna Rita Larcì1, Michele Amato1, Salvatore Valente1.

1Pulmonary Medicine, Università Cattolica del Sacro Cuore, Rome, Italy; 2Biostatistics and Radiological Sciences, Università Cattolica del Sacro Cuore, Rome, Italy; 3Department of Physical Medicine, Reina Sofia University Hospital, Madrid, Spain.

Chronic obstructive pulmonary disease (COPD) includes a range of changes ranging from chronic bronchitis to emphysema. We evaluated if integration of lung function tests and computed tomography (CT) scan allows a better characterization of patient with COPD.

23 patients (5 females) underwent lung function test and six-minute walk test (6mWT).

We used a third-generation, continuous-rotation helical 64-rows CT scanner with Siemens b30f and b50f convolution kernels. For each broncho-pulmonary segment of the lung, we can assess different features, such as length and diameter of the first airway generations, and lobar volumes (in terms of percentage of the functional residual capacity).

Results: Comparisons with experimental measurements have been done for total, tracheobronchial (TB) and lobar deposition, showing good correlation between measured and simulated values. For instance, mean experimental TB deposition fraction in the left lung is 14.5±2.4, vs. 14.9±4.1 for simulation results.

Conclusions: This work provides a scientific foundation for addressing both asymmetric and individualized lung morphologies in analytical modeling of aerosol deposition.

P658 Assessment of tumor size and movement trajectories using CT scans with different pitch settings Paul Martin Putze1,2,3, Maricela Nona Duma1, Florent Baty1, Michal Devecik1,2, Mami Bruschi1,2, Ludwig Plasswilm1,2.

1Department of Pulmonary Medicine, Università Cattolica del Sacro Cuore, Rome, Italy; 2Department of Radiation Oncology, Kantonsspital St. Gallen, St. Gallen, Switzerland; 3Department of Radiation Oncology, Technical University, München, Germany.

Assessment of tumor size and movement trajectories using CT scans with different pitch settings.

Method: A water filled 40mm table tennis ball serving as a phantom was moved along an ellipsoid trajectory by a custom assembled Locog device based on the cycle duration of 4.2 seconds. The ellipsoid trajectory was tested with a range from “fast” (2.5mm, standard pitch), “fast” (2.5mm, half pitch), and “fast” (0.625mm, half pitch).

Results: The volume of the ball was overestimated with the volume of the tumour phantom growing from 82% for the fast CT, 171% for the intermediate CT and 300% for the slow CT. The phantom trajectory could best be reconstructed in the slow CT. The different sizes can be seen here.

Conclusion: The custom lung phantom proved to work well for the specified task. The effect of CT settings during planning-CT acquisition on the resulting volumes was significant. Acquisition of slow-CT images for radiotherapy planning enables a better targeting of the moving tumor and sparing of normal lung tissue specifically when respiratory gating is not available.

P659 The role of positional CT in detecting adhesive process in the pleural cavity of TB patients under artificial pneumothorax (AP) Raul Amanashevedov, Andrei Perfiliev, Atdajan Ergeshov, Olga Demikhova.

Radiology Department, Central Tuberculosis Research Institute, Moscow, Russian Federation.

We studied 54 patients with different forms of destructive pulmonary TB, which received artificial pneumothorax (AP) during 5.5 (+1.5) months. Out of them 54.8% had infiltrative, 24.0% cavitory, 16.2% fibrocavitary, and 4.8% disseminated pulmonary TB. Sputum positive TB was established in 83.6% cases. Adhesive process in the pleural cavity was detected using polypositional computed tomography (CT). We developed the algorithm for radiographic monitoring of AP and detecting adhesions in the pleural cavity. We established pleural adhesion in 70.3% cases; thoracoacous was performed in 52.6% cases, with 100.0% effectiveness of AP.
In 47.4% cases thoracoscopic was not administered to the patients with adhesive process; out of them 55.5% had effective AP, 16.6% – partially effective AP, and 27.9% – ineffective AP. Thus, polyposidal CT demonstrated effectiveness in detecting adhesive process in the pleural cavity of TB patients.

Confocal laser endomicroscopy in diagnosis of solitary and multiple pulmonary nodular inflammation

Olesya Dandelievskaya1, Dmitry Sazonov1, Fedor Zabolotshev2, Aleksandr Averyanov1, Anastasiya Sorkina1, Anna Sotnikova1, Nikolay Urazovsky1, Oleg Kazuiev1, Oleg Shablovsky1,2,3,4,5,6. Endoscopy, Federal Research Clinical Center of the Specialized Types of Health Care and Medical Technologies FMBA of Russia, Moscow, Russian Federation; 2Pathologic Anatomy, Federal Research Clinical Center of the Specialized Types of Health Care and Medical Technologies FMBA of Russia, Moscow, Russian Federation; 3Pulmonology, Federal Research Clinical Center of the Specialized Types of Health Care and Medical Technologies FMBA of Russia, Moscow, Russian Federation; 4Anatomy, Federal Research Clinical Center of the Specialized Types of Health Care and Medical Technologies FMBA of Russia, Moscow, Russian Federation; 5Head, Federal Research Clinical Center of the Specialized Types of Health Care and Medical Technologies FMBA of Russia, Moscow, Russian Federation; 6Surgery, Federal Research Clinical Center of the Specialized Types of Health Care and Medical Technologies FMBA of Russia, Moscow, Russian Federation.

Background: Probe-based confocal laser endomicroscopy (pCLE) is a new method used during bronchoscopy by means of special minprobe Alveoflex and based on the visualization of intralveolar structures which possess autofluorescence. Till now the only lung pathology for which specific diagnostic signs are established at the visualization of intraalveolar structures which possess autofluorescence. Results: Patients diagnoses have been as follows: sarcoidosis (17), central lung cancer (1), pneumonia (5), usual interstitial pneumonia (1), bronchiolalveolar carcinoma (BAC) (4), other peripheral tumors (8). In all patients with BAC the cancer (1), pneumonia (5), usual interstitial pneumonia (1), bronchioloalveolar carcinoma (4), other diseases we haven’t found any significant difference between healthy and cancer (1), pneumonia (5), usual interstitial pneumonia (1), bronchioloalveolar carcinoma (4), other diseases.

Conclusions: pCLE could be used as an additional method of noninvasive diagnostics of BAC in vivo.

P661

Airway injury after intubation for lung surgery: Double lumen tube compared to EZ blocker

Erik (H.F.M.) van der Heijden1, Olga C.J. Schuurbiers1, Jordi Liesveld1, Garance van Rooy2, Ad F.T.M. Verhagen2, Stefan M. van de Heide2, Jo M.I. Moutoussis1,3. Pulmonary Diseases, Radboud University Medical Center, Nijmegen, Netherlands; 2Pathologic Anatomy, Radboud University Medical Center, Nijmegen, Netherlands; 3Anesthesiology, Radboud University Medical Center, Nijmegen, Netherlands.

Background: Double lumen tubes (DLT) or bronchial blockers (BB) are used for isolated lung ventilation. DLT’s can be positioned faster and remain firmly in place, but are more difficult to introduce. BB’s are more difficult to position and need more frequent intraoperative repositioning. The design of a Y-shaped BB, the EZ-Blocker (AnaesthetIQ BV Rotterdam Netherlands, EZB) combines advantages of both techniques. This randomized study investigated efficiency, efficacy and safety of DLT’s vs EZB and focused on airway injury caused by intubation.

Methods: 100 patients were randomly assigned to DLT or EZB group. Incidence and severity of damage to laryngeal, tracheal and bronchial structures were analysed by bronchoscopy before and after surgery. All procedures were recorded and injury was scored by a pulmonologist blinded for intubation type. Further the ease and time of placement, incidence of malpositions, quality of lung deflation, postoperative hoarseness and sore throat were assessed.

Results: There was a significantly higher incidence of airway injury after DLT compared to EZB. Marked tracheal and bronchial hematomas were found in 58% vs 26% (P=0.002) and 31% vs 6% (P=0.007). No differences were found in vocal cord and main carina injury. Placing single lumen tubes and EZB’s took more time but was rated easier. The majority of EZB’s and DLT’s were initially malpositioned (42/49 DLT, 37/50 EZB). Lung deflation was comparable. Fewer patients in the EZB-group complained of sore throat.

Conclusions: The EZB is an efficient and effective device for lung isolation and causes less injury and sore throat than DLT. Bronchoscopic control is recommended for both devices to ensure correct positioning.

P662

Preoperative endobronchial photodynamic therapy improves surgical radicalism for locally advanced NSCLC

Andrey Akonov1, Valentina Molodtsova1, Anatoly Rusanov2, Andrey Gerasin3, Nikita Kazarov4, Research Institute of Pulmonology, Pavlov State Medical University, Saint Petersburg, Russian Federation.

Objective: We describe the result of prospective randomized trial comparing neoadjuvant chemotherapy with and without endobronchial photodynamic therapy (PDT) followed by surgery for locally advanced NSCLC.

Methods: From Jan 2008 to Dec 2011, 42 pts with stage III central NSCLC (main bronchus/distal tracheal involvement) were randomized to either endobronchial PDT or no PDT. PDT was done with photosensitiser chlorine E6 and 662 nm laser light before each of the three courses of chemotherapy. Patients assigned to PDT (n=21) and no PDT (n=21) were similar with respect to age, sex, tumor stage, and histology.

Results: No PDT complications were observed. After neoadjuvant treatment partial remission revealed in 19 pts (90%) in PDT and 16 pts (76%) in no PDT group; these patients underwent thoracotomy. Surgery in PDT group: 14 pneumonectomies and 5 lobectomies; surgery in no PDT group: 10 pneumonectomies, 3 lobectomies and 3 exploratory. There was one postoperative death in each group. Completeness of resection was significantly higher in PDT (R0-89%, R1-11%) vs no PDT (R0-54%, R1-46%) group.

Conclusions: Combination of chemotherapy with endobronchial PDT increases effectiveness of neoadjuvant treatment and surgical radicalism for locally advanced central NSCLC.

P663

Clinical experience with a new self-expandable metal stent, SILMET, in tracheo-bronchial stenosis

Roberto Marchese1,2, Giuseppe Paglino1, Giovanni Di Giacomo1, Vincenzo Argano2,3, Interventional Pulmonary Unit, UNI La Maddalena Cancer Center, Palermo, Italy; 2Cardiothoracic Surgery Unit, Maria Elena Hospital, Palermo, Italy.

Introduction: The Implantation of Tracheo bronchial stents is a recognised treat- ment option in the management of airway disease. However, stent related side effects and complications are still an unresolved issue and are object of intense investigation. Research is currently focusing on the delivery mechanism and on biomaterials.

Aims: We evaluate the clinical result and effectiveness of the Silmet stent for treatment of benign or malignant bronchial disease.

Methods: Clinical data were collected retrospectively from 21 consecutive pa- tients. Each patient implanted were underwent to clinical monitoring, according to our protocol, consisting in endoscopic and microbiological testing at 1 day, 1 month, 3 months and 6 months after the procedure. For the evaluation of mucus plugging we used our 4 points endoscopic scoring: 0 = no secretions; 1 = moderate amount of secretions easily removable by suction; 2 = severe amount of secretions removable using a biopsy forceps, mucolytic agents instillations or other devices in addition to the suction; 3 = complete stent obstruction or deposit of thick and non-removable secretions.

Results: At the end of follow-up we recorded a single death which was not respiratory related. In one patient under chemotherapy we observed dislocation of the stent after significant tumor mass regression. No patient developed airways stenosis or trauma, airway wall damage or major complications. Nineteen patients had endoscopic score 0 and two patients score 1 in the last visit. One patient had a mild not obstructing granuloma.

Conclusions: These new Silmet stent have proved effective and free of severe complications in the treatment of tracheo-bronchial stenosis.

P664

Incidence and management of anastomotic complications after bronchial resection: A retrospective study

Olivier Ilivicki1,2, Bastien Ouvry3, Sophie Laroumagne1,2, Thomas Vanemoorevel1, Xavier D’Journo1,3, Pascal-Alexandre Thomas1,3, Philippe Astoul2,1, Herve Dutau1,2, Department of Thoracic Oncology, Pleural Diseases and Interventional Pulmonology, Hospital Nord, University of the Mediterranean, Marseille, France; 2Department of Pulmonary, Military Hospital Desgenettes, Lyon, France; 3Department of Thoracic Surgery and Diseases of the Esophagus, Hospital Nord, University of the Mediterranean, Marseille, France.

Background: Bronchial resection and re-implantation in the surgical management of.
of lung cancer are intended to spare lung parenchyma, with curative intent. We studied the incidence and management of anastomotic complications after such procedures.

**Methods:** We retrospectively reviewed charts of patients referred to our center for lung tumors, who underwent bronchial resection and re-implantation from 1991 to 2011.

**Results:** A total of 108 patients were included. Sixty-eight percent were male, and mean age was 58 years. Sleeve lobectomies were performed in 100 patients, bronchial resections without lung parenchymal resection in 8 patients. Squamous cell carcinoma represented 46.3%, carcinoid tumors 22.2%, and adenocarcinoma 18.5%. Mean time between surgery and the first bronchoscopy examination was 4.47 days, with anastomotic abnormalities detected in 20.4%. Twenty-three patients underwent therapeutic bronchoscopy for malacic or fibrotic bronchial stenoses in 9 cases, for dehiscences in 7, for obstructive granulomas in 3, and for bronchopleural fistulas in 3. Endoscopic treatment consisted in stent placement in 5 cases, mechanical dilations in 3, laser treatment for one case of bronchomalacia, and resection of granulomas in 3. No risk factors were identified as predisposing for bronchial complications. There was a trend towards lower 1-year survival in patients with bronchial complications compared to those without (71.9% vs. 83.4%, p=0.114).

**Conclusions:** Bronchial resection and re-implantation is a surgical procedure associated with an anastomotic complication rate of 21%. Regular endoscopic surveillance is advised in order to detect and treat early complications.

---

**P665 Optimizing the treatment of inflammatory tracheal stenosis according to a morphometric classification**

Rosa M. López-Lisbona 1, Gabriela Rosado 1, Noelia Cubero 1, Pablo Díaz-Jiménez 2, Raquel Tass 3, Joan Moya 2, Jordi Donca 4, Antoni Rosell 1, 1Pulmonology, Respiratory Endoscopy, Bellvitge Universitary Hospital-IDIBELL-CIBERES, L'Hospitalet de Llobregat, Barcelona, Spain; 2Thoracic Surgery, Bellvitge Universitary Hospital, L'Hospitalet de Llobregat, Barcelona, Spain; 3Pulmonology, Respiratory Endoscopy, Corachan Clinic, Barcelona, Spain

**Introduction:** A multivariable classification with its corresponding multimodality treatment has not been described in inflammatory tracheal stenosis.

**Objectives:** 1. To describe the distribution of patients according to a morphometric classification. 2. Identify the rate of success according to its corresponding treatment variables.

**Method:** Only patients with post intubation (PITS) or idiopathic inflammatory tracheal stenosis were included. Other benign non inflammatory diseases, granulomas and neoplasms were excluded. Patients were classified based on 3 endoscopic variables (Table 1). Treatment was selected according to the grouping of these variables.

**Results:** 40 patients were included: PITS in 87.5%, idiopathic stenosis in 12.5%. Distribution of patients according to treatment success are presented in Table 2. Endoscopic treatment was performed initially in 95% of patients. The treatment was successful in 45%, 26% underwent further surgical treatment and 29% needed a permanent canula or tracheal silicon stent.

Of the 12 patients who underwent surgery, 2 received no prior endoscopic treatment, and 3 required endoscopic treatment after surgery. Surgical treatment was successful in 83%. 17% of operated patients had tracheal restenosis.

**Conclusions:** 1. The more frequent tracheal stenosis group was S2D3L1 (39%). 2. Success rate with this multimodality approach was achieved in 68% of the patients. Funded partially by FUCAP.

---

**P666 Safety of percutaneous dilatational tracheostomy in obese critically ill patients when performed with bronchoscopy assistance**

Kyril-Mi Tikatszki 1, Katerina Dimakou 2, Ioannis Dimitroulis 3, Irena Tsoumboutariou 1, Konstantina Mendrinou 1, Michael Toubis 1, K. Kounoulis 1, 1ICU, “G. Gennimatas” General Hospital, Athens, Greece; 26th Clinic, “G. Gennimatas” General Hospital, Athens, Greece

**Introduction:** Intensive care unit (ICU) patients, mainly those in need of prolonged mechanical ventilation require tracheotomy. Obese critically ill patients are at greater risk for requiring intubation and prolonged mechanical ventilation. Percutaneous dilatational tracheostomy (PDT) is a well-established procedure that can be performed at the bedside by an intensivist with less surgical equipment required.

**Goal of study:** To evaluate the safety of performing PDT with bronchoscopy assistance in obese patients requiring prolonged mechanical ventilation.

**Method:** Sixty patients 17-79 yrs of age, 23 females and 37 males with body mass index 38±8 kg/m² underwent PDT with bronchoscopy assistance due to prolonged endotracheal intubation between December 2009 and January 2012. The procedures of percutaneous dilatation tracheostomy with guide wire dilator forceps (GWFD) were done bedside under general anaesthesia in the ICU. Operative and post operative complications were observed.

**Results:** Overall complication rate was low and occurred in 10 patients, there was no procedure-related mortality. Subcutaneous emphysema without pneumothorax occurred in three patients, two patients had a transient hypotension related to sedation and five patients had peristomal oozing. The mean time for procedure completion was 1.5 minutes, no patient required conversion to surgical tracheotomy. The bronchoscopy examination that was performed in 24 of the patients 20 days after tracheotomy tube removal showed no scar formation.

**Conclusions:** PDT with bronchoscopy guidance is safe for obese critically ill patients that can be done by an experienced intensivist at the bedside setting.
Conclusions: Interventional bronchoscopy plays definitive role in the treatment of surgery, were subsequently treated bronchoscopically due to anastomotic reestenosis with Nd-Yag laser (25%), electrocautery (37%) and tracheal stenting (44%).

Primary bronchoscopic treatment was the initial approach in 44%, followed by surgical intervention in 57% of cases in which tumor base could be totally visualized bronchoscopically and pathological evaluation revealed diagnosis of TC. Efficacy could be reached by the method. Tumors diagnosed as TC after pathological evaluation cryotherapy and/or coagulation with diode laser or APC tumor tissue was totally removed with core-out technique. Treatment approaches with interventional bronchoscopic methods in carcinoid tumors are non-invasive and effective in the treatment of benign tumors of the trachea. Complete cure can be obtained in all cases. Long follow up and treatment of recurrence is essential in the early period.

P669 Argon plasma coagulation in treatment of post intubation tracheal stenosis
Hamed Akhavan 1, Arda Kiani 2, Negar Shardi 1
1Mohammadreza Masjedi 1, 2, 3Tracheal Disease Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; 1Chronic Respiratory Diseases Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; 2Tobacco Prevention and Control Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Science, Tehran, Islamic Republic of Iran; 3Catholic Tuberculosis and Epidemiology Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran

Background and objectives: Acquired tracheal stenosis can be created by various causes. The most common cause of acquired non-malignant tracheal stenosis is endotracheal intubation for a short period. Argon plasma coagulation (APC) is a non-contact method of thermal hemostasis which can be used easily and fast and has low depth of penetration. Therefore, we decided to evaluate efficacy of this method in treatment of Tracheal stenosis.

Methods: This study is single blinded. Subjects were patients with tracheal stenosis after endotracheal intubation who were selected by non-probability sampling in bronchoscopy unit of Masih Daneshvari Hospital. First, for each patient a diagnostic flexible bronchoscopy was performed to identify the type, location, and severity of the stenosis. Then, under general anesthesia, patients underwent rigid bronchoscopy. After that, the stenosis was removed as possible by APC device. After two weeks a pulmonary function test (PFT) was done to check the obstructive sign.

Results: Of all 34 patients, 24 were asymptomatic for more than 1 year and responded to treatment (70%); 5 were asymptomatic for more than 10 months and less than 2 months (14.7%) and 5 did not have asymptomatic period more than 10 months and did not respond to treatment. In follow-up PFT, FEV1 in all patients was asymptomatic for more than 10 months (29 patients) showed a significant progress. (At the end of the period, FEV1 was more than 90% in 27 patients and 70-90% in 2 patients.)

Conclusion: On the whole, although the surgical treatment remains the main treatment of tracheal stenosis after intubation, if this method is not possible for any reason, APC is useful as a safe and effective method.

P670 Endoscopic approach in the treatment of carcinoid tumors
Levent Dalar 1, Ahmet Levent Karasulu 2, Sedat Onur 3, Saim Demir 4, Aysegul Akbas 1, Sedat Altin 1, Interventional Pulmonology Unit, Yedikule Teaching and Research Hospital, Istanbul, Turkey

Aim: Carcinoid tumors are the neuroendocrine tumors of the tracheobronchial tree. Treatment approaches with interventional bronchoscopic methods in carcinoid tumors have been analyzed and discussed.

Methods: In this study, 20 consecutive carcinoid tumor patient treated between January 2006 to August 2011 in our Interventional Pulmonology Unit were evaluated. All patients undergone rigid bronchoscopy. In all of the patients after coagulation with diode laser or APC tumor tissue was totally removed with core-out method. Tumors diagnosed as TC after pathological evaluation cryotherapy and/or laser was applied as a complementary procedure. Long follow up and treatment of recurrence, and resive ratios, complications, mortality and morbidity were evaluated.

Results: From the 20 cases included into the study, 17 of them were TC and 3 of them were AC. AE mean age of the cases were 56 (between 20-73) and 14 of them were female. Six cases, two of them were AC, were operated after bronchoscopic treatment. Rigid bronchoscopy was applied as a mean of 2.3±1.5 times while fiberoptic bronchoscopy was applied as a mean of 3.2 times. Radial probe EBUS and autofluorescence bronchoscopy were used in bronchoscopic follow up. No mortality due to bronchoscopic treatment was observed.

Conclusion: Bronchoscopic treatment is effective and safe in endobronchial carcinoid cases in which tumor base could be totally visualized bronchoscopically and pathological evaluation revealed diagnosis of TC. Efficacy could be reached by the method. Surgical intervention of the standard bronchoscopic procedure. Close follow up and treatment of recurrences is essential in the early period.

P671 Bronchoscopic treatment of benign tumors of the tracheobronchial tree
Levent Dalar 1, Ahmet Levent Karasulu 2, Sinem Nedime Sokac 3, Seda Onur 2, Aysegul Akbas 1, Sedat Altin 1, Interventional Pulmonology Unit, Yedikule Teaching and Research Hospital, Istanbul, Turkey; 2Pulmonology, Adiyaman State Hospital, Adiyaman, Turkey

Aim: To evaluate the efficacy of the bronchoscopic treatment approach and follow up results of the treatment of the benign tumors of the tracheobronchial tree.

Method: In this retrospective cohort study, 44 consecutive patient who underwent bronchoscopic treatment between January 2006 to June 2011 in our Interventional Pulmonology Unit were evaluated. All patients undergone rigid bronchoscopy under general anesthesia. In all of the patients firstly mechanical debridement after coagulation was applied and cryotherapy to the base of the tumor for excluding residue were applied.

Recurrence and residue ratios, early and late complications were evaluated.

Results: Most commonly treated benign tumor was hamartoma (38%, n=17). Other than this, procedures were applied to other rare tumors like as adenoma, amyloidosis, etc. In eight of the patients, tumor was located at the trachea. One to six session, even for a short period of 2.3±1.5 times was the duration of treatment. Recurrence and residue ratios, early and late complications were evaluated. In follow-up PFT, FEV1 in all patients was asymptomatic for more than 10 months and did not respond to treatment. In follow-up PFT, FEV1 in all patients with respiratory signs showed a significant progress. (At the end of the period, FEV1 was more than 90% in 27 patients and 70-90% in 2 patients.)

Conclusion: Our reported complication rates are lower than in other similar studies. We believe that a registry can potentially be utilised for database collection, bench marking and quality improvement initiatives and for training purposes in the near future. This paper-based prospective data analysis is feasible and valuable. We plan to extend this database to other French centers and in time to develop a web-based system, which will minimise the missing data fields.

P672 The feasibility of using a prospective multi-institutional database to measure outcomes from advanced bronchoscopy

Background: In France, there is no prospective registry to document activity and outcomes of the new diagnostic and therapeutic bronchoscopic technologies. We assessed the feasibility of a prospective multi-institutional outcomes database of advanced bronchoscopy.

Methods: Over a 2-month period, we have interrogated the procedure of advanced diagnostic (EBUS, EBUS-Mini-Probe, Autofluorescence) and therapeutic bronchoscopy from 5 French institutions. Information on procedure type and lesion characteristics as well as complications were documented.

Results: A total of 943 procedures were performed, of which advanced bronchoscopy represented 25%. The most related complication remains haemorrhage after biopsies, and completed technologies Autofluorescence followed by therapeutic bronchoscopic procedures. The EBUS specific complication was 3.2% in the University Hospitals, compared with a complication rate at 1.85% in the literature. The EBUS-Mini-Probe and Autofluorescence global complication rate was 6.66% and 11.3% respectively. The therapeutic bronchoscopy complication rate was 7.5% in the University Hospitals, compared with the reported global complication rate of 7%.

Conclusions: Our reported complication rates are lower than in other similar studies. We believe that a registry can potentially be utilised for database collection, bench marking and quality improvement initiatives and for training purposes in the near future. This paper-based prospective data analysis is feasible and valuable. We plan to extend this database to other French centers and in time to develop a web-based system, which will minimise the missing data fields.

P673 Interventional bronchoscopic treatment improves quality of life in patients with advanced bronchial cancer
Yaser Gad, Mohamed Mertwally, Tarek Mahfouz. Bronchoscopy Unit, Chest Diseases Department, Assiut University Hospital, Assiut, Egypt

Objective: Improvement of quality of life (QOL) is a main issue in patients with...
advanced bronchial cancer. Hemoptysis, dyspnea and irritating cough resulting from endobronchial obstruction are the main cause of QOL disturbance in those patients and interventional bronchoscopic treatment may play a role in solving this problem.

Methods: Patients with different symptoms related to endobronchial obstruction due to lung cancer were recruited into two groups. The first group was treated with argon plasma coagulation (APC) and the second group was treated with cryotherapy. All methods were applied via the fiberoptic bronchoscope under local anesthesia. The impact of bronchoscopic treatment on improvement of symptoms, arterial blood gases parameters, pulmonary function tests parameters, QOL and performance scale were evaluated.

Results: Forty five patients were recruited in the study. Twenty five patients were treated with APC and twenty patients were treated with cryotherapy. Bronchoscopic treatment was able to improve symptoms, pulmonary function test and blood gases parameters with subsequent improvement in the performance state of the treated patients.

Conclusions: Bronchoscopic treatment is an effective treatment to deal with symptoms related to endobronchial obstruction with subsequent improvement in the pulmonary function, blood gases, as well as QOL in these patients.

P674 Accurate monitoring of pulmonary air leak closure during endobronchial valve placement
Christophe Deoens, Paul De Leyn, Jonas Yserbyt, Herbert Decaluwe, Dirk Van Raemdonck, Vincent Ninane. Department of Pneumology, University Hospitals, Leuven, Belgium

Introduction: Endobronchial valves may be effective for the treatment of a prolonged pulmonary air leak (PAL). A traditional chest drainage system relying on a subjective and instantaneous assessment of expiratory bubble formation in the water-seal column lacks accuracy to aid assessments during and after valve placement.

Patients and methods: Three patients with a postoperative PAL measuring at least 1000 ml air leakage per minute (ml/min) were evaluated. We attempted air leak closure using endobronchial valves relying on a digital air leak measurement system displaying and recording the expiratory pulmonary air leak in ml/min. The number of valves used was set by either leakage cessation or residual leak of <100 ml/min.

Results: In all patients, the effect of every single valve placed was accurately assessed in ml/min during the procedure. In 1 patient the air leak stopped after lobar exclusion, while in 2 patients the air leak decreased to <100 ml/min after lobar exclusion. The continuous post-intervention assessment accurately indicated air leak cessation in these two patients within 48 hours after valve placement. Chest drain removal was successful after air leak cessation. None of the patients developed respiratory insufficiency requiring subacute endobronchial valve removal. As planned, all valves were removed 3-4 weeks after their placement.

Conclusion: Digital objective air leak assessment guides endobronchial valve placement, indicates the exact timing of air leak cessation, and allows a safe fast-tracking policy of chest tube removal.

P675 Endoscopic bronchial occlusion with Watanabe silicone prosthesis and biological glue for the treatment of alveolectra fistulas
Cayo Garcia Polo, Mercedes Merino-Sanchez, Antonio León Jimenez, Mercedes Sanchez Benitez, Mercedes Sanchez Bommarito, Aurelio Armendillo Muñoz. Pneumology, University Hospital “Puerta del Mar”, Cadiz, Spain

Introduction: Alveolectra fistula (APF) is the communication of the distal bronchial tree and pleural space, and supposes a serious problem for its associated morbimortality. The objective is to evaluate a endoscopic bronchial occlusion with a silicone prosthesis (Watanabe spigots) and biological glue.

Patients and methods: Observational, retrospective, descriptive study, collecting bronchial occlusion cases in our hospital from 2004 to 2010. General data collected, including details of previous and current illnesses, pleural drainage, fiberoptic bronchoscopy, location of dependent bronchus, spigots implanted, glue instilled, recurrences, pneumonectomies and monitoring.

Results: 6 patients and 7 sessions of bronchial occlusion. Average age 60, 3F/3M. The predisposing diseases were neoplasia, pneumonia and lung abscess. Developing as empyema or pneumonia with a drain placed 23 days on average prior to the occlusion. Performed under general anaesthesia, the responsible bronchus located with balloon catheter, ventilator volumes, dye or sight of bubbling. Two spigots placed per session on 3 occasions, and in 4 others, in sizes M and S. N-butyryl cyanurate was added in 4 sessions. The leak stopped in the operating theatre in all cases, with late recurrence in 3. No complications except expectoration of 2 spigots. Definitive lung re-expansion in 4 patients, with subsequent pleurodesis and drain removal. Two patients died from the progression of their underlying disease.

Conclusions: Endoscopic bronchial occlusion with Watanabe spigots and N-butyryl cyanurate is an effective, technically simple method without complications for the treatment of APF.
P678
Early improvements of Chartis assisted-endoscopic lung volume reduction treatments
Gianpiero Failla1, Alba La Sala2, Mario Spatafora2, Vincenzo Bellia2, Mario Giustolisi1. 1Sezione di Endoscopia Bronchiale, ARNAS-Ospedale Civico Di Cristina Benfretti, Palermo, Italy; 2DIBIMIS, University of Palermo, Italy

Endobronchial valve (EBV) treatment improves lung function and exercise tolerance in patients with pulmonary hyperinflation related to advanced emphysema. However, collateral ventilation (CV) may strongly limit the efficacy of EBV placement. This is a preliminary assessment of the role of lung volume reduction coil (LVR-C) as a possible alternative to EBV when CV occurs.

The occurrence of CV in the targeted lobes was assessed in 7 male subjects with heterogeneous emphysema by using the Chartis system. Based upon the above system, five subjects (aged 68±12 yrs) were assigned to EBV treatment (Zephyr EBV, 3 to 4 per patient), while two patients (aged 62±4 yrs), in which CV was documented, were assigned to LVR-C treatment under fluoroscopic guidance. (Nitiol coils, a total of 10 coils per patient). FEV1% pred. was 40±10% in the EBV group and 27±15% in the LVR-C group; RV% pred. was 154±28% and 171±29% respectively.

At 30 days, FEV1% pred. improved by 4.8 percentage points in the percent of the predicted value in the EBV group and by 1.5 in the LVR-C group. However, the reduction in RV% pred. was even more impressive in the LVR-C group (mean difference: -50 points) than in the EBV group (mean difference: -36 points). Similarly, the improvement in the 6 min. walking distance was higher in the LVR-C group (mean difference: +47 meters) than in the EBV group (mean difference: +17 meters).

All procedures were well tolerated and no major adverse effects were recorded in both groups. In our preliminary observations, LVR-coil treatment resulted in early improvements in lung function and exercise capacity, and can be proposed for the treatment of patients with severe heterogeneous emphysema when CV is documented.

P679
Assessment of fissure integrity for decision-making in valve treatment of emphysema: Preliminary results
Hugo Oliveira1,2, Rafael Rambo2, Silvia Oliveira1, Enio Valle1, Amariotto Macedo-Neto1, 1Emphysema Treatment Center, Hospital Moisinos de Vento, 2Thoracic Surgery, Hospital de Clínicas, Porto Alegre, RS, Brazil

Objective: To investigate if fissure integrity can determine collateral ventilation and guide endobronchial valve (EBV) treatment of emphysema.

Method: The study is underway. We employ the Apollo software (VIDA Diagnostics) for treatment planning, and developed a visual fissure integrity score using a 3D high-resolution CT scan and 61% an open lung biopsy.

Disease course: 33.3% and 43.3% had slowly progressed. Smoking status: Dyspnoea 78%, cough 63%, constitutional symptoms 25%, pain 22%.

Results: Details on 95 patients (19 deceased, 7 lost to follow-up) received. Clinical information regarding 67 cases has been received; completed by the patient, consultant or both (31 males). Age at presentation 37.1 years (SD 14.4). Presenting symptoms: Dyspnoea 78%, cough 63%, constitutional symptoms 25%, pain 22% and pneumothorax 8%. Smoking status: Ex 71.7%, current 25.0% mean (SD) 19.9 (16.9) pack years. Cannabis use 9.6%: Diagnosis: 93.8% patients had had an HRCT scan and 61% an open lung biopsy. Disease course: Symptoms resolved 23.3%, same 33.3% and 43.3% had slowly progressed. Treatment: None 56%, Steroids 29.6% immunosuppression/chemotherapy 26.5%, pleural surgery 18.7% and lung transplant 6%

Conclusions: This UK dataset indicates a high prevalence of smoking in our cohort and, despite advances in computed tomography a high percentage of patients are still diagnosed with an open lung biopsy.

P680
Pulmonary Langerhans’ cell histiocytosis (PLCH): A new UK register
Rebecca Mason1, Noleen Foley1, Howard Branley1, Toby Maher4, Martin Hefez1, Huzafia Adamali1, Jay Suntharalingam2. 1Respiratory Department, Musgrave Park Hospital, Taunton; Somerset, United Kingdom; 2Respiratory Department, Royal United Hospital, Bath; Somerset, United Kingdom; 3Respiratory Department, Bristol Royal Infirmary, Bristol, United Kingdom; 4Respiratory Department, Royal Brompton, London, United Kingdom; 5Respiratory Department, Whittington Hospital, London, United Kingdom

Introduction: PLCH is a rare interstitial lung disease, linked to cigarette smoking and may be associated with respiratory failure and death. Limited UK data has been published and little knowledge exists of the diagnostic and treatment practices employed by UK physicians.

Aims and objectives: Our study aims to characterise the epidemiological, clinical, histological, radiological and prognostic indicators in a UK cohort of patients with PLCH.

Methods: 112 cases from 53 centres (65 from the BTS British Orphan Lung Disease database and 47 new or previously unregistered). Consultants provided contact details; Patients were sent an information leaflet, consent form and questionnaire. Once consent obtained, consultants were sent a medical questionnaire. The patients’ GP provided current medication and medical history.

Results: On 95 patients (19 deceased, 7 lost to follow-up) received. Clinical information regarding 67 cases has been received; completed by the patient, consultant or both (31 males). Age at presentation 37.1 years (SD 14.4). Presenting symptoms: Dyspnoea 78%, cough 63%, constitutional symptoms 25%, pain 22% and pneumothorax 8%. Smoking status: Ex 71.7%, current 25.0% mean (SD) 19.9 (16.9) pack years. Cannabis use 9.6%: Diagnosis: 93.8% patients had had an HRCT scan and 61% an open lung biopsy. Disease course: Symptoms resolved 23.3%, same 33.3% and 43.3% had slowly progressed. Treatment: None 56%, Steroids 29.6% immunosuppression/chemotherapy 26.5%, pleural surgery 18.7% and lung transplant 6%

Conclusions: This UK dataset indicates a high prevalence of smoking in our cohort and, despite advances in computed tomography a high percentage of patients are still diagnosed with an open lung biopsy.

P681
Pulmonary manifestations of Sjogren syndrome
Serife Savas Bozbah, Esma Sevil Akkurt, Zeynep Erayman Ozan, Sule Akcay. Pulmonary Medicine, Baskent University Faculty of Medicine, Ankara, Turkey

Background: Sjogren syndrome is a chronic and autoimmune disease characterized by lymphocytic infiltrates in all exocrine glands. Dryness of the eyes and mouth are the most common symptoms of this syndrome. Primary pulmonary manifestations of Sjogren syndrome are diffuse lung and airway diseases.

Aim: 131 patients were included in our study between the years 2000-2011 who were diagnosed with Sjogren syndrome. Of these patients, 31 were examined who admitted to pulmonary diseases clinic and had Thorax computed tomography (CT). We aimed to evaluate demographic characteristics, respiratory symptoms, pulmonary function test parameters and Thorax CT findings of patients who have Sjogren Syndrome.

Results: The mean age was 57.3 years and 30 (%96.8) were women. Pulmonary function test was normal in %45.2 of the patients. 7 patients (%22.6) were smoker. 2 patients had COPD and 4 had asthma. 11 patients suffered from dyspnea and 5 from coughing. Thorax CT revealed pathological findings in 22 patients (%71.0). In Thorax CT examination 8 atelectasis, 8 pulmonary nodules, 5 pathological lymph nodes, 3 bullae formation, 2 bronchiectasis, 2 pulmonary embolism, 2 lobars, 2 infarction, 2 ground glass appearance and 2 pleural effusion were reported. Of the 23 patients who underwent echocardiographic evaluation 7 (%22.6) had elevated systolic pulmonary artery pressure (mean 63.3 +2.7mmHg).

Conclusion: Respiratory disorders are common in patients with Sjogren syndrome even if the affected individuals are asymptomatic. Therefore, close follow up of these patients in pulmonary disease clinics are recommended and Thorax CT assessment for lung involvement should be considered for early diagnosis.
Lung function follow-up, yr 5.9

Mean FEV₁ and DLCO were, respectively, ≥70% predicted at diagnosis, and similar mean rate of FEV₁ decline was found in both S-LAM and TSC-LAM groups. Significant improvement of FVC and DLCO was detected in the patients with TSC-LAM and 53 patients with S-LAM diagnosed according to ERS 2010 criteria with a lung function follow-up >2.1 year. Results are shown below:

<table>
<thead>
<tr>
<th>TSC-LAM (mean ± SD)</th>
<th>S-LAM (mean ± SD)</th>
<th>p value</th>
</tr>
</thead>

Conclusion: Although diagnosed at an earlier age than S-LAM, patients with TSC-LAM had similar mean FEV₁ at diagnosis, and similar mean rate of FEV₁ decline. Lung function follow-up similar to S-LAM may be recommended in TSC-LAM.

Effect of source of inhalation antigen on manifestation and prognosis of EAA patients

Bartosz Steczko, Martina Vasakova, Peter Pulsch. Respiratory Diseases, Thomayer Hospital, Prague, Czech Republic

Exposure to moulds in domestic environment leading to EAA is often reported. Inhalation exposure to moulds may lead to development of proliferative Th2 cells.

Aim of the study: To examine influence of inhalation antigen on EAA manifestation and prognosis.

Method: Fifty-four patients of the mean age 55±17.5 were included to the retrospective study. They underwent complex diagnostic program including detailed history assessment, physical examination, serum specific IgE tests, lung function tests (spirometry, diffusing capacity of the lung for CO), HRCT of the chest, broncho抄y with BAL and TBB. Patients were divided into five groups according to their antigen exposure history – unknown source of exposure, professional exposure in chemical industry workers, exposure to moulds, exposure to bird antigens and exposure to mammal’s fur and epithelium.

Results: Patients with mould exposure history had significantly higher FVC (p < 0.05), FEV₁ (p < 0.01) and DLco (p < 0.01) at the time of diagnosis than other exposure groups. Significant improvement of FVC and DLco was detected in the patients with history of exposure to bird antigens. We found no difference in BAL differential cell counts among patient groups. BALF PMN cell count at the time of diagnosis negatively correlated with FVC and FEV₁ a year after diagnosis in the whole group (p < 0.05).

Conclusion: EAA caused by moulds does not have a worse manifestation and prognosis that EAA caused by other inhalation antigens. Better outcome of patients exposed to bird antigens is probably influenced by easy removal of the antigen’s source. The type of inhalation antigen very likely does not influence the manifestation of EAA.

Introduction: Hypersensitivity pneumonitis (HP) is a potentially serious illness that may progress to pulmonary fibrosis and chronic respiratory insufficiency. Reliable methods are needed to diagnose the condition and, if possible, to identify that causative agent. The aim of the study was to establish the diagnostic yield of Specific Inhalation Challenge (SIC) in patients with HP.

Material and methods: All patients with suspected HP in whom SIC were performed between June 1995 and December 2010 (n=113) were included. Diagnosis of HP was established on the basis of internationally accepted criteria (M Girard, et al. Allergy 2009; 64:322-334). The SIC was considered positive in the case of a decrease >15% in FVC and/or a decrease >20% in TLOCO, or a decrease in FVC between 10-15% accompanied by an increase in temperature of 0.5°C within 24h of the inhalation of the antigen (Morell F, et al. Medicine 2006; 85:110-130).

Results: Eighty-eight patients were diagnosed with HP in 68 the SIC test was positive (73%). Of these 53 HP patients (58%) were positive, in 45 negative (51%) and 24 (21%) were recorded. The sensitivity and specificity of the test were 72% and 84% respectively, with a positive predictive value of 94% and a negative predictive value of 47%. Having HP caused by an antigen other than birds or fungi was a predictor of a false negative result (p=0.035).

Conclusions: In HP a positive SIC participating confirms the diagnosis, while a negative result does not rule it out.

Project partially funded by FIS PI 10100571 (Instituto de Salud Carlos III) and Beca SEPAR 2010.

Computer tomography lung density in smokers is correlated to measures of local inflammation in the lung

Reza Karimi, Sven Nyren, Åsa Weelock, Goran Tornling, Magnus Skold. Department of Medicine, Karolinska Institute, Karolinska University Hospital, Solna, Stockholm, Sweden Department of Molecular Medicine and Surgery, Karolinska University Hospital, Solna, Stockholm, Sweden Department of Medicine, Karolinska Institute, Stockholm, Sweden Department of Medicine, Karolinska Institute, Karolinska University Hospital, Solna, Stockholm, Sweden Department of Medicine, Karolinska Institute, Karolinska University Hospital, Solna, Stockholm, Sweden

Cigarette smoking causes an inflammatory response in the lungs. CT imaging provides means of quantifying pulmonary structure and function. We hypothesized that the inflammation in smokers may be mirrored both by an altered attenuation on CT and by measures inflammation in the lungs.

Materials: Healthy smokers (20 men, 20 women, mean age 54, 35±12 pack years, 40 healthy nonsmokers, age 57 and 40 COPD, age 59 (38±11 PY, 31 current smokers, 9 exsmokers) performed inspiratory CT scans. Values between -500 and -750 HU were considered as high attenuation area, BAL, was performed. Cell concentration were measured.

Result: Attenuation for smokers (44% ±5.7) and nonsmokers (38% ±5.6), COPD exsmokers (33% ±4.5) (p<0.001 and p<0.05 respectively). COPD smokers (41% ±5.0) did not differ from that of healthy smokers. Both smoker groups (healthy smokers: 556±259 x 10⁶/mL (mean±SD); COPD smokers: 458±263) had higher cell concentration in BAL compared to nonsmokers (121±50) and COPD exsmokers (102±29). The difference between the smoking and nonsmoking groups were significant (p<0.001). There was a significant correlation (r=0.0001) between cell concentration in BAL and CT attenuation. There was no significant correlation between cell concentrations in BAL and CT attenuation in smokers and COPD exsmokers.
Conclusion: The increased lung density in smokers compared to nonsmokers may mirror an inflammatory response induced by cigarette smoke. This hypothesis is strengthened by a positive correlation between lung attenuation and cell concentration in the lower respiratory tract. Our results provide a quantitative approach for measuring smoke-related structural changes in the lung.

D967 Determinants of fitness to fly in interstitial lung disease

P687 Different cutoff values of serum SP-D for German and Japanese to diagnose idiopathic pulmonary interstitial pneumonias are related to different SFTPD gene polymorphisms

Yasuhiro Horimasa1, Noboru Hattori1, Nobuhisa Ishikawa1, Sonosuke Tanaka1, Koji Yoshitaka2, Francesco Boncella3, Shinichiro Ohshima1, Iossane Guzman2, Ulrich Costabel1, Nobuki Kohno1

1Departments of Molecular and Internal Medicine, Graduate School of Biomedical Science, Hiroshima University, Hiroshima, Japan; 2Department of Pulmonology, Alveoli, Ruhrenlandklinik, University Hospital Essen, Germany; 3General and Experimental Pathology, Ruhr University, Bochum, Germany

Introduction: Surfactant protein (SP) D is a member of the C-type lectin superfamily. Serum SP-D is applied as a diagnostic biomarker for various interstitial lung diseases in Japan, but not in European countries. It is also known that rs721917 single nucleotide polymorphism (SNP) in surfactant protein D (SFTPD) gene might influence serum SP-D levels.

Aims: This study was aimed to evaluate serum levels and genetic backgrounds of SP-D both in German and Japanese cohorts.

Methods: Serum levels of SP-D were measured and compared between patients with idiopathic interstitial pneumonias (IPPs) and healthy subjects (HS) both in German and Japanese cohorts. In addition, rs721917 SNP was genotyped by polymerase chain reaction. The power of serum SP-D to discriminate IPPs from HS was examined by receiver operating characteristic analysis based on ethnicity and rs721917 genotype.

Results: The serum levels of SP-D in IPPs were significantly higher than in HS for both German and Japanese cohort (both p<0.001). The discriminating cutoff values of serum SP-D were higher in the German than in the Japanese cohort. Furthermore, the TT genotype of rs721917 SNP, which is more frequent in German HS than in Japanese HS, was correlated with high levels of serum SP-D, and the cutoff value of serum SP-D was different according to rs721917 genotype.

Conclusions: Our data suggest the possibility of serum SP-D to be used as diagnostic biomarker for IPPs in Germans. The cutoff value of serum SP-D is higher in the German than in the Japanese cohort, and this difference might be related to the difference of rs721917 genotype distribution.

P688 Sarcoidosis associated pulmonary hypertension (SAPH) in the Netherlands

Eva Bor, Marlies Wijnenbeek, Leon van den Toorn, Henk Hoogsteden, Bernt van den Blink

Pulmonary Medicine, Erasmus MC, Rotterdam, Netherlands

Background: The development of pulmonary hypertension (PH) is an important risk factor for early mortality in sarcoidosis. The prevalence of SAPH in Europe is largely unknown.

Aim: To investigate the prevalence of and clinical parameters associated with SAPH in the Netherlands.

Methods: We analyzed clinical data and transthoracic echocardiograms (TTEs), made routinely at our PH/Interstitial Lung Disease clinic, from consecutive patients. Sarcoidosis patients with pulmonary hypertension were excluded. The HCT level was noted, along with baseline characteristics of the patients. The HCT levels were compared among patients who had been determined to have sarcoidosis, sarcoidosis associated with pulmonary hypertension (SAPH), sarcoidosis associated with pulmonary hypertension (SAPH) with IBD, sarcoidosis associated with pulmonary hypertension (SAPH) with IBD and fibrosis, sarcoidosis associated with pulmonary hypertension (SAPH) with IBD and fibrosis and sarcoidosis associated with pulmonary hypertension (SAPH) with IBD, sarcoidosis associated with pulmonary hypertension (SAPH) with IBD and fibrosis.

Results: From 139 sarcoidosis patients, 130 were included with stage 0 (11), I (46), II (39), III (7), IV (16). 5 patients (3.8%) had PH and 6 (4.6%) possible PH. Patients with PH were all women, predominantly black (4 out of 5) with stage IV disease (4 out of 5). 4 out of 6 patients with possible PH (3 white, 3 Asian) had stage I disease. TTO % pred was lower in PH compared to no PH (median: 46.0 (18.4 – 78.5) vs 78.50 (28.0 – 119) p < 0.01). FEV1% pred was decreased in PH compared to no PH (median: 84.0 (36.0 – 96.0) vs 82.0 (30.0 – 131.0) p < 0.05). TLP was decreased in PH (median: 61.0 (51.0 – 91.0) vs 82.0 (46.0 – 116.0), but not significantly different. In possible PH pulmonary function showed no significant difference versus no PH. Conclusions: SAPH is uncommon in the Netherlands and mainly found in black women with stage IV disease and associated with decreased lung function. Unexpectedly, suspicion of PH was found in some patients with stage I disease, warranting further investigation.

P689 The influence of TNFα gene polymorphism on the therapeutic response in patients with sarcoidosis

Jadranka Popovic1, Ivana Radijovic petkovic, Ivana Stanekovic, Desa Nastasjevic Borovac, Funka Djordjevic, Zorica Ciric, Milan Radocic. Clinic for Lung Diseases and TB, Clinical Centre, Nis, Serbia

Sarcoidosis is an inflammatory disease of unclear etiology, with genetic factors playing a considerable factor in both its onset and clinical presentation. In the majority of patients, the disease goes away spontaneously, without treatment. However, longer therapy is necessary in a small number of patients.

The aim of this research was to determine the role of TNF-α-308GA polymorphism in the therapeutic response in patients with sarcoidosis. The research encompassed 66 patients with sarcoidosis, 44 of whom were females and 22 were males, of average age 51.17±1.12, who were treated for sarcoidosis at the Clinic for Lung Diseases NL. TNFa-308 GA gene polymorphism was examined in all patients using the PCR-RFLP method.

Results: 10 patients received no treatment, 48 patients underwent corticosteroid treatment, while 8 patients received combined treatment using corticosteroids and methotrexate. No statistically significant difference in the distribution of TNF-a gene polymorphism genotypes and alleles was detected between the patients receiving corticosteroid treatment and those without treatment. However, the duration of the treatment was statistically considerably lower in patients belonging to AA genotype group (14.83±9.77) when compared to those from GG genotype group (18.0±10.56), p<0.05.

Conclusion: Previous research showed that the presence of TNF-308A allele is a good prognostic sign of sarcoidosis, as it is coupled with the acute form of the disease and the absence of recidives. Our results indicate a great prognostic significance of this allele, given that this could predict a favorable outcome of the disease and a shorter duration of treatment.

P690 Determinants of fitness to fly in interstitial lung disease

J.K. Long1, A Ward1, C Nelson1, P Sestini1, T.M. Maher1, A.U. Wells1, B.A. Renaud1,2,3.1Interstitial Lung Disease Unit, Royal Brompton Hospital, London, United Kingdom; 2Department of Respiratory Medicine, University of Siena, Italy

Introduction: The predictors of in-flight hypoxia in interstitial lung disease remain unknown. The hypoxia challenge test (HCT) is widely used to evaluate fitness to fly. We assessed the predictive determinants of airworthiness using HCT.

Methods: 183 patients underwent HCT in 2005-2011 (74 males; mean age 57.6; 73 ex-smokers) of which 126 had idiopathic interstitial pneumonia, 26 hypersensitivity pneumonitis, 23 sarcoid and 8 other ILDs. 164 had lung function tests on the same day. 124 had an echocardiogram within 1 year. The HCT was performed using an inhaled gas mixture containing 15% oxygen. From BTS guidelines, the HCT was positive (in-flight oxygen required) if PaO2 < 6.6 kPa on 15% oxygen.

Results: Median PaO2 on air was 10.3 kPa (range 9.3-14.3), with median percent predicted FVC 68.1% and DLCO 38.3%. On univariate logistic regression, variables associated with a positive HCT were age (p<0.04), PaO2 on air (p<0.0001), FVC%, DLCO% and composite physiologic index (CPI) (p for all<0.0001). Pulmonary hypertension (PH) on echocardiogram was also predictive, although less strongly (p<0.015). On multivariate analysis, variables remaining significantly associated with a positive HCT were PaO2 on air (p<0.0001), lung function markers including CPI (p<0.0001), or in separate models DLCO (p<0.0001), and FVC (p=0.006), while PaO2 on echo was no longer predictive (p<0.13). On ROC analysis, area under the curve was 0.80 for PaO2 on air, 0.75 for DLCO%, 0.72 for CPI, 0.83 for combined CPI and PaO2, and 0.85 for combined DLCO and PaO2.

Conclusion: Our findings highlight the potential of PaO2 on air, DLCO and CPI levels as non-invasive predictors of fitness to fly. Identifying the best combination requires further prospective evaluation.

P691 Diagnostic yield of transbronchoscopic lung biopsy guided by CT in diffuse lung disease

Manuel Vaz1, António Moraes2,3, Natália Melo1, Conceição Soura Moura1, 1Serviço de Pneumologia, Hospital S. João, EPE, Porto, Portugal; 2Faculdade de Medicina, Faculdade de Medicina, Porto, Portugal; 3Serviço de Anatomia Patológica, Hospital S. João, EPE, Porto, Portugal

Objective: The predictors of in-flight hypoxia in interstitial lung disease remain unknown. Hypoxia challenge test (HCT) is widely used to evaluate fitness to fly. We assessed the predictive determinants of airworthiness using HCT.

Methods: Retrospective review of 56 patients clinical files with DLD, who were submitted to TLTB guided by CT between January 2009 and November 2011. Trucut18-20Gauge needles, percutaneous anasthesia and multislice CT Siemens Somatom Sensation were used.

Results: The patients included had an average age of 58.4 years and 32 (57%) were male. Diffuse micronodular was the most frequent CT pattern observed in 41 (75%) patients, consolidation in 25 (47%) patients, ground glass in 14 (25%), reticular in 14 (25%) and cysts in 5.3%. Biopsy confirmed preliminary diagnostic hypothesis in 27 (48.2%) patients and in 13 (23.2%) histological features observed guided to another diagnosis, leading to a diagnostic sensitivity of 71.4% (40/56 patients). In 16 (28.6%) patients this procedure was not conclusive. Diffuse micronodular and consolidation were the higher diagnostic yield patterns. 11 patients had complications, 7 pneumothorax and 4 non-massive hemoptysis. Organizing pneumonia (35%), sarcoidosis (12%) and silicosis (10%) were the most frequent diagnosis.

Conclusions: In this series of patients TLTB guided by CT was safe, quick and...
Background: Lung fibrosis is the most common cause of death in systemic sclerosis. CCL18 is associated with poor prognosis and disease deterioration in fibrotic lung diseases. The prognostic relevance in patients with interstitial lung disease in systemic sclerosis was shown by Tiev et al. (Tiev KP, Eur Respir J 2011 38: 1355-1360).

Objectives: To evaluate the role of CCL18 in patients with or without interstitial lung disease in systemic sclerosis.

Methods: We measured the chemokine CCL18 in sera of 126 patients with progressive systemic sclerosis by ELISA, as well as lung function testing at baseline and every 6 months during follow-up. Pulmonary fibrosis was detected by HR-CT. We computed ROC- and Kaplan-Meier-curves and Cox proportional hazards models to analyze the influence of CCL18 on time to disease progression, defined as decline of the predicted FVC<sub>10</sub>-10% or death.

Results: Patients with serum CCL18 concentrations above 140 ng/ml suffered from a significantly higher chance of disease progression (p<0.001) within one year. The hazard ratio to suffer from a disease progression was 8.9 in the univariate Cox hazard model and 8.7 in the multivariable hazard model (after adjusting for age, gender, and baseline FVC). In the subgroup of patients without pulmonary fibrosis at baseline the hazard ratio was even 21.1 (p<0.001).

Conclusion: CCL18 predicts disease progression of the lung involvement in patients with systemic sclerosis, independent of age, gender or baseline FVC, especially in patients without any evidence of lung fibrosis. CCL18 in sera might therefore be a tool to identify patients who will suffer from lung function deterioration in the future and to guide therapeutic interventions in these patients.

P693 Abnormal heart rate variability in patients with sarcoidosis

Elias Gualii<sup>1</sup>, Vasilos Kouranos<sup>4</sup>, Anastasios Kallianos<sup>4</sup>, Georgios Kalivasakas<sup>1</sup>, Ilia Peros<sup>2</sup>, Dvaid Trakas<sup>2</sup>, Georgios Diemelis<sup>3</sup>, Charalampos Kostopoulos<sup>4</sup>, Eleutherios Stamboulis<sup>5</sup>, Nikos Koulouris<sup>1</sup>, Aggeliki Rapti<sup>1,2</sup>, 11<sup>th</sup> Department of Pulmanology, University of Athens, Greece; 2Second Department of Pulmonology, Chest Disease Hospital “Sotiria”; Athens, Greece; 31<sup>st</sup> Department of Neurology, University of Athens, Greece; 4Outpatient Clinic for Sarcoidosis, Chest Disease Hospital “Sotiria”; Athens, Greece; 5Department of Neurology, University of Athens, Greece;

Background: Heart Rate Variability (HRV) can predict cardiovascular events, especially sudden cardiac death and ventricular arrhythmias. Aim of this study was the evaluation of HRV indices in sarcoidosis (Sarc).

Methods: 180 biopsy proven Sarc patients who were not taking antiarrhythmic drugs were included in this study. They were compared with 72 sex and age matched healthy subjects. All participants had cardiac stress tests, cardiac ultrasound, 24-hour Holter monitoring and cardiac MRI and were classified to group A (healthy), group B (cardiac-free Sarc) or group C (cardiac Sarc). The average heart rate (mean HR), the maximum and minimum heart rate (maxHR and minHR), the root mean square of SD of RR (RMSSD) and the standard deviation of all normal to normal NN intervals (SDNN) were calculated during 24-hour Holter monitoring.

Results: Comparison among groups of different parameters

In bivariate analysis, SNN is correlated with age (p=0.001, r=−0.397), FVC (p=0.001, r=−0.242), FEV1 (p=0.001, r=−0.261), TLC (p=0.001, r=−0.290) and DLCO (p=0.001, r=−0.264).

Conclusion: HRV is decreased in patients with sarcoidosis compared to the control group. SNN is significantly decreased in patients with sarcoidosis and is correlated with lung function indices.
Materials and methods: A549 and SKMES cell lines were treated with serum from patients with sarcoidosis, COPD and healthy individuals. Their effect on cell proliferation was examined. The influence of cytokines and EGF on cell proliferation was also investigated.

Results: When serum from patients with sarcoidosis was added to the culture medium of both epithelial cell lines, there was a statistically significant increase of cell proliferation (p<0.05). By contrast, serum from normal controls or patients with COPD had no impact. This positive influence of serum from patients with sarcoidosis was annulled by EGFR inhibitor.

Conclusions: Out of control cell growth is a basic step towards malignancy. The increase of epithelial cell proliferation in the presence of sarcoidosis serum, documented in the present study, could represent a link of this disease with neoplasia, under favorable circumstances.

P697 IL-17a expression in transbronchial biopsy samples in sarcoidosis
NurDan Koktükñ1, Nalan Akyürekñ1, Muge Ayvoduñ1, Ayse Baha1, Haluk Türkü tn1, 2Pulmonary Diseases, Gazi University Medical Faculty, Ankara, Turkey; 3Pathology, Gazi University Medical Faculty, Ankara, Turkey

Background: Th17 is a new subset of CD4 (+) T cell population and characterized by the release of cytokines such as IL-17A, IL-17F and IL-22. Multiple studies in humans and animals have described the role of Th17 cells in the pathogenesis of several autoimmune and chronic inflammatory diseases such as psoriasis, inflammatory bowel diseases, tuberculosis and lung fibrosis.

Aim: To evaluate the possible role of Th17 cells in the pathogenesis of sarcoidosis by evaluating the IL-17A levels in lung biopsy samples of sarcoidosis patients.

Methods: The IL-17A expression was evaluated with immunohistochemical analysis. The area that had higher IL-17A antibody positivity was evaluated with x40 magnification and the positive staining inflammatory cells (macrophage and lymphocyte) were counted.

Results: A total of 41 sarcoidosis patients (32 [78%] female) with the mean age of 48 years were included in the study. Among them 22 (54%) were diagnosed as Stage 1, 17 (42%) as Stage 2 and 3 as sarcoidosis. In the whole study group only 2 (5%) patients had no IL-17A (+) inflammatory cells. In the remaining, 9 (22%) patients had one IL-17A (+) staining cell, 15 (37%) had 2, 5 (12%) had 3 cells, 9 (22%) had 4 cells and 1 (2%) had 5 cells. The IL-17A (+) staining cells were identified at the periphery of the granuloma. No statistically significant correlation was identified between the number of IL-17A (+) staining inflammatory cells and plasma ACE levels, CD4/CD8 ratio and the stage of the disease (p>0.05).

Conclusion: The identification of IL17A (+) staining inflammatory cells in the periphery of the sarcoidosis granulomas, may indicate that Th17 cells have an important role in the pathogenesis of sarcoidosis.

P698 BALF TNFα level in relation to inflammatory status and phenotype of sarcoidosis
Anna Golan Geremek1, Michał Bednarek1, Elżbieta Puscinska1, Marek Kram1, Urszula Demkow2, Dorota Górecka1

Aim: To evaluate the relation of BALF TNFα levels to the inflammatory status and phenotype of sarcoidosis.

Material and methods: We have measured: TNFα, TGFβ, IL-2, IL-12, IL-10 in BALF and TNFα, TGFβ, IL-2, IL-12, IL-10 levels in serum in 184 sarcoid patients. We checked for the correlations between BALF TNFα and cytokines, selected systemic inflammatory markers and clinical factors (age, duration of the disease, PFT, 6MWT, extrapulmonary involvement).

Results: We have found important positive correlation between concentration of BALF TNFα and:
- BALF: IL-2 (r=0.4676, p=0.0001), IL-12 (r=0.4555, p=0.0001) and serum: IL-12 (r=0.26, p=0.0011), IL-10 (r=0.2832, p=0.0012), TNFα (r=0.1871, p=0.12).
- serum CRP (r=0.2427, p=0.003), γ-globulins (r=0.1685, p=0.033), Dliders (r=0.1685, p=0.035).
- the age of patients (r=0.16, p=0.029).

No relation was found between the BALF TNF alpha and the duration of the disease, PFT (except for FEV1 r=0.1466, p=0.05), 6MWT, extrapulmonary sarcoidosis (liver and spleen dimensions, hepatic enzymes, protrombine), CA and P serum nor urine levels. Weak but important negative correlation was observed between BALF TNFα and monocytosis (r=-0.1788, p=0.015).

Conclusion: Out of control cell growth is a basic step towards malignancy. The BALF cytokine inflammatory status reflects the systemic inflammation (measured by the serum cytokine network and non-specific inflammatory biomarkers).

The BALF TNFα status has no relation to the phenotype of sarcoidosis.

P699 Assessing sarcoidosis: The King’s Sarcoidosis Questionnaire and the minimal important difference
Amit S. Patel1, Arista Spinou1, Greg Keir2, Richard J. Siegert3, Toby M. Mahé1, Elisabeta A. Renzoni2, Athol U. Wells3, Irene J. Higginson3, Suninder S. Birring1, 1Asthma, Allergy and Lung Biology, King’s College London, 2Peripheral Lung Disease Unit, Royal Brompton Hospital, London. 3Department of Palliative Care, Policy and Rehabilitation, Cicely Saunders Institute, King’s College London, United Kingdom

Introduction: The King’s Sarcoidosis Questionnaire (KSQ) is a brief, validated, multi-organ, health status questionnaire. This study aimed to determine the minimal important difference (MID).

Methods: 60 patients with pulmonary sarcoidosis attending clinic (mean age 52 years; duration 7 years, 50% female, 67% Caucasian, 76% immunosuppressive medications) were asked to complete the KSQ on 2 occasions (change of therapy n=25). Combined Lung-Health Status modules (Lung-HS) consisted of 16 items and impact of medications 3 items; scoring range 0–100, 100=best. At the second visit patients also completed a 15-item global rating of change questionnaire (GRCQ). The MID corresponded to the mean change in KSQ in patients indicating a small change in GRQ (±2/3) and was also estimated by determining 1xSEM and effect size (ES) of 0.3.

Results: Health status was impaired at baseline: mean (SD) Lung-HS 54 (24) and Medication score 60 (29). 20 patients deteriorated, 18 improved and 22 were unchanged. The GRQ scores were associated with change in Lung-HS: r=0.4, p<0.01. There was a significant change in Lung-HS score in patients reporting a change of therapy (p=0.05). Combined Lung-HS MID determined by GRQC for those improving and those deteriorating was 5 and 6 and 5 point change respectively. The MID of individual General HS, Lung and Medication modules determined by GRQ were 5, 9 and 9 respectively.

Conclusion: The KSQ is responsive to changes in health status and can be used for longitudinal assessment of patients with sarcoidosis. The MID of the combined KSQ Lung-Health Status modules is a 5 point change.

P700 Corticosteroid (CS) therapy does not influence immune reactivity in patients with non-specific interstitial pneumonia (NSIP)
Anna Zaytseva1, Evgenij Shmelev2, Vladislav Gergert3. Granulomatosis Lung Diseases, Central Tuberculosis Research Institute, Moscow, Russian Federation

Aim: To assess the influence of CS therapy on immune reactivity in patients with NSIP.

Patients and methods: 27 patients (8 male 19 female, average age 57±3.2 years) with histologically proved NSIP were included. Immunosuppressive medications were used in 11 patients of group 1, the diagnosis was recently established and treatment was not yet started. 16 patients of group 2 received CS during 2–10 yrs. Blood level of IL-15, IL-2, IL-8, TNF-α basal and those deteriorating was assessed by ELISA. NSIP patients also completed a 15-item global rating of change questionnaire (GRCQ). The MID determined by GRQ was calculated for the GRQ scores of change for those improving and those deteriorating was 5 and 6 point change respectively. The MID of individual General HS, Lung and Medication modules determined by GRQ were 5, 9 and 9 respectively.

Conclusion: The KSQ is responsive to changes in health status and can be used for longitudinal assessment of patients with sarcoidosis. The MID of the combined KSQ Lung-Health Status modules is a 5 point change.

P701 Does emphysema influence the application of du Bois score in idiopathic pulmonary fibrosis?
Alime Bodliz1, Lac De lumain1, Caroline Dahliqv1, Jacques Jamart1, Giselle Maury21. Pneumologie, CHU Mont-Godinne, Yvoir, Belgium; 2USS, CHU Mont-Godinne, Yvoir, Belgium

Idiopathic pulmonary fibrosis (IPF) is the most frequent interstitial pulmonary fibrosis. Development in CT scan technology improved accuracy in lung study. Emphysema can be associated to IPF; the most common form is the “Combined pulmonary fibrosis and emphysema” syndrome (CPFE). The aim of this retrospective cohort study was to assess the impact of emphysema associated to IPF on functional parameters (Forced Vital Capacity FVC and Total Lung Capacity TLC) at baseline (t0) and on the loss of FVC after 6 months (t6) which is used in the du Bois prognostic score.
Data from 73 patients suffering from IPF were collected between 1982 and 2011 in an University Hospital with access to pharmacological studies and lung transplantation. Fifty six patients (M/F; 44/12; age 65.1±8.0) were considered for analysis. Biochemical diagnosis of emphysema was based on CT scan criteria used by Schmidt et al. [1].

IPF

With emphysema | Without emphysema | p
--- | --- | ----
N | 35 | 38
Age(years) | 65.9±9.3 | 65.3±11.8 | 0.39
Tobacco use | 15 (71%) | 24 (69%) | 0.41
History of respiratory hospitalization | 5 (24%) | 9 (26%) | 0.62
FVC ≤0.85 (L) | 86.7±18.4 | 72.6±20.6 | 0.02
TLC ≤1.8 (L) | 86.6±17.2 | 72.6±15.0 | 0.004
FVC ≤70% | -1.2±20.1 | -0.0±11.4 | NS
Du Bois score | 14.6±14.0 | 18.0±13.9 | 0.39

Emphysema seemed to influence significantly TLC and FVC at 0. In Du Bois score was not statistically different between the two groups although they corresponded to different sub domains of mortality risk. According to the Du Bois score, patients with emphysema were at lower risk of mortality than the others.

P702

Telomerase expression in idiopathic pulmonary fibrosis (IPF) and non small cell lung cancer (NSCLC).

Katarina Sanja1,2, Ivan LasihtoIki1, Giannoura Soufa2, Ioannis Giannarakos1, Maria Velivassaki2, Anna Psaraki2, Nikolaos Siafakas1,2, Katerina Antoniou1,2.1Department of Thoracic Medicine, Medical School, University of Crete, Heraklion, Crete, Greece; 2Laboratory of Molecular and Cellular Pulmonology, Medical School, University of Crete, Heraklion, Crete, Greece

Rationale: Telomeres protect chromosome ends since chromosomes lacking telomeres undergo fusion, rearrangement and translocation. Telomerase dysfunction has been linked with pathologic autoimmune responses and could play a role in both fibrogenic injury and the response to explain telomerase expression (mRNA levels of both subunits TERT and TERC) in Bronchovascular Lavage Fluid (BAL) and lung tissue of patients with NSCLC and IPF, since there are indications of common pathogenetic pathways in both diseases.

Patients and methods: We prospectively studied 44 BALF samples from NSCLC patients, 29 BALF samples from IPF patients and 13 BALF samples from control subjects. We also studied lung tissue samples from 32 IPF patients, 10 NSCLC patients and 21 control subjects. mRNA expression for both TERT and TERC was measured by Real-Time RT-PCR.

Results: (a) Lung tissue: IPF mRNA hTERT levels (0.24±0.14) were significantly lower compared to controls (0.46±0.30) (p=0.030). hTERC mRNA levels were higher in the control group (4.3±1.9) compared to NSCLC (2.8±1.5) and IPF (1.2±0.97), with strong group statistical significance (p<0.0001). (b) BALF: TERT mRNA expression was higher in the control group (0.79±0.06) compared to IPF (0.39±0.14) and NSCLC (0.34±0.29) (p=0.005). TERC mRNA expression was higher in the IPF group (1.09±0.39) compared to controls (0.54±0.40) and NSCLC (0.62±0.19), with no group statistical significance.

Conclusion: The attenuated expression of both telomerase subunits measured in NSCLC and IPF patients when compared to controls, suggests that telomerase genes may play a significant role in fibrogenesis and carcinogenesis, supporting the hypothesis of a common pathway.

P703

Specific features of pulmonary mechanics and gas exchange in patients with histiocytosis X (HX)

Marina Kamenova1, Natalia Korzina1, Olga Yuryeva1, Artem Tishkov3.1Institute of Pulmonology, Pavlov’s State Medical University, St. Petersburg, Russian Federation; 2Department of Physics, Mathematics and Informatics, Pavlov’s State Medical University, St. Petersburg, Russian Federation; 3Information Technologies in Education, Institute for Informatics and Automation of BAS, St. Petersburg, Russian Federation

Aim: To assess the changes of pulmonary mechanics and gas exchange parameters, which are typical for histiocytosis X.

Materials and methods: 67 patients with HX have been examined, including 48 men (mean age 29.1±1.4 yrs) and 19 women (mean age 27.1±2.6 yrs). Spirometry, bodyplethysmography, compliance measurement, diffusion capacity (DLCO) and blood gases were carried out for all patients.

Results: For either men or women the mean values of the lung mechanics parameters didn’t overstep the bounds of normal value, except for DLCO. Excluding 39 patients with normal value of indices, two groups of patients were identified. The first group of 20 patients shown signs of airflow limitation: decrease of the forced exhalation FEV1 (59.7±6.5%Pred) and FEF25-75 (39.7±8.9%Pred) and reduction normal TLC (98.4±6.5%Pred) by obstructive type (RV/TLC 168.0±11.2%Pred). The second group contained 8 patients with restrictive respira-

The EDD (exercise, DLco, dyspnea) index in diffuse systemic sclerosis with pulmonary fibrosis

Shahrzad Mohammadzadeh Lani1, Davood Atтарan1, Jaleh Shariatii2, Pouya Naranz3, Hassan Ghobad Marallu1, Saeid Akhlaghi1.1Lung Disease & Transplant Research Center, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran; 2Rheumatologic Diseases Research Center, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran; 3Internal Medicine, Ardabil University of Medical Sciences, Ardabil, Islamic Republic of Iran

Introduction: Pulmonary fibrosis secondary to systemic sclerosis (SSc) is the major cause of morbidity and mortality in these patients. The aim of this study was to determine the correlation of important lung function parameters with chest high resolution CT scan (HRCT).

Methods and materials: Thirty-two consecutive diffuse SSc patients (according to the criteria of american college of rheumatology) with pulmonary involvement were enrolled in this cross-sectional study. Patients with pulmonary fibrosis secondary to other reasons, previous restrictive lung disease, and history of smoking were excluded. Complete lung function evaluation was performed. Also the severity of dyspnea was evaluated by Modified Medical Research Council (MMRC) scale EDD index was calculated based on 6MWT, DLco, and MMRC.

The EDD index in scleroderma lung fibrosis

The chest HRCT was performed and the Warrick score recorded in all patients. Results: The mean age of the patients was 39.18 years ±9.39 (SD). Seventeen (53%) of patients were in EDD stage 1 (score: 0±0.3), 9 patients (28%) in stage 2 (<score ≤5), and 6 patients (19%) in stage 3 (score >5). The Warrick score was 10.84±6.94 (SD). There was statistically significant correlation between EDD index and Warrick score (p=0.001, r=0.72). Also there was statistically significant relation in EDD stages with Warrick scores (p=0.002).

Conclusion: The EDD as a useful lung function index is completely related to chest HRCT findings in SSc pulmonary fibrosis and can be used in clinical practice.

P705

Increased exhaled nitric oxide precedes lung fibrosis in a murine model of systemic sclerosis

Thong Hua-Huy1,2, Nhat-Nam Le-Dong1, Sy Duong-Quy1, Yihua Bei1, Sebastien Riviere1,2, Kien-Phong Trieu3, Carole Nico1, Frederic Batteux3, Anh Tuan Dinh-Xuan1.1Physiology, Paris Descartes University, Paris, France; 2Laboratory of Immunology, Paris Descartes University, Paris, France

Background: Exhaled nitric oxide (eNO) increased in patients with systemic sclerosis (SSc) and interstitial lung disease. Reactive oxygen species (ROS) and bleomycin induced skin and lung fibrosis in mice, mimicking the SSc in humans. Objectives: This study aimed to validate eNO measurement method in mice and to study the evolution of lung inflammatory and fibrotic processes in mice injected with HOCI or bleomycin.

Methods: C57BL/6 mice were randomized into 3 groups receiving subcutaneous injections of HOCI, bleomycin, or PBS for 2, 4, or 6 weeks. Exhaled NO was measured at the end of each injection period and after 2 resting weeks without injection (8 weeks). Mice were then sacrificed to obtain skin and lungs tissues for NO synthases (NOS) expression analysis.

Results: Increased exhaled NO, inducible NOS and 3-nitrotyrosine expression in bronchial epithelium, lung neutrophils and macrophages were observed at early phases (2 and 4 weeks) in HOCI- and bleomycin-treated mice. Interestingly, lung vascular endothelial NOS expression decreased significantly at 6th and 8th week. Skin fibrosis was significantly increased from the 4th week and lung fibrosis from 6th week.

Conclusions: Exhaled NO can be used as a sensitive biomarker of lung inflammation in these murine models in which inflammation precedes fibrotic processes in skin and lungs. Mechanisms linking inflammation and fibrosis remain to be clarified.
P706 Elevated serum B cell activating factor belonging to the TNF family (BAFF) in interstitial lung diseases associated with collagen vascular disease.

Tsunomi Hayato1, Sakakura Takuya, Keiko Mizuno, Ikuko Higashimoto, Hiromasa Inoue.

Department of Pulmonary Medicine Advanced Therapeutics

Course Cardiovascular and Respiratory Disorders, Kagoshima University

Graduate School of Medical and Dental Sciences, Kagoshima, Japan

Background: BAFF is a vital homostatic cytokine for B cells. Increased serum levels of BAFF were found in a number of different autoimmune diseases and patients with polymyositis with interstitial lung disease (ILD) had higher BAFF levels than those without ILD. However, serum BAFF levels have not been reported in patients with ILD associated with collagen vascular disease (CVD-IP) and idiopathic interstitial pneumonia (IP).

Aim: We investigated serum levels of BAFF in patients with CVD-IP and with IP to determine whether they correlate with pulmonary function.

Methods: Twenty-seven patients with CVD (n=15) and CVD-IP (n=12), who visited our institution from 2008 to 2010 and underwent pulmonary function test, were enrolled. Underlying CVDs consisted of rheumatoid arthritis (n=4), dermatomyositis (n=2), systemic sclerosis (n=2), ANCA-associated systemic vasculitis (n=1), and mixed connective tissue disease (n=1). Twenty-three healthy volunteers were included as a control group. Serum BAFF levels were measured by ELISA.

Results: Serum BAFF levels were 4.4±1.2 ng/ml for CVD-IP, 3.1±0.6 ng/ml for IP, and 2.0±0.1 ng/ml for the control. BAFF was significantly elevated in CVD-IP compared with control subjects. An inverse relationship between serum BAFF levels and DLco was noted in patients with CVD-IP.

Conclusion: We found elevated serum BAFF levels in CVD-IP patients and correlation with severity for ILD.

P707 Grape seed proanthocyanidin extract (GSPE) attenuates bleomycin-induced pulmonary fibrosis in mice.

Seung Won Ra1, Byungwon Kwon2, Hong Rae Cho3, Young Ju Min4, Kwang Won Seo5, Yangjin Jegal6, Hee Jeong Cha7, Jung Cheol Lee8, Jong-Joon Ahn9.

1Internal Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea; 2Biological Sciences, Biomedical Research Center, University of Ulsan, Ulsan, Republic of Korea; 3Surgery, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea; 4Pathology, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea; 5Pulmonary and Critical Care Medicine, Presbyterian Medical Center, Jeonju, Republic of Korea

Background: Grape seed proanthocyanidin extract (GSPE) has more powerful antioxidative activity than other well-known antioxidants, including vitamin C and E. Idiopathic pulmonary fibrosis is a chronic progressive disorder with a poor prognosis. An antioxidant-antimicrobial imbalance may contribute to the disease process in idiopathic pulmonary fibrosis.

Objectives: To examine whether GSPE which is known to act as an antioxidant has therapeutic effect on bleomycin-induced pulmonary fibrosis in mice, an animal model of idiopathic pulmonary fibrosis.

Methods: Mice were treated by intratracheal instillation of bleomycin. GSPE was administered by intraperitoneal (IP) injections (30, 60, or 90 mg/kg).

Mice were sacrificed on days 21 after bleomycin instillation.

Results: Compared with the BLM/Veh group, histologic findings in mice treated with BLM and IP injection of GSPE (BLM/GSPE) showed less fibrotic lesions in a dose-dependent manner. The mean Aschcroft’s fibrosis score in the BLM/Veh group was significantly higher than in the BLM/GSPE group. The lung hydroxyproline concentration on Day 21 was significantly higher in the BLM/Veh group than in the BLM/GSPE group (62.9 vs 55.3, 51.9, 50.4 ug/ml).

Conclusions: GSPE attenuated bleomycin-induced pulmonary fibrosis in mice. Prophylactic GSPE may be useful in the treatment of idiopathic pulmonary fibrosis.

P708 Clinical impact of irradiated lung volumetric modeling in adjuvant breast radiotherapy (RT).

Abhay Javia1, Sateesh Patel2, Rajiv Palwal2, Purvesh Patel5, Desheej Patel4.

1Pulmonary Medicine, P.D.U. Medical College, Rajkot, Gujarat, India; 2Pulmonary Medicine, Pramukhswami Medical College, Karamsad, Gujarat, India; 3Dept. of Anaesthesiology, Pramukhswami Medical College, Karamsad, Gujarat, India

Background: No relation with the ILD types.

Methods: (Pt) beginning breast RT between June ’07 & March ’10 were prospectively reviewed. Pt included were women with DCIS or Stage I–III carcinoma, who received RT using a 3D-CRT technique to the breast or chest wall (2-field RT (2FRT) ± supraclavicular/postaxillary boost (4-field RT (4FRT)).

50.4 Gy in 28 fl. Lung DVH parameters, 2D parameters are reported. Post RT all Pt underwent 3 monthly (mo) clinical/PFT & 6 monthly HRCT scan. Modeling equations to predict the PIV from 2D parameters was developed using linear regression analysis. Mann-Whitney U test was used to analyse PFT & HRCT changes over time. Binary logistic regression used to evaluate relation between PIV and Radiation pneumonitis (RP).

Results: 44 Pt met the inclusion criteria: 6 had 2FRT & 38 had 4FRT. With a medium follow-up of 14 months, 5 Pts reported mild respiratory symptoms at 1mo, which resolved completely at 3mo post-RT.A significant decrease of FVC, FEV1, MMEF25-75 & DLco was observed at 3mo,with partial recovery at 9 mo in the Pt treated with 4FRT, but there was no decrease of PFT in Pt treated with 2FRT. In HRCT at 6mo grade I opacity was present in 4 & 1 Pts (PIV 15-19.9 and Mean lung dose 10.1-15) undergoing 4FRT & 2FRT.

Conclusions: Within the range evaluated in this study, the 3D parameters (FV) better predicted an early decrease in pulmonary function, although HRCT detected RP was observed only when > 11% of the lung was irradiated in 4FRT-4FRT is associated with significant reduction in PIV but not 2FRT.

P709 Impact of diagnostic pitfalls on the management of pulmonary sarcoidosis.

1Granulomatosis Diseases/Endoscopy Depts, CTRI RAMS, Moscow, Russia; 2Pulmonary Medicine, Presbarb Medical Center, Jeonju, Republic of Korea; 3Surgery, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea; 4Pathology, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea

Background: Work-up in patients with sarcoidosis includes differentiation mainly with pulmonary TB, hypersensitivity pneumonitis and community-acquired pneumonia. Usually bronchoscopy is performed with lung biopsy and BAL, but often this option is not available, and thus diagnostic mistakes arise.

Aim: To evaluate frequency and possible impact of diagnostic pitfalls on management of sarcoidosis patients.

Methods: 127 patients with newly diagnosed sarcoidosis based on results of lung biopsy and BAL during bronchoscopy were enrolled into study. We analyzed primary diagnosis and treatment, duration of treatment, age, sex, usage of systemic steroids after the final diagnosis and mean dose of them in patients with correct (controls) and incorrect primary diagnose (study group).

Results: 23 patients (18.1%) had diagnostic pitfalls, from which 12 were treated from pulmonary TB in HRZE regimen around a year (46.57±3.32 wks), 7 treated from pneumonia for 3.11±1.13 wks with further observation for 20,33±5.52 wks, and 4 pts were diagnosed as having a hypersensitivity pneumonitis with mean treatment with steroids 30±5.25±2.89 wks. Groups were comparable for sex and age. In study group, 10/23 (43.5%) pts had relapse of disease versus 30/104 (28.8%) in controls (p<0.05), frequency of systemic steroids use was also higher (15/23 (65.2%) versus 59/104 (56.7%) in controls). The mean dose of prednisone in sudy group was significantly higher than in controls: 21.7±0.9 mg vs 17.2±0.7 mg (p<0.05).

Conclusions: Diagnostic pitfalls in work-up process among sarcoidosis patients are quite frequent, and lead to a more severe disease flow with higher frequency of systemic steroids usage and higher dose of them.

P710 Pulmonary hypertension in different interstitial lung diseases.

Laxminarayan Pinto, Beijing Chao-Yang Hospital, Capital Medical University, Beijing, China

Background: Pulmonary Hypertension (PH) has been proposed a higher incidence in Interstitial Lung Diseases (ILDs). PH in different ILDs has different pathogenesis. PH in patients with ILDs is not well recognized and can occur in the absence of advanced pulmonary dysfunction or hypoxemia.

Objective: To investigate the incidence of pulmonary hypertension in different types of interstitial lung diseases.

Methods: Two hundred and five patients with ILD between 24 and 89 years old (mean age one hundred and four male, one hundred and one female) were evaluated, to discuss the incidence of PH in ILD seems to have no relation with the ILD types.

Results: Two hundred and five ILDs in Beijing Chao-Yang Hospital, ranging from January 1st 2010 to June 8th 2011, 27 were diagnosed as PH, so the incidence of PH in ILD is 13.2%. There was no significant difference of the incidence of PH in ILD between males and females (p=0.901). There was a significant difference of the incidence of PH in ILD between age ≥60yrs and <60yrs (p=0.017).The incidence of PH has no statistically significant difference among different types of ILD (p=0.455).

Conclusion: The total incidence of PH in ILDs is 13.2%, the patients with age ≥60yrs have higher incidence of PH. Whether PH develops in ILD seems to have no relation with the ILD types.
**P711**

Profile of interstitial lung diseases in Pakistan, Karachi pulmonology clinics registry data, 2008 – 11

Mosab Ahmad1,2, Asif Naseem1, Rashid Ahmed1, Azeemuddin Muhammad1

1 Pulmonology, Liaquat National Postgraduate Medical Centre, Karachi, Pakistan; 2Pulmonology, Health Care Hospital, Karachi, Pakistan; 3Radiology, Advance Radiology Clinics, Karachi, Pakistan; 4Radiology, Aga Khan University Hospital, Karachi, Pakistan

Background & Objective: No published data is available about the status of Interstitial Lung Diseases (ILD) in Pakistan. This study ponders to determine the incidence and relative frequency of various ILDs in Karachi, its most populous multi-ethnic city.

Methods: We reviewed data from a registry cataloging to 3 pulmonology clinics in different areas of the city. Based on a detailed questionnaire it records age, gender, exposure history, clinical presentation, HRCT and PFT findings mandatorily and BAL/VATS data if available. It prospectively recorded diagnosed ILD cases between Jan 2008 and Dec 2011 and deaths occurring during follow-up.

Results: In a total of 5600 pulmonology referrals, the incidence of ILD was 2.3% (n=133) with a mean age of 55.1 years (+12.9 SD), mortality of 22.6% and median survival of 3 years. Idiopathic Pulmonary Fibrosis (IPF) (49.6%), Non Specific Interstitial Pneumonitis (NSIP) (19.5%) and Sarcoidosis (17.3%) were the most frequent ILDs followed by Collagen Vascular Disease Related (5.3%), Drug Induced ILD (4.5%) and Hypersensitivity Pneumonitis (3.8%). Reporting females (n=91) outnumbered males (n=42). The incidence of IPF/NSIP was greater in males (76%) while sarcoidosis and other ILDs occurred more in females (34%). Interestingly, out of 45 IPF diagnosed housewives living in congested areas, 42% had chronic avian exposure due to home breeding/pets.

Conclusions: Establishes for the first time the considerable presence of ILD in Pakistani population and describes its salient features. Hopefully this will improve disease awareness and help us expand this registry to other major cities for greater input towards research.

**P712**

BAL protein profiles specific of different interstitial lung diseases

Elena Bargell1, Claudia Landi1, David Bennett1, Pasquale Di Sipio1, Luca Bini1, Paola Rottoli2

1 Respiratory Disease Sect., Dept. of Clinical Medicine and Immunological Science, University of Siena, Italy; 2Functional Proteomic Lab., Dept. of Biotechnology, University of Siena, Italy

Interstitial lung diseases (ILD) are an heterogeneous group of lung disorders with different etiopathogenesis, clinical courses and prognosis. In the last ten years our group of research is focusing on the proteomic analysis of BAL in different interstitial lung diseases.

Aims of this proteomic study were to compare protein profiles of Sarcoidosis (S), Idiopathic Pulmonary Fibrosis (IPF), Langerhans cell Histiocytosis (PLCH), pulmonary fibrosis associated with Systemic sclerosis (SSc) patients in order to identify proteins of interest involved in specific pathogenetic networks or potential biomarkers with clinical value.

Methods: Population of patients was composed by 9 S, 7 IPF, 9 PLCH, 7 SSc. Proteomic analysis was performed by 2D-electrophoresis. Image analysis was done by Image Master Platinum 7.0 software. Protein identification was performed by mass spectrometry.

Results: Image analysis revealed distinct expression profiles for each ILD. Among the 280 differentially expressed in our ILD samples there were Complement C3, complement factor B, complement factor I, antithrombin III, angiotensinogen, vimentin D binding protein, Leucin-rich alpha-2-glycoprotein, 14-3-3 protein epsilon, calcyphosin, kiningen N-term, alpha-2-HS-glycoprotein.

Conclusion: The proteomic analysis of BAL confirmed the possibility to use 2D-electrophoresis to highlight different protein profiles among specific ILDs.

**P713**

Idiopathic pulmonary fibrosis: Clinical, radiological and functional significance of biomarkers of proliferation

Edwin Roger Parga, Marcel Lekevicius Costardi, Vera Capelozzi, Pathology, Faculdade de Medicina da Universidade de São Paulo, Brazil

Background: Natural course of idiopathic pulmonary fibrosis (IPF) could be predicted by proliferative markers of the fibrotic process, such as myofibroblasts and interleukins (IL)-13 and IL14. Our primary aim was to determine whether these proliferative markers influence the course of IPF course measured by a radiological/functional score.

Methods: Twenty-eight patients with biopsy-proven IPF disease, who underwent pulmonary evaluation by high-resolution computed tomography (HRCT) fibrosis score and pulmonary function tests were studied. Five normal lung tissues (NTL) were included Biomarkers in lung tissues were detected by immunohistochemistry and quantified by histomorphometry for myofibroblasts alpha-smooth muscle actin (α-SMA), anti-interleukin (IL)-4 and IL-13.

Results: Myofibroblast amount, IL-4 and IL-13 expression were higher in IPF than in NLT (p<0.01). Myofibroblast expression of α-SMA was positively correlated to IL-14 and IL-13 expression. Lung tissue from patients with high HRCT fibrosis scores expressed significantly greater α-SMA+, IL-4 and IL-13 when compared with patients with low HRCT fibrosis scores (p<0.05). Negative correlations were found between myofibroblasts α-SMA+ and VC and DLCO.

Conclusions: Proliferative markers, detected by immunohistochemistry, in lung tissue allowed recognizing a dichotomous discrimination of HRCT fibrosis course and influenced pulmonary function tests, suggesting that they may be promising markers of prognosis in these patients. Financial support: FAPESP, CNPq.

Significance of protein S in patients with interstitial lung disease

Masahiro Naito1, Osamu Taguchi1, Kentaro Fujitawa1, Masahiro Onishi2, Takashiro Takagi3, Tetsu Kobayashi3, Hirohiko Kobayashi4, Corina D’Alessandro-Gabazza5, Esteban Gabazza5

1Department of Respiratory Division, Mie University School of Medicine, Tsu, Japan; 2Department of Immunology, Mie University Graduate School of Medicine, Tsu, Japan

Background: Protein S exerts anticoagulant activity by acting as a cofactor of activated protein C for the inactivation of coagulation factors Va and VIIa. We have previously reported that protein S protects against lipopolysaccharide-induced acute lung injury by directly inhibiting the local expression of inflammatory cytokines without affecting coagulation (Takagi T, et al. 2009). However, the role of protein S in interstitial lung disease remains unclear.

Objective: The aim of this study is to evaluate the clinical significance of protein S in patients with interstitial lung disease.

Methods: This study comprised 106 patients with interstitial lung disease admitted in our institution between August 2008 and December 2011. There were 39 patients with interstitial pneumonia, 25 with sarcoidosis, 9 with collagen vascular disease-associated interstitial lung disease, 8 with organizing pneumonia, 7 with pulmonary sarcoidosis, 5 with tumour-associated ILD, 4 with hypersensitivity pneumonitis, 2 with IgG4 related multi-organ lymphoproliferative syndrome, 1 with alveolar proteinosis, and 1 patient with alveolar hemorrhage. Levels of protein S in BALF were measured using an enzyme-linked immunosorbent assay.

Results: Significant changes in the BALF levels of protein S were observed among the different types of interstitial lung diseases. The BALF level of protein S was significantly correlated with the number of macrophages, lymphocytes and with the BALF concentration of total protein and albumin.

Conclusion: These results suggest that protein S plays role in the pathogenesis of interstitial lung disease.

**P715**

Combined pulmonary fibrosis and emphysema syndrome (CPFE)

Francisco Mutio1, Inmaculada Herráez2, Elena Bolló1, Silvia Fernández1, Beatriz Carrón1, Emilio Santalla1, Florentino Díez3

1Respiratory Department, Complejo Asistencial Universitario de León, León, Spain; 2Department, Complejo Asistencial Universitario de León, León, Spain

Introduction: CPFE is a clinical entity which consists in the coexistence of emphysema of the upper lobes and pulmonary fibrosis of the lower lobes.

Method: Retrospective descriptive study of cases diagnosed of CPFE between 2007 and 2012.

Results: 44 patients, all of them men, with an average age of 69 years. All were current or ex smokers. 50% had a UIP (usual interstitial pneumonia) pattern at the HRTC, 11.4% possible UIP pattern, and 36.8% inconsistent UIP pattern. All the patients had emphysema, above all paraseptal and centrilobular. PAH was present in 10 patients. The final diagnosis was: 18 IPF, 1 possible IPF, 1 NSIP, 3 possible NSIP, 6 fibrosis associated connective tissue diseases, 1 asbestosis, 1 hypersensitivity pneumonitis, 1 drug associated fibrosis, and 12 non classificable interstitial pneumonias. During follow-up 8 patients died, 6 were diagnosed of lung cancer.

| Table 1. Results |
|-----------------|-----------------|
| **n** | **s** |
| **Age** | 44 | 69±12 (43-88) |
| **Men** | 44 | 100% |
| **Current smokers** | 15 | 34% |
| **Ex-smokers** | 29 | 65% |
| **PAH** | 10 | 22.7% |
| **PAs** | 10 | 56.3±31.7 (36-90) |
| **FVC (%)** | 38 | 101.7±21.3 (47-152.5) |
| **FEV1 (%)** | 38 | 72.4±12.5 (45.9-78.5) |
| **TLC (%)** | 24 | 89.6±23.1 (45.1-139.7) |
| **DLCO (%)** | 30 | 50.8±12.8 (39.2-104.1) |
| **DLCO/VA (%)** | 34 | 60.7±24.8 (25.4-123.7) |

Conclusions: All of the patients from this study are men with smoking history. These patients have, lung volumes preserved with a severe impairment of gas exchange. The high prevalence of PAH and its important role in the prognosis justify echocardiography. As these patients might have a high prevalence of lung cancer, a close follow-up would be advisable.
P716 Nine cases of interstitial lung disease associated with anti-CADM140 antibody positive dermatomyositis
Yuko Waseda1, Yukari Ichikawa1, Nobuyuki Katayama1, Masahide Yasui2, Kazuo Kanazawa3, Kazuhiro Tsuchiya4, Katsuki Yagi5, Satoshi Watanabe6, Ryo Matsunuma1
Kanazawa University, Kanazawa, Ishikawa, Japan; 4Department of Dermatology, Kanazawa University, Kanazawa, Ishikawa, Japan; 5Respiratory Medicine, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan; 6Respiratory Medicine, Kanazawa Municipal Hospital, Kanazawa, Ishikawa, Japan

Background: Anti-CADM140 antibody (CADM) was found in some amyopathic dermatomyositis (DM) patients in 2005. It was reported that about 50% of CADM positive patients died from acute exacerbation (AE) of DM-related interstitial lung disease (DM-ILD) despite treatment. As compared with CADM negative patients (about 6%), the rate of AE of ILD is clearly high in CADM positive pts. [Objective] To elucidate the clinical characteristics of ILD associated with CADM positive DM.

Methods: Blood examination, arterial blood gas analysis, pulmonary function testing, bronchoalveolar lavage (BAL) analysis and pattern of chest CT were examined in 9 pts who were diagnosed with CADM positive DM in our hospital. Results: Since the average value of FVC and CRP at the time of the first medical examination was 662% of the normal range in 7 pts, slightly high (217 IU/L) in 1, and significantly high (25300 IU/L) in 1. The value of KL-6 was in the nearly cut-off range in 8 pts, and significantly high in 1 (3764). Alveolar-arterial oxygen difference was increased in 3 pts. In 4 pts in which BAL was performed, the lymphocyte differentiation was all high. Concerning chest CT image, patchy shadow or patchy shadow and trabeucular shadow in outside layer of the lung fields were seen in 7 pts, GGO around broncho-vascular bundle in 1, and no abnormal shadow in 1. All of the shade were slight. Although one pt died of AE, 8 pts survive as of February 2012.

Conclusion: In DM-ILD, even if the CT image and data are slight, whenever the CT image is not typical NSIP pattern, we have to take the possibility of CADM into consideration.

P717 Chitotriosidase activity and CHIT1 gene polymorphism in sarcoidosis
Malev Harland1, Mirjana Zupanic2, Barbara Salobir1, Alek Maves1, Bozut Peterlin1, Marjeta Tercelj1, 1Department of Pulmonary Diseases, University Medical Centre, Ljubljana, Slovenia; 2Biochemical Laboratory, Pediatric Clinic, University Medical Centre, Ljubljana, Slovenia; 3Institute for Medical Genetics, Medical Faculty Ljubljana, Ljubljana, Slovenia

Introduction: Among several biomarkers of sarcoidosis activity chitotriosidase (CTO) has been found to be useful. Some subjects have a 24-base pair duplication in the CTO gene (CHIT1) that results in the production of inactive enzyme which might influence CTO activity.

Aims: The study was conducted 1) to confirm previous observations of increased CTO activity in patients with sarcoidosis and 2) to evaluate the influence of different CHIT1 polymorphism on CTO activity.

Methods: The study comprises 47 patients with newly diagnosed active sarcoidosis (27 females, 20 males, average age 42.3 years). CTO activity was determined in serum and BAL using a standard fluorimetric method. CHIT1 genotyping was done by polymerase chain reaction (PCR).

Results: A normal CHT1 genotype (NN) was present in 61.7% of the subjects. 34.0% were heterozygotes for deleted allele (ND) and 4.3% were homozygotes (DD). The mean serum CTO value was 136 nmol/mL/h (± 583) and was increased in 93.6% of patients. The mean BAL CTO value was 9.01 nmol/mL/h (± 12.8). There was no difference in serum and BAL CTO activities (p =0.70, p < 0.001).

There was no significant difference between NN and ND subjects in serum CTO activity (855±15.02 nmol/mL/h, 4.31±4.507 nmol/mL/h, p=0.001). In BAL there was no difference between CTO activity in normal and homozygotes (348 nmol/mL/h, p=0.331), but a significant difference in BAL CTO activity (12.2±15.02 nmol/mL/h, 4.31±4.507 nmol/mL/h, p<0.001). There was no CTO activity in mutation homozygotes.

Conclusions: The results confirm previous observations that the CTO activity is increased in patients with sarcoidosis. Unexpectedly, there was no significant difference in serum CTO activity between CHIT1 normal homozygotes and heterozygotes which warrants further study.

P718 Safety and tolerability of pirfenidone (PFD) in patients with idiopathic pulmonary fibrosis (IPF) receiving commonly used concomitant medications
Concepcion Gonzalez1, Carlos Alberdi1, William Bradford2, Ulrich Costabel3, Dave Feldman2, Paul Noble1, Steven Sahn4, Dominique Valeyre2, Roland du Bois2, 1Respiratory Medicine, InterMune, Inc., Brisbane, CA, United States; 2Division of Pulmonary, Critical Care, Allergy and Immunology, University of California, San Francisco, United States; 3Department of Medicine, Duke University School of Medicine, Durham, NC, United States; 4Department of Medicine, Medical University of South Carolina, Charleston, SC, United States; 5Department of Medicine, Assistance Publique–Hôpitaux de Paris, France; 6Department of Medicine, Imperial College, London, United Kingdom

Introduction: The CAPACITY Program (CAP) included two Phase 3 trials of PFD in 779 patients with IPF. Analyses were conducted to assess the safety of PFD in patients receiving commonly used concomitant medications.

Objectives: To examine the safety/tolerability of PFD in IPF patients receiving commonly used concomitant medications.

Methods: Pooled data from the CAP trials were analyzed. Commonly used concomitant medications were defined as those used by ≥25% of patients in any treatment group between the first and last dose of study drug. The percentage of patients with selected treatment emergent adverse events (TEAEs) while on or within 28 d of cessation of commonly used concomitant medications was assessed. Patients in the PFD 2400 mg daily group were evaluated using a composite safety endpoint that included any Grade 3 or 4 TEAE, discontinuation of PFD, interruption/dose reduction of PFD, or any serious AE.

Results: Commonly used concomitant medications and vaccines included: acetylsalicylic acid, azithromycin, influenza vaccine, multivitamins, omega3, paracetamol, salbutamol, and simvastatin. No evidence of a clinical pattern of TEAEs was observed with the use of PFD and these commonly used medications or vaccines. Patients receiving these medications had similar patterns of safety as those not receiving a commonly used concomitant agent.

Conclusions: These data suggest that PFD is safe and generally well tolerated in patients with IPF when used with a spectrum of commonly used concomitant medications.

P719 Systemic lupus erythematosus (SLE): Cyto- and chemokines as possible serum markers for pulmonary involvement
Johannes Streititz, Zsofia Weiszhar, Christine Balogh, Andras Bikov, Krisztina Vincze, Lilla Tamasi, Ilidiko Horvath, Veronika Muller, Department of Pulmonology, Semmelweis University, Budapest, Hungary

SLE is a systemic autoimmune disease associated with high prevalence of lung involvement. Pulmonary manifestations (PM) in SLE are difficult to diagnose and the ability of its detection with serum markers could be useful for early detection and specific treatment.

Twenty three patients with SLE (age: 45.4±14.6 years; 22 female, 10 smokers) were enrolled in pulmonary examination including physical examination, chest X-ray, lung function test, CO diffusion capacity (DLCO) measurement and blood gas analysis. Plasma of 17 patients was analyzed by protein array system with chemoluminescence imaging, including the cytokines and chemokines: 4-IBB, IP-10, IL-12 p70, IL-17, CCL14a, CCL21, CCL28, MCP-1, MCP-4, F-LAT.

PM was diagnosed in 12 patients (52.2%; age:43.1±14.2 years), including pulmonal fibrosis (3), shrinking lung syndrome (1) and ventilatory disorder (8). Ten patients had no PM (47.8%; age:50±12.1 years). In patients with PM significant decrease of static lung volumes and DLCO were noted (TLC % pred: 81.1±3.3 vs. 93.7±3.9 p <0.05, FEV1 % pred: 77.8±5.7 vs. 94.2±5.5 p=0.05, DLCO % (IT): 62.4±4.4 vs. 97.3±6.7 p<0.001). Microarray measurements confirmed significantly higher CCL21 level in SLE patients with PM, negatively correlating with FEV1 (r=0.65, p=0.04) and positively with resistance of the airways (r=0.73, p=0.02). The biomarkers MCP-1 and IP-10 as potential candidates for further analysis of PM in SLE patients.

In lupus patients PMs are prevalent and are associated with decreased lung volumes and DLCO. Microarray results identified CCL21 and MCP1, IP10 as potential candidates for further analysis of PM in SLE patients.

92. Diagnostic insights and decision making in primary care

P720 The usefulness of point-of-care-testing for C-reactive protein in lower respiratory tract infection/acute cough Elena Andreeva, Hasse Melbye, 1Family Medicine, Northern State Medical University, Arkhangelsk, Russian Federation; 2Department of Community Medicine, University of Tromsø, Norway

Background: Respiratory tract infections and acute cough are too frequently treated with antibiotics. Point-of-care test (POCT) for C-reactive protein (CRP) has in one study been shown to significantly reduce antibiotic prescribing for lower respiratory tract infections (LRTI) without compromising recovery.

Aim: The aim of the study was to evaluate the effect of using CRP test in general practice patients with LRTI on the prescription of antibiotics, referral to radiography, and the outcome of the patients.

Methods: Open randomised clinical trial, patients with LRTI/acute cough were included. CRP-test was carried out before treatment was decided in the intervention group, with the use of Afinion test system (Axis Shield). Frequency of prescribing antibiotics and referral to radiography were main outcome measures.

Results: Altogether, 179 patients were included, 101 in the intervention group tested by POCT for CRP and 78 in the control group. No significant difference in

SUNDAY, SEPTEMBER 2ND 2012
age, gender, co-morbidity, symptoms and chest findings was found between intervention and the control groups. In the intervention group antibiotics prescribing rate was significantly lower: 37.4%, than in the control group, 60.2% (p=0.005). Referral to chest X-ray examination was also significantly lower in the intervention group, 55.4%, than in the control group, 76% (p<0.01). Two weeks after start of treatment the recovery rate (% fully or almost recovered) was 92% and 93%, respectively.

Conclusion: CRP testing may reduce unnecessary antibiotic prescribing and referral to radiography in patients with LRTI and acute cough without compromising recovery.

P721
Influence of different spirometry interpretation algorithms (SIA) on decision making among primary care physicians
Anthony D'Urzo1, Pietter Jugovic1, Revenen Thirad2. 1Department of Family and Community Medicine (DFCM), University of Toronto, ON, Canada; 2Department of Family and Community Medicine (DFCM), University of Toronto, Burlington, ON, Canada

Background: Typically, the only spirometric data required for clinical decision making are the Forced Expiratory Volume in one second (FEV1) and the Forced Vital Capacity (FVC). Limitations of SIA promoted for adoption in primary care have been described (Can Fam Physician October 2011 57: 1148-1152, 1153-1156).

Aims and objectives: This study examines how different SIA may influence decision making among primary care physicians.

Method: Thirty seven primary care physicians were asked to interpret nine spiromograms presented twice in random sequence using two different SIA (as stand alone aids) and touch pad technology (remote audience response devices) for anonymous data capture and recording.

Results: We observed important differences in the interpretation of the same spiromograms using two different SIA. When the pre-bronchodilator FEV1/FVC decision node in one algorithm prompted referral, the latter SIA did not include a logic string leading to a post-bronchodilator FEV1/FVC so a definitive consideration of COPD could not be made. The absence of a post-bronchodilator FEV1/FVC decision node in one algorithm prompted referral for evaluation of low FVC.

Conclusions: This pilot study suggests that different SIA may influence decision making and lead clinicians to interpret the same spirometry data differently.

P722
Clinical assessment of a portable FEV1/FEV6 meter for the detection of airway obstruction
Jan Vandervoort1, Rosalie Buysschaert1, Sylvia Verbanck2. 1Department of Family Medicine, Vrije Universiteit Brussel, Brussels, Belgium; 2Respiratory Division, University Hospital, Vrije Universiteit Brussel, Brussels, Belgium

Objectives: To evaluate the accuracy of the portable Vitalograph-COPD-6 device in the detection of airway obstruction.

Methods: All participants underwent a measurement of FEV1, FEV6 and FEV1/FEV6 using the COPD-6 meter, and a conventional spirometry measuring FEV1, FVC and FEV1/FVC. Conventional spirometry was performed by highly trained lung function staff, whereas the COPD-6 meter was used by final-year medical students, according to the manufacturer’s instructions. Subjects were randomized to determine which measurement was performed first. The FEV1/FEV6 ratio that corresponded to the optimal combination of sensitivity and specificity was determined from a ROC curve. Agreement was analyzed by calculating sensitivity, specificity, positive and negative predictive values (PPV and NPV), and the kappa-index.

Results: Test results of 147 subjects were analyzed. The prevalence of obstruction was 42%. The area under the ROC-curve was 0.946. The FEV1/FEV6 ratio that corresponded to the optimal combination of sensitivity and specificity was 73%. For this cutoff value sensitivity, specificity, PPV and NPV were 82%, 93%, 90% and 88%, respectively. The kappa-index was 0.76. Lowering the cutoff point to 70% resulted in sensitivity, specificity, PPV and NPV of 65%, 98%, 95% and 79%, respectively. For a FEV1/FEV6 cutoff point of 80%, they were 95%, 69%, 69% and 95%, respectively.

Conclusions: The portable Vitalograph-copd-6 device is an accurate device for detection of airway obstruction. Best sensitivity/specificity for FEV1/FEV6 was obtained with a fixed cutoff point of 73%. For screening purposes, high sensitivity (95%) can be reached when using an 80% threshold for FEV1/FEV6.

P723
Is the COPD assessment test (CAT) useful in our patients?
Eskoalta Pérez1, Milagros Iriberry2, Patricia Sohbatidlo1, Lide Alalda3, Lorea Martínez1, Amaia Sagarna1, Carmen Jaca1, Sonia Castro4, 1Pneumology, Cruces Hospital, Barakaldo, Spain; 2Pneumology, Cruces Hospital, Barakaldo, Spain; 3Pneumology, Cruces Hospital, Barakaldo, Spain; 4Epidemiology, Cruces Hospital, Barakaldo, Spain; 5Pneumology, Cruces Hospital, Barakaldo, Spain; 6Pneumology, Cruces Hospital, Barakaldo, Spain; 7Pneumology, Cruces Hospital, Barakaldo, Spain; 8Pneumology, Cruces Hospital, Barakaldo, Spain

Aim: To determine the correlation between scores obtained in the quality of life (QL) questionnaires with functional and clinical parameters.

Methods: Prospective study. 56 moderate-severe COPD patients with exacerbating phenotype admitted from 1/02/11 to 30/10/11. Studied items: symptoms, MRC scale, spirometry, BML, 6MWT, CAT and St.George. Descriptive analysis.

Results: In Table 1 general characteristics are shown. Functional parameters do not correlate with CAT, and have a poor inverse correlation with St.George. BODE, 6MWT and dyspnoea have a good correlation with both questionnaires. Graphic 1: correlation between BODE and SG, Graphic 2: correlation between CAT and SG, Graphic 3: correlation between scores obtained in CAT and SG about dyspnoea in basal situation.

A pilot study on the effects of telepulmonology in primary care on efficiency and quality of care in the Netherlands
Leone Thijssing1, Chrisian Meleman2, Job van der Heijden1, Leonard Willamp3. 1Research, KSYOS Health Management Research, Amstelveen, Netherlands; 2Pulmonology, Spaarne Hospital, Hoofddorp, Netherlands; 3Research, KSYOS Telemedical Centre, Amstelveen, Netherlands

Introduction: Misinterpreting spirometry results can lead to under- and misdiagnosis of obstructive pulmonary diseases. In telepulmonology a general practitioner (GP) digitally consults a pulmonologist. We assessed the effect of the use of telepulmonology (TP) in the daily practice of Dutch GPs on prevented physical referrals and potential quality of care improvement.

Methods: GPs accessed a secured web-based consultation (TC) system (KSYOS); filled in the patient data; added a spirogram; optionally added relevant clinical information. This information was sent to the local pulmonologist. The number of prevented physical referrals was measured by asking GPs the following two questions: Before TC(Q1): “Without TP, would you have physically referred this patient?” After TC(Q2): “Do you refer this patient physically?”

Quality of care was measured by the percentage of TCs sent for second opinion, the percentage of physical referrals resulting from these TCs and the educational effect experienced by GPs.

Results: In total 872 TCs performed from January 2010 until December 2011 were analyzed. Thirty-two percent (n=283) of the TCs were intended to prevent a physical referral (Q1=yes), 70% (n=199) of these were actually prevented. Of all TCs 68% (n=589) were sent for advice or second opinion (Q1=no), 19% (n=111) of these patients were referred after TC. GPs experienced an educational effect in 9% (n=78) of the TCs.

Conclusions: Telepulmonology potentially improves efficiency of care by preventing unnecessary physical referrals. Conversely TP can improve quality of care referral of patients that would otherwise not have been referred and the educational effect experienced by GPs.

Prediction of mortality in the Swiss chronic obstructive pulmonary disease (COPD) cohort using the age dyspnoe and airflow obstruction index (ADO) 
Lucia Schimme1, Nicolas Chandelier1, Adrian Rendon2, Otto Bauerle3, Prachant N. Chahed1, Jean-William Fitting1, Thomas Geiser1, Malcolm Kohler1, Sabrina Maier1, David Medinger1, Salome Schafroth Tonkol1, Andreas Scherr1, Robert Thurnheer6, Michael Tamn1, Jörg D. Leuppi1, Internal Medicine, University Hospital, Basel, Switzerland; 3Pneumology, University Hospital, Geneva, Switzerland; 4Pneumology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; 5Pneumology, University Hospital Bern, Bern, Switzerland; 6Pneumology, University Hospital Zurich, Zurich, Switzerland; 7Internal Medicine, Kantonsspital Münleningen, Münleningen, Switzerland

Background: COPD is associated with significant mortality, being the fourth leading cause of death worldwide. The Age Dyspnoe and airflow Obstruction Index (ADO) is a simplified prognostic assessment tool for patients with COPD which has been developed in specialized settings. Aims: Our objective was to reassess the usefulness of the ADO index as a predictor of mortality in a general practitioners’ (GP’s) based Swiss COPD cohort. Methods: 409 patients with presumed GOLD stages I-IV were enrolled by their GP’s and data was collected during a total period of 24 months. The observed 2-year risk of all-cause mortality in the cohort was compared to the ADO index predicted 3-year risk of death by performing logistic regression analysis with ADO as independent variable and observed 2-year all-cause mortality as dependent variable.
Results: Complete data could be analyzed in 390 patients (70% male, mean age 68 years). 154 patients (40%) did not have COPD according to spirometric criteria (FEV1/FVC <70%). COPD GOLD stage I was found in 22 (9%) patients, GOLD stage II in 94 (40%), GOLD stage III in 90 (38%) and GOLD stage IV in 30 (13%) patients. Of the 236 patients with COPD (median ADO score of 4, IQR 3.5), 14 (6%) died during the 2-year follow up period. There was a significant association between predicted (ADO index) and observed risk of death in the cohort (p<0.01). The odds ratio for death per point increase in the ADO index was 1.9 with a 95% confidence interval (1.1-2.8). Conclusion: The ADO index seems to be a significant predictor of 2-year all-cause mortality in patients with COPD treated in primary-care settings.

Subutilization of COPD guidelines in Mexico 
Rebeca Cazares-Adame1, Otto Bauerle3, Juan Manuel Alcantar-Schramm1, Julio Ancochea2, 1Community Paediatrics, Pendleton Family Practice, Lusaka, Zambia; 2Paediatrics and Child Health, University Teaching Hospital, Lusaka, Zambia; 3CD & MA, Nosarius Farmaceautica SA, Barcelona, Spain; 4Epidemiology and Clinical Research, Fundación Caubet-CMERA, Baruelo, Spain; 5Neumología, Hospital Clinic, Barcelona, Spain; 6Neumología, Hospital de la Princesa, Madrid, Spain

Aim: To evaluate the reliability, accuracy and concordance of the lung function measured in a primary care setting using COPD6 in early detection of COPD patients in urban areas in Zambia.
Methods: A cross-sectional study was carried out in four clinics, representing different socioeconomic areas in Lusaka. A total of 1014 patients who attended the clinics for any reason were considered eligible for COPD screening. Of these, 946 patients (94%) were included in the study. A diagnosis of COPD was made according to COPD6 criteria. Reliability, accuracy and concordance of the lung function measured in a primary care setting using COPD6 in early detection of COPD patients in urban areas in Zambia were calculated. The reliability of the measurement of the forced expiratory volume in one second (FEV1) was assessed using the intraclass correlation coefficient (ICC).
Results: The mean age of the patients was 52.6 ± 20.0 years (range 16-86 years), 64.2% were female, 69.7% were living in high, 21.6% medium, and 8.5% low-density areas respectively. The educational attainment of participants was up to primary in 54.5% of the cases, up to secondary in 19.5% and higher than secondary in 24.0% of the cases. Self-reported asthma symptoms in the last year were: 48.0% cough, 25.7% night awakening, 19.7% shortness of breath, 15.8% wheezing and 7.7% asthma attack, while 6.3% reported using asthma medications currently. Medications used to alleviate asthma symptoms were mostly oral (antibiotics 40.0%, antihistamines 26.0%, SABA 24.0%, cough mixtures 16.0%, theophyllines 9.5%, and steroids 6.5%), while inhaled medications were seldom used (SABA 13.0%, steroids 7.5%, LABA none). Many misconceptions on asthma were identified, with 45% reporting that asthma cannot be symptom-free and 59.9% that asthmatics cannot exercise or engage in strenuous exercises, among others. Finally, on asthma perceptions only 47.1% reported that hospitalizations for asthma are preventable, although 68.9% thought asthma symptoms can be prevented with medications. Overall, 64.2% of participants agreed that asthma is a serious health problem in Zambia.
Conclusion: We conclude that knowledge on asthma and its management is poor. Awareness and medical education programmes would improve asthma patients quality of life.

P727
Relationship between quality of life and multidimensional assessment indices in patients with COPD 
Žarko Vrbica2, Ivan Gudelj3, Rosanda Rosandic-Piasevoli4, Karla Tudja5, Ždenka Meštrovic6, Davorka Martinkovic7, Davor Plavec8, 1Research Department, Children’s Hospital Stadium, Zagreb, Croatia; 2Department of Internal Medicine, County Hospital, Dubrovnik, Croatia; 3Department of Pneumology, University Hospital Center, Split, Croatia; 4Clinic, Family Medicine, Split, Croatia; 5Clinic, Family Medicine, Donji Muc, Croatia; 6Clinic, General Practice, Zagreb, Croatia; 7Clinic, Family Medicine, Zagreb, Croatia

Aim: To evaluate the reliability, accuracy and concordance of the lung function measured in primary care setting using COPD6 in early diagnosis of COPD patients in urban areas in Croatia.
Methods: A cross-sectional study was carried out in four clinics, representing different socioeconomic areas in Lusaka. A total of 1014 patients who attended the clinics for any reason were considered eligible for COPD screening. Of these, 946 patients (94%) were included in the study. A diagnosis of COPD was made according to COPD6 criteria. Reliability, accuracy and concordance of the lung function measured in a primary care setting using COPD6 in early detection of COPD patients in urban areas in Croatia were calculated. The reliability of the measurement of the forced expiratory volume in one second (FEV1) was assessed using the intraclass correlation coefficient (ICC).
Results: The mean age of the patients was 52.6 ± 20.0 years (range 16-86 years), 64.2% were female, 69.7% were living in high, 21.6% medium, and 8.5% low-density areas respectively. Subjective (CAT, MMRC) versus objective (PFT, 6MWD, SPO2) assessment in stable COPD patients
Hasham Gbahi Salati1, Shahrzad M. Lari, Nasrin Fouladi, 2,3
Karim Beshakhabzade. Internal Medicine (Pulmonary Division), Ardabil University of Medical Sciences, Ardabil, Islamic Republic of Iran Internal Medicine (Pulmonary Division), Mashad University of Medical Sciences, Mashad, Islamic Republic of Iran for Patient with Asthma and for patient with asthma at P731
Background: Chronic obstructive pulmonary disease (COPD) is a prevalent respiratory disease that leads to morbidity and mortality in the world. The excess of investigation has shown that this illness is not confined only to the respiratory system, but it is a systemic inflammatory disease which affects different system of patients.

The aim of this study was to investigate the relationship between subjective tests such as COPD assessment test (CAT) and Modified Medical Research Council (MMRC) scale with objective tests in stable COPD patients.

Methods: We evaluated 60 stable COPD patients in a cross-sectional study; quantifying the following: dyspnea with MMRC scale, lung function parameters, exercise capacity with six-minute walk distance (6MWD), oxygen saturation (SpO2), BODE index and the number of exacerbation during the last year. Then, the CAT questionnaire was completed by all patients.

Results: There was a significant difference between the CAT score with BODE index (p<0.001). Significant correlation was observed between CAT score and MMRC scale (p<0.001, r=0.55). The negative association was found between CAT with FEV1% and SpO2 (p<0.005, r=−0.39 and p<0.01, r=−0.47 respectively). There was negative significant correlation between the CAT score and 6MWD (p<0.001, r=−0.49). Frequent exacerbation was found in patients with higher CAT scores.

Conclusion: The CAT score is a reliable indicator of airflow obstruction, dyspnea scale, exercise capacity and saturation of arterial oxygen in COPD patients and can be used as a predictor of exacerbation risk in stable COPD.

P731
Real current situation of management and for patient with asthma at community
Van Thanh Nguyen1, Respiratory Department, National General Hospital of Can Tho (NGH-CT), Can Tho, Viet Nam
Background and the objective: Despite now we have a remarkable improvement on knowledge of pathophysiology and management for Asthma (1) but the majority of patient do not have opportunities to get them (2). So to understand and to have the solutions for this situation we must know the real current situation of management and treatment for this illness in the community. This is also the objective of this study.

Study population and methods: This investigation is carried out on the patient with Asthma in the 8 communes of Can Tho city, wich were chosen randomly. With the physician’s guidance and explanation the patient complete a questionnaire.

The internal consistency will be validated by Cronbach’s coefficients with value > 0.6. Analysis will be carried out by descriptive statistics.

Results: From data on 197 patients there are 57.9% of them with ACT score < 20 and 57.6% with ACT score < 15. 42.4% of patients don’t know their own disease as asthma. The automedication is very common. Almost of patient do not know the asthma control concept and also think that they will go to the local setting for health care when it is necessary.

Conclusion: The situation of asthma control in the community is so not good.

From these data improving the quality of health care at local setting is suitable idea in this background.

ACT: Asthma control test

Validity of spirometry performed in the primary care setting
Mohammed Harris*, Sue Church1, Sanjeev Agarwal2. Respiratory Medicine, St. Helens and Knowsley Teaching Hospitals NHS Trust, Prescot, Merseyside, United Kingdom; 2 Respiratory Medicine, Mersey University, Liverpool, Merseyside, United Kingdom
Background: Spirometry is a valuable diagnostic tool in the identification of patients with Chronic Obstructive Pulmonary Disease (COPD) in the community. In the primary care setting, low acceptability of spirometric manoeuvres has been reported which may affect the interpretation of results and clinical decision making. T R Schermer et al had demonstrated in the Netherlands that spirometric indices performed by trained general practice staff were marginally but statistically significantly higher than those measured in pulmonary function laboratory. He concluded laboratory and general practice values should not be used interchangeably.

Aims: To evaluate the validity of spirometric testing performed in the community.

Methods: Retrospective study of 405 patients found to have abnormal screening spirometry performed in the community. Screening criteria included adults with a history of smoking. This was followed by repeat spirometry in the hospital pulmonary function laboratory. Data was analyses using SPSS.

Results: N=405, mean age 54 years (range 22 to 78), 46% (187) and 41% (165) were current and ex-smokers respectively. 78.5% (318) were using short-acting beta agonists 60% (242) were already on inhaled steroids. 0.7% (3) were on oral steroids. 82% (331) had obstructive spirometry. Majority (45%) of them had moderate COPD. 32% and 11% were found to have mild and severe COPD respectively. The Mean FEV1 in the community (1.52 liters) was slightly higher than the pulmonary function laboratory (1.49 liters). Paired t test study showed the results to be in concordance to the results demonstrated by T R Schermer et al.

Conclusions: This study validates the results published in the Netherlands by T R Schermer et al.

P733
Prevalence of the chronic obstructive pulmonary disease among smokers in Georgia
Mohammed Harris1,2,3, Shahrzad M. Lari, Nasrin Fouladi, 2,3
1Medical, National Academy of Science, Tbilisi, Georgia; 2Pulmonology, Georgian Respiratory Association, Tbilisi, Georgia; 3Pediatrics, Tbilisi State Medical University, Tbilisi, Georgia
Background: The prevalence of COPD in Georgia is suspected to be high due to high smoking rate, but the real data is unknown.

Aim: The aim of the study was to assess the prevalence of COPD among smokers more than 40 years of age attending primary healthcare (PHC) facilities in Georgia.

Methods: The World Health Organization proposed questionnaire were filled in patients who visited for any reasons PHC in 10 districts of Georgia. The patients were placed into one of four diagnostic categories (mild, moderate, severe, very severe stage).

Results: Out of 4275 patients 2268 (53.5%) were current and past-smokers, among them 2054 male (90.5%) and 214 female (9.5%). Out of those 2268 patients 360 subjects were eligible for data analysis (due to smoking cough, and sputum production). 351 patients performed spirometry and 9 patients were excluded because of poor spirometry manoeuvers. Of the 351 patients 92 (26.2%) showed airflow limitation.

Most of the subjects (42 patients, 45.6%) had moderate disease (stage II). Thirty patients (32.6%) had an FEV1 less than 50% predicted (stage III). The stage I of COPD were stated in 13 subjects (14.1%). Seven cases (7.6%) of very severe COPD (stage IV) were diagnosed. Airflow limitation was significantly related to male gender and cumulative pack-years.

Conclusion: It was shown that there are potentially a number of COPD cases that are undiagnosed by GP’s in Georgia. Use of spirometry as a routine test for smoker patients will help in early detection and correct diagnosis of COPD, which subsequently will help in implementation of preventive measures.

P734
Asthma control in Tunisia
Nadia Keskes Boudawara1, Leila Boussofara2, Mona Ben Khalifa1, Imen Toulou1, Mounira Sakka1, Ilyed Ksni2, Pneumology, Tahar Sfar Hospital, Mahdia, Tunisia
Introduction: Control of asthma is related to recent daily symptoms and exacerbations; it represents the ultimate goal of treatments according to current guidelines. The definition of asthma control was derived from the Global Initiative for Asthma (GINA) criteria of severity, etiology and treatment of substance was collected. Regarding control asthma, the questionnaire response of the Asthma Control Test has classified as controlled, well controlled, or uncontrolled.

Objectives: To evaluate the prevalence of asthma in Tunisia for adult patients identified by GPs in Tunisia. Use of spirometry as a routine test for smoker patients will help in early detection and correct diagnosis of COPD, which subsequently will help in implementation of preventive measures.

Aim: The aim of this study was to assess the prevalence of COPD among smokers more than 40 years of age attending primary healthcare (PHC) facilities in Georgia.

Methods: The World Health Organization proposed questionnaire were filled in patients who visited for any reasons PHC in 10 districts of Georgia. The patients were placed into one of four diagnostic categories (mild, moderate, severe, very severe stage).

Asthma control in Tunisia
Nadia Keskes Boudawara1, Leila Boussofara2, Mona Ben Khalifa1, Imen Toulou1, Mounira Sakka1, Ilyed Ksni2, Pneumology, Tahar Sfar Hospital, Mahdia, Tunisia
Introduction: Control of asthma is related to recent daily symptoms and exacerbations; it represents the ultimate goal of treatments according to current guidelines. The definition of asthma control was derived from the Global Initiative for Asthma (GINA) criteria of severity, etiology and treatment of substance was collected. Regarding control asthma, the questionnaire response of the Asthma Control Test has classified as controlled, well controlled, or uncontrolled.

Aim: The mean of age was 49.4±15.8years. Asthma was intermittent in 3.1%, persistent mild in 31.3%, persistent moderate in 51.5% and persistent severe in 14.1%. Treatment as recommended by GINA was applied in 63% of patients. 67.5% of patients were controlled, 26% were well controlled and 6.5% were totally controlled. Factors of uncontrolled asthma were the advanced age (p<0.001) and low Forced Expiratory Volume in one second (FEV1) (P<0.001).

Conclusion: Despite all efforts through international recommendations and despite the existence of effective therapies against asthma, a significant number of patients with asthma remain uncontrolled in this study. Asthma control in Tunisia is probably as poor as in other areas of the world.
P735
Quality of care of adult asthma patients in primary health care facilities in Saint-Petersburg, Russia: Trends between 1998 and 2011
Alexeyana Emeliyanova1,2, Gleb Fedoseev1, Inessa Tsukanova1, Galina Sergeeva1, Natalia Lithizyna1, Lubov Bakanina2, Ekaterina Nikitina1. 1Department of Respiratory Disease, Postgraduate Medical Academy, Saint-Petersburg, Russian Federation; 2Hospital Therapeutic Clinic, Pavlov Medical University, Saint-Petersburg, Russian Federation
Background: This study was performed to assess the changes in diagnosis and treatment of asthma (1998-2011) in primary health care facilities in Saint-Petersburg, the second largest city in Russia.
Methods: Case record forms (CRF) of 1248 outpatients 18 to 89 years old with asthma were reviewed in 13 outpatient departments in 7 residential areas in Saint-Petersburg in 1998, 2002 and 2005 (253, 579 and 416 respectively) and telephone interviews with 205 asthma outpatients (aged 24 to 90 yrs) was conducted in 2011. Asthma control was assessed by using the Asthma Control TestTM (ACT) in 2011.
Results: During the past 12 month spirometry were performed in 81.3% of patients in 2002 and only 62.1%, 50.7% and 26.8% in 1998, 2005 and 2011 respectively (p<0.01). Inhaled corticosteroids were more often prescribed to persistent asthma patients in 2005 (87.8% vs 79.1%, 63.4% and 46% in 2002, 2005 and 1998, p<0.01), whereas oral steroids for maintenance therapy were more frequently used in 1998 and 2000 (32% and 28% vs 14.9% and 7.3% in 2005 and 2001, p<0.001). Fixed combination of budesonide/formoterol and fluticasone/salmeterol were not used in 1998 while their prescriptions were increased from 0.9% in 2002 to 32.4% and 45.4% in 2002 and 2011 (p<0.001). Asthma was uncontrolled for 72.2% of patients in 2011.
Conclusion: Quality of diagnostics and treatment of asthma in primary health care is not sufficient and should be improved. Asthma pharmacotherapy has been changed in the past 13 years according to evidence-based guidelines.

P736
Evaluation of a simplified new score of quality of life for the assessment of COPD patients in general medicine – A prospective study
Regina Szendregyecz1, Claire Andrejak2, Corinne Hybiak3, Florence Le Meunier3, Isabelle Rault3, Olivier Carre3, Dominique Proisy4, Houcine Bentayeb1, Emmanuelle Lecuyer1, Marie Boutrym1, Vincent Jouenneaux1, Yousouf Donaud1, Charles Dayen1. 1Pneumology Unit, Saint Quentin Hospital, Saint Quentin, France; 2Pneumologie Unit, Amiens Hospital, Amiens, France; 3Pneumologie Unit, Clinique de l’Europe, Amiens, France; 4Pneumologie Unit, Soissons, France
Introduction: Chronic obstructive pulmonary disease (COPD) is a common pathology in the general population and therefore in general medicine. However, it remains under-diagnosed and difficult to assess. There are some scores in the literature to scale COPD patients (Saint-Georges (SGRQ), VQ-11 and COPD Assessment Test (CAT)). We therefore wondered if a reliable and easy-to-use score could assist the practitioner in the assessment and adaptation of treatments.
Materials and method: We proposed a score called CED which measures Cough, Expectoration and Dyspnea, on a visual analogue scale. With the help of 13 general practitioners from Picardy between March and September 2011, we conducted a prospective pilot study of patients suspected of COPD (n = 31). We collected the CED, SGRQ, CAT and VQ-11 scores of our patients.
Results: The dyspnea criteria of the CED and the SGRQ, which is the gold standard of COPD quality-of-life score, were significantly correlated (r = 0.390; p<0.05). The CED was significantly correlated with the decrease in FEV1 (r = 0.534; p<0.01) and with other specific quality-of-life scores such as the SG (r = 0.484; p<0.01).
Conclusion: The CED score is significantly correlated to respiratory functional status and quality of life of the patient. CED score seems to be a good tool in general medicine for the assessment of COPD patients.

P737
A comparison of the RIQ-MON 10 and the SGRQ among patients with COPD in routine care
Ljiljana Danoevic, Snezana Radic, Srdjan Dimitrijevic, Zeljka Bozalo, Predrag Rhec. General Medicine, Health Care Centre Grocka, Belgrade, Serbia, Childrens Hospital for Respiratory Diseases and TB, KBC ‘Dr Dragisa Misovic’, Belgrade, Serbia
The short 10-item Respiratory Illness Questionnaire monitoring 10 (RIQ-MON) has been developed for the estimation of health-related quality of life in routine primary care. A cross-sectional, observational study of 31 COPD patients (25 male, 6 female, mean age 64±10.8 years; mean FVC 85.1±19.7%, mean FEV1 57.8±21.0%) was undertaken. All patients completed 6-min walk test, the RIQ-MON 10, and the SGRQ. Relationships between parameters of the 6MWT (mean 363±46.9m), the RIQ-MON 10 (mean 18.7±6.75), the SGRQ (mean 51.8±20.8), spirometry, and patient characteristics were assessed with Spearman rank correlation coefficients. Twenty patients (64.5%) performed 6MWT ≤ 400m. The correlations between the SGRQ Total scores and the RIQ-MON 10 Total scores (ρ = 0.761), the 6 min walk distance and FVEI (ρ = 0.471), and the 6 min walk distance and FEVI (ρ = 0.573) were all significant at the level of 0.01. There was no correlation between the RIQ-MON 10 Limitations domain and the SGRQ Symptoms. We proved that RIQ-MON 10, although inferior to the SGRQ, can be useful in routine primary care practice because it provides enough information for just a few minutes.

P738
CURB-65 scoring utilization in predicting mortality of hospitalized patients with AE-COPD
Nural Ideyes, Ghazal Shaista, Kumar Panjwani, Hayat Muhammad, Rizvi Nadeem. Chest Medicine, Jinnah Post Graduate Medical Center, Karachi, Sindh, Pakistan
AE-COPD is a commonly encountered problem in COPD patients leading to expensive in patient treatment and ICU admissions. It is associated with significant mortality. Historically CURB-65 score is used to predict mortality in CAP and there is no scoring system to predict the mortality in hospitalized AE-COPD patients. The aim of this study is designed to evaluate the prediction of CURB-65 score in predicting mortality in AE-COPD hospitalized patients.
This is a retrospective study conducted at JPMC, Karachi, Pakistan. Charts reviewed from July 2010 to June 2011 of hospitalized patients; only AE-COPD included in the study. Patients with other respiratory diseases (asthma, bronchiectasis, I LD and consolidation on chest x-ray or incomplete charts were excluded). CURB-65 was defined as C=Altered level of consciousness (GCS <13), U = urea >7mmol/l, R = Respiratory rate >35breaths/min, B= Blood pressure (SBP <90mmHg or DBP <60mmHg) and age is >65 years. One point awarded for each. Chi- square test was used to see statistical significance of mortality difference in CURB-65 groups. 200 charts reviewed; 97 incomplete charts; 38 patients with ILD, bronchiectasis, asthma PNA. 65 patients met the inclusion criteria. A direct correlation was observed between mortality and CURB-65; highest mortality noted with CURB-65 ≥ 3. In hospital mortality in different CURB-65 groups were, low risk (score 0-1)10.0% (2/32), moderate risk score (2) 10.0% (2/12) and high risk (score 3-5) 80.0% (16/21). The CURB-65 scoring system is effective in predicting mortality in AE-COPD; can be used in AE-COPD to stratify patients into different management groups as our conclusion indicates CURB 65 is helpful in assessing severity in AE COPD.

P739
Is there any relationship between the duration to diagnosis of COPD and severity of the disease?
Etra Yazar1, Fusun Sahin1, Engin Ayancı1, Pınar Yıldız1, Akif Örgül 1, Veyssel Timuçın1, 1Chest Disease, Yedikule Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Zeytinburnu, Turkey; 2Chest Disease, Yedikule Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Zeytinburnu, Turkey; 3Chest Disease, Yedikule Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Zeytinburnu, Turkey
The aim of this study was to investigate whether there is a relation between the duration from beginning of symptoms until diagnosis of chronic obstructive pulmonary disease (COPD) and severity of COPD.
Method: One hundred and fifty patients with COPD (140 males, 10 females) were included in the study. All the patients had a history of smoking at least 10 pack/years. None of the patient had reversibility.
Results: The CED score was significantly correlated with the decrease in FEV1 (r = 0.534; p<0.01) and with other specific quality-of-life scores such as the SG (r = 0.484; p<0.01).
Conclusion: The CED score is significantly correlated to respiratory functional status and quality of life of the patient. CED score seems to be a good tool in general medicine for the assessment of COPD patients.

121s
Background: GOLD currently recommends making treatment decisions based on a combined assessment of current symptoms and future risk. The modified MRC (mMRC) dyspnoea scale (grade 0–4) is recommended to assess the level of current symptoms, but data on the efficacy of different treatments in subgroups based on symptom-grading are lacking. Roflumilast (ROF) is a PDE4 inhibitor approved for maintenance treatment of severe COPD associated with chronic bronchitis, in adult patients with a history of frequent exacerbations. GOLD recommends ROF as an option for patients with mMRC grade ≥2, severe lung function impairment and/or frequent exacerbations (Group D).

Aims: To determine the effects of ROF on exacerbations and lung function when added to titroprocion (TIO) in patients with baseline mMRC grade ≥2.

Methods: Study M2-128 included symptomatic patients with moderate-to-severe lung function impairment. ROI 500 or placebo (PBO) was added to TIO for 24 weeks. A post-hoc subgroup analysis of patients with mMRC grade ≥2 at baseline was performed.

Results: This subgroup included 395 patients (ROI n=208, PBO n=187). ROI reduced the mean rate of moderate/severe exacerbations/patient/year by 45.5% (an-ti-trended exacerbation rate ROI:0.22, PBO:0.46; rate ratio 0.55, 95% CI 0.31, 0.96; p=0.034) vs PBO. The mean between-treatment difference in pre-bronchodilator FEV1 was 78 mL (95% CI 38, 119), p=0.0002, and in post-bronchodilator FEV1 79 mL, (95% CI 38, 118). p=0.0002.

Conclusions: ROI reduces moderate/severe exacerbations when added to TIO in COPD patients with moderate-to-severe lung function impairment and mMRC grade ≥2. These results support the GOLD recommendation for combined assessment of current symptoms and future risk.
Presently, no study has directly compared these two categories of prevention to usual care (UC) in a trial or economic evaluation.

Aim: To model the cost-effectiveness of prenatally-started unifaceted (UF) and multifaceted asthma (MF) primary prevention programmes with UC in a decision-analytic framework.

Methods: A decision-tree model was developed to compare (from a healthcare perspective) two UF and three MF programmes to UC (unstructured allergen-avoidance advice in the Netherlands). Analyses had a time horizon of 10 years. Costs and effects for each option were evaluated through incremental cost-effectiveness ratios (ICERs).

Results: UC and an MF were found to dominate the other options. UC turned out to be less effective but also less costly compared to the MF. To avoid one asthma case the costs will be €8,250 when choosing the MF over UC. Most of the uncertainty in the results was attributable to the cost estimates for low-risk children.

Conclusion: Although there is no point of reference for the amount society would be willing to pay to avoid a case of asthma, the threshold used for a QALY roughly ranges between €20,000 and €80,000. As a case of asthma prevented will certainly equal at least one QALY gained, this study gives support to the feasibility of multifaceted programmes as viable option to replace usual care in the primary prevention of asthma amongst children.

P745

Management of COPD in a primary care in Bahia, northeast of Brazil

Charlize de Abreu Pinto 1,2,3, Larissa Yamamura 1,2, Fabio Fernando Oliveira 2, Aramis Alcântara Machado 1,2, Lutemberg Costa 2, Gisele Souza 2, Antônio Carlos Lemos 1,2,3, 1 Department of Pneumology, University Federal of Bahia, Salvador, Bahia, Brazil; 2 Respira Bahia Program, Bahia State Departments of Health, Salvador Bahia Brazil; 3 College of Pharmacy, State University of the South West of Bahia, Jequiti, Bahia, Brazil

Introduction: Deficiencies in management of COPD is responsible for the disease exacerbations increased numbers.

Objective: To evaluate the current pharmacological treatment of the COPD in a primary health care center and to compare as recommended by GOLD 2010 guidelines.

Methods: A prospective cross-sectional survey was performed with COPD out-patients. The patients were recruited as a sequential sample from September 2010 until August 2011, in the primary center of Bahia State Health Department.

Results: In total, the sample was 363 outpatients (245 male, aged from 65.3±11.4 yrs) with moderate to very severe disease status (FEV1 40.6±14.4% pred). Of these, 263 (72.4%) patients were using any drug to treatment of COPD. The prescriptions according to GOLD stages are documented in the table below. Under-prescribing with bronchodilators long acting agents, particularly long-acting anticholinergic were recommended in 76% of the cases and 16.8% were using. Inhaled steroids were over-prescribed (recommended in 55%; taken by 77%). The overall analysis showed that only 97 (37.2%) patients were under treatment according with GOLD guidelines.

Table: Drug prescriptions stratified according GOLD stages and divided for drug classes

Conclusion: Our study has demonstrated that COPD patients in the primary care in Bahia-Brazil did not receive the pharmacological treatment recommended.

P746

Home visits for improving asthma follow-up consultation attendance

Javiera Corbalán 1,2, María Teresa Soto 1,2, 1 Unidad de Salud Respiratoria, Ministerio de Salud, Santiago, Chile; 2 División de Salud, Corporación Municipal de La Florida, Santiago, Chile; 3 Rama de Atención Primaria, Sociedad Científica de Kinesiología en Atención Primaria, Santiago, Chile

Background: Our Child Asthma Program provides care for around 500 patients. Every 6 months the population under control is reviewed. Since December 2010 non-attendance (missing appointments for more than 3 months) was recorded. 37.2% were non-attenders. Regular review is a marker of quality care and relates to better asthma control. Non-attendance is a frequent and concerning problem.

Aim: Improve attendance to asthma follow-up consultations and learn about the causes of non-attendance.

Methods: We implemented a home visit strategy. Every month the non-attenders were identified and a home visit was planned. Completed visits considered a visit. We measured at 6 and 12 months the non-attenders and if the home visit led to attendance or not.

Results: 147 home visits were done. 67 were completed, with a 65.7% of success (patient attends to appointment). 80 home visits failed and only 16.3% of those patients had spontaneous appointments. At 6 months 17% of patients were non-attenders, and 24% at 12 months. In one year the non-attendance rate was reduced in 35.5%.

Conclusions: Improving attendance is feasible. Looking for non-attenders is an important issue for managing asthmatic children. Causes of non-attendance are diverse and had to be explored. Feeling well despite of uncontrolled asthma and difficult to access appointments are worrisome causes. Home visits also provide the opportunity to reinforce prescriptions in patient’s natural environment.

P747

Quality of life in patients with COPD three years after a multidisciplinary program of pulmonary rehabilitation in primary care

Ann-Britt Zakrisson 1, 2, 3, Anna Ljunggren-Karlsson 1, Louise Tamm 1, Kerstin Theander 2, 3, Margareta Gustafsson 1, Family Medicine Research Centre, Örebro County Council, Örebro, Sweden; 2 School of Health and Medical Sciences, Örebro University, Örebro, Sweden; 3 Centre for Assessment of Medical Technology in Örebro, Örebro County Council, Örebro, Sweden; 4 Primary Care Research Unit, County Council of Värmland, Karlstad, Sweden; 5 Department of Nursing Science, Karlstad University, Karlstad, Sweden

Background: COPD is an irreversible widespread disease which increases dramatically. According to previous research the quality of life in (QoL) patients with COPD is impaired but can be improved by pulmonary rehabilitation.

Aim: The aim of this study was to evaluate if a six week nurse-led multidisciplinary program for pulmonary rehabilitation in primary care had effect on quality of life in patients with COPD in a three-year period.

Method: Quasi experimental design was used to evaluate the program. The intervention group consisted of 40 patients who had participated in the program. The control group consisted of 24 patients who received traditional care. QoL was measured at baseline, after one year and after three years using Clinical COPD Questionnaire (CCQ). Statistical analysis of differences within the groups over the three years was performed by means of Friedman’s test. Mann-Whitney U test was used to analyze differences between the groups.

Results: There was no statistically significant difference between the groups at baseline. There was no statistically significant difference in improvement between the groups during a three year period for CCQ total. Neither was there any statistically significant difference within the control group. During a three year perspective there was a statistically significant difference of improvement within the intervention group for CCQ total (p=0.037) and CCQ functional state (p=0.026).

Conclusion: The rehabilitation program had an improving effect on QoL, in patients with COPD within the intervention-group during a three year perspective.

P748

Omalizumab improves asthma in long term therapy

Peter Kardos 1, Hassan Alakmeh 2, Christian Franke 2, Maryam Aalamian-Mattheis 2, 1 Pneumologie, Zentrum für Allergologie, Pneumologie und Schlafmedizin am Maingau Krankenhaus, Frankfurt, Germany; 2 Innere Medizin, Praxis Drenz. Hassan Alakmeh, Bacnang, Germany; 3 Pneumologie, Gemeinschaftspraxis Drs. Franke, Sonneberg, Germany; 4 Clinical Research Critical Care, Novartis Pharma GmbH, Nuremberg, Germany

Introduction: X-TEND, a multi-center, non-interventional study on omalizumab (Xolair®), is a long-term follow-up examination on patients who participated in prior non-interventional omalizumab studies X-CLUSEIVE and X-PERTISE. Study objectives have been (i) examination of drug utilisation over several years, (ii) evaluation of changes in the course of disease, quality of life (QoL) and allergen sensitivity, (iii) assessment of long-term efficacy and tolerability of omalizumab therapy in real life.

Methods: Following data were collected during daily routine specialist care conditions.

- Mini AQLQ
- Number of asthma exacerbations in the past 12 months
- Frequency, application of dosage, therapy interruptions and discontinuation
- Tolerability assessment based on analysis of adverse events

Results: Data from 106 patients were analyzed. Mean observation period of omalizumab treatment was 5.0±0.54 years. At the visit of X-TEND, 50% were still on omalizumab. Mean treatment duration was 1253±618 days (3.4 years). Mean FEV1 improved from 1.9±0.7 L to 2.3±0.9 L (p<0.001). The median number of severe asthma exacerbations during the last 12 months was 0 per patient vs. 3 as assessed prior to initiation of omalizumab therapy. QoL scores improved in Mini AQLQ from 3.0±0.79 (at the beginning of X-PERTISE) to 4.9±1.52 (p<0.001) (at the visit of X-TEND). In patients still on treatment with omalizumab mean QoL was 4.4±1.28, whereas patients who discontinued reported 4.4±1.67 (p=0.037).

Conclusion: In this real-life observation in patients who were approximately 1253 days on omalizumab treatment, we observed an improvement in asthma exacerbations, quality of life and FEV1.
P749
Is a consultant supported community respiratory service an alternative to hospital based specialist care? – Experience of a local service improvement project
Robert Balloul1, Janet McCarlie1, Alison Anderson2, Hans Hartung1.1 General Practice, Kilwinning Medical Practice, Kilwinning, United Kingdom; 2Respiratory Managed Clinical Network, Ayrshire & Arran Health Board, Irvine, United Kingdom; 3Respiratory Medicine, Crosshouse Hospital, Kilmarnock, United Kingdom

Introduction: Better integration of primary and secondary care services and shifting the balance of care remain a major challenge with only few practical examples in respiratory care. Aims: The aim of a local service improvement project is to gain insight into an example of specialist supported, integrated respiratory care closer to the patient’s home. The objectives are to provide more flexible access, more patient centred care and develop general practitioners as partners in care. Method: Regular consultant respiratory clinics supported by a general practitioner with a specialist interest were set up in a local surgery. An interactive triage system, E-communication, meetings with primary care colleagues and consultant access to primary care patient data and radiology were implemented. Service user satisfaction, general practitioner satisfaction and number of patients seen by the general practitioner with a specialist interest were recorded for a period of 16 months. Results: 73 out of 116 service users completed the questionnaire and were all satisfied with the new service and felt well supported to manage their condition. 76 out of 77 found it easy to get a suitable appointment. All 7 general practitioners were highly satisfied. 73 of the 116 respiratory patients were seen by the general practitioner with a specialist interest.

Conclusion: Our consultant supported community respiratory service project demonstrates a model of integrated and flexible care in partnership closer to the service user’s home which could serve as a possible alternative to hospital based specialist care.

P750
The evaluation of a tele-monitoring model (Telehealth) as an aid in the case management of patients with COPD
Nasir Dar Bakti, Jane Roberts. Department of Respiratory Medicine, NHS Salford/Salford Royal NHS Foundation Trust, Salford, United Kingdom

Introduction: One of the many challenges for health care systems is to reduce the impact of chronic diseases like COPD on health care resources. Distant monitoring systems are increasingly being used for this purpose. Method: Potential COPD patients were identified through their Case Managers (CMs). Those who met the inclusion and exclusion criteria were invited to participate. Those consented received a telemonitoring device (Telehealth) with instructions and education and were remotely monitored by CMs as part of case management process. Data on hospital admissions and Health Care Utilisation (HCU) was collected for management process.

Results: Total of 16 patients were included in the analysis. Following the introduction of Telehealth, Hospital admissions halved from 20 to 10 with reduction in the number of bed-days from 134 to 96. Total cost of admissions had subsequently dropped by £20,000 (£23,400).

HCU data showed a drop in the number of home visits to patients (50 to 30) but a small increase in the number of telephone consultations (68-76).

SGRQ scores for QoL showed average of 3.3 points improvement which is below the clinically significance threshold.

HAD data is presented in table 1.

<table>
<thead>
<tr>
<th>HAD data</th>
<th>Baseline (n=16)</th>
<th>After 1 year (n=15)</th>

</tbody>
</table>

Conclusions: Telehealth appears to reduce admissions to hospital and some aspects of HCU in primary care. There is a need for more trials looking into the difficulties encountered during the implementation and evaluation of such complex technology.

P751
Assessing asthmatic patients’ satisfaction with inhalation devices
Eleftherios Zervas1, Mina Gagia, Katerina Papataxiarchou1, Nikolaos Grekas2. 17th Respiratory Clinic, Sotiria Hospital, Athens, Greece; 2Clinical Research Department, Elpen Pharmaceutical Co Inc, Pekerm, Attica, Greece

Introduction: Patients’ satisfaction with their asthma medication devices is usually decided by using properly designed questionnaires. These questionnaires are to be used to evaluate patients’ opinion, which is considered important for the selection of a device.

Objectives: The aim of this study was to reliably estimate the ease of use and the satisfaction of asthmatic patients with different marketed dry powder inhalers (DPIs). Feeling of satisfaction with inhalers (FSI-10) questionnaire was selected as the appropriate measuring tool.

Methods: A four week, open, non-interventional, multicenter, parallel study, was performed. 560 asthmatic patients (355 women), aged 19 to 97 years, participated in three groups using different DPIs (Elpenhaler®, Turbuhaler® and Diskus®). Demographics of the groups were comparable. Patients had already achieved mastery of their inhalers, were receiving their asthma treatments exclusively via the investigated route and agreed to complete the questionnaire in the second visit. They were recruited in 79 private medical offices and hospital centers all over Greece.

Results: 523 participants completed the study and the questionnaire. Although consistent and satisfactory results were obtained with all DPIs tested, certain statistically significant differences in the ratings between the devices were observed (Elpenhaler® was rated first in 7 out of 10 questions, having also the highest mean total score). No significant differences in scores from patients of different ages were observed in any of the tested devices.

Conclusions: Certain statistically significant differences were found in ratings between the tested DPIs. Devices were similarly acceptable to adult patients of different ages.

P752
Effects of the gripe vaccination, smoking cessation, and short acting beta agonist in COPD subjects
Bojan Janackov1, Zoran Stojarovski2, Jordan Minov1. 1Department for Labour Medicine, Health Center Skopje, Macedonia, The Former Yugoslav Republic of; 2Primary Health Care, MOH, Skopje, Macedonia, The Former Yugoslav Republic of; 3Functional Diagnostics, Institute for Labour Medicine, Skopje, Macedonia, The Former Yugoslav Republic of

Objective: To compare the efficacy of the seasonal gripe vaccination, smoking cessation and use of salbutamol in COPD patients.

Material and methods: We performed a cross-sectional study including 147 patients with confirmed COPD according GOLD criteria. We evaluated the number of exacerbations and the number of hospitalisations. All were immunize against seasonal influenza, ex-tobacco users and received regular consultation.

An equal number of patients were evaluate like controls. They were also COPD patients, but didn’t receive gripe vaccination, active smokers and didn’t use salbutamol according doctors recommendation. Evaluation period was 12 months.

Results: In the examined subjects our results demonstrated 29.9% of exacerbations and 8.8% hospitalizations e.g. 41 versus 12 subjects. In the controls our article confirmed 74.5% exacerbations and 28.5 hospitalisations or 102 and 39 subjects were respectively.

Conclusion: The number of COPD exacerbations/hospitalisations were significantly higher (P < 0.05) in not immunized, smokers and patients who denied to receive regular therapy.

Conclusion: Our results confirm that gripe vaccination, smoking cessation and regular therapy use, significantly decrease the number of exacerbations and hospitalisations in COPD patients.

P753
Factors affecting attitude towards pneumococcal and influenza vaccination in patients admitting to a pulmonary diseases outpatient clinic
Elif Sen, Fuat Cicek, Nalan Demir, Oya Kayacan. Department of Pulmonary Diseases, Ankara University School of Medicine, Ankara, Turkey

Patient knowledge and attitude towards influenza and pneumococcal vaccines may affect administration rates. Our aim was to assess factors affecting attitudes. A questionnaire was applied to 1058 patients (514 female 544 male) between October 2011-January 2012. Ratio of patients with a vaccination indication was 73.2% (n=775). Ratio of influenza-vaccinated (IV) patients (n:222, %21) or pneumococcal-vaccinated (PV) patients (n:61, 6.5%) were determined. Of all patients, 64.5% (n:682) defined influenza and 68% (n:719) defined pneumococcal vaccine beneficial. Vaccination rate upon physician advice was 82.4% for influenza and 83.6% for pneumococcus. More IV patients considered vaccine protective (p<0.001), decreases hospitalization rate (p=0.002), decreases pneumonia and death (p<0.02), pneumococcal vaccine is beneficial, and they were informed by the physician (p=0.001). IV patients had more cardiopulmonary disease and a vaccination rate against pneumococcs (p<0.001). Influenza-novaccinated patients were unaware of the necessity of the vaccine (p=0.001). More PV patients considered the vaccine beneficial (p=0.001) and were more frequently informed by physician (p=0.039). Pneumococcus-novaccinated patients were unaware of its necessity (p=0.001). PV patients had higher incidence of cardiopulmonary diseases. Our study shows that vaccination rates in vaccine-indicated patients were low. Vaccinated patients were more frequently informed by physician. The thought of patients that vaccination is beneficial and decreases the rate of severe conditions was distinctive in being vaccinated. The nonvaccinated patients were unaware of the vaccine’s necessity.
**P754**
Enhanced care review for people with COPD in primary care addressing quality, cost-effectiveness and productivity

Wendy Faithurst, Sandra Burns, Sam Lacy, Ram Sundat. Breathlessness Service, HealthFirst Community Interests Company, Hindley Green, United Kingdom

Department of Respiratory Medicine, Wighton, Wigan & Leigh Foundation Trust, Wigan, Lancashire, United Kingdom

An enhanced care review, delivered by nurses working for a social enterprise within University Care and supported by a Respiratory Physician has proved to be a cost effective way of improving the quality of life with patients with COPD. The aim of the project was to improve the quality of care on a number of parameters such as accurate diagnosis, treatment of exacerbations, self management plans, referral to preventative services. This was delivered through a nurse led service supported by a respiratory consultant in primary care to reduce hospital admissions and outpatients referrals.

The 12 month pilot project was delivered to 23 GP practices within an urban, deprived setting in the North of England. Specialist Respiratory nurses and practice nurses delivered the service within GP practices following education and training identifying patients at risk of exacerbations or hospital admissions and post exacerbation assessment and prevention using specialist computer software which also provided a data collection template - data was collected through GP practice readad searches together with admission data from the Primary Care Trust. Hospital admissions were reduced amounting to savings of £90,000 in comparison to other parts of the borough. Medicines management savings amounted to £40,000 were achieved through treatment optimisation. Prevalence of COPD was increased by 12.3% and there was a 56% increase in pts being diagnosed between the ages of 35-50. There was a 63% increase in referral to pulmonary rehab and 20% increase in patients coded now as ex-smokers. There was a 58% increase in patients being given a self management plan.

**P755**
Management of community acquired pneumonia (CAP): Knowledge, attitude and current practice of general practitioners (GPs) in urban areas of Pakistan

Saima Akhtar, Ashok Pajwani, Naushem Saifullah, Nadeem Rizvi. Chest Medicine, Jinnah Post Graduate Medical Centre, Karachi, Sindh, Pakistan

Background: CAP is a major burden with high prevalence and significant mortality and morbidity. Current evidences suggest that treatment of low risk patients in community is safe and reduce health costs by minimizing unnecessary hospital admissions and GPs can play an important role in primary care.

Objective: Our aim was to assess, at a community level, GPs knowledge about CAP, attitudes and prescription pattern.

Methodology: A multicentre cross sectional survey was done in 10 cities of Pakistan from November 2011 to January 2012. A total of 110 GPs were recruited, with minimum of 3 years experience, and were not engaged with University teaching or research. Convenient sampling was done and data was collected on structured questionnaire.

Results: 71% of GPs reported to work in high prevalence areas for respiratory ailments. Diagnosis of CAP was relied on physical examination in less than 5% cases. 58% of GPs used PSI and 38% CURB 65 for assessment of severity but it was alarming to note that only 58% intend to treat severe pneumonia with IV antibiotics and there was reluctance for referral to hospital.

The majority (70%) of GPs claimed awareness of recent guidelines of CAP but the antibiotic class most prevalently used was oral macrolide (54%) in mild oral quinolones (40%) in moderate and combinations of non antipseudomonal cephalosporin and Macrolide (55%) in severe cases.

Conclusion: The major problems encountered were late referral of patients to hospital, poor knowledge of recent guidelines and prescription of inadequate regimens that in turn can lead to high mortality and morbidity and emergence of resistant bacteria as cause of CAP.

**P756**
Practice patterns in the management of acute asthma and COPD in Turkey

Erdogan Cetinkaya1, Sadik Ardic2, Hilal Oneran1, Pinar Cirkin1, Ozlem Salman Sever3. 1Clinic of Chest Diseases, Yedikule Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Turkey; 2Clinic of Chest Diseases, Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey

Introduction: The recognition and management of the asthma and COPD exacerbations is a cornerstone in the achievement of optimum control of these diseases.

Aims and objectives: The “ONDINE Study” aimed to evaluate practice patterns in the management of acute asthma and COPD in Turkey.

Methods: Patients with asthma or COPD were included in this national, multicenter, cross-sectional, non-interventional study. Patient demographics, control level, exacerbation severity and the exacerbation management of asthma and COPD were evaluated.

Results: A total of 596 patients included in the study having the diagnosis of asthma [n=401; mean (standard deviation; SD): age: 45 (13) years; 74% were females] or COPD [n=295; mean (SD) age: 62 (11) years; 86% males]. Disease control was evident in 38% of COPD patients while in 51% of asthma patients while severe COPD (31%) and intermittent asthma (51%) were the most common forms of disease severity. Hospital admission due to an acute exacerbation within the last 12 months was identified in 75% of asthma and 78% of COPD patients. Emergency and intensive care unit hospitalization rates were 40% and 1% in asthma patients and 53% and 2% in COPD patients, respectively. The most commonly performed tests in asthma and COPD patients were chest X-ray (98% and 99%) and spirometry (98% and 99%). Long acting beta-agonist and inhaled corticosteroid combination was the most common continuous prophylactic treatment (69%) in asthma and (71%) in COPD.

Conclusions: The study revealed that acute asthma exacerbations were managed better than COPD exacerbations and higher control rates were obtained in both diseases as exacerbation were managed more appropriately with respect to recommendations in the guidelines.

**P757**
Beliefs and attitudes of health care workers on influenza and pneumococcal vaccine

Fatma Ciftci, Elf Sen, Nalan Demir, Oya Kayacan. Department of Pulmonary Diseases, Ankara University School of Medicine, Ankara, Turkey

It is recommended to vaccinate health care workers against influenza and streptococci pneumonia if at risk group. This study is done to determine the vaccination rates and attitudes on vaccines of health care workers. A total of 192 health care workers (100 female, 92 males) consisting of 55 nurses, 42 health officers, 21 paramedics, 19 medical secretaries, 52 auxiliary staff, and 3 domestic health care workers were questioned between October 2011-January 2012. One-hundred and fifty-five (80.7%) health care workers were nonvaccinated against influenza. The reasons of this were fear of side effects (% 30.2) or 20% doubt on efficacy %27 (1), 26%, unawareness of the vaccine %23.5 (n:23), doubt on safety %19.8 (n:19), and lack of adequate data %16.8 (n:16). Sixty-eight (48.6%) of influenza nonvaccinated workers recommended patients vaccination whereas 23 (69.7%) of vaccinated workers recommended the vaccine. Vaccine recommendation rates of influenza-vaccinated workers were significantly higher in vaccinated than nonvaccinated workers (66% and 48%, respectively). The reasons for nonvaccination were fear of side effects (% 28.9 (n:33), doubt on efficacy %25.4 (n:29), unawareness of the vaccine %23.1 (n:27), doubt on safety %20.2 (n:23), and lack of adequate data (%16.8, n:19).

As a conclusion, health care workers have a low rate of vaccination and recommendation of vaccination against influenza and streptococcus pneumoniae.

**P758**
Assessment of satisfaction with inhalation devices in COPD patients

Eleftherios Zervas1, Mina Gaja1, Nikolaos Gerekas2, Katerina Papastasiou2, Katerina Athanassious2. 17th Respiratory Clinic, Sotiria Hospital, Athens, Greece; 2Clinical Research Department, Elpen Pharmaceutical Co Inc, Pikermi, Attica, Greece

Introduction: The choice of drug delivery system is one of the most important factors for COPD management. Health care professionals, taking also in mind the opinion of their patients, consider that ease of use and patient satisfaction for an inhalation device is a key element when choosing such a device.

Objectives: The aim of this non-interventional study was the reliable measure of the ease of use and patient satisfaction with different dry powder inhalers (DPIs).

Feeling of satisfaction with inhalers (FSI-10) questionnaire was used as measuring factors for COPD management. Health care professionals, taking also in mind the recommendations of vaccination against influenza and streptococcus pneumoniae. Vaccine recommendation rates for pneumococcal vaccine were significantly higher in vaccinated than nonvaccinated workers (66% and 48%, respectively). The reasons for nonvaccination were fear of side effects (% 28.9 (n:33), doubt on efficacy %25.4 (n:29), unawareness of the vaccine %23.1 (n:27), doubt on safety %20.2 (n:23), and lack of adequate data (%16.8, n:19).

Conclusions: Statistically significant differences were found in the scores among the tested devices. Patients in advanced stages of the disease generally express higher level of satisfaction with their devices.
and/or necrosis. Increased post-surgical plasma DNA concentration was due to the presence of patients with asthma have a PAAP despite national recommendations. Our pilot involved 6 GP practices and patient focus groups to develop and evaluate a PAAP.

Partnership working has enabled us to provide structured educational sessions to health care professionals across primary and secondary care. Currently 90 GP practices are using the PAAP’s in North Staffordshire. Encouragingly practice nurses are more confident in managing asthma. Within secondary care PAAPs are given to asthma patients attending A & E wards and respiratory clinics. One year after the launch feedback from patients and health care professionals is extremely positive. Future plans include evaluating the impact of the PAAP on A & E attendances, GP visits and quality of life.

94. New results in molecular pathology and functional genomics of neoplastic and non-neoplastic lung disease

P760 Plasma DNA concentration and integrity measurement for NSCLC diagnostics and radical therapy effectiveness monitoring

Adam Szczechinski1, Joanna Chorostowska-Wynimko1, Wlodzimierz Kupis2, Krystyna Maszkowska-Kopi1, Jolanta Zaleska1, Elzbieta Radzikowska1, Elzbieta Puszynska1, Pawel Sliwinski3, Tadeusz Orlovska1, Kazimierz Roszkowski3,4, Laboratory of Molecular Diagnostics and Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; 2Department of Thoracic Surgery, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; 3Department of Thoracic Surgery, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; 4Department of Thoracic Surgery, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; 5Department of Diagnosis and Treatment of Respiratory Failure, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland

Plasma DNA concentration and integrity index (DII) were measured by real-time PCR in 60 NSCLC patients (stage I-IIIA), 100 patients with chronic respiratory inflammation (COPD, sarcoidosis, asthma) and control groups comprising 10 orthopedic patients and 40 healthy volunteers. NSCLC patients (8.0 ng/ml) presented significantly higher plasma DNA levels than patients with chronic respiratory inflammation (3.4 ng/ml), orthopedic patients (3.0 ng/ml) and healthy controls (2.3 ng/ml; p<0.0001). The cut-off point was 2.8 ng/ml provided 96% sensitivity and 80.5% specificity in discriminating NSCLC from healthy individuals (AUROC=0.90), while 56% specificity and 90% sensitivity in distinguishing NSCLC from any non-NSCLC subjects (AUROC=0.80; p<0.0001). The plasma DII was significantly higher in resectable NSCLC (3.1) and chronic respiratory inflammation (3.7) than healthy controls (1.0; p=0.0000). Resected NSCLC (68.7 ng/ml; p<0.0000) and orthopedic patients (28.4 ng/ml; p<0.0015) presented comparable plasma DNA dynamics after the surgery. During 3-6 month follow-up plasma DNA level were significantly reduced in relapse-free NSCLC patients (2.8 ng/ml), while in relapsed subjects were higher than at baseline.

Biomarkers are advanced tools for diagnosis, prognosis and monitoring of treat-ment and disease progression. The validation of biomarkers is a cumbersome process involving many steps. Serum samples from lung cancer patients were collected in the framework of a larger Lung Cancer Screening project. During the analysis of some biomarkers, differences between marker values depending on the time of blood extraction were inconsistent. Biomarker concentration differed significantly if taken before or after the induction of anesthesia. From 13 patients blood samples were drawn 1-2 days prior to surgery, on the same day and after anesthesia was applied. Markers SCC (microtiter plate), and CEA (E lectys) were analyzed. SCC showed a very strong effect in relation to the sampling time. While the first two time points were well comparable (correlation r=0.883), patients showed a highly significant (p = 0.0017) increase in concentration when comparing the first two time points with the time point after anesthesia induction. The concentration of CEA had almost no variation (r=0.993 comparing time points as above). In this study we show the unexpectedly high influence of blood extraction timing in the concentration of the protein biomarker SCC but not in CEA. Whereas the possible causes for this alteration remains to be elucidated in further studies, these results are a caveat to make sure that biomarker sampling protocols are controlled for this type of effects.

P762 Hypoxic phenotype in pulmonary metastases of different primary tumors

Thomas Schneider1,2, Christoph Nikolovsky1,2, Lukas Lehmann1, Robert Wiebringhaus4, György Lang1, Peter Birrer5, Walter Klepetko6, Hendrik-Jan Ankersnol7, Konrad Hoetzenecker1,2, Department of Surgery - Division of Thoracic Surgery, Medical University of Vienna, Austria; 1Christian Doppler Laboratory for Cardiac and Thoracic Diagnosis and Regeneration, Medical University of Vienna, Austria; 2Clinical Institute of Pathology, Medical University of Vienna, Austria

Tumor hypoxia has been shown to be a common feature in tumor growth and metastasis. It negatively affects the clinical outcome in patients with various ma-lignancies. Although hypoxia is described in many primary tumor types, data on pulmonary metastases is lacking. We determined the expression of hypoxia-related proteins in paraffin-embedded specimens of pulmonary metastases of different types of cancer (breast cancer n = 6, colon-rectal carcinoma n=29, renal cell carcinoma n=13, sarcoma n=10). All recruited patients underwent curative metastasectomy at the Department of Thoracic Surgery, MUV, between April 2009 and December 2011. Expression of carbonic anhydrase 9 (CA9), heat-shock protein 70 and HIF prolyl hydroxylase 2 was evaluated by immunohistochemistry. Metastasis free survival and estimated tumor size and overall survival was determined for all sub-groups. Hypoxia related proteins are expressed in 66.6%, 76.9%, 7.7% and 0.0% of pulmonary metastases of breast cancer, colon-rectal carcinoma, renal cell carci-noma and sarcoma, respectively. Furthermore, metastases with highly positive CA9-staining are associated with early tumor spreading to the lung (Disease free interval: 21.8±7.0 months vs. 46.1±26.6 months; p=0.008). This study provides first evidence for hypoxia marker expression in pulmonary metastases and its clinical relevance. These findings may be important for future therapeutic targets in the therapy of generalized malignant diseases.

Vitronectin expression in primary lung cancer

Lina M. Salazar-Pelaez, Magda C. Ledesma, Ana M. Herrera. School of Medicine, Universidad CES, Medellin, Antioquia, Colombia.

Rationale: Vitronectin (Vn) plays a role in extracellular matrix (ECM) remodeling during tumorigenesis. Vn is present in human bronchial submucosal glands and it is secreted by A549 lung adenocarcinoma cell line. However, whether Vn is differentially expressed in tissues of primary lung cancer has not been explored.

Methods: Lung tissue from 22 primary lung carcinoma and 36 non-lung cancer subjects were obtained from fibrobronchoscopy. Sections were analyzed by histopathological and immunohistochemical methods. The total area occupied by ECM, surface and glandular epithelium, as well as the percentage area occupied by Vn at each of these localizations were measured. Chi-square, t-student, U-Mann Whitney and ANOVA tests were used in group comparisons. Statistical significance was tested at P<0.05.

Results: Vn expression was observed in bronchial glandular and surface epithelium, as well as in ECM (Figure 1). In total, the average area of ECM, surface or glandular epithelium was 0.289mm² (± 0.032), 0.043mm² (±0.009), 0.084mm² (±0.031), respectively. The percentage area occupied by Vn in ECM, surface or glandular epithelium, was 4.899 (±1.186), 2.729 (±1.623), 3.285 (±1.038), respectively; with not significant statistical differences between lung cancer and non-cancer subjects or within different types primary lung cancer.

Conclusion: There were no statistically significant differences in Vn expression between lung cancer and non-cancer subjects, or within primary lung carcinomas.

P766

Ki-67 in non-small cell lung cancer

Arne Warth1, Judith Cortis1, Thomas Muley2, Felix J.F. Herth1, Hendrik Dienemann3, Peter Schirmacher1, Philipp A. Schnabel1, Wilko Weichert1. 1Institute of Pathology, University Hospital, Heidelberg, Germany; 2Translational Research Unit, Thoracic Hospital Heidelberg, Germany; 3Pneumology and Respiratory Critical Care Medicine, Thorasklinik Heidelberg at Heidelberg University, Heidelberg, Germany; 4Department of Thoracic Surgery, Thorasklinik Heidelberg at Heidelberg University, Heidelberg, Germany.

Uncontrolled proliferative activity is one of the determinants of malignant growth and known to be a prognostic factor in a variety of human tumors. Many works have been published on this topic in pulmonary neoplasms but most studies are underpowered or have no clinical data available.

To ultimately clarify the role of proliferation in non-small cell lung cancer (NSCLC) we investigated the proliferative activity of >1000 NSCLC by Ki-67 staining and correlated the data with clinicopathological characteristics including therapy response and survival.

The mean proliferative fraction in NSCLC was 40.7%. Adenocarcinomas (ADC) proliferated significantly less than all other types of NSCLC but proliferation was tightly linked to specific growth patterns. Overall, proliferative activity was not associated with overall, disease free and disease specific survival. However, when patients were stratified according to adjuvant therapy, those patients with high intratumoral proliferative activity and without adjuvant chemotherapy or radiation had significantly diminished survival times when compared to patients whose tumors were proliferating slowly. These associations were reverted in the group of patients who received radio-chemotherapy.

Our study comprehensively clarifies the impact of proliferative activity on outcome in NSCLC patients. Our data suggest that Ki-67 stains can be used as an adjunct in the selection of patients for adjuvant therapy.
Results: The median percentage tumour cells and quantity of DNA extracted was significantly higher in surgical vs bronchoscopic samples (80% vs 30% and 2.3±g vs 1.6±g, P<0.0001), no statistically significant difference was observed between EB11, TNBA and bronchial biopsies. Although 25% of bronchoscopic samples had <10% tumour cells, an amount of DNA extracted ≥200ng and poor DNA quality (Cp=35) were observed in 1%. Comparative results revealed high accuracy and ability to detect mutant alleles present in low fraction of tumor cells.

Highly-sensitive, robust and reliable diagnostic method is crucial for clinically useful detection of EGFR mutations in NSCLC. Due to low sensitivity, direct sequencing is restricted for samples containing at least 50% of tumor cells. PNA-LNA PCR clamp method represents allele-specific approach to gene analysis and demonstrates high accuracy and ability to detect mutant alleles present in low fraction of tumor cells.

Method: Mutated DNA was isolated from cell lines harboring endogenous exon 19 deletion or L858R mutation. Sensitivity of direct Sanger sequencing and PNA-LNA PCR clamp method was analyzed in serial dilutions of mutant allele intermixed with wild-type DNA.

Results: PNA-LNA PCR clamp method reliably detected both exon 19 deletion and L858R down to 1% DNAadmixture level. Direct sequencing presented considerably lower sensitivity detecting only down to 50% of mutated exon 19 allele in DNA mixture and down to 5% in samples with L858R mutant allele.

Conclusions: PNA-LNA PCR clamp method is the highly sensitive tool for detection of EGFR activating mutations. It might be particularly useful in heterogeneous samples with low content of mutant allele, like biopsy material. Direct sequencing presents lower sensitivity, limited by type of mutation.

P773
HOPE-BAL: A novel tool to expand the methodological capabilities in pulmonary research

1Clin.&Exp. Pathology, Research Center, Borstel, Germany; 2Experimental Pneumology, Research Center, Borstel, Germany; 3Inflammation Discovery, Roche, Nutley, NJ, United States; 4Medical Clinic, Research Center, Borstel, Germany

Bronchial/vascular lavage cells are essential biomaterials for both, basic research and clinical applications. Easy to acquire with comparatively little risks for the patients, biomaterials even from non-malignant diseases like COPD or Asthma can be used to aid diagnostics or deliver samples from the alveolar space for basic research. However, these samples are transient materials which require timely read-out if used freshly. In case of formalin-fixed, paraffin-embedded cell blocks they are built to last but with the drawback of protein cross-linking and the severe side effects like degradation of nucleic acids. Since the rapid developments in molecular based techniques, archived samples increasingly need to meet more and more requirements for modern read-outs. Here we present a novel approach to BAL cells with all the possibilities of the omics-techniques. Human BAL cells were L858R fixed and paraffin-embedded to create cell blocks that are easy to store and convenient to handle. For routine diagnostic applications, standard marker molecules were targeted by means of immunochemistry without antigen retrieval. Furthermore we show that HOPE-fixed, paraffin-embedded BAL cells can be used for proteome analysis by application of 2D gel electrophoresis. In addition these BAL blocks contain enough RNA of sufficient quality for transcriptome analysis on Agilent Whole Genome arrays. Differential regulated genes showed distinct expression patterns between healthy donors and patients with Asthma or COPD. In summary, HOPE-BAL is a novel powerful tool for both diagnostics and translational research. Additionally biobanks of HOPE-BAL will ensure proper accessibility for unrestrained investigations.

P777
The predictive model for perinatal asphyxia risk evaluation in the neonates Natalia Gorovenko1, Svetlana Kryvyachenko2, Zoya Rososka2, 1Medical and Labortoratory Genetics, National Medical for Postgraduate Education named after P.L. Shupyk, Kiev, Ukraine; 2Laboratory of Molecular Genetics, Reference Centre for Molecular Diagnostics of Ministry of Public Health, Kiev, Ukraine

Background: Perinatal asphyxia (PA) is often associated with nonreversible adverse neurological outcome. Modern tests for PA diagnostic have low predictive values.

The aim of this study was to define the genetical based predictive model for early preventive diagnostic of PA.

Methods: We performed a case-control study of 201 neonates PA cases and 110 from control group. The markers were selected based on the results of association and differential expression analysis. We used five genetic markers: rs226953, rs1002395, rs12039714, rs1027037 and rs8110310. The results of association analysis were also correlated with the presence of maternal smoking, alcohol consumption and socio-economic factors. The statistical analysis was performed using GEM software.

Results: The frequency of all investigated genotypes with mutant allele was significantly higher among PA cases.
Asbestosis and silica exposures reveal similar and divergent gene expression patterns and pathways related to fibrosis in human bronchial epithelial cells

Timothy Perkins1,2, Paul Peeters1,2, Arif Shukla1, Ingrid Arijs1, Niko Reynaert1, Emile Thomet1,2, Brooks Mosesman3,1 Respiratory Medicine, Maastricht University Medical Centre, Maastricht, Netherlands; 2Pathology, University of Vermont College of Medicine, Burlington, VT, United States; 3Gastroenterology, Translational Research Center for Gastrointestinal Disorders (TARGID), University of Ghent, Belgium; 4Gene Expression Unit, Department of Molecular Cell Biology, Catholic University Leuven, Belgium

Background: Asbestos and silicosis, two common forms of pneumoconioses are caused by excessive exposure to airborne minerals, leading to pulmonary fibrosis. However, both diseases have distinct pathological presentations, which are likely due to the physicochemical characteristics of the two minerals. The epithelium is an initial target cell to come in contact with inhaled materials. The early molecular events that therefore take place in epithelial cells have a strong influence on the molecular and cellular responses that promote inflammation, lesion formation, and fibrosis.

Methods: Primary human bronchial epithelial cells were exposed to non-lethal doses of crocidolite asbestos and cristobalite silica for 24 hours. Affymetrix/GeneSifter® analysis utilizing pairwise-comparison, hierarchical clustering and Ingenuity pathway analysis was used to reveal similar and unique gene expression patterns.

Results: Both minerals altered a number of genes related to inflammation, cell proliferation, apoptosis, cell-surface receptors, and transcription factors. Genes selectively altered by asbestos were related to evasion of apoptosis, MAPK signaling, and iron metabolism. Conversely, genes altered by silica were involved in TNF-signaling, TLR-signaling, and mitochondrial biogenesis. Similar and distinct pathways associated with inflammation and fibrosis were affected by both mineral exposures.

Conclusions: These studies exhibit initial changes in gene expression by asbestos and silica in target bronchial epithelial cells as early molecular events that may initiate the inflammatory and fibrotic responses leading to asbestosis and silicosis.

P773
The effect of cigarette smoking on BAL protein profile
Paola Rottoli1, Claudia Landi2, Elena Bargagli1, Alfonso Carleo1, Carmela Olivieri3, Pasquale Di Sipio1, Rosa Metella Refini1, Luca Bini2,3

Medicina Clinica e Scienze Immunologiche, Malattie Respiratorie e Trapianto Polmonare, Siena, Italy; 2molecular Biology, Siena University, Siena, Italy

Background: BAL protein analysis gives a panorama of the complex network of proteins of different origin and function and their modifications at alveolar level, simultaneously providing new information about events in the alveolar microenvironment and insights into lung physiology and pathology. In this study we applied the proteomic approach to the study of BAL in order to evaluate the effect of smoking exposure to BAL protein composition.

Aim: Aim of this study was to investigate qualitative and quantitative differences in BAL protein profiles from cigarette smoker and non-smoker healthy subjects.

Methods: BAL samples were obtained by 10 healthy never-smoker and 8 asymptomatic smoker subjects. After centrifugation, dialysis and denaturation of samples, BAL samples were analyzed by two-dimensional electrophoresis and proteins differentially expressed were identified by mass spectrometry.

Results: 20 BAL proteins were differently expressed: 15 were up-regulated in smokers and 5 proteins were up-regulated in never-smokers. Among these proteins some were involved in immune-regulation, host defense (i.e.Pulmonary surfactant-associated protein A2), apoptosis and inflammatory responses (e.g. antichymotrypsin) and oxidant/antioxidant balance (i.e. Glutathione S transferase P and Annexin A5).

Conclusion: In healthy subjects smoking exposure modifies the expression of several BAL proteins implicated in the regulation of crucial biological activities (such as oxidant/antioxidant balance, inflammation and tissue matrix turnover) potentially involved in the pathogenesis of several smoke-induced lung diseases.
activity of allergic inflammation. Polymorphism can predict the occurrence of fatigue in sarcoidosis patients. Based on these results, we concluded that proinflammatory gene and was absent in non-fatigue group, and we found weak significant difference frequency (29.58% vs. 19.30%, p = 0.01). After subdividing according to genotypes, the number of annexin V positive cells did not differ between patients carrying TT genotype (50.0%, 23.3–7.8% and 8.8%) with CC genotype (54.5%; 41.7–71.7%; p = 0.05). Genotyping and investigations on association between apoptosis and genotypes in larger patient-control groups are under progress. In conclusion, PBMC obtained from sarcoidosis patients showed more apoptosis resistant phenotype than cells from control subjects. In our pilot cohort, wild type ANXA11 gene and its R230C variant did not differ in terms of sensitivity to apoptosis. Further studies in a larger patient cohort are ongoing. Grant support: IGA MZ CR NS/11171, IGA PU-EL 2012_07, CZ.1.05/2.1.00/00003.

P77 Proinflammatory gene polymorphism and fatigue in sarcoidosis

Tatjana Radijevic1, Petkovic, Tatjana Pejic, Desa Nastasijevic Borovac, Milan Rancic, Ivana Stankovic, Lidija Ristic. Clinic for Lung Disease, Clinical Center, Niš, Serbia

Introduction: Fatigue is one of the most prominent symptoms in sarcoidosis patients. Cause of fatigue in sarcoidosis is still unknown. No relationship was found between fatigue and disease activity marker in sarcoidosis. Fatigue can persist many years after disease remission. Proinflammatory cytokines, TNF-α and IL-1β are involved in asthma pathogenesis (e.g. STAT6 signaling). Therefore, we evaluated the diagnostic and prognostic role of procalcitonin in sarcoidosis. Patients and methods: A total of 50 patients with AECOPD and 10 of apparently healthy individuals (control group) were studied. On presentation, serum PCT concentrations were measured, and quantitative sputum culture was performed for AECOPD. The patients were reevaluated when they had returned to their stable clinical state. The patients were classified into two subgroups: group A included patients with bacterial AECOPD (n = 20), group B included patients with nonbacterial AECOPD (n = 30).

Results: On presentation, the levels of PCT for patients of group A (2.69 ± 0.62 ng/ml) were significantly higher than in group B (0.07 ± 0.02 ng/ml) and control group (0.05 ± 0.02 ng/ml) (p < 0.001). When they had returned to their stable state, the levels of PCT for patients of group A decreased to (0.06 ± 0.03 ng/ml), which was significantly lower than in exacerbation (2.69 ± 0.62 ng/ml) (p < 0.001). But in patients of group B compared with exacerbation the levels of PCT did not change (0.06 ± 0.02 ng/ml) (p > 0.05). Asymptotic correlation was recorded between PCT levels in group A and temperature (r = 0.898, p < 0.05), leucocytic count (r = 0.889, p < 0.05), FEV1% of predicted (r = 0.898, p < 0.05).

Conclusions: Procalcitonin is a good marker for differentiation between bacterial and nonbacterial AECOPD and could be used to guide antibiotic therapy and reduce antibiotic overuse in hospitalized patients with AECOPD.

P78 Transforming growth factor-beta1 (TGF-β1) expression is related to reticular basement membrane (Rbm) hypervascularity in smokers and COPD

Sukhwinder Singh Sohal1, Amir Soltani2, David Reid1,2, Steven Weston1, Hans Konrad Muller1, Richard Wood-Baker1, Eugene Haydn Walters1, 1NHMRC Centre for Research Excellence in Chronic Respiratory Disease, University of Tasmania, Hobart, TAS, Australia; 2Iron Metabolism Laboratory, Queensland Institute of Medical Research, Brisbane, QLD, Australia

Introduction: TGF-β1 is likely to play an important role in COPD airway pathology, including angiogenesis and epithelial mesenchymal transition (EMT), but it is relatively under-investigated in this context. We have previously published that the Rbm is fragmented as a likely marker of active EMT and hyper-vascular in the airways of current smokers either with or without COPD.

Objective: This study evaluated the status of TGF-β1 in endobronchial biopsies (ebb) from smokers with or without COPD.

Methods: Ebb sections from 15 smokers with normal lung function (S-NLF), 19 current (CS) and 14 ex-smokers (ES) with COPD were immunostained for TGF-β1 and compared to 17 normal controls (NC). The percentage of area of tissue and the number and area of vessels and the percentage of vessels staining positively for TGF-β1 were compared between groups.

Results: There were no differences between groups in epithelial TGF-β1 staining of TGF-β1 stained vessels in the Rbm were increased in S-NLF, CS-COPD and ES-COPD compared to NC, but especially so in CS-COPD (median (range) for number of vessels/mm Rbm 2.5 (0.0-12.7), 3.4 (0.0-8.1) and 1.0 (0.0-7.0), p = 0.051). Percentage of vessels stained was also increased in these clinical groups compared to NC (median (range) for S-NLF 31% (0-121), for CS-COPD 40% (0-123) and for ES-COPD 22% (0-114) vs. H-N 0% (0-26), p < 0.05).

Conclusions: Vessel-associated TGF-β1 was increased in smokers and COPD, especially in CS-COPD. This is likely to be related to the pathogenesis of COPD; EMT, structural remodelling, angiogenesis and tumorigenesis.

95. Inflammatory mechanisms in COPD

P780 Procalcitonin as a diagnostic marker in acute exacerbation of COPD

Réhád Heszán1, Maged Mohamed, Eiman Ramadan, Manal Hashim, Samur Shural. Chest, Dallah Hospital, Riyadh, Saudi Arabia

Background: Rational prescription of antibiotics in acute exacerbations of COPD (AECOPD) requires predictive markers. Recently, measurement of procalcitonin (PCT) levels appears to be useful in order to minimize this problem. We aimed to evaluate the diagnostic and prognostic role of procalcitonin in COPD patients and methods: A total of 50 patients with AECOPD and 10 of apparently healthy individuals (control group) were studied. On presentation, serum PCT concentrations were measured, and quantitative sputum culture was performed for AECOPD. The patients were reevaluated when they had returned to their stable clinical state. The patients were classified into two subgroups: group A included patients with bacterial AECOPD (n = 20), group B included patients with nonbacterial AECOPD (n = 30).

Results: On presentation, the levels of PCT for patients of group A (2.69 ± 0.62 ng/ml) were significantly higher than in group B (0.07 ± 0.02 ng/ml) and control group (0.05 ± 0.02 ng/ml) (P < 0.001). When they had returned to their stable state, the levels of PCT for patients of group A decreased to (0.06 ± 0.03 ng/ml), which was significantly lower than in exacerbation (2.69 ± 0.62 ng/ml) (P < 0.001). But in patients of group B compared with exacerbation the levels of PCT did not change (0.06 ± 0.02 ng/ml) (P > 0.05). Asymptotic correlation was recorded between PCT levels in group A and temperature (r = 0.898, p < 0.05), leucocytic count (r = 0.889, p < 0.05), FEV1% of predicted (r = 0.898, p < 0.05).

Conclusions: Procalcitonin is a good marker for differentiation between bacterial and nonbacterial AECOPD and could be used to guide antibiotic therapy and reduce antibiotic overuse in hospitalized patients with AECOPD.
Blood outgrowth endothelial cells are senescent and dysfunctional in COPD due to increased DNA damage; implications for endothelial dysfunction

Kornelia Schikowski1,2,3, Richard Starke1, Nicolas Mercado1, Vassilis Gorgoulis1, Anna M. Randi1,2, Peter J. Barnes1.

Introduction: Cardiovascular disease (CVD) is a major cause of death in COPD. The molecular pathways that lead to endothelial dysfunction and CVD in COPD remain unclear. DNA damage has been recognized as an important contributor in aging disorders. Blood outgrowth endothelial cells (BOEC) - alternately named Late endothelial progenitor cells- could serve as a research tool to investigate endothelial defects in COPD patients.

Aim and objectives: To examine whether BOEC exhibit increased DNA damage linked to dysfunctional characteristics, illustrating the underlying molecular process of endothelial dysfunction in COPD.

Methods: BOEC were isolated from peripheral blood samples received from 16 healthy non-smokers (age ± SD, 57.6±2.7yr; 5 males), 10 healthy smokers (57.6±2.6yr; 5 males) and 16 COPD patients (67.1±1.6yr, 11 males). DNA damage was assessed by measuring two markers of double-strand break formation, 53BP1 and γH2AX, by immunostaining. Endothelial senescence was measured by senescence-associated β-galactosidase (SA-β-Gal) activity, and sirtuin (SIRT)1 protein levels by Western blotting.

Results: BOEC from smokers and COPD patients showed marked increases of marked DNA damage and displayed significantly reduced SIRT1 protein levels and increased senescence compared to healthy non-smokers.

Conclusions: Our results confirm that BOEC from smokers and COPD patients display increased DNA damage linked to epigenetic molecular dysfunction and increased senescence. These defects may contribute to endothelial dysfunction and cardiovascular events in smokers and patients with COPD.

P784

Increased levels of soluble intercellular adhesion molecule 1 in active smokers

Elena Arellano-Ordoñez1, Ana Montes-Worboys1, Carmen Calero-Acuña1, Eduardo Marquez-Martín1, Pilar Cepeda-Ramos1, Francisco Ortega-Ruiz12, José Luis Lopez-Campos12,13, Unidad Médico Quirúrgica de Enfermedades Respiratorias, Hospital Virgen del Rocío, Instituto Biomedicina de Sevilla (IBIS), Sevilla, Spain; 2CIBER de Enfermedades Respiratorias, CIBERES, Madrid, Spain

Objectives: Serum intercellular adhesion molecule-1 (sICAM-1) is known to be a smoking-associated inflammatory marker but data on the relationship between active smoking and sICAM-1 are lacking for COPD. In the present study we collected a group of COPD patients and non-COPD smokers and measured the sICAM-1 in order to provide information on its expression related to active smoking.

Methods: This report is based on a cross sectional analysis of a case-control study, in which 141 COPD cases and 56 controls (non-COPD smokers) were consecutively recruited. Clinical information from all subjects was registered and participants were consecutively recruited. A smoking questionnaire that included direct questions on co-morbid conditions, respiratory symptoms and tobacco history. Peripheral blood concentration of sICAM-1, together with interleukin-8 (CXCL8), C-reactive protein (CRP), and serum amyloid A (SAA) were determined in all cases.

Results: There were 89 ex-smokers and 108 active smokers of them in the sample. CRP and SAA (log-scale) were elevated in patients with COPD as compared to control subjects (p = 0.005 for CRP and p = 0.024 for SAA). SAA and sICAM-1 were associated with active smoking in the bivariate analysis. ICAM-1 retained this association when corrected by age, gender, the presence of COPD, inhaled corticosteroids use, body mass index, and FEV1 as covariates.

Conclusion: The present study confirms an association between sICAM-1 levels and active smoking in a group of COPD and non-COPD smokers. This association is specific of ICAM-1, not affecting other COPD-related biomarkers.

P785

Correlation between immunohistochemical CuZn-SOD expression and the histopathological features in small airways of patients with severe COPD

Breza T Olimpia1,2, Stefan Marklund1, Cecilia Andersson1,4, Michiko Mieto1,2, Andrzej Rubi3,5, Clas-Göran Liffå6,7, Jonas Ejefelt8,10, Department of Medicine, Trelleborg Hospital, Trelleborg, Sweden; 2Department of Experimental Medical Science, Medical Science, University, Lund, Sweden; 3Department of Medical Biosciences, Clinical Chemistry, Umeå, Sweden; 4Department of Cardiology, Medical University of Lublin, Poland; 5Department of Respiratory Medicine and Allergology, Lund University, Lund, Sweden.

The central causative factor of COPD is cumulative oxidative stress as result of long-term tobacco smoking and an extensive inflammatory response. Superoxide dismutases (SODs) are the primary superoxide-scavenging enzymes in mammalian tissues. This study investigate the relationship between inflammatory and SODs profiles in different small airways compartments according to the severity of COPD and local destructive index (DI).

The localizations of macrophages (M0), mast cells, neutrophils, CuZn-SOD, Mn-SOD, and EC-SOD were investigated by immunohistochemistry using paraffin embedded sections from 15 controls (non-smokers+s+smokers), and 25 subjects with mild-to-severe COPD. Histological/immunohistochemical analyses were performed using the same Region-of-Interest within each small airway. Significant (p<0.05) up-regulation of CuZn-SOD was observed in bronchial epithelium, pulmonary vessels, and alveolar parenchyma in very severe COPD, whereas epithelial Mn-SOD and EC-SOD expressions were less affected. The percentage of CuZn-SOD was higher in alveolar parenchyma than in severe COPD but this did not reach statistical significance. Higher Mq and neutrophils densities were found in the interstitium in very severe COPD. Statistically significant correlation was found between SOD expression in the small airways and Mq/Mn-SOD in the alveolar parenchyma.

In the small airways of patients with very severe COPD there is up-regulation of CuZn-SOD and correlates with the lower DI. The SODs had a patchy distribution in all compartments, where the intensity varied between micro-localization in small airways and alveolar parenchyma.

The impact of long-term tobacco smoking on circulating IL-16+ NK cells

Anders Andersson1, Apostolos Bossios2, Carina Malmhi1, Margareta Sjostrand2, Birgitta Houltz1, Ingemar Quvarford1, Anders Lindén1.

1Internal Medicine/Respiratory Medicine and Allergology, Medicine, Gothenburg, Sweden; 2Internal Medicine/Krefting Research Centre, Medicine, Gothenburg, Sweden

Natural killer (NK) cells constitute a first line of anti-viral host defence and tobacco smoke may cause reduced cytotoxicity. Among the cytokines expressed in NK cells, interleukin-16 (IL-16) is of interest since it is known that the extracellular concentrations of this CD4 cell chemoattractant are increased in the airways of long-term smokers. Here, we investigated whether long-term smoking alters the number and IL-16 content of circulating NK cells.

Never-smokers (NS) and asymptomatic smokers (AS) with a normal ventilatory capacity plus a normal diffusion capacity for carbon monoxide (DLCO) were included. We also examined smokers who were smoked-related or never-smokers with severe DLCO (<2SD of the predicted mean). In each subject, a peripheral venous blood sample was taken during clinically stable conditions for flow cytometry analysis of intracellular IL-16 in NK cells (HL and CD8 CD36 CD16 CD56+). The relative and absolute number of NK cells (CD3 CD16 CD56) was determined. Smokers (AS and COPD) exhibited a lower relative number of IL-16+ NK cells compared to NS (Mann-Whitney U test, p<0.05). In line with this, the absolute number of IL-16+ NK cells tended to be lower in smokers as well, although this trend was not statistically significant. Among smokers, there was a negative and statistically significant correlation for both the absolute and relative numbers of NK cells, on the one hand, and tobacco load (e. pack-years; Spearmann Rank Corr. test; p<0.05; rho=0.056 for both correlations) on the other. Our study indicates that long-term smoking exerts a negative impact on circulating NK cells, in terms of number and IL-16 content. Hypothetically, this impact may impair anti-viral host defence.

The dynamics of IV-type collagen contents in BALF of patients with COPD

Mykola Ostrovskyi, Jyrna Szewlikhov, Oleksandr Varunkiv, Magdalena Gogoc1,2, Marzana Kulchyck-Miñansk, internist, #1, Ivanovo-Frankivsk National Medical University, Ivanovo-Frankivsk, Ukraine

Background: Chronic obstructive pulmonary diseases are diagnosed in 4-6% of men and 1-3% of women above 40 years old. The persistent inflammatory process in bronchi, the development of microcirculation disorders, the increasing of hypoxia processes result in the activation of fibroblasts and their production of IV-type collagen, which is manifested by the formation of peribronchial pneumosclerosis. Purpose of the study: The evaluation of the IV-type collagen level dynamics in BALF of patients with COPD. Materials and methods: The contents of IV-type collagen in BALF has been evaluated by the Enzyme-linked immunosorben assay method in 28 patients with 2nd stage of COPD in a relapse phase, and then in the same patients again in 6,4±1,2 years during the transformation of the disease into 3rd stage of COPD. Results of the study: The contents of IV-type collagen in BALF with II stage COPD in the relapse phase was (38,6±1,21) ng/ml, which is 3,99 times higher than in almost healthy people whose level was (9,6±1,24) ng/ml. The average FEV1 magnitude was 57,4±4,2%. During the progressing of COPD and its transformation into 3rd stage, the average magnitude of the FEV1 indicator was 43,4±4,6%; the IV-type collagen level in BALF rose up to 35% in comparison with previous data and it was equal (9,6±1,24) ng/ml. Conclusions: The progressing of COPD is accompanied by the increase of the remodulation of bronchial tree due to peribronchial pneumosclerosis, which is manifested by the IV-type collagen levels rise.

Senescence marker protein-30 decreases oxidative stress in human lungs of smokers with chronic obstructive pulmonary disease
Taofan Bing, Bing Mao, Gang Wang. Department of Integrated Traditional Chinese and Western Medicine, West China Hospital, Chengdu, Sichuan, China

Introduction: Senescence marker protein-30 (SMP30) reportedly protects mice lung from oxidative stress associated with smoking. Little is known about the presence of SMP-30 in lungs of chronic obstructive pulmonary disease (COPD).

Methods: Lung tissue was examined from 47 subjects undergoing resection for peripheral lung tumors as follows: current smokers with (n=9) and without COPD (n=7), ex-smokers with (n=8) and without COPD (n=8), nonsmokers with (n=7) and without COPD (n=6). SMP-30 was investigated by immunohistochemistry in lung tissue specimens and Western analysis, qRT-PCR in total lung homogenates. Morphologic evaluations of the lungs, glutathione, malondialdehyde (MDA), interleukin-8 (IL-8) and tumor necrosis factor-a in the lung tissues were determined.

Results: Weak SMP-30 protein was localized predominantly in the cytoplasm of bronchial epithelial cells. A notable decline of SMP-30 mRNA and protein was found in lung tissue of patients with COPD compared to healthy subjects (P<0.05), also in smokers and ex-smokers with or without COPD when compared with spiroemphy matched nonsmokers. Inverse correlation was observed between SMP-30, MDA, IL-8 and alveolar destructive index (P<0.05).

Conclusions: SMP-30 decreases oxidative stress from smoking and pulmonary inflammation, which may contribute to protecting smokers from susceptibility to the development of COPD.

Relation of inflammatory process with COPD phenotype
Sibel Atis Nayci, Eylem Sercan Ozgur, Cengiz Ozge, Ahmet Ivcan. Chest Diseases, Mersin University School of Medicine, Mersin, Turkey

Aim: Chronic obstructive lung disease (COPD) does not have a uniform clinical and morphological nature. The aim of the study was to characterize the inflammatory process in two distinct forms of COPD (chronic bronchitis or emphysema).

Methods: 33 COPD patients were investigated. They were divided into two groups: emphysema (n=15) and chronic bronchitis patients (n=18). The distinguishing criteria were the presence of emphysema in HRCT and hyperinflation in pulmonary function test.

Results: The concentration of inflammatory mediators in BAL (IL-8, TNFα, MPO, myeloperoxidase (MPO), and neutrophil elastase (NE)) and blood (IL-8, TNFα, CRP, and fibrinogen) were measured.

Conclusions: We report evidence of enhanced IL-6 signaling and CCL3 activity in COPD sputum. We have observed that there is reduced CCL2 activity and enhanced CCL3 activity in COPD sputum. IL-6 may therefore promote neutrophilic inflammation in COPD through up-regulation of CCL3 expression.

P795
MMP-9 expression and activity is increased in the BAL of patients with acute exacerbation of COPD
Eleni Papakonstantinou1, Michael Tamm2, Michael Roth 2, Daiana Stolz 2
1Pharmacology, School of Medicine, Aristotle University, Thessaloniki, Greece; 2Clinic of Pulmonary Medicine and Respiratory Cell Research, University Hospital, Basel, Switzerland

Background: Exacerbations of COPD are associated with accelerated deterioration of respiratory symptoms and pulmonary function. Matrix metalloproteinases (MMP) are a family of endopeptidases involved in extracellular matrix clevage. We hypothesize that there is a difference in the expression and the enzymatic activity of MMP in bronchoalveolar lavage fluid (BALF) of COPD patients with and without exacerbation.

Methods: Seventy patients with COPD diagnosed according to the GOLD guidelines with either stable disease or exacerbation and undergoing diagnostic bronchoscopy were included in this prospective cohort study. BAL was performed by installation of 3 x 50 ml of pyrogen-free sterile NaCl 0.9% solution over the working channel of the bronchoscope according to standard guidelines. Enzymatic activity of MMP was assessed by gelatin zymography and protein levels of MMP-2, MMP-9 and of tissue inhibitors of MMP (TIMP) were measured by ELISA.

Results: Data of 40 patients with COPD (stable COPD n=20, exacerbation n=20) have been analyzed so far. Mean age was 68.9 years ±(9.5), mean FEV1%pred 49.9% ±(16.9). Mean DLCO %pred 43.1% ±(18.8). As compared to patients with COPD at stable state, the MMP-9 enzymatic activity and protein expression were increased by 73% and 62%, respectively (p<0.001) in the BALF of patients with COPD at exacerbation. In contrast, there was no significant alteration in TIMP expression, indicating a net increase of collagenase activity associated with exacerbation.

Conclusion: Increased activity of MMP-9 during acute exacerbation might contribute to tissue destruction and development of emphysema in patients with recurrent exacerbations of COPD.

Rationale: IL-6 is a pleiotropic cytokine that is involved in the regulation of inflammation. Increased serum IL-6 levels are associated with reduced FEV1 in COPD patients independent of age or smoking status. Elevated levels of plasma IL-6 in COPD patients have been associated with increased exacerbation frequency. The mechanism by which IL-6 may mediate inflammation in COPD is uncertain. We sought to determine levels of IL-6 and its soluble receptor (sIL-6R) in COPD sputum. IL-6 signaling can alter the levels of the neutrophil chemotactant CCL3 and the monocyte chemotactant CCL2; we also investigated the levels of these chemokines.

Results: Healthy smokers had the highest levels of plasma IL-6. COPD patients expressed the highest levels of sIL-6R. COPD patients also expressed the highest levels of plasma CCL3. In contrast, CCL2 expression was significantly reduced in COPD patients.

P793
Enhanced IL-6 and CCL3 activity in COPD

Introduction: IL-6 is a pleiotropic cytokine that is involved in the regulation of inflammation. Increased serum IL-6 levels are associated with reduced FEV1 in COPD patients independent of age or smoking status. Elevated levels of plasma IL-6 in COPD patients have been associated with increased exacerbation frequency. The mechanism by which IL-6 may mediate inflammation in COPD is uncertain. We sought to determine levels of IL-6 and its soluble receptor (sIL-6R) in COPD sputum. IL-6 signaling can alter the levels of the neutrophil chemotactant CCL3 and the monocyte chemotactant CCL2; we also investigated the levels of these chemokines.

Methods: 70 patients with GOLD stage IV COPD and 30 healthy controls comprising of 15 healthy smokers (HS) and 15 healthy non-smokers (HNS) underwent sputum sampling with PBS processing. Levels of IL-6, sIL-6R, CCL2, CCL3 were determined by multiplex analysis (MDx) platform of sputum supernatant.

Results: Healthy smokers had the highest levels of plasma IL-6. COPD patients expressed the highest levels of sIL-6R. COPD patients also expressed the highest levels of plasma CCL3. In contrast, CCL2 expression was significantly reduced in COPD patients.

Conclusion: We report evidence of enhanced IL-6 signaling and CCL3 activity in COPD sputum. We have observed that there is reduced CCL2 activity and enhanced CCL3 activity in COPD sputum. IL-6 may therefore promote neutrophilic inflammation in COPD through up-regulation of CCL3 expression.

Differences in cellular expression of C-reactive protein and serum amyloid A in lung tissue in patients with chronic obstructive pulmonary disease
Carmen Calaza1,2, Elena Arellano1, Ana Montes-Worthoy1, Verónica Sanchez2, Daniela Tobar1, Nicolas Moreno1, Emilia Barceló1, Jose Luis Lopez-Campos1,2,3
1Unidad Médico-Quirúrgica de Enfermedades Respiratorias, Hospital Universitario Virgen del Rocío, Seville, Spain, 2Instituto de Biomedicina de Sevilla, IBIBS, Seville, Spain, 3CIBER de Enfermedades Respiratorias, CIBERES, Madrid, Spain

Introduction and objectives: The lung bronchial and parenchyma tissues are a potential source of acute phase reactants in Chronic Obstructive Pulmonary Disease (COPD) patients as compared with resistant smokers. The aim of this study was to determine the expression of C-Reactive Protein (CRP) and Serum Amyloid A (SAA) in epithelial cells, macrophages and lung fibroblasts between COPD and resistant smokers. This expression was also studied according to the different grades of COPD.

Method: This report is based on a cross sectional analysis of a case-control study. These patients included were consecutively recruited, in elective lung surgery. Epithelial cells, macrophages and fibroblasts were obtained by magnetic separation microbeads and CRP and SAA1, 2 and 4 expression was analysed by real time PCR.

Results: The sample was formed by 19 COPD and 27 resistant smokers. Although all cell types were able to synthesize the biomarkers, fibroblasts of COPD patients had a significantly higher expression (5 folds, p=0.015) of SAA1 than resistant smokers. Our results also showed significant differences in the expression of SAA between macrophages from COPD in different stage of the disease, being higher in patients in GOLD II (25 folds higher for SAA1, p=0.015) and 30 for SAA4, p=0.014).

Conclusions: There are differences in the synthesis of SAA-1 in fibroblasts of COPD and controls. The pattern of expression in macrophages is different for SAA according to stage of disease. These findings could be useful to elucidate the contribution of each cellular compartment in the inflammatory component of the disease.
Elevated sputum complement factor H levels in COPD: Relationship with stimulation with PMA and S. aureus was more intensive during AECOPD ROS production in sputum and peripheral blood neutrophils after (p < 0.05). The most significant increase of ROS production was documented after neutrophil stimulation with 30 nM of PMA (in sputum neutrophils – during AECOPD 45±28-fold; in SCOPD 18±19-fold, HI 80±11-fold, respectively, (p=0.01); in PBN - during AECOPD 98±41-fold, in SCOPD 162±24-fold, HI 118±18-fold, respectively, (p=0.005)). The intensive ROS production in neutrophils after stimulation with S. aureus was found in AECOPD group compared with SCOPD and HI (p=0.01).

Conclusions: ROS production in sputum and peripheral blood neutrophils after stimulation with PMA and S. aureus was more intensive during AECOPD compared with SCOPD. Sputum neutrophils produce higher levels of ROS compared with PBN.

P794
Elevated sputum complement factor H levels in COPD: Relationship with disease severity
Zelka Wrezghi, Gabriella Gállyf, Zsófia Lázár, András Bikor, György Losonczy, László Heorhat. Pulmonology, Semmelweis University, Budapest, Hungary

Background: Inflammatory processes in COPD are not fully clarified yet. Complement activation products C3a and C5a are elevated in COPD spuha, but complement regulatory proteins, such as factor H, have been not investigated in this disorder.

Objective: Our primary goal was to determine airway complement factor H levels in stable and exacerbated COPD in order to gain information about the relationship between factor H level, complement activation and clinical characteristics of disease groups.

Methods: We examined complement factor H levels and SC5b-9, a marker of complement activation in plasma and spuha of 15 healthy, 15 stable and 17 exacerbated COPD subjects by ELISA.

Results: Factor H and SC5b-9 levels were both higher in spuha of stable COPD patients compared to healthy controls (Factor H: p=0.001, SC5b-9: p=0.003), which further increased in acute exacerbation (Factor H: p<0.0001, SC5b-9: p=0.02), and returned to stable level after 5-7 days of systemic corticosteroid treatment. Plasma concentrations showed similar tendencies, but with much smaller differences. There was a significant positive relationship between sputum factor H levels and FVC (%: r=0.71, p<0.01) as well as FEV1 (%: r=0.57, p=0.04) values in stable patients. Sputum SC5b-9 concentrations correlated with FEV1/FVC (%: r=0.55, p=0.04) in stable COPD.

Conclusions: Increased sputum factor H level is associated with milder airway obstruction in stable COPD, which may be connected to early inflammatory processes preceding extensive alveolar destruction.

This work was supported by the Hungarian Scientific Research Fund (OTKA 68808).

Stage-dependent regulation of brain-derived neurotrophic factor and transforming growth factor-β1 in patients with COPD
Paul Stahl1, Urs Würtemberger1, Kai Bratke1, Christiana Zingler2, J. Christian von Rochn1, Marek Lommatzscheck1.1Pulmonology, University Medical Hospital, Rostock, Germany; 2Laboratory Medicine, University Hospital, Rostock, Germany

Chronic Obstructive Pulmonary Disease (COPD) is characterised by complex inflammatory, neural and fibrotic changes. Brain-derived Neurotrophic Factor (BDNF) and Transforming Growth Factor-β1 (TGF-β1) are stored in alpha-granules of platelets. Serum BDNF and TGF-β1 are predominantly platelet-derived (released from platelets during serum preparation). BDNF is a key regulator of neuronal plasticity, whereas TGF-β1 is involved in tissue repair and emphysema pathogenesis. We have previously shown that serum BDNF but not TGF-β1 levels were found in GOLD stage 4 in contrast to asthma. This work appears to be characterised by increased concentrations of both BDNF and TGF-β1. Very severe COPD is associated with highest TGF-β1 concentrations, but relatively lower BDNF concentrations. We thus speculate that these findings might reflect a maximum of neuronal and inflammatory activity in GOLD stage 2 and 3, and a predominant activity of tissue remodeling factors in GOLD stage 4.

Gastroesophageal reflux disease (GERD) is tightly linked to bronchial asthma and COPD. In our study we evaluated serum of 54 patients. Diagnoses was as follows: asthma (n=14), COPD (n=12), GERD (n=20), asthma and GERD (n=8). Serum of 17 volunteers was studied as a control group. IL-4, IFN-gamma and TNF-alpha levels were detected by ELISA. All patients underwent upper gastrointestinal endoscopy and spirometry. For statistics nonparametric method of Kruskal-Wallis and Spearman’s correlation were used.

Results: The IL-4 and IFN-gamma levels in all groups of patients were significantly higher than control (p=2.5E-09 and 1.7E-09 respectively). Meanwhile TNF-alpha values in patients cohorts was lower than in control group (p=0.007).

Conclusions: Our results suggest that there is a significant contribution of inflammation processes in the pathogenesis of gastroesophageal reflux disease (GERD) in patients with different pulmonary diseases. Further investigations are necessary to determine the role of other cytokines in GERD in different clinical settings.

C-reactive protein and serum amyloid A overexpression in lung tissues of chronic obstructive pulmonary disease patients
Ana Montes-Webová1,2, Carmen Calero-Acuña1,2,3, Elena Arellano-Orden1,2, Belen Rojano1, Jose Luis Lopez-Villalobos1, Ana Blanco1, Miguel Morón1, José Luis Lopez-Campos1,2,3
1Instituto de Biomedicina de Sevilla, Hospital Virgen del Rocio, Seville, Spain; 2CIBER de Enfermedades Respiratorias, CIBERES, Madrid, Spain; 3Unidad Medico Quirurgica de Enfermedades Respiratorias, Hospital Virgen del Rocio, Seville, Spain

Background: Although researchers have consistently demonstrated systemic inflammation in chronic obstructive pulmonary disease (COPD), its origin is yet unknown. We aimed to compare the lung bronchial and parenchymal tissues as potential sources of major acute-phase reactants in COPD patients and resistant smokers.

Material and methods: Consecutive patients undergoing elective pneumectomy or lobectomy for suspected primary lung cancer were considered for the study. Patients were categorized as COPD or resistant smokers according to their spirometric results. Lung parenchyma and bronchus sections were obtained and C-reactive protein (CRP) and serum amyloid A (SAA1, SAA2, and SAA4) expressions in COPD patients were 1.89-fold, 3.46-fold, 3.65-fold, and 3.9-fold the control values, respectively. In the parenchyma, CRP, SAA1, and SAA2 gene expressions were 2.41-, 1.97-, and 1.76-fold the control values, respectively. SAA4 was not overexpressed in the parenchyma. The expressions were higher in the parenchymal tissue than in bronchial tissue for both COPD and controls. The protein analysis supported the results obtained in the PCR.

Conclusions: These results indicate an overexpression of CRP and SAA genes in both bronchial and parenchymal tissue in COPD. This expression differs between the parenchyma and bronchial tissue, indicating tissue/cell type specificity of these markers.

P798
T cell chemokine receptor expression in COPD
Helena Foresta, Mikael Mikko, Benita Engvall, Johan Grunewald, Åsa Wheelock, Jan Wahlström, Magnus Sköld.
Kwikisla Instituat, Stockholm, Sweden

Background: COPD is characterized by accumulation of T cells in the lung.
Recruitment is regulated by chemokines binding to receptors on the cell surface. We studied the expression of chemokine receptors on T cells from never-smokers, smokers with normal lung function and COPD patients.

**Methods:** Thirteen never-smokers, 38 smokers with normal lung function and 32 COPD patients, GOLD stage I-II (23 smokers and 9 ex-smokers) underwent BAL (5±0.5 ml). BAL and blood T cells were analysed for CD3, CD4 and CD8 in combination with the activity marker CD69 and the chemokine receptors CXCR3, CCR4 and CCR5 using multicolor flow cytometry. **Results:** The percentage of CD4+CD69+ (non-activated) T cells expressing CXCR3 was significantly lower in BAL from “normal” smokers and from COPD smokers compared to neversmokers (p<0.001 and p<0.05). CD4+ T cells from “normal” smokers had significantly higher median fluorescence intensity (MFI) of CCR5 compared to neversmokers (p<0.05). An increase, albeit not significant, was also observed in COPD patients who were current smokers. The expression of CXCR3, CCR4 and CCR5 on CD8+ T cells in BAL did not differ. In blood from COPD patients (both current and ex-smokers), we observed a higher percentage of activated (CD69+CD4+) T cells expressing CXCR3 compared to “normal” smokers (p<0.05 for both).

**Conclusions:** The lower percentage of CD4+CD69+CXCX3+ T cells and the higher MFI of CCR5 on CD4+ T cells in BAL from both smoking groups were related to smoke exposure per se, rather than the degree of airway obstruction. This was not observed in COPD exsmokers, indicating that both smoking history and current smoke exposure affect the expression. Analysis of soluble ligands for CXCR3, CCR4 and CCR5 is in progress.

*Human alveolar macrophages express mucin5B*

Josh Serpe1, Kumi Prik1, Madis Metsis2, Svetlana Sergejeva2, Sirje Marran1, Thomas Flanger1, Institute of Clinical Medicine, Tallinn University of Technology, Tallinn, Estonia; 2North Estonia Medical Centre, North Estonia Medical Centre, Tallinn, Estonia

**Introduction:** This study investigated whether alveolar macrophages (AM), in addition to epithelial cells, express mucin5B (MUC5B) in human lung environment influenced by long-term cigarette smoke.

**Methods:** We analysed MUC5B expression at the level of a polymic and mRNA in human BALF cells from fifty subjects (20 non-smokers, 17 patients with chronic bronchitis (CB) and 13 patients with chronic obstructive pulmonary disease (COPD)).

**Results:** Apomucin5B was observed in BALF mononuclear cells in 60% of all subjects whereas significantly higher frequency of apomucin5B+ cells was found in CB (95% CI 4.5-24.9) and COPD (95% CI 6.2-39.6) subjects than in non-smokers (CB: 0.1-2.5; COPD: 0.1-5.2). Apomucin5B+ mononuclear cells showed strong expression of CD163, confirming their identity as AM. MUC5B mRNA expression was detected in AM of subjects investigated by sit analysis. qPCR showed MUC5B mRNA expression in purified AM of subjects investigated. An inverse correlation between apomUC5B+ AM levels and FEV1 was found (r = 0.46, p = 0.002 in whole study group). The correlation between apomUC5B+ AM levels and smoking pack-years was positive in whole study group (r = 0.65, p < 0.001).

**Conclusion:** The level of circulating cigarette smoking human alveolar macrophages can change their expression profile in the lung.

**P801**

*Molecular mechanisms of plasminogen activator inhibitor-1 elevation in COPD sputum*

Masako To1,2, Peter J. Barnes1, Karazhuo Ito1, Kosuke Haruki2, 1Airway Disease Section, National Heart and Lung Institute, Imperial College, London, United Kingdom; 2Department of Laboratory Medicine, Dokkyo Medical University Koshigaya Hospital, Saitama, Japan

**Background:** Plasminogen activator inhibitor-1 (PAI-1) is an important regulator of fibrinolytic at sites of vascular injury and thrombus formation. Oxidative stress is known to involve in PAI-1 expression. We previously reported that mean PAI-1 levels in sputum of COPD was significantly higher than that of age-matched controls and significantly correlated with both sputum malondialdehyde (a oxidative stress marker) and NF-KB DNA binding activity in sputum macrophages. However, the precise mechanisms of PAI-1 elevation in COPD were not clarified. We hypothesised that HDAC2 reduction in COPD involves in PAI-1 elevation. The aim of this study was to investigate the association between HDAC2 reduction and elevated PAI-1 expression.

**Methods and results:** A549 cells were transfected with siRNA of HDAC2 to knockdown HDAC2 and followed by treatment with TGF-β (1 ng/ml). HDAC2 knockdown (KD) significantly upregulated PAI-1 release (Wild type (WT) vs HDAC2 KD: 2.9±0.2 vs 4.1±0.3 mg/ml with 0.1ng/mlTGF-β, 7.4±1.04 vs 8.4±1.5 ng/ml with 0.1ng/ml TGF-β). To investigate the association between NF-kB DNA binding activity and HDAC2 KD cells, we stimulated by 10 ng/ml TNFα for 2hrs, and NF-kB DNA binding activity and p65 acetylation were evaluated with TransAM NF-kB p65 Activation Assay Kit and Western blot, respectively. NF-kB DNA binding activity was significantly increased in HDAC2 KD cells (activity(OD)/protein: WT vs HDAC2 KD: 76±4 vs 98±14). Acetylation of p65 was also significantly upregulated in HDAC2 KD cells (acetyl-p65/65: WT vs HDAC2 KD: 2.3±0.1 vs 3.1±0.1).

**Conclusion:** HDAC2 reduction in COPD seems to cause PAI-1 elevation in COPD via activation of NF-kB DNA binding by p65 acetylation.
Background: Patients with refractory asthma are more susceptible to allergen- and infection-induced exacerbations. This susceptibility is poorly understood, but it may be related to an inefficient activation of innate host defence pathways. Interleukin-stimulated genes (ISGs), such as myxovirus resistance (MX1), 25'-oligoadenylate synthetase (OAS) and viperin are associated to biological activities, including antiviral, antiproliferative, and proapoptotic effects.

Objective: The aim of the study was to investigate the expression of antiviral genes in patients with refractory compared with moderate and mild asthma.

Methods: The mRNA expression of the ISGs (MX1, OAS and viperin), interferon (IFN) type 1 (I) and type III (IL-28 and IL-29) were measured by RT-qPCR in cells of induced sputum from 19 healthy subjects, 19 mild, 22 moderate and 22 refractory asthmatics. 

Results: The mRNA expression of MX1 and viperin were significantly reduced in refractory asthmatics (p<0.04 and p<0.03, respectively), while the mRNA expression of OAS, IFNIFN IL-28 and IL-29 was not different between groups.

Conclusion: The results point to a deficient innate immune response in refractory asthma demonstrated by a decreased expression of some interferon stimulated genes.

P804 Corticosteroid treatment selectively decreases mast cells in the smooth muscle and epithelium of asthmatic bronchi

Anna James1, Far Gy survivors, 1Department of Medicine and Post-Graduate Program in Health Science, University of South of Santa Catarina - UNISUL, Tubarao, SC, Brazil; 2Department of Pneumology, GRG 13 Research group, CHU, University of Liège, Liège, Belgium; 3Department of Respiratory Medicine, National Heart and Lung Institute, Imperial College, London, United Kingdom

Objective: The aim is to reveal the disorders of apoptosis in bronchial epithelium based on the estimation of expression of Bcl2, Bax, caspase-3 activity in bronchial asthma (BA) based on the estimation of expression of BA, and caspase-3 activity.

Methods: In 21 patients a fibropenic bronchoscopy was performed (patients have signed the ICF). Expression of Bcl2, Bax, CPP32 (caspase-3 activity) in bronchial epithelium was performed by immunohistochemical analysis of bronchus biopsies taken in fibrobronchoscopy using DAKO kits.

Results: In allergic BA elevation of Bcl2 expression and decrease of Bax expression compared to nonallergic BA and oral glucocorticoids taking patients were found. Activity of Bax expression was significant decreased in allergic BA compared to that in other groups. The same data were revealed on analysis of Bcl2/Bax index. Expression level of caspase-3 was high in both groups.

Conclusion: Features of apoptosis in bronchial epithelium in different variants of BA could indicate to different pathogenic mechanisms of apoptosis in allergic inflammation persistence.

P806 Role of altered level of oxidant-antioxidant in disease prognosis of asthma

Asrar Ahmad1,2, Mohammad Shameem2, Quyyum Husain1,3, Department of Biochemistry, Aligarh Muslim University, Aligarh, UP, India; 1Department of TB and Respiratory Diseases, JN Medical College, Aligarh Muslim University, Aligarh, UP, India.

Background: Asthma is a chronic airway disorder which is associated to airway obstruction. Inflammatory and immune cells generate more reactive oxygen species in asthma and lead to contribute in tissue injury. Aims and objectives: The aim of this study was to investigate the role of oxidant-antioxidant imbalance with disease severity in asthmatic patients.

Methods: In this study 140 asthmatic patients and 70 healthy controls were documented. Malondialdehyde level, total protein carbonyls and sulphydrols were measured as the indicator of oxidative stress in plasma. Antioxidants were evaluated by the activity of catalase, glutathione peroxidase, total blood glutathione and total antioxidant capacity.

Results: The present work showed that the levels of malondialdehyde (4.5±1.02 mmol/mL) and protein carbonyls (1.30±0.02 mmol/mg) were found to be significantly higher in asthmatic patients while protein sulphydrols (0.54±0.01 mmol/L) decreased as compared to controls (2.8±0.12 mmol/mL, p<0.001, 0.79±0.02 mmol/mg, p<0.01 and 0.6±0.01 mmol/L, p<0.01 respectively). We also observed increased total blood glutathione (9.8±0.02 mmol/L), decreased glutathione peroxidase (41.2±1.10 U/g Hb) and catalase activity (465±81.36 U/g Hb) in erythrocytes compared with control (0.84±0.04 mmol/mL, p<0.01, 48.3±2.47 U/g Hb, p<0.01 and 494±6.99 U/g Hb, p<0.05 respectively). The level of total antioxidant status (714.70±23.75 μmol/L) in plasma was also decreased as compared to control (840.46±28.39, p<0.001).

Conclusions: These results support the hypothesis that an imbalance in oxidant-antioxidant is associated to the oxidative stress which plays a significant role in severity of the disease.

Tobacco smoking alters the relationship between airway inflammation and airway hyperresponsiveness in asthma

Christian Grabow Westergaard, Celste Persborg, Vibeke Backer. The Respiratory Research Unit, Department of Respiratory Diseases L, Bispebjerg Hospital, Copenhagen NV, Denmark

**Background:** Smoking in asthma patients constitutes a major health problem, due to impaired steroid responsiveness, poor symptom control and an accelerated loss of bronchial reactivity. This may relate to alterations in the airway inflammation. The aim of the present study was to evaluate the effect of smoking on the relationships between airway inflammation and airway hyperresponsiveness in asthma patients not on steroid treatment.

**Material and methods:** A group of smoking asthma patients (n=27) was compared to a group of non smoking asthma patients (n=34) with induced sputum, exhaled nitric oxide (eNO) and airway hyperresponsiveness with a bronchial challenge with mannitol. Airway eosinophilia was defined as a sputum % eosinophils >2.

**Results:** A significantly higher proportion of patients with non-eosinophilic asthma was observed in the smoking group than in the non-smoking group (44% and 18%, p=0.025). The mean eNO was lower in the smoker group compared to the non-smoker group (11.7 ppb vs 38.2 ppb (p=0.001)). The proportion of subjects with a positive mannitol test was comparable among smokers (68%), and non-smokers (50%) (p=0.19). Smokers with a positive mannitol test had lower LI and lipase levels (mean difference of 26 units (p=0.03) and 9 U/L (0.001), respectively). Also, patients taking proton pump inhibitors (PPIs) had not lower LI and lipase levels (mean difference of 26 units (p=0.03) and 9 U/L (0.001), respectively). A lower LI was observed in smoking group than in the non-smoking group (587 ml, p=0.019) and an inverse relationship between LI and lung function when adjusted for the presence of asthma that is not controlled (50%) (p=0.19). Smokers with a positive mannitol test had a lower mean difference of 307 ml, p=0.019).

**Conclusion:** Our data showed that despite of a lower proportion of eosinophilic phenotype amongst the smoking asthma patients than amongst the non-smokers, no reduced degree of airway hyperresponsiveness to mannitol in the smoker group was observed, indicating that pathogenetic mechanisms other than eosinophilic airway inflammation are responsible for the tendency to airway narrowing in smoking asthma patients.

Lipid laden macrophages and lipase as markers of aspiration in patients with chronic cough

Beatriz Palomo1, José Belda1, Miguel Arias1, Almudena García1, Francisco Ruiz2, Universidad de Alcalá de Henares, Spain

**Introduction:** Gastroesophageal reflux disease (GERD) causes chronic cough by increasing the risk of regurgitation of stomach contents into the airways. GERD could be confirmed for the lipase.

**Results:** A significantly higher proportion of patients with non-eosinophilic asthma was observed in the smoking group than in the non-smoking group (44% and 18%, p=0.025). The mean eNO was lower in the smoker group compared to the non-smoker group (11.7 ppb vs 38.2 ppb (p=0.001)). The proportion of subjects with a positive mannitol test was comparable among smokers (68%), and non-smokers (50%) (p=0.19). Smokers with a positive mannitol test had lower LI and lipase levels (mean difference of 26 units (p=0.03) and 9 U/L (0.001), respectively). Also, patients taking proton pump inhibitors (PPIs) had not lower LI and lipase levels (mean difference of 26 units (p=0.03) and 9 U/L (0.001), respectively). A lower LI was observed in smoking group than in the non-smoking group (587 ml, p=0.019) and an inverse relationship between LI and lung function when adjusted for the presence of asthma that is not controlled (50%) (p=0.19). Smokers with a positive mannitol test had a lower mean difference of 307 ml, p=0.019).

**Conclusion:** Our data showed that despite of a lower proportion of eosinophilic phenotype amongst the smoking asthma patients than amongst the non-smokers, no reduced degree of airway hyperresponsiveness to mannitol in the smoker group was observed, indicating that pathogenetic mechanisms other than eosinophilic airway inflammation are responsible for the tendency to airway narrowing in smoking asthma patients.

Change of phenotype and phenotypic plasticity of alveolar macrophages in COPD

Svetlana Lyamina, Sergey Kalish, Igor Malyshev. Laboratory of Cell Biotechnologies, Department of General Medicine, Moscow State University of Medicine and Dentistry, Moscow, Russian Federation

Development of chronic obstructive pulmonary disease (COPD) is due to imbalance of Th1/Th2 immune responses which shift disorder in M1 and M2 macrophages phenotypes.

**Objective:** Assessment of macrophages phenotype and phenotypic plasticity of alveolar macrophages (AM) in COPD.

**Methods:** In vitro experiments were carried out on AM cultures of COPD patients (n=18, 59.7±3.56 y.o.). AM phenotype was assessed by flow cytometry (Beckman Coulter, FC500) by surface macrophages markers CD80, CD25 and CD163, CD206, typical for M1 and M2 phenotype, respectively. Phenotypic plasticity of AM was measured as percentage change of markers during 36 hours of AM reprogramming in the presence of standard serum (FBS) in concentrations 0%, 10%, 40%.

**Results:** In COPD patients AM of M1 phenotype prevaled, thus AM population was not monophenotypical. AM from NA donors yields 72.3±6.1% CD80, 16.3±2.1% CD25 and 9.9±1.2% CD163. Increase of FBS concentrations from 0% to 10% significantly increased M2 markers expression CD163 and CD206. After 36 hours of culturing with 10% FBS only CD80 pointed to M1 phenotype prevalence in AM of COPD patients.

**Conclusions:** In changing environment the previous condition of macrophages phenotype is longer fixed by M1 marker CD80, and CD206 can be used for phenotypic plasticity definition. Phenotypic plasticity should be assessed specific to certain factors so that different markers show different picture of phenotypic plasticity in COPD.

Phenotypic plasticity of fibrocytes upon culture with airway smooth muscle

Sadhia Sugandha, Davinder Kaur, Camille Doe, Fay Hollins, Christopher Brightling. Institute for Lung Health, Dept Infection, Immunology and Inflammation, University of Leicester, United Kingdom

Asthma is a major cause of morbidity and mortality worldwide and its prevalence is increasing. Increased airway smooth muscle (ASM) mass is a hallmark of asthma, which increases with disease severity and is associated with decline in lung function. Fibrocytes (FCs) are elevated in the peripheral blood and ASM in asthma and ASM has the potential to mediate FC recruitment (Saunders et al, J Allergy Clin Immunol, 2009;123:376-84). We hypothesised that once recruited to certain factors so that different markers show different picture of phenotypic plasticity in COPD.

**Objective:** To assess the possibility of immune response plasticity management in pulmonary diseases with inflammatory component.

**Methods:** A group of patients with chronic obstructive pulmonary disease (n=18), bronchial asthma (n=17), sarcoidosis (n=23) were cultured with various concentrations of standard serum FBS containing TGF-β and surfactant protein D (SP-D) to assess macrophages plasticity. Quality of macrophages bioprogramming was measured by morphological characteristic (light microscopy), cytokine production and surface macrophages markers expression (flow cytometry, Beckman Coulter, FC500).

**Results:** Changing of macrophages microenvironment with FBS concentration and the level of TGF-β and SP-D, respectively, purposefully programmed macrophages phenotype on M1 proinflammatory, or M2 antiinflammatory, shifting the immune response to Th1 or Th2, respectively. Decreasing FBS concentration to 0% programmed macrophages to M1 phenotype which was confirmed by morphological characteristic, cytokine production and macrophages markers expression. The consecutive increasing of FBS concentration from 20% to 40% led to bioprogramming of macrophages on M2 phenotype and Th2 response development with close relationship to concentration.

**Conclusions:** Serum model of reprogramming was effective in regulation of immunomodulation strategy for COPD patients. Our results show that FCS have the capability to undergo phenotypic plasticity, depending on culture conditions. Further work is required to understand the factors affecting FCs differentiation upon localisation to the ASM in asthma and the resultant contribution of FCs to ASM dysfunction.

Disorder of the immune response plasticity is the basis of pathogenesis of pulmonary diseases with inflammatory component.

**Objective:** To assess the possibility of immune response plasticity management in pulmonary diseases with inflammatory component by means of microenvironment components of alveolar macrophages (AM).

**Methods:** A group of patients with chronic obstructive pulmonary disease (n=18), bronchial asthma (n=17), sarcoidosis (n=23) were cultured with various concentrations of standard serum FBS containing TGF-β and surfactant protein D (SP-D) to assess macrophages plasticity. Quality of macrophages bioprogramming was measured by morphological characteristic (light microscopy), cytokine production and surface macrophages markers expression (flow cytometry, Beckman Coulter, FC500).

**Results:** Changing of macrophages microenvironment with FBS concentration and the level of TGF-β and SP-D, respectively, purposefully programmed macrophages phenotype on M1 proinflammatory, or M2 antiinflammatory, shifting the immune response to Th1 or Th2, respectively. Decreasing FBS concentration to 0% programmed macrophages to M1 phenotype which was confirmed by morphological characteristic, cytokine production and macrophages markers expression. The consecutive increasing of FBS concentration from 20% to 40% led to bioprogramming of macrophages on M2 phenotype and Th2 response development with close relationship to concentration.

**Conclusions:** Serum model of reprogramming was effective in regulation of immunomodulation strategy for COPD patients. Our results show that FCS have the capability to undergo phenotypic plasticity, depending on culture conditions. Further work is required to understand the factors affecting FCs differentiation upon localisation to the ASM in asthma and the resultant contribution of FCs to ASM dysfunction.

mature dendritic cells in fatal asthma

expression of factor XIIIa+ cells, CD207+ Langerhans cells and CD83+ subsets.

Figure 1

Fien Verhamme

subsets (IRF8) gene impair differentiation of mononuclear phagocytes into dendritic cells (DC) and confer susceptibility to mycobacterial disease. In autosomal recessive interferon regulatory factor 8 (IRF8) gene impairment, CD14+ DC in the skin is very low, whereas numbers of Langerhans cells are normal, implicating important heterogeneity in dermal DC (Hamblyton et al., N Engl J Med 2011). Since infection with Mycobacterium tuberculosis occurs via inhalation, we investigated the expression of IRF2, IRF4 and IRF8 in the 3 major resident pulmonary DC populations: Langerhans-type myeloid DC (LDC), interstitial-type myeloid DC (intDC) and plasmacytoid DC (pDC).

Lung tissue was obtained from 4 subjects who underwent pneumectomy. DC were isolated by FACS from mononuclear cell suspensions of lung digestes to obtain highly purified (≥95%) DC subsets. LDC, intDC and pDC were identified as respectively langerin+, DC-SIGN+ and BDCA2+ cells in the low autofluorescent, CD3 and CD19 fraction. RNA was extracted and expression of IRF2, IRF4, IRF8 and housekeeping genes GAPDH, HPRT1 and PPIA was analyzed by RT-PCR.

Expression of IRF8 was significantly higher in pDC compared with both LDC and intDC. LDC had the lowest IRF8 expression (Figure 1). Expression of IRF2 and IRF4 did not differ between the DC subsets.

These results suggest distinct roles of IRF8 in the development of human lung DC subsets.

P814

Expression of factor XIIa+ cells, CD207+ Langerhans cells and CD83+ mature dendritic cells in fatal asthma

Erika Cagnoni1, Diogenes Ferreira1, Luiz Fernando Silva1, Ana Laura Santos2, Ana Maria Medeiros3, Klaus Rabe2, Marisa Dollnikoff1, Thais Mauad2, 1Pathology, University of Sao Paulo Medical School, Sao Paulo, SP, Brazil; 2Pathology, Krankenhaus Grosshadendorf, Germany

Rationale: Dendritic cells (DCs) are a heterogeneous class of antigen presenting cells that initiate immune responses in the lung. Little information is known about the expression of different DCs in the airways and lymph nodes (LNs) of asthmatics. The aim was to study the expression of CD83+ mature DCs, CD207+, Langerhans cells, and factor XIIa+ reticular DCs in mediastinal LNs and airways of patients that died of asthma.

Methods: We studied 10 non-smoker fatal asthma patients (FA) and 8 non-smoker individuals that died of non-pulmonary causes (controls, CTLRs). Immunohistochemistry was performed with antibodies against CD83, CD207 and factor XIIa. The total area stained with anti-CD83/CD207 antibodies was measured on the cortical area of the LNs and on the internal, airway smooth muscle and external layers of the cartilaginous airways. Factor XIIa was analyzed only on LNs.

Results: CD83 and CD207 stained cells in the airways and all antibodies stained cells in the LNs of FA and CTLRs. No differences were found in the areas stained with CD83, CD207 and factor XIIa between FA and CTLRs. In fatal asthma CD83+ stained area in LNs correlated with CD207+ stained area in LNs (r = 0.65; p = 0.01) and CD207+ stained area in LNs correlated with CD83+ stained area in the internal (r = 0.79, p = 0.006), muscle (r = 0.78, p = 0.008) and external (r = 0.73, p = 0.02) layers of the airways. A fatal asthma episode is not associated with an increased expression of Langerhans cells, factor XIIa+ reticular cells and mature CD83+ DCs in cartilaginous airways or thoracic LNs. In asthma however, some DC cell trafficking between airway mucosa and LNs seems to occur.

P815

TCR V-beta usage in patients with sarcoidosis

Kerstin Ahlgren1, Tina Rückdeschel, Anders Eklund, Jan Wahlström, Tina Ruckdeschel, Anders Eklund, Jan Wahlström, Johanna Grunewald, Medicine, Karolinska Institutet, Stockholm, Sweden

Sarcoidosis is a granulomatous disease of unknown aetiology, mainly affecting the lungs. Elevated numbers of activated T cells are found in bronchoalveolar lavage (BAL) fluid. HLA-DRB1*0301 (DR3)+ patients, who typically have Löfgren’s syndrome, are characterized by good prognosis and an accumulation of lung CD4+ T cells using the T cell receptor (TCR) gene segment Valpha2.3 (AV2S3). However, the corresponding β-chains that are part of the TCR have been poorly characterized, and there is only limited knowledge about the TCR usage in non-acute patients.

We used antibody staining and flow cytometry to characterize TCR Vbeta usage in CD4+ and CD8+ T cell subsets in blood and BAL fluid samples from different sarcoidosis patient groups as well as from healthy controls. Overall, the TCR Vbeta usage of Valpha2.3 + CD4+ T cells was quite diverse, indicating a predominant role in antigen recognition only for the alpha chain in these T-cell expansions. However, a preference for selective use of Vbeta 22 was noted in one patient.

A higher degree of selective Vbeta expression in both BAL and blood of non-acute patients may be due to epitope spreading over time, with more antigenic epitopes available to trigger distinct T cells. The higher non-random TCR Vbeta usage in the lung compared to blood could be related to antigenic triggering at the site of active disease, although more BAL samples of healthy individuals should be analyzed to estimate the normal differences between lung and blood in this respect.

P816

CD4+/CD8+ T-cells ratio in patients with pulmonary tuberculosis

Larissa Gerbach1, Department of Research, Republican Scientific Medical Centre "Mother and Child", Minsk, Belarus

Introduction: A wide range of immune components are involved in an effective immune response against M. tuberculosis. CD4+ and CD8+ T-cells are central for protection against active tuberculosis.

The purpose of this research was studying CD4+/CD8+ T-cells ratio and parameters of spirometry in 34 patients with pulmonary tuberculosis.

Material and methods: Parameters of spirometry, CD4+/CD8+ T-cells ratio were analyzed. Depending on CD4+/CD8+ T-cells ratio patients with pulmonary tuberculosis have been shared into 2 groups: 1 group - 18 patients CD4+/CD8+ ratio < 1.3; 2 group - 16 patients CD4+/CD8+ ratio ≥ 1.3.

There was no difference in age between groups. Student’s t-test was used in the statistical analysis. Significance level was set at 0.05.

Results: Mean values of parameters spirometry in each group are submitted on the diagram.
potential mechanisms for increased mass by migration, proliferation and survival assays. 

Contraction of collagen gels impregnated with ASM cultured with FCs for 3-4d vs ASM alone increased significantly (i.e. reduction in area under curve of gel size as a percentage of the original size plotted over 30 min (AUC50). Table 1). ASM wound healing (WH) increased significantly in the presence of supernatants (SNs) from FCs/ASM 7d cultures vs control media, but no additional WH was seen in the presence of FC or FC+ASM SNs vs ASM SNs alone (Table 1). ASM proliferation and survival was unaffected by culture with FCs/FC SNs for 7d.

Localisation of FCs to the ASM-bundle could contribute to the hypercontractility of ASM in asthma, which is integral to the pathophysiology of asthma. The mechanism by which this occurs requires further investigation, but has the potential to provide future therapeutic targets.

P818

Airway wall responses to tidal breathing and deep inspiration

Thomas K Ansell 1, Peter B. Noble 1, Howard W. Mitchell 1, Peter McFawn 1. 1School of Anatomy, Physiology and Human Biology, University of Western Australia, Perth, WA, Australia; 2Centre for Neurological Research and Education, University of Western Australia, Perth, WA, Australia

Introduction: Mechanical stretch attenuates airway smooth muscle (ASM) force production, which may explain the reversal of bronchoconstriction (i.e. bronchodilation) following a deep inspiration (DI) in vivo. We measured the effect of simulated DI on both narrowing and ASM force in isolated bronchi.

Methods: Bronchial segments were dissected from pig lungs and maintained in organ bath chambers. Airway narrowing (% volume) to acetylcholine (ACh, 10$^{-7}$M - 3x10$^{-3}$M) was measured under static transmural pressure (Ptm) conditions and during fixed P0 oscillations simulating tidal breathing (3.5cmH2O) with interdial DI (25cmH2O). In a separate group of experiments, the above protocols were repeated using fixed volume oscillations to simulate tidal and DI breathing whilst measuring the increase in P0 produced by ASM contraction. Under each condition, airway wall stiffness was measured from the change in P0 and volume during tidal oscillations.

Results: Under static conditions, maximal response to ACh was 92.3m4.3% narrowing (ACh) and 73.5±9.2cmH2O P0 (ACh). DI to 25cmH2O reversed ~60% narrowing at low doses of ACh but had no affect at moderate or high doses, whereas fixed volume DI attenuated ASM force to 12.7±5.6% (ACh) conditions and during fixed P0 oscillations simulating tidal breathing (3.5cmH2O) with interdial DI (25cmH2O). In a separate group of experiments, the above protocols were repeated using fixed volume oscillations to simulate tidal and DI breathing whilst measuring the increase in P0 produced by ASM contraction. Under each condition, airway wall stiffness was measured from the change in P0 and volume during tidal oscillations.

Conclusions: The mechanical loading conditions present during tidal breathing and DI influence the airway response to mechanical stretch. Inhibition of bronchoconstriction to mechanical stretch is minimal during fixed P0m oscillations particularly at high levels of ASM activation.

P819

PI3K signalling may explain differential response of lung cells to mechanical stretch

Stefan Hammerschmidt, Hartmut Kuhn, Hans-Jurgen Seyfarth, Christian Gessner, Hubert Wirtz. Department of Respiratory Medicine, University of Leipzig, Germany

Alveolar epithelial cells may be subjected to increased mechanical stretch (MS) during ventilation although low tidal volume is applied. High amplitude MS impairs PI3K activity and leads to apoptosis in alveolar type II (ATII) cells. The response of human pulmonary microvascular endothelial cells (HPMEC), fibroblasts (HPF), human AS49 cells and rat ATII cells to MS is compared in this study.

Stretching patterns (frequency/strain) in culture media, but no additional data was chosen to mimic physiological breathing (P) and the effects of high frequency (fH), high amplitude (aH) and both (HFA). MS was compared with static cultures at 24h. Supernatant LDH, cell necrosis/apoptosis (Annexin V binding/propridium iodide-staining) and cellular PI3K activity (measured as phosphorylated Akt-kinase, pAkt) were analyzed. MS increased the release of LDH in all cell types. This effect increased with the Hf, aH and HFA stretching patterns. Viable HPMEC and ATII cells decreased significantly in response to MS with a minimum in the HfA and HfA group; predominately due to apoptosis. AS49 cells showed only a small decrease

in viable cells with little change in necrotic and apoptotic cells. HPE, however, did not undergo apoptosis in response to MS. Cellular PI3K content was reduced in response to MS in HPMEC and ATII cells, unchanged in AS49 cells and increased in HFA. PI3K stimulation increases the percentage of apoptotic cells. In contradiction with endothelial and epithelial cells, pulmonary fibroblasts do not undergo apoptosis and show increased PI3K in response to MS. In lung injury both may remain as a scaffold for the pulmonary structure leading the way for repair.

P820

Remodelling of cytoskeleton towards a softer cell by latrunculin prevents stretch-induced apoptosis in alveolar type II cells

Hartmut Kuhn 1, Thomas Fuchs 2, Franziska Weitl 2, Stephan Hammerschmidt 1, Josef A. Käs 1, Hubert Wirtz 1, 1Dept. of Respiratory Medicine, University Hospital, Leipzig, Germany; 2Institute for Experimental Physics I, Department of Physics and Geosciences, University of Leipzig, Germany

Background: Cyclic stretching of alveolar type II (ATII) cells is associated with alterations of the actin cytoskeleton that has been shown to induce apoptosis.

Objectives: We hypothesize that the cytoskeleton of ATII cells and its viscoelastic properties are involved in the mediation of high amplitude mechanical stretch-induced apoptosis. Therefore we investigated the influence of the actin-modulating drug Latrunculin D on viscoelastic properties and stretch-induced apoptosis of ATII cells.

Methods: Alveolar type II (ATII) cells from Sprague Dawley rats were exposed to cyclic stretching using a pattern characterized by frequency of 40 [min-1] and an amplitude of 30 [%]. During stretching cells were treated with Latrunculin D. After stretching we determined apoptosis and cell injury using an Annexin V-FITC Apoptosis Detection Kit and the CytoToxity Detection Kit. Further, elasticity measurements of Latrunculin treated cells were performed with the atomic force microscope (AFM) and the optical stretcher.

Results: Determination of elastic modulus using the AFM showed that Latrunculin reduced stiffness of ATII cells (83.5%). Using the optical stretcher ATII cells treated with Latrunculin showed a higher deformation than controls (25.3%). Treatment of overstretched cells with Latrunculin reduced significant the number of apoptotic cells (control 30.0%, Latrunculin 19.1%) and decrease the level of LDH (control 0.21 U/ml; Latrunculin 0.13 U/ml).

Conclusions: We conclude that the remodelling of cytoskeleton towards a softer cell is a protective mechanism against stretch-induced apoptosis in ATII cells.

P821

Surfactant release into the alveolar space protects the lung from ventilation-induced injury

Virginia Egido 1, Yemi Rojas 2, 3, Almudena Lopez-Sanchez 1, 3, Antonio Ferrueco 1, Jose Angel Lorente 1, 2, Andres Esteban 1, Cristina Casals 1, 3

1Bioquímica y Biología Molecular I, Universidad Complutense de Madrid, Madrid, Spain; 2Unidad de Cuidados Intensivos, Hospital Universitario de Getafe, Getafe, Madrid, Spain; 3Centro de Investigación Biomédica en Red de Enfermedades Respiratorias, Instituto de Salud Carlos III, Madrid, Spain

Objective: The aim of this study was to investigate mechanisms involved in resistance to ventilation-induced lung injury.

Methods: Sprague-Dawley rats were randomly exposed to an injurious low-stretch ventilation (V T =9 ml/kg, PEEP=5 cm H2O) (n=12) and an injurious high-stretch ventilation (V T =25 ml/kg, PEEP=0 cm H2O) (n=29). Animals were continuously monitored for a maximum period of 2.5 h. The high-stretch ventilation group (HV60) was subdivided in two groups: 1) animals showing a substantial P0 reduction and peak airway pressure (Paw) increase, sacrificed at 60 min (HV60=n=11); and 2) animals with insignificant Paw and Paw changes at 60 min (n=18), sacrificed at 150 min (HV150). Lung tissue, plasma, and bronchoalveolar fluid (BAL) were analyzed in the three groups. BAL provided native cytometric, inflammatory marker, and surfactant data.

Results: The HV60 group was characterized by leakage of plasma proteins into the alveoli, presence of hyaline membranes, high increase of inflammatory markers in BAL (TNF-α, MIP-2, MIP-1, C-reactive protein, and acidic sphingomyelinase), pronounced decrease of alveolar macrophages, and an accelerated conversion of freshly secreted active surfactant to inactive surfactant. In contrast, the HV150 group was characterized by high amount of active surfactant, absence of edema, and normal P0. These animals exhibited a slight decrease of alveolar macrophages and increase of some BAL inflammatory markers (IL6, TNF-α, MIP-2, and MIP-1).

Conclusions: These results suggest that increased surfactant release into the alveolar space safeguards the lung from ventilation-induced injury and that surfactant alteration might directly contribute to lung dysfunction.

97. The many roads to lung injury
Effects of PEEP-like cyclic stretch on the IL-6 protein production in normal human pulmonary artery endothelial cells in vitro

Kotone Kobayashi1, Hisashi Ozaki 2,3, Satomi Nobeishi2, Yuuka Fukaura1, Kenichi Kobubo2, Hirotsue Kobayashi1,2, Makoto Noshiro1,2,1School of Allied Health Science, Kitasato University, Sagamihara, Kanagawa, Japan; 2Graduate School of Medical Science, Kitasato University, Sagamihara, Kanagawa, Japan; 3Graduate School of Biomedical Science, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan

Background and aim: Excessive cyclic stretch is one of the main causes of ventilator-induced lung injury. However, the molecular injury of the stretch injury has not yet been fully understood. The aim of the present study was to examine the effects of PEEP-like cyclic stretch on the IL-6 protein production in normal human pulmonary artery endothelial cells (HPAECS) in vitro.

Methods: Normal HPAECS were stretched by a Flexcell® FX-4000™ Tension System (Flexcell International). The stretching rate was 15 cycles/minute, and the cells were cyclically stretched from 0 to 5%, 0 to 10%, 0 to 20%, 3 to 20%, and 5 to 20%. Stretch from 3 to 20% and from 5 to 20% simulated excessive stretch during mechanical ventilation with PEEP. The cells were stretched for various durations (0, 1, 3, 6 and 12 hours). During the experiments, culture medium was sampled 0, 3, and 6 hours after stretch started. The IL-6 concentration of the samples was determined by ELISA.

Results: Excessive stretch (0 to 20%) significantly increased the IL-6 production of the cells stretched for more than 3 hours compared to the unstretched cells (n=5, P<0.05). Moderate stretch (0 to 5% and 0 to 10%) did not yet significantly increase the IL-6 protein production of the cells at any sampling points.

Conclusions: The IL-6 protein was produced by excessive cyclic stretch (0 to 20%). Excessive stretch production was suppressed by PEEP-like cyclic stretch (3 to 20% and 5 to 20%). This result suggests that HPAECS would be protected by PEEP during mechanical ventilation even if the cells are excessively stretched.

P823
LSC 2012 Abstract – Repair of the very immature lung following brief, injurious mechanical ventilation commences within 24 hours

Nadine Bre1, Stuart Hooper2,3, Megan Wallace2,4, Richard Harding1,4,1Dept of Anatomy and Developmental Biology, Monash University, Melbourne, Australia; 2Dept of Obstetrics and Gynaecology, Monash University, Melbourne, Australia; 3Monash Institute of Medical Research, Monash University, Melbourne, Australia

Background: Very preterm infants often require mechanical ventilation (MV). This intervention can cause lung injury that contributes to bronchopulmonary dysplasia. To investigate mechanisms of injury and repair in newborns we developed a novel method of ventilating the lungs of fetal sheep. Using this model MV-induced injury resolves within 15d, but it is not known when repair starts.

Methods: Pregnant sheep at 110d and 125d gestational age (GA; term=147dGA) were exposed to a continuous positive airway pressure (CPPAP) of 10cmH2O, at 12 breaths/minute with a PEEP of 5cmH2O. After stretching we determined PKC-expression by Western blot. Next, we treated Mike cells with PMA during stretching reduced the number of apoptotic cells (control 32.8%; PMA 16.1%). Inhibition of PKC using staurosporin increased the number of apoptotic cells (control 32.8%; PMA 22.7%; Staurosporin 36.1%).

Conclusions: We conclude that activation of PKC is able to promote apoptosis in stretched cells. Remodeling of cytoskeleton to a softer cell by PKC seems to be a possible mechanism for it.

Kallistatin protects against LPS-induced mouse lung injury

Wes-Chang Lin1, Chiou-Feng Lin2,3, Shinong Liu 1, Yu-Shin Lin1

1Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan; 2Institute of Clinical Medicine, National Cheng Kung University Medical College, Tainan, Taiwan; 3Department of Microbiology and Immunology, National Cheng Kung University Medical College, Tainan, Taiwan

Acute lung injury (ALI) is caused by overwhelming lung inflammation, resulting in diffuse alveolar damage, edema, and subsequently respiratory dysfunction. The mortality remains high, and the treatments are exclusively supportive because of lacking selective and efficacious pharmaceutical agents targeting on the pathogenesis of ALI. Kallistatin is a serine protease inhibitor that exhibits pleiotropic functions in vasodilation, anti-angiogenesis, anti-inflammation, and anti-apoptosis, which may contribute to its therapeutic effects in a variety of human diseases. Kallistatin is also found in the lungs, implicating its involvement in the regulation of lung functions. However, the role of kallistatin in the pathophysiology of ALI is still unclear. Herein, we hypothesized that kallistatin plays a role in protection against lung injury. Using kallistatin gene-transfered mice by delivering plasmid DNA encoding human kallistatin into the lungs, we examined the protective effect of kallistatin against LPS-induced lung injury. We found that the severity of lung injury was attenuated in kallistatin gene-transfered mice compared with untreated mice, indicated by decreasing cell counts, LDH and protein levels of bronchoalveolar lavage fluids (BALF). BALF levels of TNF-α, IL-1β, IL-6, and IL-8 were also lower in human kallistatin gene-transfered mice than untreated mice, suggesting a decline in inflammatory response after LPS treatment. In addition, the kallistatin gene-transfered mice showed less extent of epithelial cell apoptosis shown by TUNEL staining. Our data demonstrate for the first time that kallistatin protects against LPS-induced lung injury through attenuation of inflammation and epithelial cell apoptosis.

Plant proteasome from Bauhinia bauhinioideis Kallikrein inhibitor (BbKk) attenuates mechanics, inflammation and remodelling induced by elastase in mice

Bruno Martins Oliveira1, Rafael Almeida-Reis1, Osmar A. Theodoro1, Leandro Silva Oliva1, Daniel Flechinh Mold 1, Carla M. Prado3, Milton M. Martins1, Iolanda F.L.C. Tibério1, 1Clinical Medicine, Faculty of Medicine, University of Sao Paulo, SP, Brazil; 2Bioquímica, Universidade Federal de Sao Paulo, SP, Brazil; 3Ciências Biológicas, Universidade Federal de Sao Paulo, Diadema, SP, Brazil

Proteasome plays a key role on emphysema development. This study evaluated the capacity of the plant proteasome inhibitor BbKk in the inactivation of elastase and its response modulator.

Methods: C57Bl6 mice received elastase intratracheal or saline (Ve group). After one month mice were treated with BbKk (2mg/kg) on days 1, 4, 12 after elastase instillation (E-group) or saline instilation. On day 30 mice were anesthetized and mechanically ventilated and we analyzed respiratory system resistance (Rrs), elastance (Ers), tissue elastance (Hts), tissue damping (Gms), airway resistance (Raw) and exhaled nitric oxide (ENO). Afterwards, bronchoalveolar lavage fluid (BALF) was performed and lungs were removed. By morphometry, we quantified the mean linear intercept (Lm), and the amount of collagen and elastic fibers in distal lung parenchyma.

Results: In elastase group there was a significant increase in the Ers, Rrs, Raw, Hts, Lm, ENO, total and, macrophages, neutrophils and lymphocytes in BALF, and elastic and collagen fibres compared to controls (p<0.05). The BbKk treatment of elastase group decreased the Lm (59.3±4.7 μm), Raw (0.33±0.05 cmH2O/ml/s), Ers (36.8±5.73 cmH2O/L), Rrs (0.84±0.19 cmH2O/ml/s), Hts (37.3±6.2 cmH2O/L), cells/mLs), neutrophils (19.3±9.1±106 cells/mls), lymphocytes (19.5±1±2±104 cells/mls) in the BALF, ENO (19.6±8.33 μm), and elastic fibers content (30%±0.1%) compared to E-group (p<0.05).

Conclusions: This proteasome inhibitor (BbKk) reduced elastase-induced pulmonary inflammatory and extracellular matrix remodeling alterations. Financial Support: FAPESP, CNPq, LIM-20 HCFMUSP.
A single dose of a specific serpin inhibitor attenuated the protease-antiprotease imbalance in an experimental model of emphysema. Claire R. Oliveira1, Juliana D. Lourenço1, Luciana Neves1, Francine Almeida1, Carla M. Prado1, Iolanda C.L. Tibério1, Aparecida Tanaka2, Sergio Saaksi2, Milton A. Martins1, Fernanda D.T.Q. Lopes1, 1Medicine, School of Medicine of University of Sao Paulo, SP, Brazil; 2Biological Science, Universidade Federal de Sao Paulo, SP, Brazil; 3Medical Chemistry, Universidade Federal de Sao Paulo, SP, Brazil; 4Human and Natural Science, Universidade Federal do ABC, Sao Paulo, SP, Brazil

We showed that a single dose of specific serpin inhibitor in mice attenuated parenchymal destruction with an improvement in lung function in emphysema.

Objectives: To study the possible effects of this inhibitor in pathological mechanisms that contribute to emphysema.

Methods: Mice were submitted to either a nasal instillation of porcine pancreatic elastase (PPE) or saline (S) and 1h after, animals received a second nasal instillation of either a protease inhibitor (r-BMIA, 35.54mol) or vehicle (VE). After 21 days, we evaluated the number of macrophages (MAC) and cells expressing metalloproteinase 12 (MMP-12). We measured the protease-antiprotease imbalance. We quantified caspase-3 to evaluate apoptosis and expression of 8-iso-prostanate as a marker of oxidative stress.

Results: We observed an increase in MAC in groups that received PPE and only PPE-VE group showed higher values of MMP-12. There were no differences between groups when we analyzed caspase-3 and 8-iso-prostanate.

*Compared to control groups; **compared to other groups.

Conclusions: Although this inhibitor treatment has not diminished the macrophages in animals that received PPE, it reduced MMP-12 positive cells, suggesting that the improvement in parenchyma destruction and in lung function occurred due to attenuation in protease-antiprotease imbalance. Supported by FAPESP, LIMHC-FMUSP, Brazil.

Plant proteinase inhibitor from Enterolobium contortisiliquum (EcTI) attenuates elastase-induced pulmonary inflammatory, remodeling and mechanical alterations in mice

Omar A. Theodoro-Junior1, Ricardo Henriques Marques2,3,4, Rafael Almeida-Reis1, Bruno T. Martins-Oliveira1, Leandro V. Oliva1, Tales Lopes1, Carla M. Prado1, Maria L.V. Oliva1, Milton Martins1, Iolanda F.L.C. Tibério1, 1Clinical Medicine, Faculty of Medicine, University of Sao Paulo, SP, Brazil; 2Núcleo de Ciências da Saúde, Universidade de Mogi das Cruzes, SP, Brazil; 3Bioclinic Biologics, Universidade Federal de Sao Paulo, Diadema, SP, Brazil; 4Bioquímica, Universidade Federal de Sao Paulo, SP, Brazil

Aims: To evaluate if a plant Kumit; proteinase inhibitor EcTI contributes to inactivation of elastase-induced mechanical, inflammatory and remodelling alterations.

Methods: C57Bl/6 mice received elastase (E-group). Control group received saline (VE-group). Mice were treated with EcTI (2mg/kg) on days 1, 14 and 21 after elastase instillation (IE-group). On day 30, mice were anesthetized, mechanically ventilated and we analyzed respiratory system resistance (Rrs) and elastance (Ers), tissue damping (Gtis), airway resistance (Raw) and exhaled nitric oxide (ENO).

Results: In-8 group there was a significant increase in the Ers, Raw, Hts, Lm, ENO, total cells and macrophages, neutrophils and lymphocytes in BALE, elastic and collagen fibers compared to controls (p < 0.05). In IE-group there was a decrease in Lm (57.63±5.5μm), Raw (0.29±0.05cmH2O/ml/s), Hts (39.47±0.02%), total cells (1.17±0.104 cells/ml) and ENO (0.00±0.01 104 cells/ml) in BALE compared to ELA group (p < 0.05).

Conclusions: This proteinase inhibitor (EcTI) reduced elastase-induced pulmonary inflammatory, remodeling and mechanical alterations induced by elastase. Although more studies need to be performed, this inhibitor may contribute as potential therapeutic tool for COPD management.

P829

Treatment with proteinase inhibitor, BbCI, modulates inflammatory response, mechanic alterations, and remodeling on elastase-induced emphysema in mice

Rafael Almeida-Reis1, Bruno T.M. Oliveira1, Omar A. Theodoro-Junior1, Leandro V. Oliveira1, Nathalia Pinheiro1, Marlon V. Brito1, Fernanda D.Q.T. Lopes1, Carla M. Prado1, Milton A. Martins1, Maria Luiza V. Oliva1, Iolanda F.L.C. Tibério1, 1Clinical Medicine, School of Medicine, University of Sao Paulo, SP, Brazil; 2Biotech, Biomedical Research Center, University of Sao Paulo, Brazil; 3Biological Sciences, Federal University of Sao Paulo, Diadema, Brazil

Bubiha bauhinioiides Z Crucipain Inhibitor (BbCI) is a proteinase inhibitor that neutralizes neutrophil elastase and cathepsin G. The present study evaluated the capacity of BbCI in the treatment of elastase-induced emphysema.

Methods: Mice received elastase intratracheally (EAL group) or saline (SAL group). Afterwards, mice were treated with BbCI (2 mg/kg) at days 1, 15 and 21 after elastase (EALBI group) or saline instillation (SALBI group). At day 28, mice were ventilated and respiratory resistance (Rrs), elastance (Ers), tissue elastance (Hts), tissue damping (Gtis), airway resistance (Raw), and exhaled nitric oxide (ENO) were analyzed, and BALF was obtained. We also quantified, mean linear intercept (Lm), elastic and collagen fibers.

Results: In ELA group, there was a significant increase in the Ers, Rrs, Hts, ENO, total cells, macrophages, neutrophils and lymphocytes in BALE, elastic and collagen fibers compared to controls (p < 0.05). In ELA group, we observed a decrease in Ers (37.08±1.6 cmH2O·L⁻¹·s⁻¹), Hts (39.47±1.7 cmH2O·L⁻¹·s⁻¹), Lm (58.2±7.5) μm, elastic content (0.34±0.03%); total cells (11.7±0.1 104 cells/ml) and neutrophils (0.00±0.01 104 cells/ml) in BALE compared to ELA group (p < 0.05).

Conclusions: The treatment with BbCI reduced inflammatory, mechanics and extracellular matrix remodeling alterations induced by elastase. Although more studies need to be performed to elucidate the mechanisms involved in this process, we may consider BbCI as a therapeutic tool for COPD management.

Supported by: FAPESP, CNPq, LIM-20 HCFMUSP.
anti-inflammatory system in several diseases and ACh release depends on neu-
rotransmitter storage in synaptic vesicles mediated by the vesicular acetylcholine transporters (VACHT).

Aim: To investigate the role of the cholinergic system on emphysema in mice with reduced levels of ACh release.

Methods: Mice with decreased expression of VACHT (VACHT KDHOm 70%) (HOM) and littermate wild-type mice (WT) received intranasal elastase or saline on day 0. On day 28, pulmonary mechanics, bronchoalveolar lavage fluid (BALF), mean linear intercept (Lm), elastic and collagen fibers in alveolar septa were evaluated.

Results: WT-treated elastase animals presented a reduction in tissue elastance (Hiss) and an increase in Lm, total cells and macrophages in BALF, and colla-
gen and elastic fibers in lung parenchyma compared to saline groups (p<0.05). The HOM-treated elastase animals presented high values of total cells, macro-
phages, lymphocytes and neutrophils in BALF compared to WT-treated elastase group (p<0.05). There were no differences between WT-treated elastase and HOM-treated elastase groups. Lm, collagen and elastic fibers contents between.

Conclusions: Reduction of endogenous ACh worsens pulmonary inflammation in mice with emphysema without changing pulmonary function and remodeling, suggesting that the major determinant of pulmonary inflammation in this model. Our results suggest however a major role of the cholinergic anti-inflammatory system in the control of inflammatory response induced by elastase.

P832 Activation of the coagulation system following exposure of mice to chlorine Nadiya Monogarova1, Inna Vasilenko2, Olena Semendyayeva3, Natalia Surgay2, Chair of Pathomorphology, Donetsk National Medical University named after M. Gorky, Donetsk, Ukraine; 2Chair of Pulmonology, Donetsk National Medical University named after M. Gorky, Donetsk, Ukraine

Chlorine (Cl2) is a highly irritant and reactive gas produced in large quantities throughout the world. The accidental release of large amounts of Cl2 in 30 large cities has caused significant injury to humans and animals. Our previous findings show that exposure of rodent to Cl2 causes both pulmonary and systemic injury (Zorziannis et al. J Respir Cell Mol Biol, 2011; 15(2):386-92). Honwar et al Am J Respir Cell Mol Biol, 2001; 145(2):419-25). Herein we tested the hypothesis that exposure to Cl2 activates intraalveolar and systemic coagulation cascades which in turn may contribute to the development of lung and other end-organ injury. Male C57B16 mice (6-8 weeks) were exposed to either Cl2 (600 ppm for 45 minutes in environmental chambers) or air (0 ppm). Mice were returned to room air and sacrificed immediately or at 1 h post-exposure and their lungs were lavaged. Mice exposed to Cl2 had much higher levels of Thrombin/antithrombin (TAT) antigen (measured by ELISA) as compared to those exposed to air both in the BAL (10±2 ng/ml vs. 0.5 ± 0.1; mean ± SE; n=6; p<0.01) and plasma (25±1 ng/ml vs. 0.1±0.05; mean ± SE; n=6; p<0.05) at 1 h post exposure. In addition, clotting time in the blood (measured by thromboplastin time) was significantly prolonged in Cl2 exposed mice as compared with air controls (275±25 sec. vs. 150 ±10; mean ± SE; n=6; p<0.01). In contrast, there was no significant change in the clotting time blood taken from mice immediately after Cl2. Taken together, these data demonstrates a strong activation of the coagulation with the airspace as well as development of a systemic disseminated intravascular coagulation after Cl2 exposure in mice.

P833 Novel swine model of transfusion-related acute lung injury (TRALI) Fatima Telavarys Ceric1,1, Karl Otto Larsen1, Oystein Sandanger2, Else Marit Laberg3, Geir Arve Christensen1, OleHenningSkjønsberg1, 1Department of Pulmonary Medicine, Oslo University Hospital Ulleval, Oslo, Norway; 2Institute for Experimental Medical Research and Center for Heart Failure Research, Oslo University Hospital Ulleval, University of Oslo, Oslo, Norway; 3Research Institute for Internal Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; 4Department of Pathology, Oslo University Hospital Ulleval, Oslo, Norway

Aim: To study circulating levels of IL-18 during one week of hypoxia exposure in mice, and to investigate whether induction of IL-18 correlates with inflammatory changes in lung parenchyma.

Methods: IL-18 levels in blood was determined in C57Bl/6j mice (n=4 at each time point) exposed to hypoxic conditions at 6 hours (h) and 1-7 days. Lungs were harvested at each time point for histological analyses. Concentration of MIP-2 in blood was determined at 6h, 12h, 1-3 days.

Results: The levels of circulating IL-18 were significantly increased at all time points peaking at day 1 (Figure 1A) compared to normocitic controls. Histology revealed perivascular infiltration of neutrophil granulocytes increasing from day 1 to
to day 3. At day 7 neutrophils were still present, but to a lesser extent than at day 3. The concentration of MIP-2 was significantly increased at day 1 (Figure 1B).

Conclusions: The increase in IL-18 induced by alveolar hypoxia may promote the subsequent influx of neutrophils in lung parenchyma, possibly mediated through the neutrophil chemoattractant MIP-2.

P836
Combined treatment with EPO and MSC can reduce acute lung the atrophy of the corresponding zones in the other groups. LPS + EPO group were found in the lymphoid tissue - considerable hyperplasia infiltration and kidney tubular necrosis. The most significant differences in the group 5 we observed significantly less leukocyte lung interalveolar septal injury and kidney damage, cause hyperplasia of lymphoid tissue and enhance the injury and kidney damage, cause hyperplasia of lymphoid tissue and enhance the

Mesenchymal stem cells and recombinant erythropoietin treatment in an experimental sepsis model
Alexander Averyanov1, Anatoly Konoplyannikov2, Fedor Zaborzlaev3, Dmitry Akulishn1, Oleg Kozlov1, Anastasia Sorokina1, Biomedical Technologies Dept., Federal Research Clinical Center of the Specialized Types of Health Care and Medical Technologies FMBA of Russia, Moscow; 2Cell Technologies Dept., Medical Radiology Research Center, Obninsk, Russian Federation

As recently found the surface of mesenchymal stem cells (MSCs) have receptors for erythropoietin (EPO), we hypothesized that the introduction of EPO together with MSCs may enhance their effect and improve efficiency of sepsis treatment.

Aim: To evaluate effects of combined treatment with EPO and MSC in an experimental LPS sepsis model.

Methods: 50 Wistar rats were randomized into 5 groups: Group 1 - the healthy controls, Groups 2-5 were intraperitoneally introduced bacterial LPS 20 mg/kg. Two hours later LPS injection animals received the following intravenous treatments: Group 3: 4 x 10^6 allogeneic MSCs, Group 4: 8.5 μg of recombinant EPO-beta, Group 5: MSCs and EPO in the same doses. Surviving animals were euthanased on the 4th day.

Results: The highest white blood cells count was determined in group 5 (8.15 x 10^9 cells/ml) compared with controls (2.15 x 10^9 cells/ml) and LPS controls (6.52 x 10^9 cells/ml). Serum IL-1β level in groups 2 and 4 was significantly higher than in healthy and treated with MSCs and EPO + EPO animals. Histologically in the group 5 we observed significantly less leukocyte lung interalveolar septal infiltration and kidney tubular necrosis. The most significant differences in the LPS + EPO group were found in the lymphoid tissue - considerable hyperplasia of spleen white pulp up to 64.9% and thymus cortex up to 69.7% in contrast to the atrophy of the corresponding zones in the other groups.

Conclusions: Combined treatment with EPO and MSCs can reduce acute lung injury and kidney damage, cause hyperplasia of lymphoid tissue and enhance the immune response more than separate treatment in an experimental model of sepsis in rats.

P838
Derivation and characterization of young and aged stem cell populations in an interleukin 1 receptor antagonist mouse model system
Daniel Pelaz1, Robert Jackson1, Qingzhou Li1,2, Roy Levin1,4,5, Herman Cheung1,6,7,8, 1Geriatric Research Education and Clinical Center, Miami Veterans Affairs Medical Center, Miami, FL, United States; 2Research Service, Miami Veterans Affairs Healthcare System, Miami, FL, United States; 3Department of Anesthesiology, University of Miami Miller School of Medicine, Miami, FL, United States; 4Anesthesiology, Miami Veterans Affairs Medical Center, Miami, FL, United States; 5Hussman Institute of Human Genetics, University of Miami Miller School of Medicine, Miami, FL, United States; 6Department of Biomedical Engineering, University of Miami, Coral Gables, FL, United States

Recent evidence suggests that the IL1 receptor antagonist (IL1RN) assumes an important role in regulating stem cell senescence, and a deficiency of IL1RN may contribute to impaired lung tissue repair associated with COPD pathogenesis. Here we isolated stem cells from the teeth of transgenic mice and compared them to bone marrow (BM) derived stem cells from control B6C3 F1 mice. B6 IL1RN overexpressing transgenic mice (T16); and B6 IL1RN knockout mice (IL1RN KO) and tested the hypothesis that the IL1 pathway would also regulate stem cell functions in this unique dental stem cell pool. BM cells were obtained by flushing the medullar space of both femurs and establishing adherent cultures. Dental cells were obtained by digesting excised teeth and mandibular pocket overnight, followed by plating single cell suspensions for culture. Cells were then analyzed by immunohistochemistry for stem cell associated as well as for endothelial pro- genitor and pluripotency-associated markers. A viable stem cell population was obtained and established from the BM and the dental tissues of all mice strains. BM stem cell populations displayed CD105 and KDR surface markers and contained populations expressing the VEGER2 endothelial progenitor marker, indicating a possible population of circulating endothelial progenitors. Dental cells from both young (8 wks) and old (10 mo) animals contained the pluripotency associated markers OCT4, Sox2, and NANOG, as well as the CD105 and Connexin43 surface markers. These results demonstrate that dental tissue derived precursor cells may be obtained from transgenic mice and tested in experimental emphysema models.

Factors predicting exercise-induced oxygen desaturation in stable COPD
Khaled Hussein1, Atef Farkok Alkarn1, Samaia Hamal1, Raafat El-Sokkary1, Hamdy Shams1, 2Department of Chest Diseases, Faculty of Medicine, Assiut University, Assiat, Egypt; 2Cardiology Department, Faculty of Medicine, Assiut University, Assiat, Egypt

Background and objective: Some resting pulmonary function and blood gas parameters might predict exercise-induced oxygen desaturation in patients with stable COPD. We aimed at studying these factors.

Patients and methods: We tested 55 patients with stable COPD (FEV1/FVC%: 45.31). Resting pulmonary function, arteriolar blood gases, echocardiography, and incremental cardiopulmonary exercise testing were done for all patients. We classified exercise caused desaturation as significant (FEV1% predicted <90%) and non-significant (FEV1% predicted ≥90%). We compared desaturated (DS) with non-desaturated (NDS) patients.

Results: Exercise induced oxygen desaturation (DS) occurred in 28 subjects while 27 were non-desaturated (NDS). FEV1% of predicted was significantly lower in DS (33.75±10.28) than NDS patients (49.4±19.86, P<0.001). Diffusing capacity DLCO % predicted was significantly lower in DS (47.54±20.25) than NDS patients (67.35±19.62, P<0.001). Resting O2 saturation SaO2% was significantly lower in DS (91.9±2.88) than NDS patients (95.94±2.9, P<0.001). Resting PaCO2 mmHg was significantly higher in DS (63.46±11.58) than NDS patients (38.97±6.38, P<0.001). Pulmonary artery systolic pressure mmHg was significantly higher in DS (42.21±11.90) than NDS (34.15±12.14, P<0.01). Medical Research Council MRC dyspnea score was significantly lower in DS (3.5±0.69) than NDS patients (2.4±0.97, P<0.001). On the other hand, there were no statistically significant differences in FEV1/FVC%, total lung capacity, residual volume, and resting heart rate between the DS and NDS patients.

Conclusion: FEV1 %, DLCO, resting SaO2, resting PaCO2, pulmonary artery sys- tolic pressure and MRC dyspnea score can predict exercise-induced desaturation in stable COPD.

P840
A 4-min, self-paced step test to assess exercise impairment in COPD patients
Mauro Gomes, Beatriz Amorim, Miguel Rodrigues, Mayron Oliveira, Meline Almeida, Adriano Acedo, Aline Souza, Thulio Cunha, J. Alberto Neder. Department of Medicine, Division of Respiratory Diseases, Federal University of Sao Paulo, SP, Brazil

Background: There is a long-standing interest in developing “field” exercise tests for patients with chronic obstructive pulmonary disease (COPD) which can be easily performed in the consulting room with a minimum of technical support.

Objectives: To investigate whether a 4-min, self-paced step test (4MST) would be useful to assess exercise tolerance and oxygen/hemoglobin desaturation by pulse oximetry (SpO2) in a large group of outpatients with COPD.

Methods: 191 patients (GOLD stages: I= 16, II= 63, III= 79, IV= 33) prospectively underwent the 4MST. Patients were allowed to stop the test as needed and re-start it within the allowed 4-min.

Results: There were no significant test-related complications. There was a large variability in the steps climbed (ranging from low 20’s to more than 100). Based on the number of steps climbed, patients were separated into sub-groups of progressive impairment (Group A, N≥ 62; Group B, N= 61; Group C, N= 68). Group

Factors associated with aerobic fitness in adolescents with asthma

Sveinnja Birna Mennhag1, Karin C. Ludvig Carlsen2,3, Sigurd Alfred Anderssen4,5,6, Peter Mowinckel1,7, Kai-Håkon Calrsen3,4,1, Department of Public Health, Sport and Nutrition, University of Agder, Kristiansand, Norway; 2Department of Paediatrics, Oslo University Hospital, Oslo, Norway; 3Faculty of Medicine, University of Oslo, Norway; 4Department of Sports Medicine, Norwegian School of Sport Sciences, Oslo, Norway.

Background: In adolescents with asthma, information on factors associated with aerobic fitness levels is limited. The present study aimed to determine if physical activity as well as skin fold thickness, asthma exacerbations, use of inhaled corticosteroids or lung function influences direct measurements of peak oxygen uptake (VO2peak) in adolescents with asthma.

Methods: From the general population based birth cohort, Environment and Child-

hood Asthma study in Oslo, Norway, in a nested case-control study 86 13 years-old adolescents with and 76 without asthma performed maximal running on a treadmill with VO2peak measured. The sum of four skin fold thicknesses was recorded, fol-

lowed by wearing an activity monitor for four consecutive days. Lung function was measured by maximum forced expiratory flow-volume curves and body plethys-

mography. Asthma exacerbations and use of medication were registered by parental

structured interview. Data were analyzed using multiple regression analysis.

Results: Vigorous physical activity (coefficients with 95% confidence intervals; 1.73 (0.32 - 3.14) and body fat -0.35 (-0.41, -0.28)) were significantly associated with VO2peak in adolescents with asthma. Neither use of inhaled corticosteroids, lung function nor number of asthma exacerbations was associated with VO2peak when taking physical activity and skin fold thickness into account. In the adolescents without asthma only skin fold thickness was associated with VO2peak.

Conclusions: VO2peak appears to be determined by vigorous physical activity level and skin fold thickness in Norwegian adolescents with asthma and not by asthma related factors such as use of inhaled corticosteroids, lung function nor number of asthma exacerbations.

P842 Predicting VO2max in elderly: Could equations established in younger

P843 Reference values for cardiorespiratory fitness in a 20 – 85 year old population

Elisabeth Edvardsen1,2, Bjarke H. Hansen1, Ingmar M. Holme1,2, Sindre M. Dyrdal3, Sigurd A. Anderssen4, 4Department of Pulmonary Medicine, Oslo University Hospital, Ullevål, Oslo, Norway; 2Department of Sports Medicine, Norwegian School of Sport Sciences, Oslo, Norway; 3Department of Education and Sport Science, University of Stavanger, Norway.

Background: Existing reference values used during clinical exercise testing have been obtained with rather small none randomly sample sizes, lack of women and elderly or poor maximal end-criteria. The aim was to establish reference values during maximal exercise in a representative sample of men and women.

Methods: 904 randomly sampled healthy men and women (20 – 85 yr old) measured in a modified Bakle protocol to exhaustion.

Results: 759 participants met the criteria for an acceptable VO2max, based on RER>1.10 or BOR≥17. In the age group 20-29, the VO2max (ml/kg·min−1) was 40.3 (SD 7.1) and 48.6 (SD 9.6) in women and men, respectively. A linear decline (6% per decade) was observed after age 30 in both genders.

Conclusions: The present study establishes VO2max, and other typical cardiorespiratory variables during maximal exercise and may be used as reference values.

P844 Exercise in patients with lymphangioleiomyomatosis: Performance and the prevalence of dynamic hyperinflation

André Albuquerque, Bruno Baldi, Suzana Pimenta, Joao Marcos Salge, Ronaldo Katulski Carlos Carvalho. Respiratory Department, Heart Institute (Incor) - University of Sao Paulo Medical School, Sao Paulo, Brazil.

Introduction: Previous studies suggested multiple factors for exercise cessation in LAM. Although airflow limitation is frequent in LAM, the dynamic hyperinflation (DH) and its repercussions during exercise have not been evaluated yet.

Objectives: To evaluate the prevalence and repercussions of DH in LAM and also the dynamic responses during maximal exercise, in comparison to controls.

Methods: 42 patients performed pulmonary function tests (PFT) and symptom-

limited incremental cycle exercise, in comparison to ten age-matched healthy women.

Dyspnea intensity, inspiratory capacity, oxygen saturation (SpO2), car-

diac, metabolic and respiratory variables were obtained during exercise. 6MWT was performed by LAM patients indeed.

Results: Compared to controls, LAM had higher baseline dyspnea, obstructive pattern, air trapping and lower DLCO in PFT. In LAM, maximal exercise perfor-

mance was reduced, associated with ventilatory limitation, greater desaturation and dyspnea. DH occurrence was higher in LAM than controls (55 vs. 0%), with a significant correlation to airflow obstruction, air trapping and DLCO. Patients who developed DH had not only a ventilatory contribution to exercise cessation on cycling, but also greater desaturation and dyspnea intensity during 6MWT, compared with non-DH subgroup.

Conclusions: Ventilatory limitation is an important reason for exercise cessation in LAM, compared with controls. DH was prevalent and had association with severity of disease, higher dyspnea and lower SpO2. On 6MWT, desaturation and increased dyspnea were greater in DH subgroup. Future interventions to reduce DH might contribute to improve dyspnea and exercise tolerance in LAM.
Exercise respiratory cycle time components in patients with emphysema

Alessandro Maria Ferrazza, Patrizia Pascaletti, Gabriele Valli, Paolo Oronati, Danu Mattaolin, Michela Mordenti, Francesco Vaccaro, Paolo Palange.

Department of Public Health and Infectious Diseases, Lung Function Unit, Sapienza University of Rome, Italy

Background: We have recently demonstrated that in patients with COPD the severity of emphysema (E) measured by high resolution computed tomography (HRCT) correlated with: ratio VTepeak/FEV1; VE/VCO2 slope and PETCO2 values at peak exercise. The aim of this study was to further investigate if exercise respiratory cycle time components correlated with % of E measured by HRCT.

Method: Twelve patients (age = 65.1±8 yrs; FEV1 = 55±17%pred) with moderate to severe E (quantified by lung HRCT as % voxels < -910 HU) were evaluated with incremental cardiopulmonary exercise testing (CPET). Mean inspiratory time (TiM), mean total respiratory cycle time (TotM), mean expiratory time during exercise (TeM-end) and mean expiratory time during the last third of exercise (TeM-end) has been calculated.

Results: Both TeM and TeM-end had a good linear correlation with % of E (r = 0.61, p = 0.004 and r = 0.63, p = 0.003).

Conclusions: VO2 is highly influenced by oxygen utilization in exercising muscles, as well as by blood oxygenation levels and cardiac function. However, the impact of skeletal muscle utilization during exercise on VO2peak varied greatly among the patients.

P847

Inspiratory muscle constraint during exercise in patients with pulmonary arterial hypertension

Barbara Isopan-Haraske,1 Gilles Garcia,2,3, Christian Strauss,1 Elise Arnaud Macaux2,4, Xavier Jan5,6, David Montano7,8, Laurent Savale9,10, Olivier Sibon2,11, Gérard Simonneau2,3,5, Marc Humbert2,3,5, Thomas Similowski12,13, Pierantonio Lavenziana14,15,16,17, 1Equipe de Recherche ER 10 UPMC, Laboratoire de Physio-pathologie Respiratoire, Faculté de Médecine Pierre et Marie Curie (site Pitié-Salpêtrière), Université Paris 6, France; 2Faculté de Médecine, Université Paris-Sud, Le Kremlin-Bicêtre, France; 3Centre Chirurgical Marie Lannelongue, INSERM U999, Le Plessis-Bouchard, France; 4Service de Physiologie, Assistance Publique Hôpitaux de Paris, Hôpital Antoine Béclère, Clamart, France; 5Service de Pneumologie et Réanimation Respiratoire, Centre National de Référence de Vascular Pathologies Pulmonaires Sévères, Assistance Publique Hôpitaux de Paris, Hôpital Antoine Béclère, Clamart, France; 6Service de Pneumologie et Réanimation Médicale, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Pitié-Salpêtrière, Paris, France.

We examined the impact of potential inspiratory muscle constraint on dynamic operating lung volumes response during symptom-limited incremental cardiopulmonary cycle exercise testing (CPET) in patients with pulmonary arterial hypertension (PAH).

Thirty-three young non-smoking PAH patients (idiopathic=26; heritable=7) with normal body mass index and no spirometric evidence of obstructive ventilatory defect (FEV1/FVC=115±10% predicted) performed a CPET to limit of tolerance. Ventilatory profile, operating lung volumes [derived from inspiratory capacity (IC) measurements] and inspiratory flow reserve (IFR), an indirect index of inspiratory muscle constraint/fatigue, were assessed throughout CPET.

Twenty-two patients (67%) decreased IC (i.e., dynamic hyperinflation) throughout exercise by 0.5L (PAH-H), whereas the remaining patients (33%) increased IC by 0.36L (PAH-NH). V̇E and V̇O2 at peak exercise were considerably different among the two groups. Despite these differences in operating lung volumes response, IFR at peak exercise was not statistically different between PAH-H and PAH-NH (1.9±1.0 vs 2.0±0.8L/s, p=0.7).

Both PAH-H and PAH-NH achieved inspiratory tidal flows that approached a similar percentage of the maximal available inspiratory flows (i.e., similar IFR), suggesting that the inspiratory flow-generating reserve of the inspiratory muscles at peak exercise was similar (but occurred at different operating lung volumes). The presence of inspiratory muscle constraint/fatigue and its contribution in modulating the dynamic operating lung volumes response to CPET is unlikely.

Support: 1) International Re-integration Grants (IRG), FP7-PEOPLE-2010-IRG; 2) PFIZER Investigator-Initiated Research (IR).

P848

A metabolic evaluation of a group of obese children: Oxygen consumption (VO2) and power

Martina Tubaro1, Ilenia Benfatto1, Mario Cancian1, Francesca Valent2, 1Allergology and Pulmonology Unit, Department of Pediatrics, DPMSC, University of Udine, Italy; 2Hygiene Department, School of Medicine, DPMSC, University of Udine, Italy.

Obesity, which has been considerably increasing in the last decades, is related to significant metabolic alterations.

The aim of this study was to evaluate whether this condition can also alter the VO2 (considered as the best assessment of cardiorespiratory form in healthy children) and the power in a group of obese children compared to a group of control children.

We tested 98 children; 42 controls and 56 obese children. Each child underwent a metabolic test on the cycle ergometer according to a protocol of increasing effort. VO2 values were 207.6 ± 24.8 ml/min for the group of controls and 207.8 ± 24.7 ml/min for the obese children (p=0.05). The higher value of power was obtained in the group of control children (140 watt) and lower in the obese children (120 watt) (p=0.05). This parameter normalized for the mass was higher in the group of controls (2.7 watt/kg) compared to obese children (1.9 watt/kg) (p=0.01).

Given the greater body mass of obese due to an increased fat component, it is not surprising that the VO2 is higher. These subjects must in fact move a large mass, with a considerable consumption of energy, to the detriment of their ability to work. The VO2/kg values are lower in the obese children 32.3 ml/kg compared to the group of controls 38.7 ml/kg/min (p=0.01).

Support: 1) International Re-integration Grants (IRG), FP7-PEOPLE-2010-IRG; 2) PFIZER Investigator-Initiated Research (IR).
PS49
Determinants of exercise capacity in patients with COPD without other comorbidities
Gloria Samperiz, Laura Madre, Pablo Cubero, Marta Forner, Elena Forcen, Santiago Carrizo, Jose M. Martin, Miguel Servet, Zaragoza, Spain

Introduction: The 6 min walking test (6MWT) is frequently used to assess exercise limitation and exertional dyspnoea in COPD. Age, sex, metabolic, cardiovascular, neuromuscular and respiratory variables can contribute to determine the final individual value of the 6MWT.

Aims: To evaluate exercise performance with the 6MWT in COPD patients free of other co-morbidities.

Methods: From the Bode International Cohort Study we selected 148 men with COPD and no other cardiovascular, cerebrovascular, metabolic or neuromuscular disorder. In addition, patients who were taking beta-blockers or anti-hypertensives were also excluded. A pre-specified protocol including two standardized 6MWT was applied to all patients.

Results: The mean ± SD of the post bronchodilator FEV1% predicted and 6MWT was 62.8±21 and 398±99 meters respectively. Walked distance correlated significantly with age, height, weight, baseline dyspnoea (as assessed by the MRC scale) and respiratory rate (RR) pre and post rehabilitation programme (RP) measuring oxygen uptake (V'O₂), carbon dioxide output (V'CO₂ ) and ventilation (V'E). The ventilatory efficiency was evaluated using the VE/CO₂ slope. Breathing patients was evaluated using iso-ventilation, i.e. maximal V'E, tidal volume (VT) and respiratory rate (RR) pre RP compared to the same parameters during iso-V'O₂ post RP. Exercise training in the RP consisted of endurance and strength training 5 days a week for six weeks.

Results: Exercise endurance increased and ventilatory requirements reduced post RP. Breathing pattern was improved in COPD pts but ventilatory efficiency was unchanged in both groups (Table 1).

1Department of Physiology, University of Iceland, Reykjavik, Iceland; 2Department of Heart and Lung Rehabilitation, Reykjavik, Rehabilitation Centre, Mosfellbaer, Iceland

Ventilatory efficiency to evaluate the effect of exercise training on ventilation in these pts.

Methods: 25 COPD pts (11 males; 64±9 yrs old, GOLD 3-4) and 25 CHF pts (12 males; 65±10 yrs old; NYHA class II-III, ejection fraction <35%) underwent a standardized 6MWT and an isometric endurance test of the M. deltoideus voluntary contraction, followed by an isometric endurance test of m. deltoideus (10 s) against baseline and post bronchodilator. Ventilation, oxygen uptake (V'O₂), carbon dioxide output (V'CO₂ ) and ventilation (V'E). The ventilatory efficiency was evaluated using the VE/CO₂ slope. Breathing patients was evaluated using iso-ventilation, i.e. maximal V'E, tidal volume (VT) and respiratory rate (RR) pre RP compared to the same parameters during iso-V'O₂ post RP. PS53
Short-term ingestion of salbutamol increases isometric muscle power in endurance athletes
Anders Kalse1, 2, Morten Hestrup2, Jens Bangsbø2, Vibke Backer2
1Respiratory Research Unit, Bispebjerg University Hospital, Copenhagen, Denmark; 2Department of Exercise and Sport Sciences, University of Copenhagen, Denmark

Rationale: Salbutamol is on WADA’s prohibited but is allowed by athletes in therapeutic doses. Positive effects of oral salbutamol have been shown in active males and females. Yet, studies are needed examining the effects in athletes. Furthermore, no studies have examined whether oral salbutamol improves isometric muscle power and endurance. We examined whether acute and short-term intake of oral salbutamol improved isometric muscle power and endurance, and submaximal exercise performance in endurance athletes.

Method: Twenty non-asthmatic endurance athletes (M), aged 25.8±4.4 yrs, weight 74.9±11.2 kg, height 178.4±6.1 cm, were enrolled in a randomized double-blind parallel study, into either oral salbutamol 8 mg (SAL) or placebo (PLA). The protocol consisted of three tests. Isometric muscle power of m. quadriceps was measured by maximal voluntary contraction, followed by an isometric endurance test of m. deltoideus to exhaustion and a submaximal cycling test to exhaustion at 90% of VO₂max (TTE@90%). The protocol was performed at baseline, after acute ingestion, and after 14 days of ingestion.

Results: Short-term intake of salbutamol significantly increased isometric muscle power, 709.6±115.2 vs 662.8±100.8 at baseline (p<0.05). Furthermore, there was a significant linear trend of increased isometric muscle power with SAL throughout the intervention (p<0.05). No differences were found in the PLA-group. Neither SAL nor PLA had any impact on isometric endurance or TTE@90%.

Conclusion: Short-term intake of salbutamol might augment training response and increase isometric muscle power in endurance athletes. Salbutamol had no effect on submaximal exercise at 90% of VO₂max or on isometric endurance.
PS84
Effects of acute and two week intake of salbutamol on anaerobic power and capacity during repeated bouts of exercise in elite cyclists.

Morten Hostrup1,2, Anders Kalsen3,2, Jens Bangsbo2, Viveke Backer1.

1Respiratory Research Unit, Bispebjerg University Hospital, 2Department of Exercise and Sport Sciences, University of Copenhagen, Denmark

Rationale: Salbutamol was of 2011 relieved from WADA’s prohibited list needing a strict diagnosis of asthma, and can now be used more freely among athletes. Some studies have showed enhancing effects of oral salbutamol on anaerobic power in recreational men and women. However, no studies have investigated this in elite athletes. The aim of this study was to examine whether oral salbutamol, taken acutely and over a period of two weeks, increases anaerobic power during repeated Wingate tests in elite cyclists.

Method: We enrolled 20 non-asthmatic elite cyclists (M), aged 25.8±0.4 yrs, VO2peak 68.6±5.8 mln/min/kg, and a training volume of 14.4±3.6 h/wk. The cyclists were randomized into either oral salbutamol 8 mg (SAL) or placebo (PLA) in a double-blinded parallel study. The protocol consisted of three 30-s Wingate tests separated by two minutes of recovery. The intervention consisted of study visits at baseline, after acute ingestion, and after two week ingestion taken two-three hours prior to the cyclists’ regular training.

Results: Two week ingestion of salbutamol significantly increased peak power in the first (p<0.05) and second (p<0.001) Wingate, 894±64 W and 885±51 W versus 861±53 W and 848±54 W at baseline. Furthermore, the SAL-group had a significant higher mean peak power over 5s at both the first (p<0.05) and the second (p=0.05) Wingate, with 861±42 W and 829±56 W versus 809±58 W and 795±50 W at baseline. Acute ingestion of salbutamol didn’t increase any parameter in the SAL-group. No differences were found in the PLA-group.

Conclusions: Two week daily intake of salbutamol taken prior to training improves anaerobic power in elite cyclists.

PS85
Inspiratory muscle warm-up does not improve cycling time trial performance

Ian Gregson1, Dean Mills1, Javier Gonzalez2, Graham Sharpe1.

1Sports Science, Nottingham Trent University, Nottingham, United Kingdom; 2Sport and Exercise Sciences, Northumbria University, Newcastle upon Tyne, United Kingdom

Combining an inspiratory muscle warm-up (IMW) with a sport specific warm-up improved intermittent running (Tong and Fu: Eur J Appl Physiol 2006: 97:637-680) and 6 min rowing time trial (Volaniut et al. Med Sci Sports Exerc 2001; 33:1189-1193) performances more than a sport specific warm-up alone. This study tested the hypothesis that inspiratory muscle warm-up would also improve cycling time trial performance.

Ten competitive cyclists (VO2max 64.7±3.9 ml/min/kg) performed three 10 km cycling time trials preceded by either no warm-up (CONT), a cycling specific warm-up (CYC) comprising three consecutive 5 min bouts at powers corresponding to 30, 70, and 90% of the aerobic gas exchange threshold, or a cycling specific warm-up preceded by an IMW (CYC+IMW) comprising two sets of 30 inspiratory efforts against a pressure-threshold load of 40% maximal inspiratory pressure (MIP). During CYC and CYC+IMW the cycling was performed after a 2 min rest period before the start of the time trial.

Performances during CYC (14.7±0.75 min) and CYC+IMW (14.7±0.75 min) were not different, although both were faster than CONT (14.9±0.90 min) (P<0.05). At 2.5 km intervals heart rate, rating of perceived exertion for leg and breathing, blood lactate concentration and pH, were not different between CYC and CYC+IMW. Baseline MIP during CONT and CYC were 151±31 and 156±39 cmH2O, respectively, and these were unchanged following the time trial. IMW increased MIP from 152±27 to 164±27 cmH2O and no further change was observed following the time trial.

In conclusion, improvements in 10 km cycling time trial performance following a specific cycling warm-up were not magnified by the addition of a specific inspiratory muscle warm-up.

PS86
Minute ventilation (Ve) and heart rate (HR) relationship during exercise in chronic cardiac and pulmonary diseases

Paolo Onorati, Paolo Marinielli, Patrizia Pasiele, Alessandro Maria Ferrazza, Gabriele Vaili, Mattia Internullo, Dario Martolini, Paolo Palange. Dipartimento di Pubblica e Malattie Infettive, Policlinico Umberto I, “Sapienza”, Università di Roma, Rome, Italy

We have demonstrated in healthy subjects that the rate of increase in minute ventilation over heart rate (ΔVe/ΔHR), during incremental exercise, is described by a bilinear response, with a slope’s change at the ventilatory compensation point (VCP) (Onorati P. Eur J Appl Physiol. 2008;104:87-94).Med Sci Sports Exerc 2012 in press). We aimed at analyzing the exercise ΔVe/ΔHR response in patients with chronic cardiopulmonary diseases.

Method: Patients with chronic obstructive pulmonary disease (COPD) (n=10) and cardiovascular diseases (CVD) (Pulmonary Arterial Hypertension, PAH, n=9; and Chronic Heart Failure, CHF, n=10) underwent one-minute incremental cycling exercise. Gas exchange, Ve, HR were measured breath-by-breath. ΔVe/ΔHR response, before (S1) and after the VCP (S2) were computed by linear regression analysis.

Results: In all patients we observed a linear response of the ΔVe/ΔHR relationship; in COPD patients S2 was steeper vs PAH and CHF and approached the maximal voluntary ventilation (MVV). S2 slope was observed mainly in CVD patients and approached the maximal predicted HR.

A good agreement (Bland-Altman test) for VCP detection was observed between ΔVe/ΔHR vs the ventilatory equivalent for CO2 (Ve/VECO2) methods.

Conclusions: In patients with COPD, PAH and CVD, the ΔVe/ΔHR response during cycling incremental exercise can be utilized to discriminate between ventilatory and circulatory limitation.

PS87
Influence of ventilatory inefficiency in to limit exercise capacity in COPD patients

Iván Caviedes, Rodrigo Soto. Laboratorio Broncopulmonar, Clínica Alemana de Santiago, Facultad de Medicina Clínica Alemana, Universidad del Desarrollo, Santiago, Chile

Background: We recently demonstrated an influence of Ventilatory efficiency (VE/VO2) over exercise capacity in COPD (Respi Care 2012 in press). Purpose: to demonstrate increase of ventilatory inefficiency depending on the severity of COPD, and its influence into reduce exercise capacity.

Methods: 58 Gold I-III patients, mean age 61, mean FEV1: 98, 68.5 and 44.3%, mean DCO: 68, 59.5 and 45%.

A cardiopulmonary stress test measuring Power (Wmax), Oxygen consumption (VO2max), VE/VO2, expiratory flow limitation (EFL) and dynamic end expiratory volume (DEELV) was performed. In patients with hypertension correlations and multiple regressions between BMI, EFL, DEELV and VE/VO2 were analyzed. Patients were divided in 3 groups: GOLD I, GOLD II and GOLD III

Results: Patients ended the test due to dyspnea with increased VE/VO2 (mean 34). Depending on the severity of COPD, VE/VO2 was higher. 36 patients presented hyperinflation (mean DEELV 0.5 L), with a reduction in Wmax and in VO2max (mean: 63 and 76%). Significative correlation was demonstrated between VE/VO2 over VO2max and Wmax (r=0.5 and 0.5). In multiple regression the relation between VE/VO2, Wmax and VO2max was significative (p<0.05 and <0.05), but not to BMI, EFL and DEELV.

Conclusions: In COPD patients ventilatory inefficiency increases depending on the severity and is related with a reduction in the exercise capacity. Ventilatory inefficiency is an independent factor to reduce exercise capacity in COPD.

PS88
Respiratory muscle endurance training (RMET) with normocapnic hyperpnea (NH) improves ventilatory function and exercise performance in triathletes

Eva Bernhard, Enzo Mollonoi, Gaia Mandoleso, Luca Pomidoli, Annalisa Cogo. Biomedical Sport Studies Center, University of Ferrara, FE, Italy

Recent studies show that RMET reduces dyspnea perception, improves exercise performance and decreases VE during exercise in healthy subjects. Aim: To evaluate the effect of 5 weeks of RMET with NH by means of Spiret® on respiratory function, cycling and running performance in triathletes.

Methods: 15M triathletes (aged 21-43) were allocated in 2 groups: RMET (10M) and Control (5M) group.

At baseline (T0) athletes underwent: pulmonary function tests (FEV1, FVC, MIP, MVV) and exercise tests (maximal incremental and endurance cardiopulmonary tests performed with both cycle ergometer and treadmill) and repeated the same tests after 5 weeks (T1). RMET group trained at home for 5 weeks: 20 min daily at the same ventilation level measured at the RC point during incremental test. Between T0 and T1 all subjects maintained the same training program.

Results are reported in Table 1. The trend of VO2, VE and RR showed lower values after RMET (p<0.05; ANOVA test). No change was found in control group.

Mean±SD; *p<0.05; T test.
Conclusion: RMET significantly improves MIP and MVV in triathletes and increases exercise performance. Furthermore the VE becomes more efficient as shown by the reduction of VE, RR and by the lower dyspnea Borg score; the new data is the lower trend of VO2 during incremental test.

99. New issues in pulmonary function

P859 Patterns of lung function abnormalities in smokers as possible manifestation of "early" COPD phenotypes

Anthony Cozza1, Laura Carrozza2, Francesco Postile2, Erica Gin1, Federica Albicini1, Amelia Grosso1, Ferruccio Aquilini1, Rosanna Niniano1, Federica Imberti1, Eric Tsama Tegomo1, Marta Agnesi1, Antonio Foresi1, Isa Cerveri1.
1. Respiratory Diseases Department, Foundation IRCCS “San Matteo”; 2. Cardiothoracic and Vascular Department, University Pulmonary Unit, University Hospital, Pisa, Italy; 2. Respiratory Pathophysiology Unit, Sesto San Giovanni Hospital, Sesto San Giovanni, Italy

The notion that the earliest manifestation of COPD is an increase in gas trapping, with a decreasing VC that forces the FEV1 to decline with it, has been recently re-evaluated [1]. To assess the prevalent patterns of lung function abnormalities in smokers at the onset of COPD, we evaluate cross-sectional data of a longitudinal study on 321 non-outpatient smokers (mean age 55±10 years; 60% males) belonging in part to a smoking cessation program and in part to a lung cancer screening study. Smoking history and chronic respiratory symptoms were collected, and spirometry and lung volumes were determined, according to standardized protocols. Mean pack-years were 38±22 and 38% of the smokers reported chronic cough and/or phlegm and/or dyspnea; they were significantly older and smoked more pack-years than those without symptoms (for both p<0.0001). Mean value of all lung function parameters was within the normal range, however lung function abnormalities were observed in 43% of smokers: 15% had FEV1/VC lower limit of normal and FRC >115% predicted, 19% had only airflow obstruction and 9% had an isolated increase in FRC without airflow obstruction. A similar pattern of increase in gas volume was found regardless the presence of respiratory symptoms or by considering either RV or RV/TLC. In conclusion, air trapping is not the prevalent pattern of lung function abnormalities in these two groups of smokers, isolated airflow obstruction or isolated increase in air trapping could be an "early" expression of two different phenotypes of COPD.

P860 Airway distensibility with lung inflation following allogeneic haematopoietic stem-cell transplantation (HSCT)

Giovanni Barzino1, Pasquale Pio Pompilio2, Andrea Racicalupo3, Riccardo Pellegrino1, Alex Coie4, Raffaele Dellaca3, Claudia Brasacca3, Emanuele Crimi1, Teresa Lamparelli3, Vito Brasacca3, 1 Fisiopatologia Respiratoria, IRCCS AOU San Martino - IST, Genova, Italy; 2 Dipartimento di "Respiratoria, IRCCS AOU San Martino - IST, Genova, Italy; 3 Ematologia 2, IRCCS AOU San Martino - IST, Genova, Italy

Aims: To study whether this effect may be due to increased airway distensibility.
Methods: 23 subjects were studied before and 1-3 and 3-6 mo after HSCT. Resistance (Rrs) and reactance (Xrs) of the respiratory system were measured by FOT (5, 11 and 19 Hz) at FRC and TLC. The ratio of changes in respiratory conductance (Grs) from FRC to TLC to changes in lung volume (ΔGrs/ΔVl) was used to estimate airway distensibility. Results: Grs at FRC was larger at all frequencies whereas Xrs at 5 Hz was less negative after than before HSCT (Figure 1). TLC was decreased by 5±2% whereas FRC was not changed. ΔGrs/ΔVl was steeper after than before HSCT (P<0.001), without differences after salbutamol (Figure 2, interrupted lines).

Conclusion: In uncomplicated HSCT, absolute lung volume is reduced but is the ability to reverse induced bronchoconstriction by deep-breath is enhanced.

Background: In uncomplicated HSCT, absolute lung volume is reduced but the drive and effectiveness of respiratory muscles contraction. They are useful in the diagnosis of advanced chronic lung diseases that accompany CO2 retention.

Results: TVs at 5 Hz was less negative after than before HSCT (Figure 1). TLC was decreased by 5±2% whereas FRC was not changed. ΔGrs/ΔVl was steeper after than before HSCT (P<0.001), without differences after salbutamol (Figure 2, interrupted lines).

P861 Study on mouth occlusion pressure in normal subjects and patients with obstructive or restrictive lung diseases

Hong Yeol Lee, Ha Sung Nam, Jae Hwa Cho, Jeong Seon Ryu. Department of Internal Medicine, Inha University College of Medicine, Incheon, Korea

Mouth occlusion pressure (P0.1) is the mouth pressure developed against a complete occlusion at 0.1 second after beginning of inspiration from FRC. Consciousness, autogenous reflexes and various lung mechanics do not affect it. We did this study in sequence of arterial blood gas examination, flow-volume curve, body plethysmography, diffusion capacity and measurement of P0.1. We divided the subjects into 4 groups such as normal control groups below 35 and above 50 years old, and the patient groups of obstructive and restrictive lung diseases. We measured P0.1 during breathing of the ambient air and, again during 6% CO2 rebreathing with simultaneous measurement of ventilatory parameters such as MV (minute ventilatory volume)/P0.1, TTV/Ti (inspiratory time/total respiratory time), TV/Ti, and P0.1/TV/Ti. During breathing of the ambient air, and, again during 6% CO2 rebreathing, there was a characteristic change of P0.1 in the hypercapnic patient group compared with the normocapnic patient group. As a result, P0.1 and P0.1/TV/Ti are the valid indices of central inspiratory neuromuscular drive and effectiveness of respiratory muscles contraction. They are useful in the diagnosis of advanced chronic lung diseases that accompany CO2 retention.
P864
Expiratory capnography in brown Norwegian rat: Feasibility and effect of acute bronchoconstriction
Malthe Guiberti, Loic Deugrulliers, Franck Robelot, Françoise Rougereux, Francois Marchal, Bruno Cheunel, Sam Bayal, P. Petriol EA2485 UM01, University of Picardie Jules Verne Medical Faculty, Amiens, France; 2Pediatric Cardiology and Respiratory Medicine, Amiens University Hospital, Amiens, France; 3EA 3450 Faculté de Médecine, Université Henri Poincaré, Vandoeuvre les Nancy, France
Rationale: The phase III slope of the expiratory volumetric capnogram (S3v) has been shown to increase with bronchoconstriction in asthmatics (ERJ 1994;7:318-323), however, the mechanisms involved remain speculative. We assessed the feasibility of expiratory capnographic slope analysis during acute bronchoconstriction in an experimental model in rat.
Methods: Rats underwent a separate study were divided into 2 groups: sensitized to ovalbumin (OVA) and exposed either to air or to NO2, 10 ppm, 6d/wk for 4 weeks. 24h after exposure, animals were anesthetized and mechanically ventilated. Respiratory mechanics were measured using multiple linear regression analysis of capnogram and after infusion of methacholine at 15 μg/kg/min (vs). Exhaled capnograms were recorded during tidal breathing using a rapid CO2 analyzer. The S3v was computed and averaged in a minimum of 10 respiratory cycles in each condition.
Results: Respiratory system resistance (Rs) and elastance (Es) significantly increased in response to MCH. Similarly, S3v increased during MCH infusion. This increase was significantly larger in NO2-exposed animals.
Table 1

<table>
<thead>
<tr>

*p<0.05 vs. baseline, within a group; *p<0.05 vs. Air-OVA, within a condition, by Kruskall- Wallis ANOVA on ranks.

Conclusions: Measurement of S3v is feasible in rat, and significantly increases following bronchoconstriction. This new experimental model will allow further study of the mechanisms associated with the increase in S3v.

P865
Effects of thoracic gas compression on airway responsiveness in asthma
R. Torchio, A. Antonelli, C. Gutola, E. Crimi, C. Crimi, V. Brusasco, R. Pellegrino, Lab. Fisiopatologia Respiratoria Centro Sento, AOI S. Luigi, Orsaria, TO, Italy; 2Fisiopatologia Respiratoria. Dipartimento S. Croce e Carlo, Cuneo, Italy; 3MAR 1, AOI S. Luigi, Orsaria, TO, Italy; 4Fisiopatologia Respiratoria, University, Genova, Italy; 5Pneumologia, University, Catania, Italy
Background: The response to a bronchial challenge is usually assessed from the changes in the forced expiratory in 1 s (FEV1). Yet this measurement is negatively affected by the thoracic gas compression. Aim: To examine the effects of thoracic gas compression on the dose-response curve to methacholine (MCh) in asthmatics. Methods: 28 male and 25 female asthmatic patients participated in the study. Methacholine challenge was performed in a flow-type body plethysmograph to compute simultaneously FEV1 and compression-free FEV1 (FEV1/PLETH). The doses of MCh that caused a decrease in FEV1 and FEV1/PLETH by 20% of control were calculated by linear interpolation of the dose-response curve and transformed into natural logarithm. Results: On average, lnPd20FEV1 was significantly less that lnPd20FEV1/PLETH (5.49±0.94 vs. 5.74±1.00, p<0.001). The difference between lnPd20FEV1 and lnPd20FEV1/PLETH was positively correlated with absolute TLC (r=0.40; p<0.05 vs. baseline, within a group; *p<0.05 vs. baseline, within a condition, by Kruskall-Wallis ANOVA on ranks.

Conclusions: Thoracic gas compression has a significant effect on airway responsiveness, which depends on absolute lung volume and, thus, anthropometric characteristics.

P866
Change of CP location during bronchodilatation
Ole Pedersen, Riccardo Pellegrino, Pasquale Pompilio, Institute of Public Health, University of Aarhus, Denmark
Background: The wave-speed concept of flow limitation predicts a unique relationship between the MFSR-curve and the tube laws of the airways containing the choke points (CP). If the frictional loss pressure (Pfr) cannot be neglected J = Pel – Pfr must be substituted for Pel.
Aim: 1) To analyse data from Lambert et al. (JAP 52:44–46) in terms of motion pressure during expiration. 2) To measure upstream viscous pressure losses (Pfr) and J = Pel – Pfr. Meth: Physiological Volume 1, 2011: 1861-1881. The relationship between cross-sectional area (A) and transmural pressure (Ptm) – the tube laws were calculated from the relationship between Vmax and J.

P862
An integrative and comprehensive approach to evaluate lung mechanics in seated and upright positions
Andre Albuquerque, Pedro Caruso, Renata Pletsch, Pauliane Santana, Leticia Cardenas, Andre Apanavicius, Gabriel Rozin, Marcelo Macchione, Joao Marcos Salge, Carlos Carvalho. Respiratory Department, Heart Institute (Incor) - University of Sao Paulo Medical School, Sao Paulo, Brazil
Ventilatory and sensorial differences have been found between treadmill and cycle in respiratory diseases. However, there are still many doubts about lung mechanics in these two body positions.
Methods: 5 male healthy were evaluated at quite breathing (QB) and voluntary hyperventilation (VH) in seated (ST) and upright (UR) with transdiaphragmatic pressure (Pdi) - oesophageal and gastric sensors, electromyography (RMS) of sternocleidomastoid, Intercostal, Rectus abdominis and External Abdominal Oblique (OmEGM), ribcage (RC) and abdominal (Ab) bi-dimensional movement by inductance (V0.5) and flow measurement (V0.1).
Results: At QB in ST with similar flows, we found: the chest wall movement was mainly the Ab, with similar Pdi than UR (20.9 vs 28.1 cmH2O) but with a lower gastric pressure (11.2 vs 21.9cmH2O, NS). Inspiratory muscles accessory were poorly recruited in both positions, but UR lead to higher activity of abdominal muscles (p<0.08).
During (VH): the chest wall increase was mainly dependent of RC in ST, while in UR the contribution of RC and Ab was the same. The increase of Pdi was equivalent (30% vs 29%) in both positions during VH, gastric pressure augmented more in ST than UR (169 vs 109%, NS). Finally, VH in ST resulted in similar recruitment of inspiratory muscles but superior of exp muscle (incOmEGM 118% vs 83% NS) than UR.
Conclusion: Seated is characterized by greater contribution of Ab to chest wall movement than UR. The lower gastric pressure and also lower exp muscle recruitment than UR. During hyperventilation, the increase of Ab contribution was also greater in ST. Ab compartment is more recruited and less contributing to chest wall mechanics in UR.
Results: Bronchial dilatation increases maximal flow in all cases, but Pfr increases in two cases and decreases in two. Pfr increases when density dependence DD decreases, and increases when DD decreases. The A-Pun curves show an irregular appearance reflecting the elastic properties of the more and more peripheral airways containing the CP during the expiration. Central and peripheral airways could be detected in each case. In three of four subjects CP at 50%FVC moved to more central airways after bronchodilatation.

Conclusion: The magnitude of Pfr is small, and the study is inconclusive. However, the study indicates that CP moves centrally in 3 of the 4 subjects with bronchodilatation. More experiments are needed.

P867 Lung-packing and stretching increases vital capacity in recreational freedivers
Otto Johansson, Erika Schagaty. Department of Engineering and Sustainable Development, Mid Sweden University, Östersund, Sweden

Introduction: Lung volume is as an important factor for apneic diving performance, with a driver's ratio volume 50% larger than in matched controls. Some of this effect is likely due to predisposition, but elite divers often use stretching and “lung packing” in their training to improve lung capacity. Our aim was to study the effects on vital capacity of a training program involving a series of maneuvers typical of freedivers training.

Methods: Subjects were 13 recreational freedivers with a mean (SD) height; 197cm (8.4), weight; 73kg (13.8), age; 23 years (9.7), training apneic diving in average 1-2 h per week, and 6 matched control non divers. The diver’s lung training involved a set of 5 different lung exercises with yoga and lung packing maneuvers 5 times a week for 11 weeks. Subjects VC was determined before and after the training program using 3 maximal expirations for low VC, with the largest volume used.

Results: Mean (SD) VC had increased across the training period, from 5.9 (1.4) to 6.4 (1.1) L (P < 0.01). An increase in VC was observed in all but 1 subject. In the control group mean (SD) VC was 4.6 (0.7) L in test 1 and 4.7 (0.8) L in test 2 (NS), showing that the effect in divers was likely not due to retesting.

Discussion: The training used by elite divers, involving lung packing and stretching, may improve VC in recreational divers, despite previous dive training. The increase is more than twice as great as that previously obtained with only lung packing (Lindholm et al 2007). The main mechanism responsible could most likely be reduced chest recoil after stretching.

Conclusions: We conclude that vital capacity can be improved by training.

P868 Low-density lipoprotein cholesterol is associated with inspiratory capacity to total lung capacity ratio in AECPD patients
Xiaoming Bi, Li Zhao. Respiratory Department, Beijing institute of Respiratory Medicine, Beijing, China

Introduction: Air trapping leads to a reduction in inspiratory capacity/total lung capacity (IC/TLC) ratio in patients with chronic obstructive pulmonary disease (COPD). Knowledge of the effects of low IC/TLC ratio (IC/TLC <0.25) on nutritional status and respiratory impairment during acute exacerbations of COPD (AECOPD) is limited.

Material/Methods: In 108 patients admitted to the hospital due to an AECOPD (75% median age 72 years [interquartile range 60-85 to 70 years], FEV1 75% of predicted, BMI 24.4±4.5 kg/m2, FEV1/FVC ratio 0.35±0.21), the following data were collected: smoking status, sex, age, BMI, presence of comorbidities (diabetes, hypertension, COPD, asthma), smoking status, obesity, comorbidities, and respiratory symptoms. The results were compared with those of 108 healthy controls (age and sex-matched).

Results: In IC/TLC <0.25, BMI was significantly lower than in IC/TLC ≥0.25 (24.4±4.5 vs 25.5±4.0 kg/m2, p=0.042) and there was a significant difference in smoking status (22% in IC/TLC <0.25 vs 11% in IC/TLC ≥0.25, p=0.042). There was a significant difference in BMI between IC/TLC <0.25 and IC/TLC ≥0.25 (24.4±4.5 vs 25.5±4.0 kg/m2, p=0.042).

Discussion: The results of this study indicate that low IC/TLC ratio is associated with lower BMI, increased smoking status, and more severe disease. These findings suggest that low IC/TLC ratio may be an indicator of more severe disease in COPD patients. Further studies are needed to confirm these findings.

Conclusions: The results of this study suggest that low IC/TLC ratio may be an indicator of more severe disease in COPD patients. Further studies are needed to confirm these findings.
Conclusion: In mild-to-moderate asthmatics, 30min of high-intensity intermittent and continuous NH with humid and warm air resulted in no clinically relevant changes in lung function, airway resistance and reactance. Thus NH by partial rebreathing might be a promising strategy to specifically train the respiratory system of asthmatics.

### P872

**The relationship between long-term correlations (self-similarity) in PEF and FEV1 in COPD**

Gavin Donaldson1, Terence Seemungal2, John Hurst1, Jadwiga Wedzicha1.

1Academic Unit of Respiratory Medicine, UCL Medical School, London, United Kingdom; 2Clinical Medical Sciences, University of the West Indies, St. Augustine, Trinidad and Tobago.

**Conclusion:** Detrended fluctuation analysis (DFA) quantifies the rate of decay in self-correlation in a time series with an exponent “alpha” that is related to COPD exacerbation frequency. The relationship between α of different spirometric parameters in the same individual on the same days is not known.

**Methods:** We examined data from the London COPD cohort on 28 COPD patients who had recorded both FEV1 and FVC and PEF on daily diary cards for 300 days. Measurements were made after medication in the morning. At recruitment, these patients had a mean age (SD): 65.3 (9.3) years; FEV1, 1.08 (0.36) L; FEV1/FVC % predicted 37.3 (14.1); FEV1/FVC ratio 0.43 (12.8). DFA has been described (Frey et al Nature. 438: 667-70, 2005). The analysis was also repeated with data collected during exacerbations removed.

**Results:** The patients had an α of 0.97 (SD 0.22) for PEF, 0.93 (0.22) for FEV1, and 0.95 (0.23) for FVC. No differences was seen in any of the estimates (p>0.24). Figure 1 illustrates the relationship between alpha for FEV1 and PEF (r=0.69; p<0.001). There was no significant difference if data collected during exacerbation data were excluded. PEF α was 0.95 (SD 0.19); FEV1 α = 0.95 (19) and FVC α = 0.97 (SD 0.20).

**Conclusion:** In COPD patients, long-term correlations (self-similarity) exist in daily FVC, FVC and PEF. The estimates of α are similar and linearly related to each other.

### P873

**Feasibility and safety of mannitol challenge in pre-school children using forced oscillation technique**

Aaf Albloushi1, Shannon Simpson1,2, Stephen Stick1,3, Graham Hall1,2,3.

1School of Paediatrics and Child Health, University of Western Australia, Perth, WA, Australia; 2Paediatric Respiratory Physiology, Telethon Institute for Child Health Research, Perth, WA, Australia; 3Department of Respiratory Medicine, Princess Margaret Hospital for Children, Perth, WA, Australia.

**Background:** The mannitol dry powder challenge is used to identify exercise induced bronchoconstriction (EIB) in adults and school-age children. The forced oscillation technique (FOT) is suitable for assessing lung function in pre-school children and can be combined with inhaled challenge testing in this age group.

**Aims:** This study aimed to assess the safety and the feasibility of a mannitol challenge using FOT in young children with asthma and in healthy controls.

**Methods:** Healthy children and children with exercise induced symptoms (EIS group) aged 3-7 years were recruited. A mannitol challenge (Aridol, Pharmaxis, Australia) was performed. A positive response to mannitol was defined as wheeze on auscultation, persistent cough, SpO2 <90% or increase in respiratory system resistance at 8Hz (Rrs8) > 50% from control. The mannitol challenge was considered safe if the child completed the challenge to the final dose or a positive response was noted.

**Results:** To date, 6 healthy and 10 EIS children have been studied. 14 children successfully completed the mannitol challenge with no adverse events. Two healthy children aged 3 years did not complete the test due to lack of cooperation. Three children with reported EIS responded to the challenge with symptoms, and three children responded by an increase in the Rrs8 by >50% from the control measurement.

**Conclusion:** These preliminary results suggest that a mannitol challenge test is feasible in young children and can be performed safely.

**Funded by:** ANZSRS Research Grant, Asthma Foundation WA.

### P874

**Contribution of β2-adrenoceptors to bronchodilatation during exercise in healthy humans**

C. Gulotta1, A. Antonelli1, R. Torchio1, Alberto Terzi1, L. Bertolaccini1, E. Roffo2, L. Dutto3, P. Agostoni1, V. Brusasco1, R. Pellegrino1, J. Malattie Apparato Respiratorio 1, AOU S. Luigi, Orbassano; 2Fisiopatologia Respiratoria, Ospedale S.Croce e Carle, Cuneo; 3SSD Lab FPR e Centro Sonno, AOU S. Luigi, Orbassano; 4Chirurgia Toracica, Ospedale S.Croce e Carle, Cuneo; 5Cardiologia, Ospedale S.Croce e Carle, Cuneo; 6Medicina d’Urgenza, Ospedale S.Croce e Carle, Cuneo; 7Centro, Cardiologico Monzuno, Milano; 8Fisiopatologia Respiratoria, Università, Genova, Italy.

**Background:** Exercise in healthy subjects is usually associated with progressive bronchodilatation, which has been attributed to a decrease of vagal tone.

**Aim:** To examine whether β2-adrenoceptors also contribute to bronchodilatation during exercise in healthy humans.

**Methods:** 14 healthy male volunteers participated in the study. Maximum exercise test was performed at control conditions and after a non-selective β-adrenoceptor blocker (carvedilol 12.5 mg tablets b.i.d until heart rate decreased by 10 beats/min at least) or an inhaled β2-adrenoceptor agonist (albuterol 400 mg through a spacer).

Airway function was estimated from the partial flow at 40% of control forced vital capacity (V’p40) at rest and the slope of linear regression of V’p40 vs. minute ventilation (V‘E) every 2 min during an incremental exercise test until exhaustion.

**Results:** After carvedilol, resting V’p40 was not significantly different from control (2.80±0.98 vs. 2.96±1.38 L s⁻¹) but the V’p40 vs V‘E slope decreased from 0.03±0.019 to 0.01±0.014 L s⁻¹ 1⁻¹ (p<0.05, ANOVA), suggesting less bronchodilator response to exercise. After albuterol, resting V’p40 significantly increased from control to 4.79±1.68 L s⁻¹ (p<0.001) but did not increase further during exercise (V’p40 vs. V‘E slope 0.05±0.012 L s⁻¹ 1⁻¹).

**Conclusions:** In healthy subjects, bronchodilatation during exercise is at least in part mediated by β2-adrenoceptor activation.

### P875

**Ventilation parameters in asthmatic children after one week at 1400 meters altitude**

Alessandro da Ponte, Annarita Tullo, Bruno Grassi, Mario Canciani. Department of Medical and Biological Sciences, Udine University, Udine, Italy Pediatric Clinic, Udine University, Udine, Italy.

**Introduction and background:** Bronchial asthma prevalence is increasing. Many triggers are known but little about protective factors.

**Aims and objectives:** To find out whether 1400 meters altitude could modify ventilation parameters, NO (Nitric Oxide) concentration and clinical symptoms in 13 children after a week of uncontrolled physical activity.

**Methods:** Thirteen asthmatic children were evaluated at arrival and departure from a mountain resort for: FVC, FEV1, FEF 25-75 and exhaled NO concentration. Unscheduled physical activity were encouraged for eight hours daily.

**Results:** All the children showed improvement of FVC, FEV1, FEF 25-75.

**Main ventilation parameters and NO concentration**

<table>
<thead>
<tr>
<th>Main Ventilation Parameters</th>

<td>1.00±0.00 165±16</td>
</tr>
</tbody>
</table>

**p<0.05 test paired two tails.**

**Conclusions:** After a week permanence at 1400 meters resort all subjects showed an improvement in ventilation parameters, together with no episode of asthma exacerbations. This study suggests that physical activity in an healthy environment can be safe and feasible for asthmatic children.

### P876

**Airway resistance in COPD**

Marion Heiß-Neumann1,2, Dorothe Burggraf1,2, Matthias Wjst1,2, Helmholtz Zentrum München, Gausing, Germany; 3Institute for Lung Biology and Disease, Helmholtz Zentrum München, Neuherberg, Germany.

**Background:** Chronic obstructive lung disease is characterized by airflow limitation, usually
assessed by forced expiratory maneuvers (FEV1 and FVC). These maneuvers reflect a complex, dynamic relationship between patient effort, muscle strength, elastic recoil as well as airway resistance, which plays a dominant role in airflow limitation. Within the Emphysema versus Airway Disease study (EvA) we examine postbronchodilator values for total resistance, in- and exspiratory resistance (Rin, Rexp) and specific resistance (rSR) in COPD patients (n= 509; GOLD stage I-III, no current smoking).

Mean postbronchodilator values for total airway resistance are higher in patients compared to controls (0.35 vs 0.19 kPa*sec/L). Looking at Rin versus Rexp, the increase in patients is mainly due to a higher Rin (mean 0.50 versus 0.22 kPa*sec/L) compared to Rin (0.25 vs 0.15 kPa*sec/L). Specific resistance, which is adjusted for volume to avoid errors because of hyperinflation, is elevated as well (1.64 vs 0.71 kPa*sec/L). All reported differences in mean values are highly significant with p < 1*E-15. Mean values for Rin and Rexp are remarkably elevated in COPD and show a good association with GOLD stages, so they may be preferred for monitoring of COPD since they are obtained with tidal breathing.

Supported by EU FP7 project #200605.

P877 The predictive value of inspiratory fraction to exercise capacity in patients with stable moderate to severe chronic obstructive pulmonary disease

Yan Zhang1, Jinning Liu2, Wenlan Yang1, Xiaoqun Tan1. 1Dept of Pulmonary Function Test, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; 2Dept of Respiratory Medicine, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

Objective: To study the relationship between inspiratory-to-total lung capacity ratio or inspiratory fraction to exercise capacity in patients with stable moderate to severe chronic obstructive pulmonary disease.

Methods: Pulmonary lung function test (PFT) and Cardiopulmonary exercise testing (CPET) were performed in 50 patients with stable moderate to severe chronic obstructive pulmonary disease and 34 controls, and measured the parameters of ventilation and gas exchange. The stopped reasons at the end of exercise testing were noted.

Results: (1) IF was significantly associated with peak peak VO2/Spred (r=0.52, p<0.001) in COPD and remained as independent predictor in the final model: peak VO2/Spred = 65.11 + 0.45IF, SEpred = 35.8 (R2 =0.39, p<0.001), the sensitivity and specificity of IF for predicting exercise capacity were both better than FEV1/Spred. (2) The patients with IF<0.23 had more severe hyperinflation and lower exercise capacity. In the peak exercise, the patients with IF<0.23 had lower peak VT than the patients with IF ≥0.23, and their peak breath frequencies had no significant difference.

Conclusion: Inspiratory fraction provides the efficient information to reflect lung hyperinflation and to estimate the exercise capacity in patients with stable moderate to severe chronic obstructive pulmonary disease, and its predictive value is better than FEV1/Spred.

P878 Effect of pulmonary rehabilitation on systemic inflammatory markers, muscle cross section area and functional parameters in interstitial lung disease

Balakrishnan Menon1, Vishal Bansal2, Brijesh Prapajal3. 1Pulmonary Medicine, Vallabhbhai Patel Chest Institute, University of Delhi, New Delhi, India; 2Physiology, Vallabhbhai Patel Chest Institute, University of Delhi, New Delhi, India

Introduction: Intersitial Lung Diseases (ILD) are chronic debilitating diseases with severe exercise limitation. We studied the effect of pulmonary rehabilitation (PR) on systemic inflammatory markers, muscle cross sectional area and other functional parameters in patients of ILD.

Aims and Objectives: To evaluate the levels of C-Reactive Protein (CRP), Matrix Metalloproteinase 9 (MMP9), Tissue Inhibitor of Metalloproteinase (TIMP), 6 minute walk distance (6MWD), Mid high Cross Sectional Area on CT (MTCSAeV) and Carbon Monoxide Diffusion Capacity (DLCO) before and after PR in patients of ILD.

Methods: Fourteen patients of ILD were evaluated at baseline and after 4 weeks of standard therapy. Supervised PR along with standard medications was then given for further 8 weeks. Results: Mean values of CRP changed from 5.76±5.11 to 2.18±1.02 mg/L after rehabilitation [p=0.01]. MMP9 was 838.07±522.37 before and 547.93±108.57 ng/ml after PR [p=0.05]. Mean values of TIMP changed from 182.07±105.07 to 660.47±354.85 ng/ml after PR [p=0.04].

The mean values of 6MWD changed from 379.43±47.94 to 493.78±47.47 m after PR [p=0.001]. Levels of DLCO changed from 6.23±2.45 to 13.87±3.85 ml/min/mmHg after PR [p=0.05]. Mean values of MTCSAeV changed from 802.00±141.96 to 1018.00±1752.10 mm2 after PR [p=0.02].

Significant correlation was obtained between MMP9 and MTCSAeV [r=0.70, p=0.005] and between 6MWD and DLCO [r=0.76, p=0.001].

Conclusion: Pulmonary rehabilitation causes significant improvement in systemic inflammatory markers, muscle cross sectional area and functional parameters in ILD patients along with significant improvement in gas exchange.

P979 The effects of swimming training on alterations in structure and function of sternohyoid muscle of model rats of metabolic syndrome

Liaqing Zhang, Xiaorui Bi, Wanzhen Yao, Jiandong Wang, Bei He. Respiratory and Critical Care Medicine, Peking University Third Hospital, Beijing, China

We investigated the effects of swimming training on alterations in structure and function of sternohyoid muscle in model rats of metabolic syndrome. Male Sprague-Dawley rats were randomly divided into 3 groups: control group (group A), MS group (group B), swimming training MS group (group C). The level of malondialdehyde of sternohyoid muscles in group B was significantly higher than those of group A and group C. The Superoxide dismutase level of sternohyoid muscles in group B was significantly lower than those of group A and group C. The capillary density, capillary-to-fiber ratio (CFR), cross-sectional area of type I and II fiber, percentage of type I fiber of the isolated sternohyoid muscles in group B were significantly lower than those of group A and group C. In group B, mitochondriums were swelling, vacuolization and reduced, myofilibril was dissolved locally. In group C, sternohyoid myofilibril was arranged normally, ultrastructure of mitochondriums was normal roughly, occasionally vacuolization. The tensions of sternohyoid muscle of group B were significantly lower than those of group A and group C. In fatigue test, the tension percentages of sternohyoid muscle of group B were significantly lower than those of group A and group C. We concluded that the abnormalities in histological structure and ultrastructure of upper airway muscle induced by MS, via oxidative stress, led to reduction in contractile function in upper airway muscles, contributing to sleep apnea, and swimming training improved contractile dysfunction of upper airway muscles by inhibiting oxidative stress in MS.

P880 Mechanical ineffectiveness of augmented genioglossus activity in OSA during sleep

Vany Dona1, Giora Pillar2, Luis Gatin1, Arie Oliven1, 1Internal Medicine, Bnai Zion Medical Center, Haifa, Israel; 2 Sleep Laboratory, Rambam Health Care Campus, Haifa, Israel; 3Anesthesiology, Bnai Zion Medical Center, Haifa, Israel

The pathophysiological cause of OSA is sleep-induced decline in dilator muscle activity. However, dilator muscles activity often increases during obstructive apneas and hypopneas (OAHS), but fails to improve airflow. It has been postulated that neuromuscular activity does not increase sufficiently to overcome the negative pressures that develop during obstructed breathing. The present study evaluate this hypothesis.

Methods: Intramuscular GG-EMG, esophageal pressure (Pes) and airflow were recorded in 70 OSA patients. In 6 of the patients, we recorded also EMG of the tongue retractor styloglossus (SG-EMG). While awake, EMGPeas was assessed while patients breathed through a variable resistor, to estimate the EMG required to prevent pharyngeal collapse. During sleep, EMGPeas was evaluated during flow limitation. Pre-arousal peak inspiratory EMG (sleepEMG) was compared to peak EMG at the same Pes during wakefulness (awakeEMG). SleepEMG/awakeEMG (at equal Pes) >1 indicated a level of EMG sufficient to prevent pharyngeal collapse.

Results: Patients had AHII of 51.7±10.5/hr. OAHS triggered increasing negative Pes and increasing GG-EMG. SleepEMG/awakeEMG >1 was observed in all but one patient, with highest (mean of 5 events) ratios of 3.27±1.81. In contrast, SG-EMG maintained tonic activity in 4/6 of the patients during OAHS, and the ratio exceeded 1 in one patient only (0.68±0.58).

Conclusions: In OSA patients, large augmentation of GG-EMG can be observed without improvement in airflow. This mechanical inefficiency is not explained by high inspiratory suction pressures. Co-activation of tongue retractors appears to be reduced during sleep.

P881 Treatment with auto-servo ventilation of patients with sleep-disordered breathing, stable systolic heart failure and concomitant diastolic dysfunction: A randomized controlled pilot study

Background: Systolic heart failure (HF) is frequently accompanied by diastolic dysfunction and sleep-disordered breathing (SDB). We evaluated, whether...
auto-servo ventilation (ASV, BiPAP ASV, Philips Respironics) improves echocardiographic measures of diastolic function in patients with systolic HF and SDB.

Methods: 32 patients with stable systolic HF and concomitant diastolic dysfunction (age 66±9, LVEF 30.7±%, NYHA class II 72%) and SDB (AHI 48±19, 53% OSA) were randomized to either ASV (n=19) or optimal medical treatment alone (control, n=13). Polysomnography and echocardiography was performed at baseline and after 12 weeks.

Results: AHI improved significantly more in the ASV group compared to the control group (42±13.2% vs. 6±3.7%, P<0.001, respectively). Patients who had impaired left ventricular relaxation, and SDB (8% vs. 5%) had a pseudonormalized filling pattern. At the 12-weeks control visit, diastolic function as assessed by the isovolumetric relaxation time (IVRT, 10.3±3.6 ms vs. 9.3±4.2 ms, P<0.05) and deceleration time (DT, 43.9±88.6 vs. 12.4±68.8, P<0.05) did not significantly improve after ASV treatment. Likewise, the proportion of patients whose diastolic dysfunction improved was non-significantly higher in the ASV than in the control group, respectively (37% vs. 15%, P<0.05).

Conclusions: ASV-treatment efficiently abolishes SDB in patients with stable systolic HF and concomitant diastolic dysfunction. These data provide estimates of effect size and support the justification for the evaluation of the effects of ASV in patients with SDB associated with chronic heart failure – A matched control study

P884 CPAP therapy in idiopathic pulmonary fibrosis (IPF) patients with obstructive sleep apnea

Charalampos Mermigkis, Iroide Bouloskui, Katerina Antoniou, Giannis Giannarakis, Demetrios Mermigkis, Nikolao Siafakas, Sophia Schiza.

Sleep Disordered Unit, Department of Thoracic Medicine, University of Crete, Heraklion, Crete, Greece

Background: Recent literature shows an increased incidence of OSA in patients with IPF. However, there are no published studies related to CPAP treatment in these patients.

Aims and objectives: We aimed to assess CPAP effectiveness and adherence in sleep and overall quality of life parameters in IPF patients with OSA.

Methods: Twelve patients with newly diagnosed IPF and moderate to severe OSA were included and CPAP therapy was initiated. The patients completed the Epworth Sleepiness Scale (ESS), the Pittsburgh Sleep Quality Index (PSQI), the Functional Outcomes in Sleep Questionnaire (FOSQ), the Fatigue Severity Scale (FSS), the SF-36 quality of life questionnaire and the Beck Depression scale (BDS) before and 1, 3, 6 months after CPAP therapy.

Results: Statistical significant improvement was observed in the FOSQ at CPAP initiation and after 1 and 3 and 6 months (p<0.05). Improvement, although not statistically significant, was noted in ESS score (p<0.05), PSQ (p<0.04), FSS (p<0.05), SF-36 (p<0.05), and BDS (p<0.05). All patients had risk factors for OSA - age and smoking. Two patients experienced difficulties in CPAP acceptance and stopped usage after the first month. Heat humidification was added in all patients in order to improve compliance.

Conclusion: Effective CPAP treatment, with intense follow up by the CPAP clinic, in IPF patients with OSA, results in a significant improvement in daily living activities based on the FOSQ, namely an OSA specific follow up questionnaire. Improvement, though not statistically significant, was also noted based on other questionnaires, probably related to the multifactorial influences of IPF in physical and mental health.

P885 Obstructive sleep apnea syndrome and cardiovascular diseases risk in patients with COPD

O.S. Khmel’, L.A. Glynya, A.A. Molchanov, V.V. Rodionova. Hospital therapy and Profpathology, Dnepropetrovsk Medical Academy, Dnepropetrovsk, Ukraine

Purpose: To define the correlation between obstructive sleep apnea syndrome (OSAS) and increasing of cardiovascular risk in patients with chronic obstructive pulmonary diseases (COPD).

Design: There were examined 33 patients in the age of 63.9±1.5 years with COPD stage 2 (85%) and stage 3 (15%). Duration of disease was 10-14 years. - 22 patients (62%) and 15-24 years – 11 patients (33%). 60% of patients were smoking, 40% - of smoking - 14,7±0,48 pack-years. Control group included 10 practically healthy persons.

Methods: Holter monitor test with theopheneurometry, spirometry, X-ray examination, six-minute walk test, calculation of cardiovalvular insufficiency, calculation of occurrence of atrial fibrillation (AFib).

Results: There were revealed correlations between duration of apnea cases and cardiovascularcheological risk in patients with chronic obstructive pulmonary diseases (COPD).

Conclusion: Patients with both COPD and OSAS have evidently increased risk for fatal complications.

P886 The frequency of overlap syndrome in patients who were evaluated in sleep laboratory and its effects on severity of obstructive sleep apnea syndrome and quality of sleep

Banu Salareci, Ali Fidan, Nesrin Kiral, Elif Torun Parmaksiz, Gulsen Sarac, Sevda Sener Comert, Benan Caglayan. Chest Diseases, Dr. Lutfi Kirdar Kartal Teaching and Research Hospital, Istanbul, Turkey

‘Overlap Syndrome’ is the coexistence of Obstructive Sleep Apnea Syndrome (OSAS) with Chronic Obstructive Pulmonary Disease (COPD) and asthma. We aimed to determine frequency of COPD and Asthma in OSAS patients and effect of these diseases on quality of sleep and severity of OSAS. The frequency of overlap syndrome in patients who were evaluated in sleep laboratory and its effects on severity of obstructive sleep apnea syndrome and quality of sleep

Banu Salareci, Ali Fidan, Nesrin Kiral, Elif Torun Parmaksiz, Gulsen Sarac, Sevda Sener Comert, Benan Caglayan.
in the sleep laboratory in January 2005-January 2010 were analysed. All cases were examined for COPD, Asthma and severe daytime sleepiness according to Epworth Sleepiness Scale (ESS),Pulmonary function tests and polysomnographic tests were administered to all. For diagnosis of COPD, GOLD criteria, for EGG scoring, Rechtschaffen - Kales criteria and for respiratory scoring, AASM 1999 criteria were used. Out of 998 cases 98.2% were diagnosed as OSAS, 11.1% COPD,6.6% asthma,11.2% of OSAS cases had COPD. Age, frequency of male sex and ESS were significantly higher in patients with OSAS and COPD than patients with OSAS-without COPD. No significant differences in terms of BMI and sleep parameters were found in OSAS+asthma cases (6.7%) - BMI, frequency of female sex and ESS were found to be significantly higher than in patients with OSAS-with asthma, no statistical differences were found in terms of sleep parameters. In older male patients with OSAS+COPD is more frequent than in younger female patients. Asthma is more frequently seen in OSAS than general population. In asthmatics, sleep efficiency is lower, thermore ESS is higher. No relation between severity of OSAS and presence of COPD or asthma was determined. In patients with OSAS, symptoms of COPD and asthma must be questioned and pulmonary function tests administered.

P887

Risk factors of hypercapnia in patient with obstructive sleep apnea

Jihen Ben Amar, Leila El Gharti, Besma Dhaht, Mohamed Ali Baccar, Sabina Azhizi, Hichem Assina, Hend Bouacha. Pulmonary Department, Charles Nicolle Hospital, Tunis, Tunisia

The severe obesity sometimes leads to a chronic alveolar hypventilation: obesity hypventilation syndrome (OHS). The association with OSAS is frequent. Aim: The aim of the present study is to specify favorising factors that lead to hypventilation in a population of obese persons with SAS and to deduce the type of association between OHS and SAS. Methods: 62 patients were enrolled. We excluded patient with bronchial obstruction and we have compared anthropometric, functional, gasometric and polysomnographic details of the group 1 (G1): OHS+ and of the group 2 (G2): obesity without hypventilation=53. Results: We haven’t identified a difference between the two groups concerning age, sex, frequency of smokers, nasopharynx region abnormalities, AHAS severity and the respiratory functional exploration. We noted that there is a positive interrelation between BMI and Paco2. We identified severe gasometric perturbation in G1 (Paco2=61±17.4 mmHg) versus G2 we noted a moderate hypoxemia. Patients of the group 1 make minimal desaturation of 63±17% and a SaO2 average of 81±20% what is meaningfully important than in the G2.

Conclusion: The alveolar hypventilation in SAS seems to be in correlation with the degree of obesity. The hypcapnia in the OHS is related neither with the SAS nor with obesity. The OHS-SAS association is usual but not syncronous, OHS is an autonomous disease.

P888

The impact of OSA on nocturnal hypoxia in obese patients with chronic asthma

Abdul-Jamiesh J., Ajit Thomas L., Shahirad Taherii A., Adel Mamar B., Deb Banerjee C.

1 The Severe and Bristle Asthma Unit, Birmingham Heartlands Hospital, Birmingham, West Midlands, United Kingdom; 2 The Academic Department of Sleep and Ventilation, Birmingham Heartlands Hospital, Birmingham, West Midlands, United Kingdom; 3CEDAM, University of Birmingham, West Midlands, United Kingdom

Background: There is increasing evidence that asthma, obesity and OSA co-exist with resulting increased usage of health care resources. This cohort may have worse asthma control due to increased nocturnal hypoxia augmenting airway and systemic inflammation. The prevalence of OSA and degree of hypoxia in obese patients with asthma remains unclear. Methods: A retrospective survey of obese patients with chronic asthma referred to the sleep clinic between 2009-2010 undergoing overnight sleep monitoring. Male sex was undertaken using RemLogic software (in-hospital polysomnography). Scoring of the respiratory data was as per American Academy of Sleep Medicine (AASM) guidelines 2007. OSA was defined as an apnoea/hypopnoea index (AHI) of ≥5/hour and moderate-severe as ≥15/h.

Results: 26 patients (19 females) were analysed. Mean (SD) BMI =45.2 (10.8)kg/m². Mean (SD) age=45±12.2years. Six had Type 2 Diabetes Mellitus and had hypertension. OSA was found in 12 (46%), 7 (27%) had moderate severe asthma. Those with OSA were more likely to have T3DM (31% vs 12%). There was no significant difference in BMI between the two groups. Those with OSA: (median (IQR))AHI=21.5 (13.45)/yr were more hypoxic during the night compared to those without OSA (AHI=2 (0.93)/yr). Mean nocturnal O2 sats (Mean (SD)): 91.6% (3.4) vs 95.3 (1.2), P=0.003, minimum O2 sats: 80.1% (11.8) vs 90.5% (2.0), P=0.001.

Conclusions: OSA is common in obese patients with chronic asthma. Patients with OSA in this group were more hypoxic during the night. Clinicians looking after obese chronic asthma patients should consider screening for OSA. Prospective studies are required to further establish the prevalence of OSA in obese asthmatic patients, and the value of CPAP in this group.

P889

Complex approach in the study of clinical and functional features in patients with severe bronchial asthma with and without respiratory disorder during sleep

Liudmyla Iashyna, Yuriy Feshchenko, Svitolina Moksalenko, Inna Zvol, Irina Chumak. Diagnostic, Therapy and Clinical Pharmacology of Lung Diseases, National Institute of Phthisiology and Pulmonology named after F.G. Kanovsky NAMS of Ukraine, Kiev, Ukraine

Aim of study: Comparison of clinical and functional diagnostic criteria in patients with severe bronchial asthma and in combination with obstructive sleep apnea

Materials and methods: 60 patients with severe asthma were divided into 2 groups: 1 group of patients with OSA were 30 patients (16 women and 14 men age (58±2.2) years) and II group of patients without OSA consisted of 17 women and 13 men age (50±2.1) years. In both groups PEV1, ranged from 54±3.1 to (58±2.6) months. The following studies were performed: respiratory function, polysomnography, diurnal blood pressure measurement. Holter monitoring of ECG.

Results: Asthma Control Test score revealed that patients with OSA had poor control of asthma symptoms (15±0.4) compared to patients without OSA (18±0.4) and higher scores for breathlessness on MRC8. Results of the questionnaire of OQ9 revealed that patients with OSA had more symptoms due to asthma and significant limitation of activity (67±1.3) than patients without OSA (60±2.6) (-p<0.05). Patients with OSA had an increase in pulse blood pressure, minimum of daily, a maximum of night, and a marked increase in the average heart rate per night, the increase variability in blood pressure. In the night period, compared with patients without OSA, p=0.05.

Conclusion: The use of a wide range of diagnostic methods will allow for an adequate pathogenetic treatment and improvement of disease control in patients with severe asthma and in combination OSA.

P890

Cardiopulmonary exercise response in children with obstructive sleep apnea syndrome

Labeni Damjanidou1, Andreas Giannopoulos 1, Maria Eboriadou1, Katerina Hadjopoulou 1, Fotis Kivassilis 1, Kalliopi Kontoudi2, Ioannis Tzanakas2, Fani Athanasiadou1. 1 2nd Department of Pediatrics, AHEPA Hospital, Aristotle University, Thessaloniki, Greece; 2 3rd Department of Pediatrics, Ivykastro Hospital, Aristotle University, Thessaloniki, Greece; 3 4th Department of Pediatrics, Papageorgiou Hospital, Aristotle University, Thessaloniki, Greece

Introduction: Cardiopulmonary exercise testing (CPET) is a valuable tool in the evaluation of cardiac and pulmonary function. In adults’ patients with obstructive sleep apnea syndrome (OSAS), recent studies addressed reduced exercise capacity, but there is no data in literature for pediatric patient. Aim: To evaluate cardiopulmonary response to exercise in children with OSAS.

Methods: Twenty seven subjects, without any systematic disease, aged 7 to 14 years (mean age 10.5±1.8 years), referring for evaluation of systematic snoring (>4 nights/week), underwent overnight polysomnography (PSG) and CPET. According to the Apnea Hypopnea Index (AHI) subjects were divided into two groups: A. mild OSAS (1≤AHI<5, n=15). B. moderate – severe OSAS – (AHI≥5, n=12). Control group (group C) consisted of 13 children.

Results: There were no significantly differences in age, sex, BMI among groups (p>0.05). Mild OSAS had 55.6% of children (group A) and moderate to severe 44.4% (group B). According to CPET children with OSAS had shorter duration of exercise (12.4±2.6min vs 13.3±2.5min), significantly lower VO2max (30.4±3.8 mg/kg/min vs 47.6±7.9 mg/kg/min, p=0.013), significantly lower VO2max (%) (77.4±15 vs 92.9±10.5, p=0.002), higher VO2 (%) (46.2±14.7 vs 43.7±1.9) and higher systemic blood pressure level at peak exercise (145±27.4mmHg vs 143.9±20.2mmHg) compared to control group. Children with mild OSAS had higher VO2max (%) (80.8±9.3 vs 73.8±11.7) but not statistically significant compared to moderate - severe OSAS.

Conclusion: The present study demonstrates that young patients (mean age 10.5±1.8 years) with and without mild OSAS, had reduced exercise capacity (lower VO2max) as compared to control group.
Obstructive sleep apnea in patients with idiopathic pulmonary fibrosis
Ahmed Sh. Mohamed1, Ibrahim Ibrahim2, Mohamed Hantera1, 2
1Chest Department, Tanta University Hospital, Faculty of Medicine, Tanta, Gharbia, Egypt; 2Chest Department, Tanta University Hospital, Faculty of Medicine, Tanta, Gharbia, Egypt

Background: The outcome of patients with idiopathic pulmonary fibrosis (IPF) is poor. Breathlessness and coughing are usually progressive and about 50% of the patients die within 3 years after diagnosis. The role sleep disordered breathing in IPF should be investigated.

Objective: The aim of this study was to investigate obstructive sleep apnea and associated daytime sleepiness in IPF patients and investigate the correlation between IPF and OSA.

Subjects and methods: 28 patients with IPF and 10 control subjects matched on age and BMI were included in the study. Sleep quality and its daytime consequences were assessed by the Epworth Sleepiness Scale and all-night polysomnography.

Results: 23 patients had an abnormal ESS (82.1%). 24 IPF patients (85.71%) had OSA; 21 patients (75%) had mild-to-moderate OSA, and 3 patients (10.71%) had severe OSA. AHI was statistically significantly correlated with, ESS, FVC, and TLC.

The prevalence of OSA in IPF patients

<table>

<td>14.29</td>
</tr>
</tbody>
</table>

Conclusion: Patients with IPF are at high risk for OSA that may account for reversible daytime fatigue, possibly wrongly ascribed to IPF. Further, without treatment the sleep deprivation and lack of oxygen caused by sleep apnea increases health risks that have a significant negative effect on prognosis of IPF that already carries a poor prognosis.

Recommendation: Sleep evaluation should be extended to IPF patients routinely and the scientific work should focus on the improvement of sleep quality during sleep and day time.

CPAP versus adaptive servoventilator (ASV) in patient with congestive heart failure and sleep disorder breathing
Donato Lacedonia1, 2, Massimo Iacoviello2, Felice Gadaleta3, Vito A. Falcone3
1Department of Medical and Occupational Science, Institute of Respiratory Medicine, Tanta, Gharbia, Egypt; 2Chest Department, Tanta University Hospital, Faculty of Medicine, Tanta, Gharbia, Egypt

Objectives: The aim of this study was to evaluate the effects of nocturnal ventilation by two different ventilatory support: CPAP or Adaptive Servo Ventilator (ASV) in patients with heart failure and sleep disorder breathing, in particular on echocardiographic parameters.

Methods: Ambulatory patients with congestive heart failure were screened for presence of Sleep Disorder Breathing (SDB). After a full night polysomnography the patients were divided in OSA, CSA-CSR or noSDB. All patients with SDB were titrated at the begin by CPAP but if CSA-CSR occurred or was not resolved they were switch to ASV.

All patients were evaluated at baseline and after six month of treatment by echocardiographic study and clinical evaluation.

Results: 52 patient were enrolled, age was 63.2±10.06, FE 31.2±8.9. Of them 13 patient (25%) were no SDB,21 were OSA (40%) 18 were CSA-CSR (35%). There was no differences among groups according to age, FE, TAPSE and NT-proBNP. All patients with SDB were admitted to nocturnal ventilation: 14 received CPAP, 16 received ASV while 9 refused treatment. After 6 months, any change was obtained in FE and NT-pro-BNP and in TAPSE, as well as on the other echocardiographic parameters in all groups.

Conclusion: In patients with CHF sleep disorder breathing are very common, however CPAP o ASV nocturnal ventilation have no impact on improvement of echocardiographic parameters.
Background: Recent data suggested that obstructive sleep apnea (OSA) is an important contributor of severe uncontrolled asthma. This study was aimed to investigate clinical features including asthma control, quality of life and airflow inflammation in adult asthmatics with high OSA risk.

Methods: A total of 217 patients with asthma who visited tertiary-care clinic were randomly recruited in this study. They completed Berlin questionnaire validated for Korean population. Patients with high OSA risk showed significantly older age, higher prevalence of hypertension, higher BMI, and non-atopic predisposition. High risk OSA group showed lower ACT score than low OSA risk group, but it was not statistically significant. The expressions of I-κB, IL-18, IFN-γ, and IL-23 were increased with intermittent hypoxia in high OSA risk group than low OSA group.

Conclusion: Asthma-related quality of life is significantly decreased in adult asthmatics with high OSA risk. Further studies are required to clarify the exact mechanism of asthma deterioration in OSA patients with high risk of hypoxia and inflammation.
Concerning APAP parameters, the 95-percentile pressure (P95) was lower in patients with positional OSA (p=0.003). Leaks and residual AHI were not different between the two groups.

Conclusions: We found a high prevalence of positional OSA in patients with mild to moderate OSA. Most patients with positional OSA were not compliant to therapy with APAP (64.7%). So, despite continuous positive airway pressure is considered the gold standard treatment of OSA, patients who did not have compliance should be encouraged for positional therapy.

P900

Automatic computation of apnea–hypopnea index in patients with sleep apnea based on multivariate adaptive regression splines

Felix del Campo 1, Roberto Hornero 2, Victor J. Marcos 2, Daniel Alvarez 2, María Gonzalez 2, 1Medicina, Dermatología y Toxicología, Universidad de Valladolid; 2Biomedical Engineering Group, E.T.S.I. Telecomunicación, University of Valladolid, Spain; 3Servicio Neurológico, Hospital Río Hortega, Valladolid, Spain

Nocturnal polysomnography (PSG) is the gold standard for SAHS diagnosis. Despite its high diagnostic performance, PSG presents some drawbacks since it is complex, expensive and time-consuming. Simplified diagnostic techniques are desirable.

This study proposes a novel method to estimate the AHI based on automated analysis of oxygen saturation data using signal-processing methods as multivariate adaptive regression splines (MARS).

Patients and methods: 240 patients were included in the study. The patients were randomly divided into a training set with 96 patients (52 non SAHS and 44 SAHS) and a test set (60%) with 144 patients (48 non-SAHS and 96 SAHS). Oximetric recordings were parameterized by means of 14 characteristics from four feature subsets: time domain statistics, frequency domain statistics, spectral and nonlinear feature. Regression analysis was performed to estimate the functional relationship between the extracted features and the AHI. Multiple linear regression (MLR) and MARS were evaluated.

Results: The MARS algorithm achieved the highest performance with an intraclass correlation coefficient (ICC) of 0.90 (0.87-0.93), and MLR of 0.80 (0.74-0.85).

The highest accuracy of both algorithms was achieved for a decision threshold of 30 h-1, which represents a more conservative definition of SAHS. The MARS provided a correct decision rate of 93.75% (97.70 – 89.80) whereas the MLR model achieved 90.28 (95.12 – 85.64). Fig. 1 show Bland-Altman plots for MLR and MLP models.

Conclusions: The proposed MLP-based method could be used as an accurate alternative for SAHS diagnosis. Our results indicate a high agreement between actual and predicted AHI by MARS.

P901

Correlation of total sleep time (TST) by SenseWear Armband (SWA) and nocturnal polysomnography (NPSG), in a population with and without OSA

A. O'Brien, A. McGowan, L. Stewart, K. Fennell, K. Bolger, J. Faul, L. Cormican. Dept. of Respiratory and Sleep Diagnostics, Connolly Hospital, Dublin 13, Ireland

Portable devices that determine TST may act as an adjunct to level 3 diagnostic devices. The SWA is such a device, and measures TST using a proprietary algorithm. Calculation of TST could improve the accuracy of a level 3 diagnostic device.

Aims: Correlation of TST by SWA and NPSG, in a population with and without sleep apnoea.

Methods: 89 consecutive patients undergoing NPSG because of a suspicion of OSA were an SWA on the same night. Patients were stratified by the presence and severity of OSA. Correlation coefficient for TST were determined between SWA and NPSG for all subjects and in the OSA subgroups.

The prevalence of normal PSG, mild moderate and severe OSA was 22 (24.7%), 31 (34.8%), 12 (13.4%) and 24 (26.9%) of 89 subjects. and the respective correlation coefficients were r=0.66, 0.74, 0.85 and 0.25. Clinically important differences are presented with Bland-Altman plots (Fig. 1 & 2).

Correlation of TST between the two methods was weakest in those with severe OSA. The determination of TST by SWA in a population with severe OSA is likely to be unreliable. NPSG remains the gold standard for determination of TST.
Methods: Between March-September 2010, the patients were submitted to an questionnaire. The sleep study was carried at home, with the Apnealink® device (AL). The Apnea/Hypopnea Index (AHI) was defined as suggestive of SAHS for AHI ≥ 5 event/hour (e/h) and classified as mild (AHI 5-14), moderate (AHI 15-29) and severe (AHI ≥ 30). According to the result of the AHI and the patient’s symptoms, they were referred for treatment.

Results: 118 patients, after the exclusion of 32, 52.7% were male, mean age of 58age ± 7 years. The average body mass index was 29.8±4.5 kg/m² and hemoglobin glycosylated 0.1% 7.2±1.7. There was a history of high blood pressure in 76.8%, Dyslipidemia in 54.6%, Ischemic heart disease in 8%. The patients complained, either frequently or occasionally, of snoring 56.6%, waking up 47%, poor sleep quality 35%, and witnessed apneas 17%, with a Scale of Epworth of 5.6±6.4. The mean AHI of the AL was 1.19±1.11 e/h (0.55). The AHI ≥ 5 was observed in 70.3% of the patients, 29% had AHI 15-29 and 9% AHI ≥ 30.

Conclusion: In our sample we find one high percentage of studies suggestive of SAHS, both mild, moderate and severe. The AL can be a useful tool for the screening of SAHS in patients with DM2 in collaboration with the PC.

P907

A portable device for assessment of daytime sleepiness
Miaofang Liu, Yunming Lai, Nianshan Zhong. State Key Laboratory of Respiratory Disease, Guangzhou Medical College, Guangzhou, China

Many studies have shown that sleepiness is a major cause of traffic accidents. Patients with obstructive sleep apnea usually have daytime sleepiness. Ewepth sleepiness scale has been used to subjectively assess daytime sleepiness in patients with OSA, but it was far from perfect. Osler test was a useful alternatively objective test for daytime sleepiness and has been used in clinical practice. However, Osler test was usually performed in hospital. It is important to develop an easy-to-use portable device to assess daytime sleepiness at home. We have recently developed a portable device based on the principles of Osler test. The purpose of the present study was to determine whether the onset of sleep detected by our portable device was the same as that detected by conventional polysomnography. Eight patients with OSA and eight normal subjects were studied. Sleep latency as judged by portable device was the same as that judged by conventional polysomnography and sleep latency measured from patients with OSA (18.1±9.1 minutes) was significantly shorter than that measured from normal subjects (> 40 minutes), p<0.01. In conclusion, the portable device designed for use at home was as useful as conventional polysomnography in assessment of daytime sleepiness. This work was funded by NSFC (Grant No. 8112108001).

P908

The use of bispectral index (BIS) as a marker of sleep staging
Christina Estrada1, Nina Grau1, Encarna Guardiola1, Miquel A. Feix1, Carlos Sauleda1, Lluís Guitart1, Josep Cornet2, Albert Alonso-Fernandez, Eusebi Chiner, Francisco-José Vázquez-Polo, Jose Maria M. Montserrat.

BIS values decrease during sleep and change according to its stages. BIS values below 70 have a high sensitivity and specificity for detecting deep sleep. To analyze the impact of Portapres BP measurement on sleep quality during overnight PSG recordings with additional Portapres monitoring and 20 gender randomly with or without simultaneous Portapres BP measurement. The results of this pre-study suggest that Portapres BP measurement during overnight PSG does not have a clinically relevant impact on sleep quality and might therefore be a good diagnostic tool for future research on HT and BP changes in sleep apnea.

Introduction: Automatic home respiratory polygraphy (HRP) scoring functions can potentially confirm the diagnosis of sleep apnea-hypopnea syndrome (SAHS)
(obviating technician scoring) in a substantial number of patients. The result would have important management and cost implications.

**Objectives:** To determine the diagnostic cost-effectiveness of a sequential HRP scoring protocol (automatic and then manual for residual cases) as compared to manual HRP scoring, both with in-hospital polysomnography.

**Methods:** We included suspected SAHS patients in a multicentric study and assigned to home and hospital protocols at random. We constructed Receiver Operating Characteristic (ROC) curves for manual and automatic scoreings. Diagnostic agreement for several cut-off points was explored and costs for two equally effective alternatives were calculated.

**Results:** Of 366 randomized patients, 348 completed the protocol. Manual scoring produced better ROC curves than automatic scoring. There was no sensitive automatic or subsequent manual HRP apnea-hypopnea index (AHI) cut-off point. The specific cut-off points for automatic and subsequent manual HRP scorings (AHI>10 in both) had a specificity of 88% and 97%, respectively. The costs of manual and sequential HRP protocols were similar but less than the half that of polysomnography.

**Conclusion:** A sequential HRP scoring protocol is a cost-effective alternative to polysomnography, although with a marginal cost savings compared to HRP manual scoring.

**P910**

**Nasal pressure variation measurement with a microphone: A new low cost tool for diagnosis of obstructive sleep apnoea in a resource poor setting**

Chatura Wirasinghe1,2, Shirini Godiriwathage3, Dushantha Madgedera4,5,6,7,8

1Respiratory Medicine, Teaching Hospital, Kandy, Central Province, Sri Lanka; 2Emergency, Teaching Hospital, Kandy, Central Province, Sri Lanka

**Background:** Lack of polysomnography in Sri Lanka leads to under investigation of OSA. Nocturnal saturation (SpO2) was used instead. Pressure variations due to turbulent flow through nose measured by a microphone fixed to a nasal cannula can be demonstrated to be proportional to nasal air flow, which allows calculation of obstructive events (OEs).

**Objective:** To test if nasal pressure variation measurement increases accuracy of diagnosis of OSA than SpO2 alone.

**Method:** 31 patients with clinical features of OSA were enrolled. Their overnight nasal pressure variations were picked up by a microphone fixed the distal end of a nasal cannula. The microphone signal was processed with elimination of baseline noise, and airflow measurements were derived. Airflow was analyzed together with SPO2 to calculate AHI.

**Results:** The Epworth sleepiness scale (ESS) of patients ranged 0 to 19 (mean 8) and Mallampati grade (MG) ranged 1 to 4 (mean 2). The mean BMI was 28.4 ± 3.1 kg/m2 (range 20.4 to 40.48). The oxygen desaturation index (ODI), the number of desaturations per hour, ranged 0 to 15 (mean 2). The mean AHI was 8 (range 0 to 40). AHI significantly correlated with ODI (Pearson correlation coefficient = 0.63 p< 0.00). 13 patients were diagnosed with OSA using AHI. ODI alone would result in 4 true positive, 9 false negative and 2 false positive diagnosis of OSA.

**Conclusions:** Nasal pressure variation measured by a microphone can be combined with SPO2 to increase accuracy of diagnosis of OSA in patients with clinical likelihood, in a resource poor setting. Further validation this technique may be used for a low cost portable home based apparatus to derive AHI.

**P911**

**STOP-Bang questionnaire as a preoperative screening tool for obstructive sleep apnoea in bariatric surgery patients**

Ali Khodabandeh1, Ryan Chua1, Antonio De Gorordo Arzamendi1, Elizabeth’s Medical Center, Tufts University, Boston, MA, United States

**Introduction:** STOP (snoring, tiredness, observed apnea, high blood pressure) questionnaire is a screening tool to identify surgical patients with high risk of obstructive sleep apnoea (OSA). Incorporating BMI, age, neck size, and gender (Bang) has been shown to further increase the sensitivity and negative predictive value. The STOP-Bang questionnaire has not been validated as a screening tool for OSA in patients undergoing bariatric surgery.

**Method:** We retrospectively reviewed prospective data on bariatric surgery patients. Patients were asked to answer the STOP-Bang questionnaire during their preoperative assessment. The BMI, age, neck circumference and gender were documented. All patients underwent overnight polysomnography as one of the assessments prior to bariatric surgery.

**Results:** A total of 49 patients were included. The mean age was 42±12.2 years; 29% males; BMI 48±8.2 kg/m2. We classified 43 patients (88%) as high risk based on the STOP-Bang questionnaire (23 positive responses). A total of 36 patients (73%) were diagnosed with OSA (AHI>5); 13 patients as mild, 10 patients as moderate (30<AHI<15) and 13 patients as severe OSA (AHI>30). The sensitivity of the STOP-Bang questionnaire for all OSA patients (AHI > 5) and for moderate and severe OSA patients (AHI > 15) was 92% and 100%, respectively. The specificity was 33% and 23%. The positive predictive value was 81% and 54%. The negative predictive value was 57% and 100%.

**Conclusion:** The preliminary results of the STOP-Bang questionnaire suggest a high sensitivity to detect bariatric surgery patients with obstructive sleep apnea. The negative predictive value was high only in patients with moderate and severe OSA.

**P912**

**Overnight pulse propagation time derivation from oximetry is associated with daytime blood pressure in patients with sleep apnoea**

Ludger Grote1, Dirk Sommermeyer1,2, Ding Zou1, Derek Eder1, Joachim Ficker1, Winfried Randerath1, Ingo Fietze2, Bernd Sanner3

1Institute for Monitoring, Diagnosis and Assistance, SRH University Heidelberg, Heidelberg, Germany; 2Institute of Pulmonary Medicine, Carl-Thiem-Klinikum, Gothenburg, Sweden; 3Institute of Monitoring, Diagnosis and Assistance, SRH University Heidelberg, Heidelberg, Germany; 4Dept. of Pulmonary Medicine, Clinical Nürburg Nord, Nürburg, Germany; 5Dept. of Pulmonary Medicine, Bethanien Hospital, Solingen, Germany; 6Dept. of Cardiology, University Hospital Charité, Berlin, Germany; 7Dept. of Pulmonary Medicine, Bethesda Hospital, Wuppertal, Germany

**Introduction:** The state of sleep is characterized by unloading of the autonomic nervous system and represents an opportunity to investigate the properties of the cardiovascular (CV) system. We investigated overnight pulse propagation time (PPT) as an indirect measure of vascular stiffness during sleep and its association with daytime blood pressure (BP).

**Methods:** The digital pulse wave, derived from finger oximetry, was recorded during sleep in 495 subjects (169 females, age 54±12 y, BMI 30.6±9.6 kg/m2, AHI 19±4.23 h) referred to five sleep centers. Office BP and established CV risk factors were assessed. PPT was calculated as the time between the top and the subsequent diastolic notch of the digital pulse wave. Mean PPT across the entire sleep period was calculated.

**Results:** PPT was associated with age, systolic BP, diastolic BP, the number of apneas as well as hypoxic events during sleep (r=0.54, 0.19, -0.21, -0.13, and -0.11, p<0.01 respectively). PPT was lower in patients with hypertension compared to normotensive (160±34 ms vs. 178±47 ms, p<0.01). In a multivariate analysis, PPT was independently associated with age, height, waist, smoking, hypertension and diabetes but not sleep apnea indices.

**Conclusions:** PPT determined by overnight oximetry reflects daytime BP and presence of hypertension. Assessment of PPT during sleep may be a useful tool for classification of overall CV function and risk.

The study was supported by Weinmann GMBH, the Swedish Heart and Lung Foundation and the University of Gothenburg.

**Development of a new scale to evaluate sleepiness in obstructive sleep apnea (OSA): The Barcelona sleepiness scale (BSS)**

Marc Gasull1,2, Montse Romero-Cardos2, Manuel Salamanro2, Isabel Vilaseca2, Josep M. Montserrat3, Cristina Embid4,5, Alejandro Iranzo4, Joan de Pablo6,7,8

1Neurology, Hospital Clinic, Barcelona, Spain; 2Clinical Psychology and Psychiatry, Hospital Clinic, Barcelona, Spain; 3Otorhinolaryngology, Hospital Clinic, Barcelona, Spain; 4Pneumology, Hospital Clinic, Barcelona, Spain

**Background:** Excessive daytime sleepiness (EDS) is a common problem with serious consequences for health and social activities of the patients. There is no simple method to reliably quantify sleepiness. Objective methods (Multiple Sleep Latency Test, MSLT; Maintenance of Wakefulness Test, MWT) and subjective ones (Epworth Sleepiness Scale, ESS) are poorly correlated.

**Aim:** To develop and validate a new sleepiness scale for clinical use in OSA.

**Methods:** Generation of items: 30 consecutive patients with OSA and their partners were interviewed using focus group techniques and cognitive interviews generating a preliminary list of sleepiness items. This list was reduced to 16 common items. A composite of MSLT and MWT was calculated as an objective criterion of sleepiness. Exhaustive regression analysis of all the subsets of the list was performed. Mallow’s Cp minimization was used to choose the best item combination.

**Results:** Two items (In the morning, when I get relaxed & In the afternoon, while standing in a line) achieved the minimum Cp score and comprised the BSS. The correlation between the BSS and the composite score of MSLT and MWT was 0.51, much higher than that found with ESS (0.23).

**Conclusion:** Our data suggest that the BSS, a simple sleepiness scale of 2 items, shows the best correlations with objective tests.

Support by R01AT00318.

**The role of desaturation index evaluated by nocturnal pulse oximetry in recognition of sleep apnea syndrome in patients with morbid obesity**

Ioan Dumitrache-Rujinski, George Calciulai, Dragos Zaharia, Alina Croitoru, Miron Bogdan

1Dept. of Pulmonary Medicine, Teaching Hospital, Kandy, Central Province, Sri Lanka; 2Neurology, Teaching Hospital, Kandy, Central Province, Sri Lanka

**Introduction:** The nocturnal pulse oximetry is used as a validated screening tool for the diagnosis of obstructive sleep apnea syndrome (OSAS) in patients with morbid obesity. The nocturnal pulse oximetry is used as a validated screening tool for the diagnosis of obstructive sleep apnea syndrome (OSAS) in patients with morbid obesity.

**Method:**We retrospectively reviewed prospective data on morbid obesity patients. Nighttime oximetry was recorded with a pulse oximeter. A combined oximetry and sleep apnea apnea index was derived as the product of AHI and the percentage of time below 90% SPO2.

**Results:** A total of 34 patients were included (23 females, age 48±14 years). The mean AHI was 31±9 h. The mean percentage of time below 90% SPO2 was 15±5%. The correlation between the AHI and the percentage of time below 90% SPO2 was 0.73 (p<0.001).

**Conclusion:** The nocturnal pulse oximetry is used as a validated screening tool for the diagnosis of obstructive sleep apnea syndrome (OSAS).

The diagnostic value of self-reported symptoms for the detection of sleep apnea syndrome in stroke patients
Jannke Nachegaal, Justine Aaronson, Emmy Groot, Tijis van Beezijj, Coen van Bennekom. Research & Development, Meliome, Wijk aan Zee, Netherlands

Introduction: Sleep apnea syndrome (SAS) is a common sleep disorder in stroke patients and associated with decreased functional recovery, increased risk of recurrent stroke and mortality. Despite the high prevalence and poor functional outcome, no guidelines for SAS screening in stroke rehabilitation are available.

Objective: This study evaluated the predictive value of a self-report symptom questionnaire, socio-demographic and clinical variables for detection of stroke patients with a high risk of SAS.

Methods: 306 stroke patients were screened with pulse-oximetry to determine their oxygen desaturation index (ODI). An ODI ≥ 15 was classified as a high risk of SAS. Potential predictors included socio-demographic variables, disease characteristics (history of stroke, hypertension), and self-reported symptoms (snoring, apneas, restless legs, morning headaches, waking up feeling unrefreshed, daytime sleepiness, falling asleep during daytime, fatigue, concentration loss, irritability and mood changes). With univariate logistic regression analysis, the associations between potential prognostic indicators and the primary outcome of ODI ≥ 15 were examined. Significant variables (p-value ≤ 0.20) were selected for a backward multivariate logistic regression and checked for co-linearity.

Results: The high risk of SAS was predicted by gender, body mass index, systolic blood pressure and the presence of the self-reported symptoms apneas, snoring, restless legs, morning headaches, waking up feeling unrefreshed, daytime sleepiness, falling asleep during daytime, fatigue, concentration loss, irritability and mood changes. The associations between potential prognostic indicators and the primary outcome of ODI ≥ 15 were examined. Significant variables (p-value ≤ 0.20) were selected for a backward multivariate logistic regression and checked for co-linearity.

Conclusion: The diagnostic value of self-reported symptoms SAS alone is very low in stroke patients. Therefore, socio-demographic and clinical variables should be included in the screening of SAS in stroke rehabilitation.

Analysis of BMPR2 mutations, and endothelin-1 and nitric oxide synthase genes polymorphisms in pulmonary arterial hypertension
Diana Valenzuela1, Adolfo Balona2, Guillermo Pousada1, Marta Núñez2, Carlos Villarino3. 1Genetics, Universidad de Vigo, Pontevedra, Spain; 2Respiratory Diseases, Hospital Montecelo, Pontevedra, Spain; 3Respiratory Diseases, Hospital de Vigo, Vigo, Pontevedra, Spain

PAH may be heritable. Much of what is known about the genetic basis of PAH is related to bone morphogenetic protein receptor 2 (BMPR2). We studied variants in BMPR2, endothelin-1 (ET-1) and nitric oxide synthase 2 (NOS2).

Patients with idiopathic and associated PAH were included. DNA was amplified for the 17 validated amplicons spanning the coding sequence of BMPR2 gene. For ET-1 gene the polymorphism K198N was selected because homozygous for Asn (T/T genotype) have higher levels of ET-1. NOS2 play a key role in endothelial dysfunction. CCTTT repeat polymorphism was studied. Larger studies are needed to confirm the significance of these findings.

Conclusion: Frequency of pathogenic mutations in BMPR2 in non heritable PAH was 14%. It would be interesting to perform functional studies of non pathogenic mutations to test their effect on BMP proteins. CCTTT repeat polymorphism showed statistical differences between patients and controls. K189N (G/T) polymorphism in ET-1 gene showed similar distribution.

P917
Evaluation of acute right ventricular failure in scleroderma and idiopathic pulmonary arterial hypertension
Neal Chaisson, Arantza Campo, Stephen Mathai, Paul Hassoun. Division of Pulmonary and Critical Care Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States

Background: The ability to maintain adequate right ventricle (RV) function is paramount to survival in pulmonary arterial hypertension (PAH). However, little is known about RV function in patients with established PAH who are hospitalized for acute RV failure. Since RV adaptation is often worse in scleroderma-associated PAH (SSc-PAH) than in patients with idiopathic PAH (IPAH) despite similar afterload, we sought to compare RV function in hospitalized PAH patients using tricuspid annular plane systolic excursion (TAPSE), a non-invasive measurement of RV function that strongly associates with invasive hemodynamics and survival in both SSc-PAH and IPAH.

Methods: 47 patients with SSc-PAH or IPAH were evaluated during their first admission to a hospital for RV failure. All patients received transesophageal echocardiography. Vital signs and survival from time of admission were recorded.

Results: This cohort was composed of 91% females, with mean age 56 (range 23-81). There were 68% SSc-PAH and 32% IPAH patients. Mean TAPSE was 0.3 cm larger in IPAH compared to SSc-PAH (1.4cm ± 0.424, vs. 1.1cm ± 0.33, p=0.01). This relationship persisted despite controlling for age, admission vital signs, and time since diagnosis. 1-year mortality was 47%. Relative risk of mortality was 53% less in the IPAH group than in those with SSc (10% ± 0.32 vs. 63% ± 0.49, p=0.004).

Conclusion: SSc-PAH patients admitted with acute RV failure had both lower TAPSE and higher 1 year mortality than those with IPAH. This association suggests that TAPSE may offer prognostic information in patients with acute RV failure. Larger studies are needed to confirm the significance of these findings.

P918
Non-invasive versus invasive hemodynamic evaluation in an heterogeneous pulmonary hypertension population: When echo goes in the cath-lab
Michèle D’Allo, Emanuele Romeo, Paola Argiento, Anna Corresza, Berardo Sarubbi, Maria Pignatello, Angela Carminati, Raffaele Calabrò, Maria Giovanna Russo. Cardiology, Second University of Naples, Monaldi Hospital, Naples, Italy

Aim: To evaluate the accuracy of doppler echocardiography (DE) in estimating the key measurements of right heart catheterization (RHC) in an heterogeneous pulmonary hypertension population: When echo goes in the cath-lab

Methods: One hundred thirty-five consecutive patients referred to our PH tertiary center from January to December 2011 underwent standard DE within 1 hour of a clinically indicated RHC.

Results: Twelve/135 (9%) did not have PH. Of 123 PH patients with PH, 54 (40%) had group 1, 39 (29%) group 2, 22 (16%) group 3, and 8 (6%) group 4. PH echo showed a satisfactory correlation to invasive evaluation.

Conclusion: Despite DE is frequently inaccurate in estimating the CWP leading to a misclassification in 22/123 (18%) of analyzed patients. In particular, sensitivity of echo for pre-capillary PH was 82% and specificity 83%.

Effect of targeted therapy on circulating endothelial progenitor cells in pre-capillary pulmonary hypertension
Roberto Del Pozo, Jessica Garcia, Sandra Pizarro, Nuria Coll, Isabel Blanco, Yolanda Torralba, Victor Peinado, Joan Albert Barberà. Pulmonary Medicine, Hospital Clinic-IDIBAPS, Barcelona, Spain

Introduction: Endothelial dysfunction plays a key role in the development of...
pulmonary hypertension (PH). Bone marrow-derived endothelial progenitor cells (EPCs) may differentiate into functioning endothelial cells and contribute to endothelial repair.

**Aim:** To investigate whether the number of circulating EPCs in patients with pre-capillary PH differs from control subjects and to assess the effects of target therapy on circulating EPCs.

**Methods:** 36 control subjects (55±3 yrs) and 39 treatment naïve patients with pre-capillary PH (50±13 yrs; mean pulmonary arterial pressure 44±13 mmHg). 33 patients had pulmonary arterial hypertension (PAH) (17 idiopathic; 16 associated with chronic thromboembolic pulmonary hypertension (CTEPH)). 28 patients were re-evaluated at 6 months after the initiation of target therapy. The number of circulating EPCs was measured using flow cytometry. Circulating EPCs were defined as CD34+/CD133+ cells from a population that did not express CD45bright and expressed as the percentage of lymphomonocytic cells.

**Results:** In patients with pre-capillary PH the number of circulating EPCs was lower than in control subjects (Md 0.060 [0.037-0.075] and 0.086 [0.063-0.120] % lymphomonocytes, p<0.01)and was not correlated with functional class or hemodynamic measurements. After 6 months treatment, in patients with PAH (n=14) circulating EPCs increased from 0.058 (0.048-0.069) to 0.073 (0.050-0.097) % lymphomonocytes, respectively.

**Conclusion:** Patients with pre-capillary PH have reduced numbers of circulating EPCs that seems to increase as a result of targeted PH therapy. Supported by grants from SEPAR, SOCAP and GSK.

**P920**

**HBAlC in pulmonary arterial hypertension – A marker of prognostic relevance?**

Michael Belly1, Henning Tiede1, Olchowski Horst1, Ghofrani Ardechiri1, Seeger Werner2, Frank Renchenberger1, 1Department of Internal Medicine, University of Giessen Lung Center, Giessen, Germany; 2Department of Pulmonology, Medical University Graz, Graz, Austria

**Background:** Patients with pulmonary arterial hypertension (PAH) exhibit impaired glucose metabolism and increased insulin resistance. The clinical consequences of these metabolic changes are not known.

**Patients and methods:** We assessed HBAlC levels (indicative of perturbed glucose metabolism) in 115 patients newly diagnosed with PAH (79 female, 36 male; mean age 48.8 years; idiopathic n=66, collagen vascular disease n=17, congenital heart defect n=19, pulmonary veno-occlusive disease n=8, porto-pulmonary n=5). No patients had been diagnosed with diabetes, or received antidiabetic medication or systemic steroids. After initiation of pulmonary vasoactive treatment, patients remained in long-term follow-up.

**Results:** At initial presentation patients were in an advanced stage of disease (mean pulmonary arterial pressure 53±18 mmHg, median pulmonary vascular resistance 767 dyn.s.cm-5, cardiac index 2.3±0.8 l.m-1.min-1) with a six-minute walking distance of 131±70 m. They were categorised as NYHA functional class III-IV.

The HBAlC was 5.7±3.3% (75%). The 5-year survival rate for the entire group was 68%. Univariate Kaplan-Meier analysis and multivariate Cox proportional hazard regression analysis revealed that initial HBAlC quartile had a significantly better 5-year survival rate compared with the highest (83.6% versus 50.6%; log-rank p=0.038). Correcting for demographic and clinical covariates HBAlC was a predictor of all-cause mortality with a hazard ratio of 2.29 (95% CI 1.20 to 4.38; p=0.02) per 1 Unit increase.

**Conclusion:** In patients with pulmonary arterial hypertension, the HBAlC level at time of diagnosis is an independent predictor of long-term prognosis.

**P921**

**Efficacy and safety of oral bosentan in patients with Down’s syndrome and pulmonary arterial hypertension due to congenital heart disease**

Michele D’Allo1, Emanuele Romeo2, Paola Argiento1, Anna Correra1, Berardo Sarabu1, Maria Pignotello2, Antonetta Caronna1, Carmine Dario Vizza2, Raffaele Calabrò1, Maria Giovanna Russo1, Dario Vizza2, Raffaele Calabrò1, Maria Giovanna Russo1, 1Cardiology, Second University of Naples, Italy; 2Cardiology, University La Sapienza, Rome, Italy

**Aim:** To evaluate the long-term effects of oral bosentan in adult patients with pulmonary arterial hypertension (PAH) due to congenital heart disease (CHD) with and without Down’s syndrome.

**Methods:** WHO functional class, 6-minute walk test (6MWT) and hemodynamics

PH patients with and without Down’s syndrome were assessed at baseline and after 12 months of bosentan therapy in CHD-PAH patients with and without Down’s syndrome.

**Results:** Seventy-four consecutive patients were enrolled: 18 with and 56 without Down’s syndrome. After 12 months of bosentan therapy, both groups showed an improvement in WHO functional class, 6-minute walk distance and hemodynamics. No differences in the efficacy of therapy were observed between the two groups.

**Conclusions:** Bosentan was safe and well tolerated in adult patients with CHD-related PAH with and without Down’s syndrome during 12 months of treatment. Clinical status, exercise tolerance, and pulmonary hemodynamics improved, regardless of the presence of Down’s syndrome.

**P922**

**Assessment of left ventricular function in COPD**

Javanta Malik, Kaushik Saha, Supriya Sarkar, Arpita Bannerjee. Pulmonary Medicine, N. R. S. Medical College, Kolkata, WB, India Pulmonary Medicine, N. R. S. Medical College, Kolkata, WB, India Pulmonary Medicine, N. R. S. Medical College, Kolkata, WB, India Pulmonary Medicine, N. R. S. Medical College, Kolkata, WB, India

**Introduction/Background:** To evaluate the left ventricular (LV) function in chronic obstructive pulmonary disease (COPD) in absence of known LV disease by echocardiography.

**Methods:** The study was an observational cross sectional study including 50 cases of stable COPD patients. Confirmation of cases for COPD were done by GOLD criteria and staged accordingly. Known cases of LV disease diagnosed on the basis of history, clinical findings, echocardiography and other investigations were excluded from the study. All cases were subjected to 2D echocardiography for LV evaluation.

**Results:** LV diastolic dysfunction was noted in 84% cases and both systolic and diastolic dysfunction was recorded in 2% case. We found statistically significant positive correlation of the LV diastolic dysfunction with the age of the patients, duration of symptoms and stage of diseases. But we did not find any significant co-relation between LV dysfunction with nature of symptoms and chest x-ray findings.

**Conclusions:** We concluded that there was a definite association between LV diastolic dysfunction and COPD even if the known causes of LV disease were excluded. We suggested that left ventricular function should be evaluated in COPD patients not responding to usual management even in absence of clinical evidence of LV disease.

**P923**

**Role of right ventricular ejection fraction by electrocardiogram-gated 320-slice CT in pulmonary hypertension**

Toshishika Suzuyo, Nobuhito Tanabe, Yukiko Matsuura, Ayumi Sekine, Renshou Tatsuma. Department of Respiriology, Graduate School of Medicine, Chiba University, Chiba, Japan

**Purpose:** Right ventricular function is an important determinant of exercise capacity and survival in pulmonary hypertension (PH). We aimed to study correlation of right ventricular ejection fraction (RVEF) determined by 320-slice CT with hemodynamic factors in patients with PH.

**Materials and methods:** 59 subjects (17 male, 56±13 yrs) with PH (41 chronic thromboembolic pulmonary hypertension and 18 pulmonary arterial hypertension) underwent enhanced retrospective ECG-gated volume 320-slice CT (Aquilion ONE, Toshiba) and right heart catheterization (RHC). CT images were reconstructed every 5% from 0.95% of the R-R interval. RV end-systolic and end-diastolic true volumes were measured from 3-dimensional reconstruction and used to calculate RVEF. We compared RVEF with the results of RHC.

**Results:** In 320-slice CT, RVEF were 46±4.14%. In RHC, mean mPAP (mPAP), pulmonary systolic (SV) were 41.5±11.3 mmHg, 655±317 dyne.s.cm-5 and 63.7±17.7 ml, respectively. The correlation coefficient of RVEF with mPAP, PVR, SV were -0.52 (<0.001), -0.63 (<0.001) and 0.61 (<0.001), respectively.

**Conclusions:** RVEF by ECG-gated 320-slice CT correlated significantly with PVR and SV in subjects with PH.

**P924**

**Relevance of persistent foramen ovale in PAH patients on pulmonary vasoactive treatment**

Ingo Mascher1, Henning Tiede2, Christian Tanislav2, Robert Vovwinkel1, Hossein A. Ghofrani1, Werner Seeger1, Franz Renchenberger1, 1University Giessen Lung Center, University Hospital Giessen, Germany; 2Department of Neurology, University Hospital, Giessen, Germany; 1Allgemeine Pneumologie, Asklepios Fachklinik München Gauting, Gauting, Germany

**Background:** Persistent foramen ovale (PO) has been suggested to improve outcome in pulmonary arterial hypertension (PAH), despite causing hypoxaemia.

**Methods:** We evaluated the impact of PO on long term follow up in patients with PAH and severe hypoxaemia (pO2 < 65 mm Hg in air) on pulmonary vasoactive treatment. PO was detected on contrast-enhanced transcranial doppler sonography (TCD). After diagnosis of PAH the patients were started on treatment with PDE 5 inhibitor, endothelin receptor antagonist or prostanoids and remained in regular follow up.
Both patient groups exhibit the same baseline haemodynamic and clinical characteristics (P<0.05 for the differences in age and in pulmonary arterial pressure at rest (RAP)).

Results: Between January 2010 and December 2011 we detected 65 patients with PAH and severe hypoxaemia (age 57±14 years, 34 males, 39 IPAH, 18 PAH associated with CTD, 5 portopulmonary hypertension, others: 3). In 27 patients a PFO was detected on TCD (group 1). In 26 patients a PFO could be excluded (group 2). 12 patients had to be excluded because of ambiguous result in TCD.

Introduction: HIV-associated pulmonary hypertension (P-PAH) is an uncommon complication of the natural history of HIV infection and an independent factor of death in HIV-infected patients, regardless of the use of High Activity Antiretroviral Therapy (HAART).

Results: 3 patients were diagnosed as HIV-PAH (prevalence 0.25%). All the patients died within 2 years. Hepatitis C virus was present in 2 cases. There was a positive response to therapy with HAART at the moment of diagnosis of PAH. All of them had an initial positive response to therapy with bosentan. At 2 years from the beginning of the follow 2 patients had died by congestive cardiac failure.

Conclusion: The bibliography reflects, confluence with HIV-PAH is very common in the patients with PAH-HIV. There is a big variability in the evolution of the disease, the immunological status of the patients and the development of PAH. We did not find any predictive clinical or laboratory markers regarding which patients would have a poor prognosis. Because of PAH is the main cause of death in patients with HIV infection, and its low prevalence, a strategy for active search could increase early diagnosis so making easier both treatment and control of the disease.

P926 Effects of oral dual ERA therapy on pulmonary function testing and 6MWT in patients with idiopathic pulmonary fibrosis and pulmonary hypertension

Antonio Russo1,2, Angelo Romano1,3, Gaetano Beatrice1, Marco Del Donno1, UOC Pneumologia, G. Rummo, Benevento, Italy

PH can be present in 37% to 59% of patients with IPF and is a predictor of mortality, which appears to be the cause of additional burden of exercise capacity. The aim of our study was to investigate the role of oral dual ERA therapy in 2 groups of patients with PH associated to IPF with or without Bosentan therapy during 24 months. The primary endpoint was the change of exercise capacity up to month 24, measured by a modified 6MWT. We evaluated retrospectively 16 patients: 8 pts (6 M; mean age of 72 yrs old) with moderate-sever PH and IPF (mPAP measured by RCH estimated as a mean value of 38±4.8 mmHg), treated with Bosentan (PH-IPF ERA group); 8 pts (5 M; mean age of 70 yrs old) with moderate PH and IPF not treated with Bosentan (PH-IPF control group). At baseline, there were differences about hemodynamics and pulmonary functional test profile between the two groups of pts. At T 24, the 6MWT increased in PH-IPF ERA group showing a mean increase of +150 mt, while in the PH-IPF control group we observed a reduction of 41% compared to the 6MWT values baseline (p = 0.003) in PH-PD group treated with ERA, FVC% and DLOC% were reduced of 8% and 32%, respectively, while in PH-IPF control group were reduced of 6.6% and 22% compared to the baseline (p = 0.009). The NYHA functional class was decreased in group treated with ERA (3.5 vs 2, p = 0.009) and improved in control group (2.12 vs 3.52, p = 0.007). In patients with moderate-severe PH and idiopathic pulmonary fibrosis, treated by Bosentan, there was a clinical improvement, measured by a six minute-walk test and a change in NYHA functional class, without affecting pulmonary functional test.

P927 Efficacy of exercise training in congenital heart disease associated pulmonary hypertension

Fabio Becker-Grunewald1, Nicola Elken1, Matthias Gorenflo2, Alfred Hager3, Michael Halamka4, Hans Klose5, Mona Lichtblau6, Andreas Meyer7, Frank Reichenberger8, Stephan Sorachter9, Rudolf Speich9, Silvia Ulrich9, Ekkehard Gruenewald1. 1Pulmonary Hypertension, Thoracale;thin, University of the University of Heidelberg, Germany; 2Department of Pediatric Cardiology and Congenital Heart Diseases, University Heidelberg, Germany; 3Department of Pediatric Cardiology and Congenital Heart Diseases, Deutsche Herzzentrum München des Freistaates Bayern, Technical University, Munich, Germany; 4Department of Pneumology, Technical University, Dresden, Germany; 5Department of Pneumology, University Hamburg; Eppendorf; Hamburg, Germany; 6Department of Pneumology, Clinics of Maria-Hilf, Monchengladbach, Germany; 7Department of Pneumology, University of Giessen and Marburg, Giessen, Germany; 8Department of Pneumology, University of Freiburg, Germany; 9Pulmonary Hypertension Program, University Hospital, Zurich, Switzerland

Objective: This prospective study was to assess the efficacy of exercise training as add-on to medical therapy in patients with pulmonary arterial hypertension associated with congenital heart disease (CHD-PAH).

Methods: Patients with invasively confirmed CHD-PAH received in-hospital exercise training for 3 weeks and continued at home. Efficacy parameters were evaluated at baseline, after 3 weeks and 15 months. Medical treatment remained unchanged during 15 weeks after baseline. The survival rate was assessed in a follow-up period of 21±14 months.

Results: Twenty consecutive patients (16 female, 4 male, mean pulmonary arterial pressure 60±23 mmHg, 9 patients were operated, 10 ASD, 11 VSD, 1 PFO, 2 PDA, 10 Eisenmenger syndrome were included. Patients significantly improved the mean distance walked in 6 minutes compared to baseline by 63±47 meters after 3 weeks (p<0.001) and by 67±59 meters after 15 weeks (p=0.001). Quality of life score (p=0.005), peak oxygen uptake (p<0.003) improved significantly by exercise training after 15 weeks. The 1- and 2-year survival rates were 100%. In one patient lung transplantation was performed 1 year after exercise training.

Conclusion: Exercise training as add-on to medical therapy may be effective in patients with CHD-PAH, improving quality of life, work capacity and further prognostic relevant parameters. It was also associated with an excellent long-term survival. Further randomized controlled studies are needed to confirm these results.

P928 The utility of brain natriuretic peptide in patients with stable chronic lung diseases

Yoko Kiya, Hiromi Tomioka, Reina Sekiya, Syuji Yamasita, Toshihiko Kaneda, Chiharu Nishio, Masahiro Kaneke, Hiroshi Fujii, Kyousuke Ishihara. Respiratory Medicine, Kobe City Medical Center West Hospital, Kobe, Hyogo, Japan

Background: Cor pulmonary and pulmonary hypertension with chronic lung diseases are related to low exercise capacity and poor prognosis. Plasma brain natriuretic peptide (BNP) is a useful biomarker for monitoring of heart failure.

Objective: The aim of our study is to investigate the utility of BNP in stable chronic lung diseases (COPD, intestinal pneumonia, post-tuberculous lung disorder and others).

Methods: 111 patients with chronic lung diseases (male/female=73/38, age 74.8±8.0 yrs; excluding AF, rhythm, LVEF<40% and renal dysfunction) who were admitted to a three-weeks comprehensive inpatient pulmonary rehabilitation program, were assessed by pulmonary function tests, 6-minute walking test, and health-related quality of life as evaluated by SF-36. Plasma BNP was measured and echocardiography was also performed.

Results: It made no difference among types of lung disease for BNP (56.4±57.2 pg/ml, mean±SD). BNP (44-4.6±12.2 mmHg, mean±SD) and LVEF (62.3±11.5%, mean±SD). LVEF was not correlated with BNP. Compared BNP normol group (<18.4pg/ml) with high group (≥18.4pg/ml), there was a difference for BNP score at rest (0.8±0.77, 2.02±6.57, p=0.004*7) and 6MWD (262.2±73.3, 188.5±93.0, p=0.004*4). BNP was significantly correlated with 6MWD (r=0.2270, p=0.047*). BNP was also correlated with LVEF and SpO2 both at rest and on effort. But no significant correlation was shown between BNP and RVSP (r=0.1541, p=0.1540). Also, BNP was not correlated with QOL score (SF-36) and pulmonary function.

Conclusions: Plasma BNP was correlated with exercise capacity in stable chronic lung diseases. BNP may be a useful biomarker for administrating cor pulmonary and pulmonary hypertension with chronic lung diseases.

P929 Resolution of portopulmonary hypertension (PPOH) following liver transplantation

Michael Krowka. Mayo Clinic, Rochester, MN, United States

Resolution of portopulmonary hypertension (PPOH) in chronic liver disease is an uncommon and usually benign event. However, when resolution occurs in patients with PPOH due to chronic liver disease, the possibility that there will be a sustained improvement of pulmonary pressures is unknown. In this prospective study, we determined whether patients referred for liver transplantation with PPOH, a consequence of portal hypertension (POPH), will have resolution of PPOH following liver transplantation.
Aims: To summarize the Mayo Clinic medical management and LT outcomes in moderate to severe POPH.

Methods: From 2002-2012, we analyzed the pulmonary vasoconstricting (PV) treatments and LT outcomes in consecutive POPH patients with right heart catheterization (RHC) criteria: mean pulmonary artery pressure - MPAP ≥ 35 mmHg and pulmonary vascular resistance - PVR ≥ 3 Wood units). All patients underwent sequential transesophageal echocardiography (TEE; both pre and post-LT) and RHC (pre-LT baseline, with therapy and intraop; not done post-LT). TTE assessed right ventricle (RV) size, function and RV systolic pressure estimate (RVSP).

Results: We managed 65 POPH patients; LT was attempted in 13/65 patients only if PV therapies resulted in MPAP < 35 mmHg and PVR < 5 wood units or normalization of PVR (< 3 Wood units). RV size and function were abnormal in all patients pre-LT. Mean pre-LT baseline treated hemodynamics were significantly improved: MPAP (44 ± 32 mmHg, p < 0.04); CO = 6.1 ± 9.7 L/min, p < 0.005; and PVR (5.9 ± 2.3 Wood units, p < 0.02). Intraoperative death (1), transplant hospitalization (death) (1) occurred. All survivors (9/13) normalized RV function; 6 normalized RV size; 69 were weaned off PV therapies. Post-LT mean RVSP improved significantly vs pre-LT (33 mmHg; range 26-41 vs 71 mmHg; range 38-121).

Conclusions: LT can result in POPH resolution (defined by sequential TTE) and liberation from PV therapies in selected patients.

P930 Factors determining outcome in patients with heart failure and normal ejection fraction
Caroline Tiffany, Julia Mascherbauer, Beatrice Marzluf, Thomas Binder, Irene Lang, Diana Bonderman. Department of Internal Medicine II, Division of Cardiology, Medical University Vienna, Austria

Background: Patients with heart failure and normal left ventricular ejection fraction (HFNEF) face an adverse outcome. Our aim was to identify factors that determine prognosis.

Methods: Patients diagnosed according to current ESC guidelines were recruited. Death and/or hospitalization for HF were defined as primary outcome variables. Outcome groups were compared with respect to potential prognostic predictors using the t-test. Multivariable logistic regression analysis determined whether parameters of interest were associated with adverse outcome. P < 0.05 indicated statistical significance.

Results: Between December 2010 and January 2012, 49 patients (34 f/15 m, mean age 70 ± 8 years) were registered. After a mean follow-up of 5.4 ± 9 months, 14 (29%) patients were hospitalized or died. The adverse outcome group was characterized by higher body mass index (BMI, 35 ± 5 vs 29.4 ± 5, p < 0.005), higher systolic pulmonary pressure on echo (sPAP in mmHg, 69 ± 15 versus 55 ± 14, p < 0.005), shorter 6-minute walk distance (6-MWD in m, 271 ± 131 versus 364 ± 100, p = 0.019), higher transpulmonary gradient (TPG in mmHg, 15.4 ± 8 versus 12.4 ± 4, p = 0.013) and a higher pulmonary vascular resistance (PVR in dynes·cm−2, 2.3 ± 0.97 versus 19.8 ± 71, p = 0.030). Diabetes mellitus II (DM II) (75% versus 24%, p < 0.002) and atrial fibrillation (92% versus 51%, p = 0.033) were more prevalent among patients with adverse outcome. In the multivariable regression model, only DM II (OR 25.34 [95% CI, 2.06 to 311.45]; p = 0.012), BMI (OR 1.25 [95% CI, 1.00 to 1.56]; p = 0.02), and PVR (OR 1.02 [95% CI, 1.00 to 1.05]; p = 0.032) remained independent predictors of outcome.

Conclusions: Presence of DM II, higher BMI and higher PVR worsen prognosis in HFNEF patients.

P931 Pulmonary hypertension frequency in patients with chronic obstructive pulmonary disease exposed to biomass or tobacco smoke
Bunyamin Sertogullarinda, Hasan Ali Gumrukcuogulu1, Cengizhan Sezgi2.
1Pulmonary Medicine, Yuzuncu Yil University Medical Faculty, Van, Turkey; 2Pulmonary Medicine, Dicle University Medical Faculty, Diyarbakir, Turkey.

Introduction and aim: Pulmonary hypertension (PH) is a common complication of COPD. This study was designed to investigate the PH frequency and its relations in hospitalized tobacco and biomass exposed COPD patients.

Methods: The study was a retrospective review of inpatients with COPD defined by higher body mass index (BMI, 35 ± 5 vs 29.4 ± 5, p < 0.005), higher systolic pulmonary pressure on echo (sPAP in mmHg, 69 ± 15 versus 55 ± 14, p < 0.005), shorter 6-minute walk distance (6-MWD in m, 271 ± 131 versus 364 ± 100, p = 0.019), higher transpulmonary gradient (TPG in mmHg, 15.4 ± 8 versus 12.4 ± 4, p = 0.013) and a higher pulmonary vascular resistance (PVR in dynes·cm−2, 2.3 ± 0.97 versus 19.8 ± 71, p = 0.030). Diabetes mellitus II (DM II) (75% versus 24%, p < 0.002) and atrial fibrillation (92% versus 51%, p = 0.033) were more prevalent among patients with adverse outcome. In the multivariable regression model, only DM II (OR 25.34 [95% CI, 2.06 to 311.45]; p = 0.012), BMI (OR 1.25 [95% CI, 1.00 to 1.56]; p = 0.02), and PVR (OR 1.02 [95% CI, 1.00 to 1.05]; p = 0.032) remained independent predictors of outcome.

Conclusions: Presence of DM II, higher BMI and higher PVR worsen prognosis in HFNEF patients.

P932 A study of suspected pulmonary embolism (PE) in pregnancy management and a survey of guideline awareness
Imogen Felton, Katie Wimbish, Paul Murray. Respiratory Department, Ashford and St Peters NHS Foundation Trust, Chertsey, United Kingdom

Introduction: A recent report showed PE as a major cause of maternal death in the UK (CMACE/BLOG 2011:118(Suppl.)1:20-25); delays in diagnostic tests, treatment and poor knowledge of radiological safety are contributing factors. The Royal College of Obstetricians & Gynaecologists provides a protocol for suspected PE (Greet, I.A et al RCOG Green-top Guideline No 28 Feb 2007).

Aims: To gauge the level of guideline-awareness in medical trainees and evaluate the management of suspected PE in pregnancy in a UK District Hospital.

Methods: A survey of medical trainee knowledge of investigative pathways, radiation-exposure risks and guideline awareness. We also analysed management of pregnant women with suspected PE between 2009-11.

Results: 76% of medical trainees and 58% of Respiratory SpRs were unaware of guidelines and had poor knowledge of radiation risks.

Table 1. Respondents’ score of relative radiation risk to fetus: lowest (1) to highest (4) from the most commonly used investigations

p<0.25 respondents.

41 women had symptoms of PE and were investigated as shown.

3 patients had PE confirmed (7.3%). Only 15% of women were investigated as per RCOG guidelines.

Conclusion: Our study revealed poor guideline-awareness for PE in pregnancy highlighting the need for better dissemination of these guidelines to medical trainees.

31
LaFarge/Miettinen's formula for the assumption of oxygen consumption (VO2) is one of the most used in hemodynamic calculations. Considering the importance of VO2 for the calculation of hemodynamics needed for disease evaluation (e.g. pulmonary hypertension), the need for an acceptable agreement between assumed and measured VO2 becomes obvious. A well-known variation of the original formula is the one by Bergstra. In both equations, age, sex and BSA are factors determining the VO2 plus the heart rate (HR) in the original formula. We compared directly measured VO2 with values calculated by both the LaFarge/Miettinen and the Bergstra equations. VO2 of 122 volunteers (20-65y) was directly measured by the Innocore™ (Innovision). VO2 was then recalculated by both the equations. Directly measured VO2 (VO2,DM) was 30.3±84 ml/min in males, 22.4±52 ml/min in females. VO2 calculated by Bergstra was 29.8±42 ml/min in males, and 23.3±48 ml/min in females. VO2 by LaFarge/Miettinen was 25.9±24 ml/min in males, 18.2±21 ml/min in females. Direct comparison of VO2,DM with calculated VO2 showed significant differences between all the methods. Factors found to be influencing the VO2 in our cohort included sex, HR and BSA whereas age seemed to have no effects. Significant correlations were found between VO2 and hemoglobin, oxygen saturation (SpO2), fitness level and systolic blood pressure.

Comparison of directly measured VO2 values with assumed data obtained by both the LaFarge/Miettinen and Bergstra equations showed that none of the formula is satisfying in terms of agreement with measured data. Using VO2 equations may result in major bias of hemodynamics and we therefore urge that resulting data should be interpreted critically.

Background: Pulmonary hypertension (PH) is associated with dysfunction of pulmonary endothelium. Stress- and pressure-dependent arterial endothelial dysfunction has been found in various cardiovascular diseases and data in PH is limited. The aim of this study was to evaluate peripheral endothelial function in IPAH and CTEPH and the relation to right heart function.

Methods: Flow-mediated dilation (FMD) of the brachial artery was determined in 26 patients (55±15y, PAPm: 48±13mmHg, PVR: 837±476 dyn s cm⁻5) with IPAH or CTEPH and 14 healthy controls. FMD was defined as the maximal change in relative vessel diameter after reactive hyperemia. Right ventricular function was examined by echocardiography.

Results: Patients and controls were similar in terms of peripheral flow conditions and cardiovascular risk factors including intima-media thickness (IMT) (IMT: 0.57±0.14 vs. 0.59±0.14 mm, p=0.39). Patients with PH demonstrated impaired peripheral endothelial function (FMD absolute change: 0.17±0.15 vs. 0.26±0.14 mm, p=0.008, relative change: 5.32±5.31 vs. 8.12±5.15%, p=0.01). There were no differences in peripheral endothelial function between IPAH and CTEPH (FMD: 3.39±5.76 vs. 4.12±3.80%, p=0.69). A correlation with right atrial diastolic area (RAAa) was found (r=0.43, p<0.01).

Conclusions: In addition to changes of the pulmonary vascular bed, PH is associated with peripheral arterial endothelial dysfunction in patients with IPAH and CTEPH. An increased RAAa points to chronically increased RV filling pressures and therefore a failing ventricle. The negative correlation with FMD might be regarded as result of impaired hemodynamics rather than a primary endothelial defect.

103. Pulmonary circulation: clinical PAH, registries and treatments

P935
Assessment of pulmonary hypertension in patients over 70
Christopher Valerio,1 Benjamin Schreiber1 Clive Handler1, Christopher Denton,2 John Coghlan1,1 Pulmonary Hypertension, Royal Free Hospital, London, United Kingdom; 2Rheumatology, Royal Free Hospital & UCL Medical School, London, United Kingdom

Background: Recent registry data suggests that the average age of patients with PAH is rising. Pulmonary hypertension affects elderly people and there is increasing prevalence of cardiac and respiratory disease with age.

Methods: We report the findings for 120 consecutive patients aged over 70 referred to a tertiary service during 2008-09 for invasive haemodynamic studies to confirm or exclude a diagnosis of pulmonary hypertension.

Results: Four patients died within 30 days of referral and before being assessed, 15 patients did not undergo cardiac catheterisation. 50% of those assessed had an associated connective tissue disease. 36 patients had resting pulmonary artery pressures <25mmHg, eleven with respiratory and ten with cardiac disease to explain their symptoms. 65 patients were diagnosed with pulmonary hypertension following invasive studies: 19 related to left heart disease, 7 related to chronic lung disease, 7 CTEPH, five mixed aetiology, and 27 PAH. Three patients with idiopathic PAH, one case associated with an atrial septal defect, 23 with connective tissue disease. Follow up log10NT-proBNP testing in 24 patients with PAH showed a significant reduction at 12 months (-0.21, p<0.05 students’ t-test).

Conclusion: Pulmonary hypertension of all types may be present in older patients. Thoracic assessment may provide insight into the drivers of symptoms in older patients and help to guide treatment, which can be successful.

P936
Pulmonary hypertension in a district general hospital
Van-Pin Lim,1 Dominick Davenport, Natasha Shrikishna, Abigail Cole, Harpreet Ramp. Respiratory Department, St. Richard’s Hospital, Western Sussex Hospitals NHS Trust, Chichester, United Kingdom

Introduction: There is an increasing awareness to identify patients with pulmonary hypertension (PH). Classification of the underlying cause defines further management and referral to specialist centres.

Aim: To assess the burden of PH at St Richard’s Hospital, which serves a population of 230,000.

Methods: All departmental transhoracic echocardiographs (TTEs) between 1st January 2009 and 30th June 2009 were reviewed using ERS suggested criteria to identify patients with possible PH and likely PH. Further investigations were performed to identify the underlying aetiology in those with likely PH.

Results: A total of 2038 TTEs were reviewed. 93 (5%) had likely PH with a pulmonary artery systolic pressure (PASP) of >50mmHg. 624 (31%) had possible PH with either the presence of additional echocardiographic variables suggestive of PH or a PASP 37-50mmHg. Of those with likely PH, 48% were male and 52% were female. The median age was 45 years (range 32-98). The overall mortality rate was 39% at 1 year and 58% at 2 years. Only 13% had right heart catheterisation locally.

Pulmonary arterial hypertension prototype for national protocol and registry
Masb Marjahi1, Fanak Fahimi1, Babak Shariatzadeh1, Mohammad Reza Masjedi1,2,3,4,5,6,7. 1,2,3,4 National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran; 5, 2Clinical Chemical and Critical Care, National Research Institute of Tuberculosis and Lung Disease, Tehran, Islamic Republic of Iran

Background: Pulmonary Hypertension (PH) has been defined as an increase in mean pulmonary arterial pressure (PAP) ≥ 25 mmHg at rest as assessed by right heart catheterization. The idiopathic form so called idiopathic pulmonary arterial hypertension (iPAP) is a fatal disorder with a prevalence of 8.6 per million of population. In the current report we introduced a registry site for iPAP patients, named www.pah.ir for better delivery of subsidized antiphypertensive medications (now only Bosentan).

Methods: The registry was opened since November 2009. The first step of this action is to add iPAP patient’s information with a username and password in the site. Data entry is only available to the physicians and healthcare organizations via internet that are given a personalized username & password for entry. Following the patient’s profile submission in the site, a scientific committee composed of a cardiologist and a pulmonologist who are selected by Ministry of Health (MOH), would then evaluate the data. The eligibility of the patient to receive the medications is announced in the site after evaluation. If a patient is eligible, 82% of bosentan cost is paid by MOH.

Results: Till now, one hundred and sixteen patients (82 females, 34 males) are registered. Measured mean pulmonary arterial pressure by right heart catheterization was 69.24±17.63 mmHg (ranging from 35 to 115 mmHg).

Conclusion: The first online Iranian registry program for iPAP patients has recently been started and it is believed that this national program will supply essential information for health care providers in the field.

P938
Pulmonary hypertension: The experience of a large UK district general hospital
Sarah Clarks, Gemma Swarbrick, Sally Baddeley, Julie Chadwick, Tarek Saba. Department of Respiratory Medicine, Blackpool Victoria Hospital, Blackpool, Lancashire, United Kingdom

Introduction: Recent advances in therapy make early identification of patients with Pulmonary Hypertension (PH) important. The 2008 consensus statement reported an average UK treatment rate of 24.9 per million. (1)

Aim: Our institution is a District General Hospital serving a population of 330,000. Our aim was to compare our treatment rate to the national average since the appointment of a physician with an interest in PH.

Method: Retrospective casenote review of patients attending our monthly PH clinic since 2006.

Results: We identified 102 Outpatient and 35 Inpatient referrals. 28 went on to receive specialist treatment for PH; mean age 66 (range 36-85); 24 female 4 male. Diagnoses: Chronic thromboembolic 10, Idiopathic 8, Collagen vascular disease 5, Congenital left to right shunt 2, COPD 2 and Portal hypertension 1. Haemodynamics (mean): Cardiac catheter: mean Pulmonary Artery Pressure (PAP) 66±16 mmHg (n=22, range 22-78), cardiac output 4.8±4.8 (n=22, range 2.5-7.7), cardiac index 2.8±1.8 (n=22, range 1.47-5.14) and pulmonary vascular resistance 760±220 (n=22, range 123-1600). Echocardiography: systolic PAP 66±40mmHg (n= 13), 13±4(10). Treatment: Oral Monotherapy 11, Prostanoid Monotherapy 1, Combination therapy 10. Intolerant of therapy 1, Pulmonary Endarterectomy 6, Transplant referral 4, Shunt repair 1.

Outcome: 18 out of 28 patients survive on medical and surgical therapies. This is equivalent to 54 patients treated per million, considerably higher than the national average [1].

Conclusion: Diagnosis and treatment rates for PH in the UK can be substantially improved in many areas by developing local services with the support of the regional Specialist centre.

Stability of a new formulation of intravenous epoprostenol sodium
Olivier Lambert1, Dirk Bandilla2. 1Technical Operations, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; 2Global Quality Management, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland

Epoprostenol sodium with (undisclosed) excipients (epoprostenol XX) is a new formulation of epoprostenol, a pulmonary arterial hypertension treatment. This study assessed stability and determined shelf-life of epoprostenol XX. Stability of epoprostenol XX, either diluted for immediate use and tested at 25°C, 30°C and 40°C for up to 72h, or following storage for up to 8 days at 5°C after reconstitution and immediate dilution with further exposure at 25°C and 30°C for up to 48h, was assessed at 3,000, 15,000 and 60,000 ng/mL. Potency was measured by HPLC.

The time period over which potency remained ≥90%, relative to 100% at time 0, determined shelf-life. Relative potency of diluted epoprostenol XX for immediate use was temperature-dependent and remained ≥90% after storage at 25°C, 30°C and 40°C for 48h, 24h and 8h, respectively (3,000 ng/mL), 48h, 24h and 12h, respectively (15,000 ng/mL), and 72h, 48h and 24h, respectively (60,000 ng/mL).

The relative potency of reconstituted and immediately diluted epoprostenol XX after storage for 8 days at 5°C was ≥95% and remained ≥95% after further storage for 24-48h at 25°C or 30°C, depending on concentration. The table shows shelf-life of epoprostenol XX based on these results.

P940
Pulmonary arterial hypertension: Long term effects of oral ambrisentan on clinical status, exercise capacity and haemodynamics
Michele D’Alto, Emanuele Romeo, Paola Argiento, Anna Correra, Berardo Sarubbi, Antonello D’Andrea, Antonietta Caronna, Maria Pignatello, Nicola Grimaldi, Rafaela Calabro, Maria Teresa Russello. Cardiology, Second University of Naples, Monaldi Hospital, Naples, Italy

Aim: To evaluate the efficacy and safety of oral ambrisentan in adult patients with pulmonary arterial hypertension (PAH) by assessing its long term effects on clinical status, exercise capacity and cardiopulmonary haemodynamics.

Methods: This was a single-centre, open-label, single-arm, prospective study. Clinical status, resting transcutaneous oxygen saturation (SpO2), 6-minute walk distance, serumology and RHC were assessed at baseline (before starting ambrisentan therapy) and at one year follow-up.

Results: Twenty-seven consecutive adult patients (18 female, age 51±1y) with PAH (15 with idiopathic, 7 with congenital heart disease-related and 5 with connective tissue-related PAH) were enrolled. No patient treated with ambrisentan developed aminotransferase concentrations >3 times the upper limit of normal. After 12±4 months of therapy, an improvement in clinical status, 6-minute walk distance, pro-brain natriuretic peptide and haemodynamics was observed.

Clinical and haemodynamic variables at baseline and after oral ambrisentan therapy

Conclusion: Long term ambrisentan therapy is safe and well tolerated at 12-month follow-up. Outcome in a significant improvement in clinical status, exercise capacity and cardiopulmonary haemodynamics.

P941
Incidence of subdural hematoma in patients with pulmonary arterial hypertension (PAH) in two randomized controlled clinical trials
Gerald Simoncini1, Lie-Ju Hwang1, Simon Teal2, Nazzareno Galleri2, 1Dept of Pneumology and TIC, Hospital Antoine Béclère, Paris, France; 2Institute of Cardiology, University of Bologna, Italy; 3Speciality Care Business Unit, Pfizer Inc., New York, United States

Background: Recent reports have emerged of increased incidence of subdural haematoma in patients with PAH, a serious adverse event with high mortality and morbidity. We evaluate the event rate in two randomized controlled trials, SUPER-1/2 and PACES-1/2.

Methods: In SUPER-1/2, 277 patients (IPAH, CTD-, CHD-PAH, WHO FC II-IV, mean baseline PVR 810.5 dyne/cm²) naive to targeted therapy received placebo or sildenafil 20/40/80mg TID for 12 weeks. In the open-label extension (OLE) phase patients were up-titrated (as tolerated) to 80mg TID. In PACES-1/2, 267 patients (IPAH, CTD-PAH, WHO FC II-IV, mean baseline PVR 810.5 dyne/cm²) were stable on IV epoprostenol received placebo or sildenafil (up-titrated to 80mg TID, as tolerated) for 16 weeks. Patients in both OLE trials received sildenafil for ≥3 years. Treatment with conventional agents (anticoagulants, diuretics, digoxin, oxygen, calcium-channel blockers) was permitted. We determined the annual event rate of subdural haematoma by treatment exposure in person-years. Patients on therapy does not include days on placebo.

Results: 2 patients experienced subdural haematoma, both during OLE, one received placebo in PACES-1, one sildenafil 40mg TID in SUPER-1. Patients were...
female, aged 58 and 62 years, diagnosed with IPAH, WHO FC III, mean PVR 557 (PACES-1) and 1073 dynes·cm⁻² (SUPER-1) at baseline. Both patients received oral anticoagulants. In SUPER-1 and PACES-1, 73 and 82% of patients were on anticoagulants, respectively. Incidence of subdural haematoma in these 2 studies was 0.0015 events/patient-year.

**Conclusion:** Subdural haematoma is a rare event in PAH patients in these 2 randomized controlled trials.

**P942**

Long-term bosentan therapy improves exercise capacity and hemodynamics in sarcoidosis-associated pulmonary hypertension

Debbie Qua¹, Veronika Palermo², Roxana Sulejac, Division of Pulmonary, Critical Care and Sleep Medicine, Beth Israel Medical Center, New York, NY, United States; ²Division of Pulmonary, Critical Care and Sleep Medicine, St. Luke’s-Roosevelt Hospital Center, New York, NY, United States

**Introduction and Rationale**

Therapeutic options in sarcoidosis-associated pulmonary hypertension (SHP) are limited. We evaluated the long-term efficacy of Bosentan in SHP.

**Methods:** Out of 60 consecutive patients with SHP retrospectively reviewed, 45 were eligible for Bosentan therapy and followed for 36 months. We recorded baseline characteristics, hemodynamics and 6-minute walk distance (6MWD) before/after treatment, side effects, and vital status. Statistical analysis was performed using Student t-test and 1-way ANOVA.

**Results:** There were 66% Blacks; 64% women, with mean age of 53 years. Most patients (62%) had pulmonary fibrosis, and mean diffusing capacity was 37%. Additional SHP therapy was required in 45% cases; bosentan was discontinued in 5 patients due to liver abnormalities (incidence 1%). One- and 3-year survival rates were 73% and 48%. In 29 patients that remained on bosentan at three years, there were significant improvements in the 6MWD (p=0.005) and hemodynamics.

**Conclusions:** A subset of SHP patients may benefit from bosentan therapy.

**P944**

An international survey of current pulmonary arterial hypertension (PAH) management

Ioana Preston¹, Barbara Hinzmann², Nicholas Badwen³, Henning Tie牲⁴.

¹Pulmonary and Critical Care and Sleep Medicine Departments, Tufts University School of Medicine, Tufts Medical Center, Boston, United States; ²Global Market Research Department, Bayer HealthCare Pharmaceuticals, Berlin, Germany; ³Healthcare Department, Ipsos MORI, London, United Kingdom; ⁴Medical Clinic 2, University of Giessen Lang Centre, Giessen, Germany

**Background:** The therapeutic approach to PAH is evolving, multiple classes of agents are available and physicians from expert centres and the community treat this condition.

**Objectives:** To compare therapeutic management of PAH between countries and explore physicians’ attitudes towards PAH-specific therapies.

**Methods:** Quantitative online survey conducted in 5 European countries, the US, and Canada during 2010. Physicians involved in PAH treatment decisions with experience in managing PAH for ≥2 years completed a perceptual questionnaire. Retrospective clinical records from last 5 patients (pts) seen by each physician were analysed.

**Results:** 472 physicians (43% cardiologists, 29% pulmonologists, 20% rheumatologists, and 8% internists), 62% based in pulmonary hypertension centres, entered data for 2360 pts. Among those, 51% had idiopathic PAH and 42% had PAH associated with other conditions; 38% had significant physical limitation (NYHA functional class III/IV) at diagnosis. US pts were more likely to be diagnosed in the community (40%) than pts in Europe (6%) and Canada (28%). Globally, 73% were on PAH-specific therapy, with PDE-5 inhibitors, endothelin receptor antagonists, and prostacyclins used in 57%, 54%, and 26%, respectively. Of pts treated, 29% were on combination therapies; highest usage was in the US (36%) and lowest in Italy (17%). For 95% of pts, their physicians were satisfied to some degree with the current treatment regimen. Main reasons for satisfaction included symptom control or improvement and stable disease condition.

**Conclusions:** This multinational survey highlights significant differences in PAH management between countries and illustrates physicians’ perceptions of treating this condition.

**P945**

Comparison of the pharmacokinetic, pharmacodynamic, and safety profiles of three different formulations of intravenous epoprostenol sodium

Laurent Nicolas, Marcelo Gutierrez, Jasper Dingemans. Clinical Pharmacology, Actelion Pharmaceuticals Ltd., Allschwil, Switzerland

A change in exipient of epoprostenol sodium, an i.v. pulmonary arterial hypertension treatment, from glycine-mannitol (epoprostenol GM, Flolan®) to arginine-mannitol (epoprostenol AM, Veletas®) or to undisclosed excipients (epoprostenol XX) has led to improvements in stability of the latter two formulations. The pharmacokinetic (PK), haemodynamic, safety, and tolerability profiles of these formulations were compared in this 2-part study. 20 healthy males in Part 1 and 20 different subjects in Part 2 received epoprostenol AM and epoprostenol XX, and epoprostenol GM and epoprostenol XX, respectively, in a crossover design, in sequential 2h i.v. infusions of 2, 4, 6 and 8 ng/kg/min.

PK profiles were assessed by analysing plasma concentration-time curves of the primary epoprostenol metabolites 6-keto-prostacyclin F1α (kPF) and 13,14-dihydro-prostacyclin F1α (dPF) obtained after treatment with the different epoprostenol formulations. For Part 1, the ratio of the geometric means (90% CI) of AUCs(0–∞) calculated after epoprostenol AM and epoprostenol XX treatment was 0.91 (0.88–0.95) for kPF and 0.88 (0.84–0.92) for dPF. For Part 2, the ratio of AUCs(∞) determined after epoprostenol GM and epoprostenol XX treatment was 0.97 (0.91–1.03) for kPF and 1.08 (1.02–1.14) for dPF. Haemodynamic variables, assessed by echocardiography, showed similar increases in cardiac output, cardiac index, and heart rate for all formulations with maximum values attained after 6–8h. Almost all subjects reported ≥1 adverse event.

These results suggest the 3 formulations of i.v. epoprostenol sodium have the same PK, haemodynamic, safety, and tolerability profiles.

**P946**

Lack of relevant pharmacokinetic interactions between the new dual endothelin receptor antagonist macitentan and sildenafil in healthy subjects

Patricia Sidharta¹, Paul van Giersbergen¹, Michael Wolzt², Jasper Dingemans³.

¹Clinical Pharmacology, Actelion Pharmaceuticals Ltd., Allschwil, Switzerland; ²Clinical Pharmacology, Medical University of Vienna, Austria

Macitentan, a new potent, dual endothelin receptor antagonist (ERA), is a potential treatment for pulmonary arterial hypertension (PAH). As PAH treatment may involve combination therapy of an ERA with sildenafil, the mutual pharmacokinetic (PK) interactions were investigated using a randomised, 3-way crossover study.
design (AC-055-106). Twelve healthy male subjects were treated as follows: A) macitentan alone for 4 days (loading dose of 30 mg, thereafter 10 mg o.d.), B) sildenafil alone for 4 days (20 mg i.d. on Days 1–3 and 20 mg o.d. on Day 4), C) treatments A and B combined. Plasma concentrations of macitentan and its pharmacologically active metabolite ACT-132577 (A and C) and sildenafil and its N-desmethyl metabolite (B and C) were measured on Day 4. Tolerability was assessed daily. The PK of macitentan was not altered (geometric mean ratios for Cmax and AUC, close to 1.0 with 90% confidence intervals within 0.8–1.25 bioequivalence limits) by sildenafil while the exposure to ACT-132577 decreased (Cmax, 0.82 [0.76–0.89]; AUC, 0.850 [0.80–0.91]). Exposure to sildenafil increased in the presence of macitentan (Cmax 1.26 [1.07–0.89]; AUC, 1.15 [0.94–1.41]), while that to N-desmethylsildenafil was unaffected. All treatments were well tolerated but combined treatment resulted in a higher incidence of adverse events (most commonly headache) and decreased diastolic blood pressure.

As no clinically relevant PK interactions were observed between macitentan and sildenafil, dose adjustment of either compound is not necessary during combined treatment.

P947

EPITOME-2: Evaluation of a new formulation of epoprostenol sodium in pulmonary arterial hypertension patients switched from an originally approved formulation

Oleger Sitbon1, Marion Delcroix2, Emmanuel Berrog3, Anco Boonstra4, Pilar Escriptano Sabi3a, Nazzareno Galibi4, John Granton5, David Langleben6, Thomas Piister7, Jean-Christophe Lemari8,9, Gerald Simonneau1,2, 3Service de Pneumologie, Hôpital Universitaire de Bicêtre, Université Paris-Sud, Le Kremlin Bicêtre, France; 2Pneumologie, Académie Hospitalière Gstaadspital, Gstaad, Switzerland; 3Servicio de Pneumología, Hópital Côte de Nacre-CHU, Caen, France; 4Pulmonology, VU University Medical Center, Amsterdam, Netherlands; 5Servicio de Cardiología, Hospital Universitario 12 de Octubre, Madrid, Spain; 6Institute of Cardiology, University of Bologna, Italy; 7Pulmonary Hypertension Program, Toronto General Hospital, Toronto, Canada; 8Jewish General Hospital, McGill University, Montreal, Canada; 9Global Medical Science, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; 10Effi-Stat, Effi-stat, Paris, France

Introduction: Epoprostenol sodium originally approved with glycine-mannitol excipients (epoprostenol GM; Flolan®) is an i.v. pulmonary arterial hypertension (PAH) treatment. Epoprostenol sodium with undisclosed excipients (epoprostenol XX) is a new formulation with improved room temperature stability and simplified storage requirements. EPITOME-2 is an ongoing PAH study evaluating switch from epoprostenol GM to epoprostenol XX.

Methods: Adult PAH patients treated with epoprostenol GM for ≥12 months and on a stable dose for the last 3 months were switched to epoprostenol XX. Changes from baseline to 3 months were evaluated for cardiac haemodynamic and clinical parameters, including pulmonary vascular resistance (PVR) and WHO functional class (FC). Safety and tolerability were also evaluated.

Results: Of the 42 patients enrolled, data are available for the first 10 completers. Mean (range) age was 45 (25–78) years and 5 were female. Mean (range) time from diagnosis was 10.57 (1.6–37.1) years. Following switch, patients remained on a stable epoprostenol XX dose at 3 months. There was no change from baseline to 3 months were evaluated for cardiac haemodynamic and clinical parameters. mPAP, mmHg 54.7 (42–65) 55.0 (37–73) CO, L/min 5.7 (4.3–6.7) 5.7 (4.6–7.4) WHO FC I, II, III (n) 1,5,4 1,6,3

Conclusion: Epoprostenol XX dose, haemodynamics and WHO FC.

Outcomes from use of targeted therapy in pulmonary hypertension associated with sarcoidosis (PHAS)

John Cannons, Colm McCagh, Joanna Pepke-Zaba, Karen Sheares. Pulmonary Vascular Disease Unit, Papworth Hospital, Cambridge, United Kingdom

Pulmonary hypertension is a recognised complication of sarcoidosis and may arise from several aetiological pathways. We report our experience of patients with PHAS-GroupV on targeted treatment.

Retrospective study of patient outcomes with PHAS. All patients underwent right heart catheterisation satisfying criteria for diagnosis of PAH. We reviewed 16 patients, 10 of whom died in mean f/u 32m. Patients dichotomised into 2 groups (responders and non-responders) based on improvement in log ntproBNP and PVR, dyne/cm²/m². Responders (n=8) Non-responders (n=5) p value

Conclusion: In this cohort of patients with PHAS, ambrisentan proved to be safe and efficacious for the therapy of PHAS patients. Ambrisentan resulted in significant improvement in hemodynamics and normalization of RV size, function and PVR in the majority of the patients.

P949

Ambisentan for therapy of portopulmonary hypertension (POPH): Update on safety and efficacy

Rodrigo Caru-Ceba, Karen Swanson, Michael Krowka. Pulmonary and Critical Care, Mayo Clinic, Rochester, MN, United States

Aim: To present an update of the long-term hemodynamic response and clinical outcomes of POPH patients treated with ambisentan.

Methods: Observational study of POPH patients from 01/2007 to 12/2011 treated with ambisentan. Clinical data, baseline and follow up thoracic echocardiograms (TTE) and right heart catheterisations (RHC) were accomplished and compared.

Results: A total of 27 patients with POPH were started on ambisentan (female=15). Median age (IQR) was 56 (53-60). Median follow up 874 days (472-1548). Medium time on ambisentan 391 days (259-839). Ten patients underwent liver transplantation successfully. Nine out of 27 patients died, 7 deaths due to complications of chronic liver disease, one patient of sepsis, and one died of an acute coronary syndrome. Follow up RHC data were available in 20 patients. Mean pulmonary artery pressure (mPAP) improved from 42 mmHg (35-57) to 38.5 (28-43.5), p=0.007; pulmonary vascular resistance (PVR) improved from 434 dyne·sec·cm⁻⁵ (311-611) to 228 (154-361), p=0.001; and cardiac output increased from 6 L/min (5.7-4.7) to 7.9 (6.4-9.2), p=0.005. TTE data showed that RV size and function improved in 19 and 18 patients respectively. Ambisentan was well tolerated in all but one patient who developed severe edema and required discontinuation after 2 weeks of initiation. No significant elevation of transaminases requiring discontinuation of the medication was identified.

Conclusion: In this cohort of patients with POPH, ambisentan proved to be safe and efficacious for the therapy of POPH patients. Ambisentan resulted in significant improvement in hemodynamics and normalization of RV size, function and PVR in the majority of the patients.

P950

Lack of relevant pharmacokinetic and pharmacodynamic interactions between the new dual endothelin receptor antagonist macitentan and warfarin in healthy subjects

Patricia Sidharta 1, Hartmut Dietrich 2, Jasper Dingemans 1. 1Clinical Pharmacology, Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; 2ClinPharmCologne, MEDA Manufacturing GmbH, Cologne, Germany

Macitentan, a new, potent, dual endothelin receptor antagonist (ERA), is a potential treatment for pulmonary arterial hypertension (PAH). In this study (AC-055-105),
the effect of macitentan on the pharmacokinetics (PK) and pharmacodynamics (PD) of a single dose of warfarin was investigated in 14 healthy male subjects. Subjects received treatment sequence A/B or B/A separated by a 2-week washout. Treatment A: macitentan for 8 days (loading dose of 30 mg, thereafter 10 mg o.d.). On Day 4, a single dose of 25 mg warfarin was given with macitentan. Treatment B: A single dose of 25 mg warfarin on Day 1. Blood samples were assessed for warfarin PK (R- and S-warfarin) and PD (INR and Factor VII). Plasma trough levels of macitentan and its active metabolite, ACT-132577, were determined. Twelve subjects were included in the PK/PD analysis. The plasma concentration-time profiles of R- and S-Warfarin (Figure 1) and PD parameters of INR and Factor VII were comparable between treatments.

Warfarin did not impact the trough levels of macitentan and ACT-132577. Both treatments were well tolerated. Based on these results, no dose correction of macitentan or warfarin is needed when using these drugs together.

**P951 Absorption behavior of riociguat (BAY 63-2511): Bioavailability, food effects, and dose proportionality**

Cerina Becker1, Reiner Frey1, Christiane Hesse1, Sigrun Unger2

Michael Reber1, Wolfgang Mueck1.1 Clinical Pharmacology Department, Bayer AG, Wuppertal, Germany; 2Global Biostatistics Department, Bayer Pharma AG, Wuppertal, Germany

**Introduction:** Riociguat, an oral soluble guanylate cyclase (sGC) stimulator, is currently investigated in the treatment of PH. Riociguat increases cGMP production through a novel dual mode of action: direct NO-independent sGC stimulation and increasing sGC sensitivity to low NO levels.

**Aim:** To characterize the biopharmaceutic properties of riociguat including absolute bioavailability (BA), interaction with food, and dose-proportionality.

**Methods:** Pharmacokinetics (PK) following IV and oral administration of immediate release tablets were characterized in 3 open-label, randomized, crossover studies in healthy male subjects: absolute BA (n=22), food effect at 2.5 mg (n=24), and dose-proportionality over 0.5–2.5 mg (n=24). Safety and tolerability were also assessed.

**Results:** Absolute BA was 94% (90% CI: 83–107). A high-fat breakfast delayed absorption with little effect on the extent of riociguat absorption (ratio AUCoral/AUCfasted 88% CI: 82–95). PK were dose-proportional over 0.5–2.5 mg (common slope of AUC 1.09 [90% CI: 1.04–1.14]; Cmax 0.98 [90% CI: 0.93–1.04]).

**Conclusion:** Riociguat shows complete oral absorption, and no clinically relevant food effect. At 0.5–2.5 mg, riociguat systemic exposure increased dose-proportionally over 0.5–2.5 mg (n=24). Safety and tolerability were also assessed.

**P952 Effect of ambrisentan, bosentan and macitentan on human hepatic uptake and efflux transporters**

Hunter Gillies1, Irene Lepisi2, Jia Hao2, Adrian Ray2.1 Clinical Research, Gilead Sciences Inc, Foster City, CA, United States; 2Drug Metabolism, Gilead Sciences Inc, Foster City, CA, United States

**Background:** The putative mechanism for hepatic adverse reactions observed with bosentan, an endothelin receptor antagonist (ERA), is inhibition of the hepatic transport of bile salts (Fattinger K 2001). The ERA ambrisentan has a low risk of hepatic adverse reactions.

**Objective:** Bosentan, ambrisentan and macitentan, an experimental ERA in clinical development, were tested for inhibition of hepatic transporters in vitro.

**Methods:** Inhibition constants (IC50) were measured for human BSEP, sodium taurocholate cotransporting polypeptide (NTCP), multidrug resistance protein 2 (MRP2), P-glycoprotein (Pgp), breast cancer resistance protein (BCRP), organic anion-transporting polypeptide 1B1 (OATP1B1), and OATP1B3 in transfected cell-lines. Known inhibitors were used as positive controls.

**Results:** The most potent inhibition observed was for OATP1B1 (range 2 μM to 47 μM). Ambrisentan had no measurable effect on BSEP and NTCP while inhibition was observed for bosentan and macitentan. The most potent inhibition of these transporters was observed for macitentan with IC50 values of 12 and 8 μM for BSEP and NTCP, respectively.

**Conclusions:** Macitentan inhibited hepatic transporters the greatest whilst ambrisentan showed little or no effect.

**P953 Bosentan influence on catecholamines levels in patients with idiopathic arterial pulmonary hypertension**

E. Kobal, T. Martynyuk, O. Arkhipova, V. Masenko, S. Nakonechnikov, T. Chazova. Systemic Hypertension, Russian Cardiology Research-and-Production Complex, Moscow, Russian Federation

**Aim:** To assess the influence of endothelin receptor antagonist Bosentan on catecholamines levels in pts with idiopathic pulmonary arterial hypertension (IPAH).

**Methods:** In the single-center comparative study we included 35 pts aged 35.2±9.6ys with IPAH confirmed by RHC (WHO Functional Class (FC) II-IV) without systemic inflammation signs. On top of stable therapy with anticoagulants, diuretics, glycosides, calcium antagonists for at least 3 months, Bosentan therapy was started 62.5 mg twice daily for 4 wks. At wk4 the pts were randomized 1:1 by the envelope method to bosentan 125 or 250 mg/day. At baseline, at wk3 and wk12 the pts underwent the clinical and lab assessment, including catecholamines (HPLC).

**Results:** At baseline IPAH groups were comparable by age, sex, disease duration, hemodynamic parameters. In both groups the levels of norepinephrine were significantly higher than normal values (139.9±41.2). Otherwise the epinephrine levels were decreased as compared with controls (69.4±12.1).

**Conclusion:** In IPAH pts Bosentan therapy influenced on catecholamines levels by significant reduction of initially increased norepinephrine levels. This effect was more pronounced in Pts treated with Bosentan 125mg daily.

**P954 Endothelin-1 downregulates BMP signaling in pulmonary artery smooth muscle cells**

Hidekura Manuyama1, Celine Dewachter1, Asmael Belhaj1, Benoit Rondelot1, Myriam Remmelink2, Jean-Luc Vachery3, Robert Nairje1, Laurence Dewachter1, Physiopathology Laboratory, Université Libre de Bruxelles, Brussels, Belgium; 2Service d’Anatomie Pathologique, CUB-UlB Hopital Erasme, Brussels, Belgium; 3Pulmonary Vascular Diseases Clinic, CUB-UlB Hopital Erasme, Brussels, Belgium

Increased endothelin-1 (ET-1) and decreased bone morphogenetic protein (BMP) receptor type 2 (BMPR2) signaling pathways have been shown to be implicated in the pathogenesis of pulmonary arterial hypertension (PAH). However, little is known about the interaction between these two signaling pathways and its implication in the generation of altered pulmonary artery smooth muscle cell (PA-SMC) phenotype in PAH.

We therefore quantified BMP signaling in PA-SMCs isolated from PAH patients and the effects of ET-1 treatment on the expressions of BMPR2, BMP agonists (BMP4) and antagonists (gremlin-1, gremlin-2 and noggin) in PA-SMCs.

We therefore quantified, by RTQ-PCR, the gene expressions of BMPR2, BMP agonists (BMP4) and antagonists (gremlin-1, gremlin-2 and noggin) in PA-SMCs. We therefore quantified, by RTQ-PCR, the gene expressions of BMPR2, BMP agonists (BMP4) and antagonists (gremlin-1, gremlin-2 and noggin) in PA-SMCs.
ET-1 (10-6M and 10-7M) on the expression of these BMP signaling members in PA-SMCs. Furthermore, we observed that oral BH4 supplementation increased in PA-SMCs isolated from PAH patients. Stimulation of control PA-SMCs with ET-1 induced an increase in mRNA encoding BMP antagonists (gremlin-1, gremlin-2 and noggin), while BH4 supplementation expression decreased dose-dependently. However, in ET-1 treated PA-SMCs, BH4 supplementation expression did not change. Furthermore, treatment levels of BMPR2 and BMP antagonists were similar as those observed in PA-SMCs isolated from PAH patients. Evidence derived ET-1 seems to contribute to altered BMPR2 signaling observed in PAH patients.

104. Pulmonary circulation: clinical diagnosis, treatment, end-points and animal models

P955
PLA2 polymorphism of platelet glycoprotein Ib/IIa but not Factor V Leiden and prothrombin G20210A polymorphisms is associated with venous thromboembolism in an animal model of bleomycin-induced lung fibrosis.

Hamid Rouhi Borojeni1, Batoul Pourgheysari2, Ali Hasheminia 3.

Introduction: Inherited thrombophilic gene polymorphisms have been linked to the pathogenesis of venous thromboembolism (VTE). As they are very limited data on these polymorphisms in Iranian population we aimed to investigate them in these patients.

Methods: 72 patients with VTE and 306 healthy control subjects were recruited to the study. Genotyping from EDTA taken venous blood for the factor V Leiden (FVL), prothrombin (FII) G20210A, methylene tetrahydrofolate reductase (MTHFR) C677T and PLA2 polymorphisms was undertaken by PCR – RFLP.

Results: 570 investigated polymorphisms with the mean of 0.792 per individual and 151 with the mean of 0.494 were found in patients and control respectively (p=0.001). FVL and FII G20210A were found in 5.6% and 1.4% of the patients compared with 2.3% and 1% of the controls respectively (p=NS). PLA2 polymorphism of GPIIb/IIla was seen in 27.8% and 10.1% in patients and controls respectively (OR=3.4, CI: 1.08-6.44, P<0.001). 21.5% of carrier VTE patients compared with 9.6% of carrier controls had confluence of more than one genetic risk factor (P=0.007) and more recurrent events were occurred in them. Patients with PL A2 polymorphism had more recurrent events than the other patients (P=0.02). Patients with more than one genetic risk factors and recurrent events were younger.

Discussion: Higher prevalence of PLA2 polymorphism of GPIIb/IIla in VTE patients demonstrates the impact of this polymorphism in the pathogenesis of VTE in this population that need to manage these patients differently.

Tetrahydrobiopterin improves pulmonary vascular remodeling following mouse-intraaeraloeal bleomycin administration

Patricia Almudever1, Ricardo Guaymari2, Javier Miilar3, Kaya Marini4, Julio Cortijo4. 1Pharmacology Department, Valencia University, Valencia, Spain; 2Thoracic Surgery Department, Valencia University (General Hospital), Valencia, Spain; 3Biochemistry Department, Politiecen University, Valencia, Spain; 4CIBEREC, Valencia University, Valencia, Spain

Background/Objective: Pulmonary hypertension in pulmonary fibrosis portends a poor prognosis. Recent evidence suggests that tetrahydrobiopterin (BH4), the cofactor of nitric oxide synthase, is involved in pulmonary hypertension. However the role of BH4 in pulmonary hypertension secondary to pulmonary fibrosis is unknown. The current study investigated the role of BH4 on pulmonary remodelling in an animal model of bleomycin-induced lung fibrosis.

Methods: C57Bl/6J mice were instilled intra-tracheally with a single dose of bleomycin at 3.75 U/kg at day 1. BH4 (20mg/kg) or vehicle (control) was administered orally once a day, from day 1 until the end of experiment (day 14). At the end of the treatment period, mice were sacrificed and plasma, lungs and hearts were removed. Plasma BH4 concentration was measured by high performance liquid chromatography. The right ventricular (RV) wall of the heart was dissected free from the blood and weighed along with the left ventricle wall plus septum (LV + S), and the resulting weights were reported as RV/LV + S ratio to provide an index of right ventricular hypertrophy. TGF-β1 and ET-1 gene expression were measured by real-time RT-PCR in lung homogenates as pulmonary vascular remodeling markers.

Results: Bleomycin reduced ∼2.3-fold the BH4 plasmatic levels, augmented the RV/LV + S ratio to 0.075 mg/mg over control, and increased the ET-1 and TGF-β1 gene expression to ∼2.5-fold and ∼6-fold versus control respectively. Oral BH4 suppressed the bleomycin-induced right ventricular hypertrophy and reduced the ET-1 and TGF-β1 gene expression to control levels.

Conclusions: BH4 inhibits blomycin-induced right ventricular hypertrophy in mice.

Molecular analysis of genes BMPR2 and KCNA5 in Spanish patients with pulmonary arterial hypertension

Guillermo Posada1, Adriilo Balazrica2, Carlos Vilariño1, Diana Valverde1.

1Biosquimica, Genética e Immunologia, Universidad de Vigo. Pontevedra, Spain; 2Servicio de Neumología, Complejo Hospitalario de Pontevedra, Pontevedra, Spain; 3Servicio de Neumología, Complejo Hospitalario de Vigo, Vigo.

Pulmonary arterial hypertension (PAH, OMIM 178000) is a rare and progressive vascular disorder characterized by obstruction of precapillary pulmonary arteries. PAH results from extensive remodelling of the pulmonary vasculature caused by an increased muscularization of small arteries and the twinning of the intima that leads to obliteration of small pulmonary arteries. Without treatment, progression of pulmonary hypertension leads to right ventricular failure and death in three years from diagnosis. Approximately 75% of patients with the familiar form of PAH have a mutation in the gene encoding bone morphogenetic protein receptor type II (BMPR2). However, some other candidate genes have been advocated, including potassium voltage-gated channel, shaker-related subfamily, member 5 (KCNA5). We included 30 PAH patients and 50 controls. The DNA extraction was performed with Qiagen FlexiGene DNA kit. BMPR2 and KCNA5 genes were amplified by PCR and sequenced. A total of 20 BMPR2 nucleotide changes were identified in 22 of 30 patients with PAH. Only 3 changes were identified with the Polyphen software as pathogenic (p.C84F, p.Q26L and p.W928Stop). These mutations were found in 4 patients. For KCNA5 gene 10 nucleotide changes were detected in 11 patients. Three were classified as pathogenic (p.F169R, p.R148P and p.E208X) we have found these mutations in 4 patients. None of the pathogenic mutations identified here were detected in a panel of control individuals from control endomorphisms.

In conclusion, mutations in genes BMPR2 and KCNA5 have been detected in the 28.5% of our pool of patients indicating that these genes are the most important genes implicated in the development of PAH.

P958
The German version of the Cambridge Pulmonary Hypertension Outcome Review (CAMPFHR) – Four-stage translation and validation

Katharina Cima1, James Twiss2, Rudolf Speich3, Stephen P. McKenna2, Ekkehard Gruning3, Christian M. Kahler1, Nicola Ehlers1, Ursula Troeder2, Sigrid R. Crawford3, Lars C. Huber1, Silvia Viale1, 1Internal Medicine, University Hospital, Innsbruck, Austria; 2Galen Research Ltd, Galen Research Ltd, Manchester, United Kingdom; 3Pulmonary Hypertension Programm, University Hospital of Zurich, Switzerland; 4Cardiology at Thorax Clinic, University of Heidelberg, Germany

Background and objective: Individuals with precapillary pulmonary hypertension (PH) experience impaired quality of life (QoL). A disease-specific outcome measure, the Cambridge Pulmonary Hypertension Outcome Review (CAMPFHR) is validated in English. We translated the instrument and validated it for German-speaking population.

Methods: A multi-step procedure including bilingual translation process, lay panel assessment, cognitive debriefing interviews, validation and evaluation was performed. It included 107 patients with precapillary PH (60 females, age 60+15 years) from centres in Austria, Germany and Switzerland.

Results: The translation process was straightforward. The field-test interview participants found the questionnaires relevant, comprehensible and easy to complete. Psychometric analyses showed that the German adaptations were successful. High test-retest coefficients for the scales after controlling for change in respondent’s QoL (FC: 0.92 to 0.96, EC: 0.85 to 0.99) indicated a high degree of reliability. The CAMPFHR scales had good internal consistency (Cronbach’s alpha coefficients 0.90 to 0.92 and 0.88 to 0.92, respectively). Also the three CAMPFHR scales (symptoms, activity limitations and quality of life) had excellent test-retest reliability (r=0.90-0.91, P<0.001) and internal consistency (Cronbach’s alpha >0.90).

Predicted correlations with the NYHA class, the 6-minute walking distance and the Nottingham Health Profile provided evidence of an excellent construct and group validiy of the CAMPFHR scales.

Conclusions: We have shown the CAMPFHR to be valid and reliable in the German population and recommend its use in clinical practice.

P959
Reference values for the 6-minute walk test in healthy children

Silvia Ulrich1, Florian Hildenbrand1, Ursula Troeder1, Manuel Fischer2, Rudolf Speich1, Margrit Fastnacht3. 1Heart-Vessel-Thorax, Respiratory Clinic, University Hospital, Zurich, Switzerland; 2Internal Medicine, City Hospital Waid, Zurich, Switzerland; 3Pediatric Cardiology, Childrens Hospital, Zurich, Switzerland

Background: The 6-minute walk test (6MWT) is a simple and reliable tool to assess exercise capacity in various diseases. The aim of this study was to establish reference values for the 6MWT in healthy children and adolescents in middle
Europe and to investigate the impact of age, anthropometrics, heart rate, blood pressure and reported physical activity on the distance walked.

Methods: Age- and sex-stratified children and adolescents between 5-17 years had short questionnaire assessments about the health state and physical activities. Thereafter anthropometrics and vitals were measured, a 6MWT was performed according to guidelines and exercise vitals were reassessed.

Results: Age-adjusted 6MWT distance from 496 children (252 girls) was obtained. Age, height, weight and the exercise heart rate all predicted the distance walked according to different regression models: age was the best single predictor and mostly influenced walk distance in younger age, anthropometrics were more important in girls and adolescents. Exercise heart rate was an important distance predictor in addition to age and outreach anthropometrics in the majority of subgroups assessed.

Conclusion: Performing the 6MWT is feasible and practical in children and adolescents. The 6MWD depends mainly on age, however, exercise heart rate, height and weight significantly add information and should be taken into account mainly in adolescents. Reference equations allow to predict 6MWT distance and may help to better assess and compare outcomes in young patients with cardiovascular diseases.

P960
The adenosine A2B receptor antagonist GS-6201 reduces small artery muscularization and plasma endothelin-1 in a short term cigarette smoke exposure model
Joanne Wright1, Hongyan Zhong2, Dewan Zeng2, Luiz Belardinelli2, Andrew Chan2, Patricia Murnane2, Andrew W French2, Andrew Churg1, 1Pathology, University of British Columbia, Vancouver, BC, Canada; 2Research and Development, Gilead Sciences, Palo Alto, CA, United States

Adenosine plays an important role in the development and progression of lung injury with increased levels of adenosine and expression of A2B receptors. The A2B antagonist GS-6201 has shown anti-inflammatory effects in an acute model of cigarette smoke-induced lung injury. We have previously shown that exposure to cigarette smoke induces small artery remodelling and increased pulmonary arterial pressures in the guinea pig. Because A2B adenosine receptors are highly expressed in the pulmonary vasculature, we hypothesized that the A2B antagonist GS-6201 may prevent this remodeling. We exposed groups of six guinea pigs to 5 cigarettes per day 5 days per week for 4 weeks; groups were given oral vehicle, GS-6201 in doses of 1, 10 and 30 mg/kg (QD) 2 hours prior to smoke exposure, and a group was exposed to room air. 24 hours after final exposure, the animals were anesthetized and pulmonary arterial pressure was measured directly. One lung lobe was lavaged, and inflammatory cell counts obtained, one lobe was inflated with agarose for morphometric analysis of muscularization of small pulmonary arteries. Plasma was obtained for measurement of endothelin-1 (ET-1).

We found that cigarette smoke induced a non-significant increase of the pulmonary arterial pressure, but a significant increase in small arterial muscularization that was reduced by GS-6201 in a dose-dependent manner. Plasma ET-1 was increased by smoke exposure, and significantly decreased in a dose-dependent manner by GS-6201 as well. Our data suggest that adenosine receptor A2B antagonists may prevent the development of COPD associated pulmonary hypertension.

P961
End-tidal CO2 pressure may facilitate differential diagnostics between PH patients with chronic heart or lung disease and CTEPH
Maria Tschermak1, Gabor Kovacs2,3, Vasile Foris2, Stefan Scheidl1, Alexander Avian1, Andrea Olschewski1,2, Horst Olschewski1,2, Ludwig-Boltzmann-Institute for Lung Vascular Research, Graz, Austria; 2PL-D, Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria; 3Medical Informatics, Statistics and Decision Support, Ludwig-Boltzmann-Institute for Lung Vascular Research, Graz, Austria

Background: End-tidal CO2 pressure (PETCO2) is a simple parameter, which may be assessed at rest or during exercise during cardiopulmonary exercise testing (CPET). PETCO2 changes have been described in patients with cardiac failure and acute pulmonary embolism, as well as in pulmonary hypertension (PH), but it is not known if PETCO2 may be helpful in differentiating between PH subgroups.

Patients and methods: We retrospectively investigated PETCO2 data of patients with a meanPAP > 25 mmHg at rest, due to chronic left heart (LH-PH), and pulmonary disease (LH-PH) or CTEPH. PETCO2 was measured at rest and during maximal exercise. Mean values were compared by ANOVA and multiple comparisons were performed with Scheffe as post hoc test.

Results: N=46 patients were included (LH-PH: n=14, mean PAP 40±11 mmHg, PVR 327±188 dyn s cm⁻⁵, PWP 21±5 mmHg; Lu-PH: n=15, meanPAP 34±8 mmHg, PVR 441±266 dyn s cm⁻⁵, PEVI10.2%±3.7%); CTEPH: n=17, meanPAP 46±10 mmHg, PVR 732±308 dyn s cm⁻⁵). PETCO2 at rest was 4.97±1.04 mmHg, 4.70±1.19 mmHg, and 3.55±0.71 mmHg in LH-PH, Lu-PH and CTEPH patients. The PETCO2 difference between LH-PH and CTEPH was 1.38 (CI 95% 0.48 to 2.29 p=0.001), and between Lu-PH and CTEPH 1.14 (CI 95% 0.24 to 2.04 p=0.007). Comparable similar results were obtained with PETCO2 during maximal exercise.

Conclusion: PH caused by CTEPH is characterized by lowered PETCO2 as compared to PH due to chronic heart or lung disease.

P962
Human pentraxin 3 (PTX3) as a novel biomarker for the diagnosis of pulmonary arterial hypertension
Yuchin Tamura1, Masataka Kawana2, Kenji Inoue1, Tomohiko Ono1, Makoto Takeda1, Tsumehisa Yamamoto1, Masaharu Kataoka4, Motoaki Sano1, Toru Satoh4, Keiichi Fukuda1, 1Department of Cardiology, Keio University School of Medicine, Tokyo, Japan; 2Department of Pulmonary Medicine, Keio University School of Medicine, Tokyo, Japan; 3Department of Cardiology, Juntendo University Nisera Hospital, Tokyo, Japan; 4Department of Cardiology, Kyorin University School of Medicine, Tokyo, Japan

Background: Although inflammation is an important feature of pulmonary arterial hypertension (PAH), the usefulness of local inflammatory markers as biomarkers for PAH is unknown. In this study, we tested plasma concentrations of human pentraxin 3 (PTX3), a local inflammatory marker, would be a useful biomarker for detecting PAH.

Methods: Plasma PTX3 concentrations were evaluated in 50 PAH patients (27 with idiopathic PAH, 17 with PAH associated with connective tissue disease (CTD-PAH), and six with congenital heart disease). 100 age and sex-matched healthy controls, and 34 disease-matched CTD patients without PAH. Plasma concentrations of B-type natriuretic peptide (BNP) and C-reactive protein (CRP) were also determined.

Results: Mean PTX3 levels were significantly higher in all PAH patients than in the healthy controls (4.0±0.37 vs. 1.9±4±0.99 mmHg, respectively; P < 0.001). Using a threshold level of 2.84 mmL, PTX3 yielded a sensitivity of 74.0% and a specificity of 84.0% for the detection of PAH. In CTD-PAH patients, mean PTX3 concentrations were significantly higher than in CTD patients without PAH (5.02±0.69 vs. 2.40±0.14 mmHg, respectively; P < 0.001). There was no significant correlation between plasma levels of PTX3 and BNP or CRP. Receiver operating characteristic (ROC) curves for screening PAH in patients with CTD revealed that PTX3 (area under the ROC curve 0.866) is superior to BNP. Using a PTX3 threshold of 2.85 mmL, maximized true-positive and false-negative results were obtained (91.4%, specificity 85%).

Conclusion: Plasma concentrations of PTX3 are more excellent than BNP in the detection of PAH, especially in patients with CTD.

P963
Acute vasoreactivity testing with sildenafil vs nitric oxide in patients with PAH
Karin Müller1, Henning Tide1, Janine Felix2, Friedrich Grimminger1, Werner Seeger1, Hossein Ghoftani1, 1University of Giessen Lung Center, Justus-Liebig University, Giessen, Germany; 2Department of Epidemiology, Erasmus MC, University Medical Center, Rotterdam, Netherlands

Introduction: Vasoreactivity testing with inhaled nitric oxide (iNO) is recommended in patients with pulmonary arterial hypertension (PAH) because of therapeutic and prognostic implications. Sildenafil is a promising agent for acute vasoreactivity testing since it is more stable and easier to handle than iNO. But it is not known if the acute responses to sildenafil and NO are equal.

Objectives: The aim of this study is to compare acute vasoreactivity in response to sildenafil vs iNO in patients with PAH.

Methods: In this retrospective, open-label, and single-centre study we included all patients who were admitted to our adult pulmonary hypertension unit from 2002 to 2011, met the criteria for PAH, and underwent vasoreactivity testing with iNO and sildenafil.

Results: 198 patients were included. 9.6% of the patients met the responder criteria (as defined by the current guidelines) for iNO and 11.6% for sildenafil. Intra-individually, the responses in mPAP and cardiac index (CI) after sildenafil and NO administration correlated (r=0.516, p<0.001, r=0.451, p<0.001). At mean there was a significantly higher CI after sildenafil than after iNO application (CIANO=2±0.4±0.69m[mL/min/m²], CIiNO=2.56±0.76ml/min/m²). Applying the current response criteria, the sensitivity to detect NO-responders by sildenafil vasoreactivity was 81.3%, the specificity was 94%, the positive predictive value was 56/

Conclusions: In PAH patients the vasoreactive response to sildenafil is stronger than to iNO. The intra-individual vasoreactive responses to both drugs correlate. The sensitivity to detect NO-responders by using sildenafil for vasoreactivity testing was moderate, but the positive predictive value was low.

P964
The clinical role of routine non-invasive parameters in the diagnostic work-up of patients with risk for pulmonary hypertension
Gabor Kovacs1,2, Vasile Foris2, Maria Tschermak1, Alexander Avian1, Xhylsime Kqiku1, Andrea Olschewski1,2, Horst Olschewski1,2, 1Pathology, University of British Columbia, Vancouver, BC, Canada; 2Internal Medicine, Division of Pulmonology, Medical University of Graz, Austria; 3LBI, Ludwig-Boltzmann-Institute for Lung Vascular Research, Graz, Austria; 4Medical Statistics, Medical University of Graz, Austria; 5Anesthesiology and Intensive Care Medicine, Medical University of Graz, Austria

Background: The work-up of patients with risk for pulmonary hypertension (PH) is challenging. Doppler Echocardiography is the most specific non-invasive screening tool, but the role of other routine measures in the diagnostic work-up of patients is not clearly defined. We hypothesized that a diagnostic algorithm using a combination of simple non-invasive parameters might help to identify patients with PH.

Objective: Pulmonary hypertension (PH) is diagnosed by right heart catheterization. Doppler Echocardiography is the most specific non-invasive screening tool, but the role of other routine measures in the diagnostic work-up of patients is not clearly defined. We hypothesized that a diagnostic algorithm using a combination of simple non-invasive parameters might help to identify patients with PH.
Patients and methods: We retrospectively analyzed all patients who received a right heart catheterization and a routine non-invasive assessment between 2005 and 2010. The pretest probability for PH was 50%. As first step, the ratio of the S and R waves of lead I of the ECG (<0.9) was considered as right axis deviation (RAD). In a second step, further simple non-invasive parameters were analyzed by logistic regression for their association with PH.

Results: We included n=395 patients. RAD was present in n=87 of them. Within these, n=82 had PH, and n=5 did not, revealing a positive predictive value of 94%. In the remaining n=308 patients, we identified n=60 patients with a combination of NT-proBNP>393pg/Ml, DICO<0.5, arterial SO2<95% and Borg dyspnoe score<3 at the end of six-minute walk test, of which only n=4 suffered from PH revealing a negative predictive value of 93%.

Conclusion: Our retrospective analysis on a large, heterogeneous cohort of subjects including patients with and without PH suggests that the combination of simple, non-invasive parameters allows a reliable identification of subjects both with a very high and with a very low probability of PH. Further validation in prospective, population based studies is needed.

P965
Patients’, relatives’ and practitioners’ views on pulmonary arterial hypertension
Sophie Alami1, Vincent Cotin2, Dominique Desjeux1, Luc Moutounet1, Serge Pouriaudé1, Esther Quezzette1, Olivier Sibou1, 1Faculté des Sciences Humaines et Sociales, Université Paris Descartes, Cerfa, Interlia, Paris, France; 2Service de Pneumologie, Centre National de référence des Maladies Pulmonaires rares, Centre de Compétences Régionale Rhône-Alpes HTAP, Hôpital Louis Pradel Université Lyon 1, UMR 754, Lyon, France; 3Université Paris Descartes, Faculté de Médecine, Pôle de Médecine Interne, Centre de référence pour les Vascularités néo-croissantes et la Sclérodermie Systemique, Hôpital; 4Université Paris Descartes, Faculté de Médecine Médecine, Service de Médecine Physique et Réadaptation, Hôpital Cochin, AP-HP; INSERM Institut Feldgraf de Recherche Sur le Handicap; 5Département Médical, Lilly France, Suresnes, France; 6Université Paris-Sud, Faculté de Médecine, Service de Pneumologie et Réanimation Respiratoire, Centre National de référence de l’Hypertension Pulmonaire Séroïve, Hôpital Antoine Béclère, Clamart, France.

Purpose: To study practitioners’, patients’, and relatives’ views regarding pulmonary arterial hypertension (PAH) and identify potential improvements in medical care strategies.

Methods: A qualitative study based on semi-structured interviews involving 16 patients, 4 relatives, and 9 practitioners.

Results: Patients, relatives, and physicians have divergent perspectives on PAH. The discrepancies identified concerned their perceptions of the illness and its impact on patients’ daily lives. Patients had a broader view, including social, identity, financial, and functional dimensions of PAH impact on their lives, while practitioners’ views were more focused on functional aspects. The study also pointed out divergent approaches among physicians to assessing patients’ New York Heart Association functional class. The expectations of patients, relatives, and physicians also differed. Patients expected improvement in PAH diagnosis and better coordination between primary care physicians and PAH medical centers. They also valued reduction of side effects, less restrictive medications, and greater consideration of their views in the medical decision making process. Physicians’ expectations focused more on identifying and validating therapeutic strategies.

Conclusion: Our results suggest several potential improvements in patient management. Finally in order to obtain more consensus-based treatment and to achieve a more uniform approach of PAH functional impact assessment process. The findings may also be useful for enhancing therapeutic education for patients and their families. Finally, this qualitative database may help develop patient-reported outcome measures with better content validity.

P966
A slower life in a smaller world. Patients’ perspective on living with pulmonary arterial hypertension
Aruni Maligam1, Denise Hunt1, Ruth Wilson1, Joana Peppe-Zaba2, 1Chest, Critical, Sleep Medicine, Papworth Hospital NHS Foundation Trust, Papworth Everard, Cambridge, United Kingdom; 2SPECIALTY, Pfizer UK, Tadworth, Surrey, United Kingdom.

Background: The pulmonary arterial hypertension (PAH) patient management pathway is often defined from the clinician or commissioner perspective. We wanted to go an in-depth understanding of the patient self reported experience living with PAH.

Objectives: Working to understand how a diagnosis of PAH impacts a patient’s quality of life. Exploring the journey through first symptoms to specialist care and the ‘life changes’ needed.

Methods: Over 1000 General Practitioners were approached to put forward patients with PAH to participate in semi-structured, in depth qualitative interviews designed to determine the key themes emerging from the individual experiences of PAH. Interviews were audio-recorded for subsequent analysis using interpretive phenomenological analysis methodology.

Results: A total of 8 patient view interviews were analysed who had the following underlying aetiologies: IPAH (n=3) and AChD (n=5), aged between 30 – 70 years and treated with different targeted PAH therapies. Patients interviewed were being managed at 4 different PAH Specialist Centres in the UK. Areas where patients’ needs were perceived not to be met by healthcare delivery included: 1) patient information materials did not cover PAH impact on co-morbidities, 2) dealing with a crisis on their own, 3) effective counseling when treatment fails, 4) securing disability allowance, 5) being able to live a normal life, 6) minimising the impact of PAH on their family.

Conclusions: Specific areas have been highlighted where healthcare delivery does not meet patients’ needs. Living with a rare disease has its own unique challenges requiring careful consideration with potential to further improve the patient experience.

P967
Exhaled nitric oxide in reactive pulmonary hypertension
Caterina Bocus1, Pierluigi Omedè2, Walter Grosso Marra3, Irene Parisi3, 1Arianna Vandalò1, Marta Malandrà1, Monica Muscore1, Ludiana Brussoni1, Corrado Magnino2, 1A. Milan, 2Clinical Pathophysiology, University, Torino, Italy; 3Dip. Medicina Ed Oncologia Sperimentale, University, Torino, Italy; 4Cardiologia I, AOU San Giovanni Battista, Torino, Italy.

Background: Pulmonary hypertension (PH) frequently complicates heart failure. In some patients, pulmonary vessels undergo reactive changes due to the chronic elevation of the left ventricular pressure, resulting in severe pulmonary hypertension and increased transpulmonary gradient (TPG). There is evidence that nitric oxide (NO) synthesized by the respiratory epithelium plays a role in the regulation of pulmonary artery pressure.

Aims and objectives: To evaluate whether exhaled NO has a role in reactive PH

Methods: Seven patients with reactive PH (rPH) were compared to 14 patients with passive PH (pPH) and to 15 control patients without PH. All the patients underwent heart catheterization, lung function tests and exhaled NO (FENO), assessed at multiple flow-rates. Alveolar NO and bronchial NO flux (JawNO) were calculated using the slope-intercept model.

Results: The results are displayed in the Table.

Comparison of haemodynamics. lung function and JawNO among CP, rPH, pPH patients

Patient with PHs had significantly lower FEV1/VC% ratio, lung diffusion (TLCO) and JawNO. JawNO was closely inversely related to TPG (r=0.385, p=0.032). Conclusion: It is still unknown why some patients develop severe and/or fixed PH with the same degree of elevated left-sided filling pressure. Our findings suggest that decreased bronchial NO flux and lung diffusing capacity may contribute to reactive PH.

P968
Unique hemodynamic profile of HIV+ patients with portal hypertension: Comparison with HIV-associated PAH and porto-pulmonary hypertension
Masayuki Nigo1, Gianfranco Tulliano2, Roxana Sulica2, 1Pulmonary, Critical Care and Sleep Medicine Division, Beth Israel Medical Center, New York, NY, United States; 2Division of Infectious Diseases and Immunology, New York University, New York University, New York, United States.

Introduction and objectives: HIV-associated PAH (HIV-PAH) and porto-pulmonary hypertension (PoPH/TN) have well described cardiovascular profiles. However, little is known about the hemodynamic characteristics when both conditions coexist (HIV-PoPH/TN). We hypothesise that in these cases right heart catheterisation (RHC) findings differ from those with HIV-PAH and PoPH/TN alone.

Methods: We performed a retrospective analysis of consecutive patients with HIV-PAH, PoPH/TN and HIV-PoPH/TN and compared their baseline RHC results: right atrial pressure (RAP), mean pulmonary artery pressure (mPAP), pulmonary artery occlusion pressure (PAOP), cardiac index (CI), pulmonary vascular resistance index (PVRI) and pulmonary artery saturation (Psat). One-way ANOVA and Student t-test between groups were used for analysis.

Conclusion: HIV-PoPHTN has a similar hemodynamic profile to HIV-PAH. Both groups have worse RV function compared to PoPHTN.

P969
Cardiac index by thermodilution and from non-invasive pulse pressure profiles analysis in PAH
Frédéric Lador1, Olivier Siboni2, Gérald Simonneau2, Philippe Hervé2, 1Service of Pulmonary Medicine, Geneva University Hospital, Geneva, Switzerland; 2Service of Pulmonary and Critical Care Medicine, Antoine-Béclère Hospital, Clamart, France; 3Service of Functional Exploration, Marie-Lannelongue Hospital, Le Plessis-Robinson, France

Background: Cardiac index (CI) is an essential parameter to assess severity of pulmonary arterial hypertension (PAH). It is usually measured by thermodilution (TD) during right heart catheterization (RHC).

Aim: We aimed to compare CI measured in PAH patients by RHC to Modelflow© (MF) method from non-invasive fingertip pulse pressure profiles, testing the hypothesis that MF is reliable for CI evaluation in PAH.

Methods: We simultaneously determined CI at rest by TD (CITD) and MF (CIMF) in 22 consecutive patients diagnosed with PAH. Cardiac output (CO) was the mean of 3 values for TD and 100 beat-by-beat values for MF. CI was calculated as CO/body surface area.

Results: Clinical and RHC data are reported in the table. The figure shows (right) CITD as a function of CIMF (Regression line: y = 0.9024x + 0.5382, R² = 0.86) and (left) a Bland–Altman analysis (Mean: 0.22; limits of agreement: -0.56 and +0.99).

Conclusions: We simultaneously determined CI at rest by TD (CITD) and MF (CIMF) in 22 consecutive patients diagnosed with PAH. Cardiac output (CO) was the mean of 3 values for TD and 100 beat-by-beat values for MF. CI was calculated as CO/body surface area. The CITD as a function of CIMF (Regression line: y = 0.9024x + 0.5382, R² = 0.86) and (left) a Bland–Altman analysis (Mean: 0.22; limits of agreement: -0.56 and +0.99).

P970
Heart rate variability: Possible implications for management of pulmonary arterial hypertension patients
Krstyna Serem1, Lyubomyr Solovy2, Marta Karapinka2, Olha Yelisyeyeva1, 1Internal Medicine #1, Lviv National Medical University, Lviv, Ukraine; 2Intensive Care Department #2, Lviv Regional Clinical Hospital, Lviv, Ukraine

The aim: to study heart rate variability (HRV) and its relationships with pulmonary hemodynamics and level of NT-proBNP in pulmonary arterial hypertension (PAH) patients.

Material and methods: 6 patients with idiopathic PAH and 3 with congenital heart disease associated PAH with (mean age 31±12 years, 7 patients with FC II and 2 patients with FC III by NYHA/WHO) were enrolled. All subjects underwent right heart catheterization. Level of NT-proBNP was determined in blood. The short-time ECG records obtained in supine position and during orthostatic test were analyzed by Poly-Spectrum software (Neurosoft, Russia). Nine healthy subjects served as a control.

Results: Severe pulmonary hypertension was found in all patients with mean pulmonary arterial pressure 53±14 mmHg, resting pulmonary vascular resistance 1180±550 dyn s cm⁻⁵. Total power of PAH patients ranged from 150 ms² to 2540 ms² with the very low frequency and low frequency bands predominance in the spectral structure. The orthostatic test caused dramatic lowering in all HRV indices in PAH subjects. Borderline values of NT-proBNP (up to 400 pg/ml) in PAH subjects were accompanied by some decrease in HRV. Simultaneously, significantly increased NT-proBNP levels (400-3200 pg/ml) were associated with marked HRV lowering both in supine position and during orthostatic test.

Conclusion: Patients with severe PAH were shown with individual various range of HRV parameters, correlating with the level of a neurohumoral activation marker NT-proBNP. HRV can be used in clinical practice to monitor progression of right-sided HF and, consequently, to determine prognosis in PAH patients.

P971
Impact of a wireless implanted pulmonary artery pressure monitoring system in heart failure patients with comorbid chronic obstructive pulmonary disease
Gerard Criner1, Robert Bourge2, Raymond Benza3, Philippe Adamsson4, William Abraham5, Brad Jeffries6, Pam Cowart6, Jordan Bauman6, Lyubomyr Solovy2, Marta Karapinka2, Olha Yelisyeyeva1, Khrystyna Semen1, Matthias Geyer1, Henning Tiede2, Andreas Rieth3, Ardeschir Ghofrani1, Ulf Müller-Ladner1, Robert Dinser4, Walter Hermann1, William Abraham4, Brad Jeffries6, Pam Cowart6, Jordan Bauman6, Khrystyna Semen1, Matthias Geyer1, Henning Tiede2, Andreas Rieth3, Ardeschir Ghofrani1, Ulf Müller-Ladner1, Robert Dinser4, Walter Hermann1

The CHAMPION trial enrolled 550 patients with NYHA class III HF who were followed for an average of 15 months. In the treatment group, clinicians used PAP data to guide therapy decisions in addition to standard care versus standard care in the control group.

Results: In the entire CHAMPION cohort, treatment had a 37% reduction in HFH rates (0.46 vs. 0.73, HR 0.63, 95% CI: 0.52-0.77; p<0.0001, Anderson-Gill). In the subgroup of 187 patients with comorbid COPD, treatment had a 41% reduction in HFH rates (0.55 vs. 0.96, HR 0.59, 95% CI: 0.44-0.81; p=0.0099). Reductions in PAP were analyzed using an area under the curve (AUC) methodology. Overall, treatment had an average AUC reduction of 201.5 mmHg days compared to an increase of 106.5 mmHg days in control (p=0.0299, ANCOVA). In the COPD subgroup, treatment had an average reduction of 353.1 mmHg days compared to a reduction of 57.0 mmHg days in control (p=0.367).

Conclusion: Patients with COPD experience high HFH rates but have pronounced benefit from PAP monitoring. Further investigations that analyze the relationship between PAP, COPD, and HF and its implication towards new treatment strategies are warranted.

P972
Is nailfold videocapillaroscopy a valuable diagnostic tool in pulmonary hypertension?
Robert Mein1, Matthias Geyer1, Henning Tiede2, Andreas Rieth3, Hossein Ardebilchi-Ghafam1, Ulf Müller-Ladner1, Robert Dinser4, Walter Hermann1, 1Dpt of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff-Klinik, Bad Nauheim, Germany; 2Dpt of Internal Medicine, Medical Clinic II, University Hospital of Giessen and Marburg GmbH, Giessen, Germany; 3Dpt of Internal Medicine and Cardiology, Kerckhoff-Klinik, Bad Nauheim, Germany

Background: Pulmonary hypertension (PH) can be based on idiopathic pulmonary arterial hypertension (iPAH), connective tissue diseases such as systemic sclerosis

Conclusion: As previously reported for healthy subjects, MF could be useful for CI estimation in PAH but a calibration against a reference method is required.
(SSC-PAH), left heart disease (LHD-PH), chronic obstructive pulmonary disease (COPD-PH), or chronic thromboembolic events (CTEPH).

Objectives: Analysis of microvascular patterns of patients with PH has been performed using nailfold videocapillocoscopy (NVC). The benefit of NVC in PH was evaluated with focus on SSC patients.

Methods: NVC was performed in 81 patients. 2nd-5th fingers were bilaterally analyzed. Pictures were scored for capillary density (CD, capillaries/mm), and dimensions. Parameters such as hemorrhages and neoangiogenesis or capillary alterations such as ectasia (>20μm) and giant shape (>50μm) were qualitatively assessed.

Results: 14.8% had iPAH, 14.8% LHD-PH, 7.4% COPD-PH and 17.2% CTEPH. 45.7% had SSC and 12.3% SSC-PAH. The CD in SSC-PAH was significantly lower compared to all other PH forms (4.9 ± 10.2, 11.7 ± 9.4 and 9.7 ± 4.9 in iPAH, LHD-PH, COPD-PH and CTEPH; p < 0.001), but did not differ compared to SSC non-PAH (4.7 ± 0.73). In general, capillary dimensions were larger in SSC-PAH (80%), but to some extent present in other forms (e.g. COPD-PH 71.4%). Giant capillaries were only present in SSC (84.6% and 70%). Hemorrhages occurred in all disease forms of this study, mostly in CTEPH (85.7%) and SSC (80%).

Conclusions: Capillary density in SSC-PAH is a powerful tool to discriminate mostly in COPD-PH (85.7%) and SSc (80%).

P973 Right ventricular global strain and right ventricular dysfunction can predict success to pulmonary vasodilators therapy in PH patients

Beatrice Lamia, Luis-Carlos Molano, Catherine Viacroze, Antoine Cavelier, Jean-Francois Sarfati, Pierre Million and Caref Caumes
University of Rouen, France

Background: Transthoracic echocardiography (TTE) is used to evaluate right ventricular (RV) function in pulmonary hypertension (PH) patients. RV function is assessed using TAPSE or RV end-diastolic area/LV end-diastolic area ratio (RVEDA/LVEDA). RV speckle tracking strain can quantify regional contraction. Pulmonary vasodilators can improve functional status and prognosis but their effects on RV function are poorly described. The aim of our study is to test whether response to pulmonary vasodilators can be predicted by change in RV regional strain.

Methods: 16 patients were prospectively included. They underwent right heart catheterization, usual and 2D strain TTE at baseline and after 3 months of pulmonary vasodilators. PDE5 inhibitors, endothelin receptor antagonists, prostacyclin (single or combination therapy). Success or failure to pulmonary vasodilators were defined according to the guidelines.

Results: At baseline, TAPSE was 44 ± 11 mmHg, PAOP 11 ± 3 mmHg, cardiac index 3 ± 0.07 ± 3 L/min/m², RVEDA/LVEDA 1.03 ± 0.03, RV global strain 12.29 ± 5.34% and RV dysynchrony: 124/78 μsec. A change in global RV strain higher than 70% (>100 to 122%) could predict success to pulmonary vasodilators with a specificity of 100%, a change in RV dysynchrony of 96 μsec could predict success to treatment with a sensitivity of 100%. Change in TAPSE or RVEDA/LVEDA were not accurate enough to predict response to pulmonary vasodilators.

Conclusions: Success to pulmonary vasodilators therapy in PH patients can be predicted by changes in regional right ventricular contraction using longitudinal right ventricular strain and right ventricular dysynchrony analysis.

P974 Role of C-terminal pro-endothelin in pulmonary hypertension

Ralf Kaiser, Philipp M. Lepper, Robert Balz, Heinrich Willems. Dept Internal Medicine V, University of Saarland, Homburg/Saar, Saarland, Germany

Introduction: The endothelin pathway is upregulated in various forms of pulmonary hypertension. Its disease promoting activity has lead to the development of endothelin receptor blockers as specific therapeutics. The highly unstable active product of the endothelin cascade.

Methods: We examined 36 patients retrospectively. Therapy was applied following contemporary guidelines. Samples of platelet free EDTA plasma were stored at -80°C since collection between 2000 and 2003. Biomarker levels were determined by a Kryptor compact (BRAHMS, Germany) according to vendor instructions.

Results: Patients were categorized according to DanaPoint classification as class 1 (n=16), class 2 (n=1), class 3 (n=9), class 4 (n=8) and renal failure (n=6). The mean follow-up time was 4.67 years. Survivors had significantly lower levels of CT-proET (53.7 [31.2-171.8] vs 91.1 [30.6-151.6] pmol/L, p=0.006). ROC analysis for survival yielded an AUC of 80.8%. The optimized cut-off for survival was determined as 65pmol/L. The log-rank test of Kaplan-Meier-analysis for survival was highly significant (p=0.01) with a hazard ratio of 3.06.

Conclusions: CT-proET was significantly elevated in non-survivors of the follow-up period. Optimized cut-offs at 65pmol/L resulted in a significant Kaplan-Meier-analysis for survival. CT-proET-levels above 65 pmol/L are associated with decreased survival in pulmonary hypertension. CT-proET might be a useful biomarker to determine high-risk patients, while offering the advantage of a stable product of the endothelin cascade.
P977 Prevalence of respiratory symptoms and airflow obstruction in a nationally representative random sample in England

Maria M.7, Jenny Mindell7, Rachel Craig1, Joanne Clarke1, Anne Moger1, Kevin Holton1, Robert Winzer1, Sue Hill1.1, Department of Health, Medical Directorate, London, United Kingdom; 2Department of Epidemiology & Public Health, London, United Kingdom; 3NutCen Social Research, NatCen Social Research, London, United Kingdom; 4Cambridge University Health Partners, Addenbrooke’s Hospital, Cambridge, United Kingdom

Introduction: Chronic Obstructive Pulmonary Disease (COPD) causes 23,000 deaths p.a. in England with direct health costs of over £1bn. 835,000 people are registered on general practice (GP) COPD registers. An estimated 2.7 million are undiagnosed. Poor symptom recognition by the public and clinicians contributes to late diagnosis.

Aims: To estimate the prevalence of respiratory symptoms and airflow obstruction in the population of England.

Methods: The annual Health Survey of England is a cross-sectional study of a random, nationally representative sample of 8,000 adults. It includes detailed interviews and objective measures by nurses. The 2010 survey focused on lung disease and included spirometry (without bronchodilator).

Results: 15% of men and 23% of women aged 16+ had MRC dyspnoea score 2-5; half of these scored 3-5. 4% of men and 5% of women had ever been told by a doctor that they had chronic bronchitis, emphysema or COPD, compared with GP register prevalence of 1.6%. Measured FEV1/FVC ratio was inversely associated with income. FEV1/FVC was below 5th centile (indicating probable airflow limitation) in 8% of men and women; only a quarter of these had been told by a doctor that they had chronic bronchitis, emphysema, or COPD.

Conclusions: This large population survey confirms that substantial numbers of people experience respiratory symptoms and probable undiagnosed airflow obstruction. Failure to diagnose COPD early matters because it adversely affects outcomes and quality of life. To tackle this, a national Outcomes Strategy for COPD and Asthma has been launched to promote lung health awareness, earlier diagnosis and proactive disease management.

P978 Prevalence of COPD in Algerian military

Kherbi Salah. Pneumologie, HIMIRC, Constantine, Algeria

The Survey is about one of the determinants of the chronic obstructive pulmonary disease (COPD), tobacco and the military environment. The objective is to measure the prevalence of this pathology and to make a first assessment of it in order to elaborate an efficient anti-tobacco policy and to associate a better handling of this pathology within our institutions.

It is a through a transversal survey that uses the questionnaire and the spirometry on a population of soldiers and civilian staff working for the army aged 40 years and more, current smokers or former smokers having accumulated 10 P/Y and more, belonging to 10 randomly chosen military camps belonging to the fifth military region. So 720 men have been included in the investigation and have been questioned during the period of November 01/2008 to October 31/2009.

The prevalence of the chronic obstructive pulmonary disease (COPD) is of 5.35% for the whole population, of 6.37% for current smokers and 3.75% among the former smokers. The prevalence of the different stages of severity is of 2.67% for the two stages I and II. The active tobacco addiction or weaned was the only factor of risk found with a percentage of 43.15% and 36.06% respectively, associated with the passive tobacco addiction.

The chronic obstructive pulmonary disease (COPD) in the military institution is a real problem that challenges medical community and decision-makers on the emergency of the elaboration of a health policy based on the prevention through strict measures of struggle against the tobacco addiction and the early detection of patients in a precarious stage by the practice of the minimal advice and the popularization of the breath measure.

P979 A detached island residents’ smoking habits and their prevalence of COPD

Yoshihide Yanagita1, Kahori Oue2, Takako Tanaka1, Hideaki Senjyu1. Medical Science, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan; 2Department of Rehabilitation Medicine, Nagasaki-Urino Hospital, Nagasaki, Japan

Background: The prevalence of COPD is high worldwide. It has been reported that the prevalence rate of subjects aged 40 years and over is about 8.6% in Japan. However, no reports have examined the prevalence of COPD by region, such as whether there are differences in subjects living in urban areas, or on a detached island.

Aims and objectives: The purpose of this study was to evaluate the influence of the region (mainland versus a detached island) on the general population’s smoking habits and the prevalence of COPD or respiratory function. A general population of 5221 subjects was targeted.

Methods: All of the candidates’ health survey items (age, sex, body composition, smoking habit, Brinkman Index, respiratory function and COPD disease) were investigated. Candidates were classified into a mainland group and a detached island group according to the location of the institution that performed their medical checkup, and each health survey item and respiratory function parameter were compared.

For the statistical analysis, two-sample t-tests, chi-square tests, and Mann-Whitney U tests were used.

Results: The former smoker rate (mainland 51.7% vs detached island 73.7% p<0.001) and Brinkman Index (mainland 322.0±497.7 vs detached island 406.2±416.7 p<0.001) were higher in the detached island group. Nevertheless, the prevalence of COPD was lower in the detached island group (mainland 8.5% vs detached island 7.0% p<0.05).

Conclusions: According to the guidelines of the GOLD, tobacco smoke is a primary factor related to the development of COPD. Our findings indicate that the living environment is also related to the prevalence of COPD.

P980 Distribution of COPD patients in the GOLD assessment framework by exacerbations

G. Nadeau1, L. Adamack1, M. Small1, 1Respiratory Center of Excellence, GSK, Uxbridge, United Kingdom; 2Adelphi Real World, Adelphi Group, Macclesfield, United Kingdom

In GOLD 2011 proposes a new COPD assessment framework focussed on symptoms measured by the COPD Assessment Test (CAT™) or the mMRC and on risk based on poor lung function (FEV1<50%) and a history of ≥2 exacerbations in the previous year. This analysis focuses on exacerbations.

The 2011 Adelphi Disease Specific Programme dataset was used to understand the distribution of patients in the GOLD framework. Exacerbation events defined as those not brought under control by rescue medication were recorded by physicians. We included 1041 EU COPD patients with documented CAT, mMRC, FEV1 and exacerbation history in the previous year (401 (38.5%) were from primary care and 640 (61.5%) from specialty clinics. Almost all (97.7%) were on maintenance treatment. 104 subjects (10%) reported good health status (CAT<10); only 7 of these were repeat exacerbators or had poor lung function. 4 of all patients (48.6%) had no exacerbations and 18.5% had 1 exacerbation in the previous year.

<td>32.9% (342)</td>
</tr>
</tbody>
</table>

In observational databases, 1 exacerbation increases the risk of future exacerbations and negatively impacts health status and outcomes. Therapeutic interventions reduce the number and severity of exacerbations in patients with 1 or more exacerbations. Nearly 1/5 of patients in the Adelphi dataset had 1 exacerbation in the previous year and would fail to be included in GOLD high risk category. These observations may have important clinical implications.

P981 Chronic bronchitis phenotype in subjects with and without COPD: The PLATINO study

Maria Montes de Oca1, Ronald J. Halbert2, Maria Victoria Lopez1, Rogelio Perez-Padilla3, Carlos Talamo1, Dolores Moreno1, Adriana Muñoz1, Jose Roberto Jardim1, Gonzalo Valdivia1, Julio Pertuz2, Ana Maria B. Menezes1, 1Pulmonary, Universidad Central de Venezuela, Caracas, Venezuela; 2School of Public Health, UCLA, Los Angeles, United States; 3Pulmonary, Universidad de la Republica, Montevideo, Uruguay; 4Pulmonary, Institute of Respiratory Diseases, Mexico City, Mexico; 5Pulmonary, Federal University of São Paulo, Brazil; 6Public Health, Pontificia Universidad Católica de Chile, Santiago de Chile, Chile; 7Faculdade de Medicina, Universidade Federal de Pelotas, Brazil

Background: Little information exists regarding the epidemiology of chronic bronchitis (CB) phenotype in unselected COPD populations. We examined the prevalence of CB phenotype in COPD and non-COPD subjects of the PLATINO study, and how it is associated with important outcomes.

Methods: Post-bronchodilator FEV1/FVC<0.70 was used to define COPD. “Phlegm most days, at least three months a year for ≥2 years” was used to define CB. We also analyzed another definition: “cough and phlegm most days, at least three months a year for ≥2 years”.

Results: Spirometry was performed in 5,314 (759 COPD and 4,554 non-COPD). The proportion of subjects with and without COPD and CB defined as “phlegm most days, at least three months a year for ≥2 years” was 14.4 and 6.2%, respectively. Using the other definition the prevalence was lower (COPD 7.4%, and non-COPD 2.5%). Among subjects, with COPD those with CB had worse lung function and general health status, and had more respiratory symptoms, physical activity limitation, and exacerbations.

173s

SUNDAY, SEPTEMBER 2ND 2012
Conclusions: Our study helps to understand the prevalence of CB phenotype at a particular point in time and suggest that CB in COPD is possibly associated with worse outcomes.

Prevalence characteristics of COPD in never smokers

Ramadan Balk
Ibrahim Elmahallawy
Chest Diseases, Faculty of Medicine, Menoufya University, Shebin Elkorn, Menoufya, Egypt Chest Diseases, Faculty of Medicine, Menoufya University, Shebin Elkorn, Menoufya, Egypt

Background: Smoking is by far the most important documented cause for COPD. However, COPD can still be recorded among a percentage of non-smoker patients, due to other different causes.

Methods: This study comprised 300 COPD patients, 230 patients (76.66%) were men and 70 patients (23.34%) were women. The mean age of the patients was 60.7±5.35 years (range 42-83 years).

Results: 300 COPD patients were included in this study, 120 (40%) were never smokers and 180 (60%) were ever smokers. Women made up 41.7% of the never smokers (50 of 120) and 11% of the ever smokers (20 of 180). Never smokers were significantly older than smokers (65.08±5.03 years vs 56.33±6.7 years (P < 0.001)) and were more likely to be women (41.7% vs 11% (P < 0.001)).

Never smokers made up to 40% (120/300) of all COPD cases; 78% (70/90) of all GOLD stage II cases, 45.5% (50/110) of all GOLD stage III cases. Among never smokers, 58.3% (70/120) fulfilled the criteria for GOLD stage II and 41.7% (50/120) fulfilled the criteria for GOLD stage III and no patients fulfilled the criteria of either GOLD stage IV. Never smokers were shown to have more occupational exposure to organic and inorganic dust and irritating gases at work place [41.7% (50/120) vs 27.7% (50/180), P < 0.05], more biomass exposure [41.7% (50/120) vs 0% (P < 0.001)], less education [41.7% (50/120) vs 72.2% (130/180), P < 0.001], more exposure to passive smoking [75% (90/120) vs 22.2% (40/180), P < 0.001].

Conclusions: Never smokers still constitute a significant proportion of the Egyptian COPD patients.

Profilin dyspnoea in primary care patients with COPD

Hana Mullerova1, Chao Lu1, Maggie Tabberer1, 1Worldwide Epidemiology, GlaxoSmithKline R&D, Uxbridge, United Kingdom; 2Worldwide Epidemiology, GlaxoSmithKline R&D, Research Triangle Park, NC, United States; 3Global Health Outcomes, GlaxoSmithKline R&D, Uxbridge, United Kingdom

Objectives: Identify descriptors of clinically significant dyspnoea in patients with Chronic Obstructive Pulmonary Disease (COPD).

Methods: A COPD cohort was identified in the UK General Practice Research Database (GPRD) using a record of COPD diagnosis in 2008 and nearest recorded spirometry (FEV1/FVC <70%). Dyspnoea was identified using Medical Research Council (MRC) dyspnoea scale, recorded as a part of the Quality Outcomes Framework, during observation period, from the latter of Apr1 2009 or cohort entry until censoring (earliest of death, transfer out of practice or follow-up end at March 31 2011). The first MRC score recorded, within observation period, defined patients as (A) with (MRC ≥ 3) or (B) without (MRC < 3) clinically significant dyspnoea, other traits were collected on or before MR C score date. Stepwise multivariate logistic regression estimated independent associations with dyspnoea.

Results: 38,256 COPD patients with MRC dyspnoea score were identified: females 46%, mean age (SD) 70 (10) yrs, GOLD stage I=15%, II=50%, III=27%, IV=6%. Of these, 16,919 (44%) reported clinically significant dyspnoea. Most of these, 75.5%; exposure time more than 20 years, smokers and non/ex smokers, BMI, FEV1 and FEV1/FVC were measured and their correlation calculated generally and separately, for younger and older than 51 years, in both sexes.

Results: In men,generally,BMI strongly positively correlated with both FEV1 and FEV1/FVC (p<0.001),the same in smokers,but less in non/ex-smokers (p< 0.02),with stronger significance in older than 51 years (p< 0.001) than in younger (p< 0.03).In women older than 51 years BMI strongly positively correlated only with FEV1 (p<0.001), especially in years BMI didn't show any significant correlation with both FEV1 and FEV1/FVC.

Conclusions: Gender and age are unchangeable risk factors for every chronic disease and COPD as well.These data,showing that BMI strongly positively correlates with both lung function parameters in men and only with FEV1 in women,especially in smokers and older than 51 years,with absence of any correlation in women younger than 51, may indicate that pathophysiologic changes in COPD are different, but sex and age dependent.

Body mass index (BMI) and lung function decline with age in COPD patients

Ivana Filipovic1, Ljiljana Isakovic1, Jelena Isakovic2, 1Worldwide Epidemiology, GlaxoSmithKline R&D, Uxbridge, United Kingdom; 2Surgery, Clinical Center of Serbia, Belgrade, Serbia

Introduction: Body mass index (BMI) and lung function physiologically decline with age, but in COPD that is an inevitable consequence of disease too. Other changes that come with ageing are menopause and andropause, affecting BMI and lung function, as well. Average age for woman entering the menopause is 51 and andropause is suggested to start in men between 40 and 60 years (mean 50 years).

Aim: To examine influence of gender and age on correlation between BMI and lung function among COPD patients.

Material and methods: In 341 COPD patients (269 men and 72 women) older than 40 years smokers and non/ex smokers BMI, FEV1 and FEV1/FVC were measured and their correlation calculated generally and separately, for younger and older than 51 years, in both sexes.

Results: In men,generally,BMI strongly positively correlated with both FEV1 and FEV1/FVC (p<0.001),the same in smokers, but less in non/ex-smokers (p<0.02), with stronger significance in older than 51 years (p< 0.001) than in younger (p<0.03). In women older than 51 years BMI strongly positively correlated only with FEV1 (p<0.001), especially in years BMI didn’t show any significant correlation with both FEV1 and FEV1/FVC.

Conclusions: Gender and age are unchangeable risk factors for every chronic disease and COPD as well. These data, showing that BMI strongly positively correlates with both lung function parameters in men and only with FEV1 in women, especially in smokers and older than 51 years, with absence of any correlation in women younger than 51, may indicate that pathophysiologic changes in COPD are different, but sex and age dependent.

Cardiovascular comorbidity and mortality in patients with chronic obstructive pulmonary disease

Mladen Fajž1, Ivaver Havel1, 1Department of Pulmonology and Phthisiology, University Hospital „Dr. Georgi Stranski” Pleven, Pleven, Bulgaria; 2Internal Diseases Clinic, University Hospital „Dr. Georgi Stranski” Pleven, Pleven, Bulgaria

Aim: To determine the prevalence of cardiovascular diseases (CVDs) and cardiovascular mortality in patients with chronic obstructive pulmonary disease (COPD).

Method: COPD patients (n=3571) were checked if they had CVDs (CAD – coronary artery disease, HF – heart failure, AH – arterial hypertension, CCP – chronic cor pulmonale, CVD – cerebrovascular disease) and mortality. Of these, 2642 (74%) were male and 929 (26%) were female, aged 65 (SD: ± 9.7), and FEV1 = 49.8 (± 18.9%) pred. The risk for CVDs (OR - Add Ratio) was compared with that of 150 controls.

Results: Among COPD patients 84.5% had CVDs: 59% (GOLD B), 74% (GOLD B), 86% (GOLD III) and 99% (GOLD IV) (OR =3.5, p=0.001), OR=1.9. Correlation was found between age and prevalence of CVDs: 47.8% (40-49yrs), 71.6% (50-59yrs), 85% (60-69yrs) and 96.9% (>70yrs) (p<0.001).

Patients with COPD had a higher prevalence of CVDs and cardiovascular risk: CAD (66%; OR = 1.8), HF (74%; OR = 1.9), AH (45%; OR = 1.2), CCP (46%; OR = 3.8) and CVD (33.3%; OR = 1.6). In 33% of COPD deaths cardiovascular causes of death were found: 36.7% myocardial infarction, 33.3% pulmonary embolism, 12.2% HF and 18% of CVD.

Conclusion: The study found an increased risk and mortality from cardiovascular diseases, especially in adult patients with severe COPD.
Prevalence of comorbidities in subjects with airflow obstruction in Japan
Hirotsugu Kohrogi 1, Yasuyuki Ogata 1, Tohru Tsuda 1, Hirotsugu Kohrogi 1, Takahiko Katoh 1, 2 Public Health, Faculty of Life Sciences, Kumamoto, Japan; 1 Respiratory Medicine, Japanese Red Cross Kumamoto Health Care Center, Kumamoto, Japan; 2 Respiratory Medicine, Kiryuoka Tsuda Hospital, Kitakyushu, Fukuoka, Japan; 4 Respiratory Medicine, Faculty of Life Sciences, Kumamoto, Japan

Background: COPD is one of the leading causes of mortality in Japan. Little is known about the prevalence of comorbid conditions in subjects with COPD in Japan.

Objective: The aim of this study was to examine the prevalence of comorbidities between subjects with and without airflow obstruction (AO).

Methods: This study included 19,340 subjects (11,549 men, 7,791 women), aged 16-96 years, who underwent spirometric lung function tests at a medical check-up held between April 2009 and March 2010 at the Japanese Red Cross Kumamoto Health Care Center, Kumamoto, Japan. Data on medical history and life style information were collected by means of an interview questionnaire. All subjects were evaluated by a physician. AO was defined according to Global Institute for Chronic Obstructive Lung Disease (GOLD) criteria (FEV1/FVC<0.7).

Results: In logistic regression models adjusted for age, smoking and BMI, prevalence of subjects with diabetes (odds ratio [OR], 1.28; 95% confidence intervals [95%CI], 1.10-1.51), asthma (OR, 4.09; 95%CI, 3.15-5.31) and lung cancer (OR, 3.84; 95%CI, 1.89-7.80) were significantly higher in subjects with AO compared to subjects without AO in male. In female, prevalence of subjects with hypertension (OR, 1.43; 95%CI, 1.15-1.79), diabetes (OR, 1.40; 95%CI, 1.05-1.86), asthma (OR, 3.22; 95%CI, 2.22-4.67) and lung cancer (OR, 4.52; 95%CI, 1.62-12.62) were significantly higher in subjects with AO compared to subjects without AO.

Conclusions: This study documented that numerous comorbidities are frequently associated with AO. Therefore, efforts toward earlier detection of AO and the identification of comorbidities may become an integral part of the core prevention of COPD.

Metabolic and cardiovascular comorbidity in COPD patients classified using the GOLD 2011 assessment framework
P988
Sara Maia 1, Sandra Balducci 1, Marco Borbotti 1, Franco Martin 1, Patrizia Silvi 2, Giuseppe Sarno 1, Sonia Cerrai 1, Anna Paola Pala 1, Giovanni Vieggi 1,2
1Pulmonary Environmental Epidemiological Unit, University of Cagliari, Cagliari, Italy; 2Institute of Biomedicine and Molecular Immunology, National Research Council, Palermo, Italy

Background: Chronic obstructive pulmonary disease (COPD) represents an important and increasing burden worldwide. COPD often coexists with other diseases that may have an impact on prognosis.

Aims: To evaluate the association between different COPD severity levels and comorbidity in Italian patients of general practitioners (GP).

Methods: Prospective observational study in different Italian areas. 176 GP enrolled 2288 patients with COPD diagnosis. Questionnaires were used to collect data on COPD management, health status and quality of life. Univariate analyses were used to assess the relationship between COPD severity levels (mild, moderate, severe, very severe) and demographic characteristics (age, sex), smoking habits, comorbidities. Multinomial regression analysis was used to assess the relationship between COPD severity levels and comorbidity adjusting for demographic characteristics and smoking habits.

Results: Univariate analyses showed a significantly higher frequency of high severity levels in males, older age, ex-smokers, subjects with cardiovascular dis-eases, osteoporosis/skeletal muscle dysfunction, anemia, depression and weight loss. The Multinomial regression analysis confirmed the associations between COPD severity and COPD and cardiovascular disease (OR 1.30; severe COPD and cardiovascular disease (OR 1.35), osteoporosis/skeletal muscle dysfunction (OR 1.43), anemia (OR 2.06) and weight loss (OR 2.77); very severe COPD and weight loss (OR 6.34) and depression (OR 2.50).

Conclusions: This study indicates that COPD stages are significantly associated with different kinds of comorbidities which need to be taken into account in disease management.

COPD and comorbidity in somatic practice
Arcady Vertkin, Anton Skotnikov, Michail Rumyantsev. Therapy, Clinical Pharmacology and Ambulance, Moscow State Medical Stomatological University, Moscow, Russian Federation

The aim of our study was to determine the clinical features of comorbidity in patients with COPD and other somatic pathology. Based on the evidence of post-mortem autopsies, we planned to examine the characteristics of occurrence and the structure of comorbidity. We analyzed the 3469 deaths cases of patients admitted to hospital due to decompensation of somatic pathology. Comorbidity was found in 2751 (78.3%) cases (1035 men (37.6%) and 1716 women (62.4%)). The average age of patients with comorbidity was 72.6 years old (by men - 69.4 and by women - 76.1). We found that the greatest number of nosological units (5.9 diseases per person) occurs in elderly patients (80-89 years). Combination of the two diseases occur in 17.5% of patients with comorbidity, three diseases - in 34.9%, four diseases - in 26.9%, the five diseases - in 14.7% and more than 5 disease - in 6% of patients with somatic pathology. For example, chronic obstructive pulmonary disease in 57.5% of cases combined with arterial hypertension, in 74.6% of cases - with coronary heart disease, in 97.3% of cases - with chronic cerebrovascular disease, in 63.5% of cases - with the pathology urogenital system, in 22.1% of cases - with diabetes mellitus type 2. Comorbidity in patients with COPD in 18% of the cases makes it difficult identify malignant tumor, in 13.5% - intracerebral hemorrhage, in 13% - acute myocardial infarction, in 8.3% - chronic cerebrovascular disease, in 7.6% - ischemic heart disease, in 6.8% - stroke, in 5.2% - aortic dissection and in 4.8% of cases - mesenteric thrombosis. Comorbidity alters the clinical picture and course of underlying disease (ex. COPD), the nature and severity of its complications and degrades the quality of life of patients.

Disease severity and complexity in patients with acute exacerbation of chronic obstructive pulmonary disease in Lazio, Italy
Ursula Kirchmayer 1, Sara Agabiti 1, Danilo Fusco 1, Riccardo Pestelli 1, Vittoria Colamesta 1, Marina Davoli 1, 2 Department of Epidemiology, Lazio Regional Health Service, Rome, Italy; 2 Department of Respiratory Physiology, Catholic University, Rome, Italy

Population based estimates of disease severity and comorbidity in patients with acute exacerbations of Chronic Obstructive Pulmonary Disease (COPD) give insight into the burden of this degenerating condition on patients and health care systems. Hospitalized COPD patients were characterized in terms of COPD severity and complexity. A cohort of 21,144 residents in Lazio, discharged after acute COPD exacerbation in 2006-9 was enrolled from the Hospital Information System. Disease severity was defined as presence of admissions during 12 months prior to index admission with diagnosis of COPD, respiratory failure (RF), invasive respiratory procedures, transfer to intensive care, COPD emergency visits, or oxygen therapy (O2), linked
from drug claims register. Comorbidities were retrieved from index admission and admissions during 24 months before.

More than half of patients were men (53.9%), mean age was 74.6 years for men and 76.8 years for women. RF and O2 were the two factors detected more often (46.9% and 21.9%, respectively), with higher values in men (RF: 48.5%, O2: 24.5%). Most important comorbidities were hypertension (24.8%), diabetes (20.4%), ischemic heart disease (13.0%), heart failure (12.6%), arthritism (12.3%), pulmonary infections (10.3%), and cerebrovascular disease (9.5%), with higher prevalence in men for all but diabetes and hypertension.

Patients requiring for acute exacerbations are typically old and more often men. Almost half of patients are affected by respiratory failure, more than a fifth is treated with oxygen. Many patients suffer from cardiovascular disease or diabetes. Partially funded by National Medicines Agency, Prot. FARM8ZBT93.

**P992 Characteristics of COPD exacerbations in Greece**

Foteini Mali1, Zoe Danili1, Eleni Bania2, Evangelos C. Alexopoulos3, Foteini Malli1, Zoe Daniil

Characteristics of COPD exacerbations in Greece P992

Partially funded by National Medicines Agency; Prot. FARM8ZBT93.

Men for all but diabetes and hypertension.

Important comorbidities were hypertension (24.8%), diabetes (20.4%), ischemic heart disease (13.0%), heart failure (12.6%), arthritism (12.3%), pulmonary infections (10.3%), and cerebrovascular disease (9.5%), with higher prevalence in men for all but diabetes and hypertension.

Patients requiring for acute exacerbations are typically old and more often men. Almost half of patients are affected by respiratory failure, more than a fifth is treated with oxygen. Many patients suffer from cardiovascular disease or diabetes. Partially funded by National Medicines Agency, Prot. FARM8ZBT93.

**Methods:** The cohort consisted of 390,269 adults, between 1994 and 2008, went through a fee-for-service, standard panel of health screening program. COPD was defined by Gold criteria. Mortality and cancer incidence were identified in an average of 8.5 years of follow-up. Cox proportionate model was used to calculate the hazard ratios (HR).

**Results:** More men (48.5%) than women (38.8%) and more smokers (53.7%) than non-smokers (37.3%) had COPD, with a mean age of 50. The excess all-cause mortality for smokers (HR: 2.51) was three times larger than non-smokers (HR: 1.53), when compared to those without COPD. Not only smokers (4.5-fold) but also non-smokers (1.4-fold) had lung cancer mortality significantly increased, implying the independent effect from COPD. Other than lung cancer and respiratory diseases, COPD had increased risks for CVD (HR: 1.76), including ischemic heart disease (HR: 1.63) and stroke (HR: 1.80), and kidney diseases (HR: 2.32). The extra-pulmonary causes constituted 77% for non-smokers and 58% for smokers.

**Conclusion:** Three quarters of the excess deaths among nonsmoking COPD subjects died from causes beyond the lungs. They had increases in stroke, heart renal and infectious diseases, in addition to lung cancer. These extra-pulmonary risks, under-appreciated by clinicians and unaware of by the patients, are major challenges to overcome.

**P994 Insufficient education about COPD is main factor for low diagnosis rate**

Florin Mihailă1, Roxana Nemeș2, Amelia Iancu1. 

1Pulmonology, National Institute Pulmonology Maria Nasta, Bucharest, Romania; 2Primary Care, Novartis Pharma Services, Bucharest, Romania

**Background and aims:** To evaluate if prolonging duration of education and testing COPD campaign will increase presentation for testing (spirometry) and number of newly diagnosed COPD cases, in population exposed to risk factors.

**Methods:** One-week campaign was conducted in 2009-2010 and 2 weeks in 2011 on World Day of COPD. Target population had open access to office based spirometry tests. Through personalized letters from President of Romanian Society of Pneumology that inform about 12 reasons to take a spirometry test and the consequences of COPD, population was encouraged to access informative COPD web-site. The primary outcome measure was number of newly-diagnosed cases of COPD as a result of campaign.

**Results:** In 2009 (1 week campaign), 3494 persons presented for testing, 847 were newly diagnosed with COPD (24% diagnosis rate). In 2010 (1 week campaign), 4058 persons were tested, 1259 were diagnosed (29% diagnosis rate). In 2011, 2 weeks campaign resulted in 10523 persons tested, 3593 new diagnosed COPD patients (34% diagnosis rate). Growth 2011/2010 for persons presenting to test was 148%, vs 23% growth 2010/2009; for new diagnosed COPD patients, growth 2011/2010 was 186%, vs 48% 2010/2009.

**World Day of COPD Campaign results 2009-2011**

<table>
<thead>
<tr>
<th>Year</th>
<th>Number of person tested</th>
<th>Number of new diagnosed patients with COPD</th>
<th>Diagnosis rate</th>

</table>

**Conclusion:** Prolonging duration for awareness disease campaign on case-finding for COPD increased testing presentation and interest for learning on COPD. Intensifying efforts for education, not limiting only to celebrating event as World COPD Day, can increase diagnosis rate.

**106. Healthcare utilisation and treatment of asthma and COPD**

**P995 Health, social and economic consequences of chronic obstructive pulmonary disease (COPD): A controlled national study**

Anders Løkke1, Ole Hilberg1, Philip Tonnesen2, Jakob Kjellberg2, Rikke Ibon2, Poul Jensøn3. 

1Department of Respiratory Medicine, Aarhus County Hospital, Aarhus, Denmark; 2Department of Pulmonary Medicine, Gentofte University Hospital, Gentofte, Denmark; 3Danish Institute for Health Services Research, Danish Institute for Health Services Research, Copenhagen, Denmark; 4Itracks, Itracks, Aarhus, Denmark; 5Danish Center for Sleep Medicine, Department of Clinical Neurophysiology, Center for Healthy Ageing, Faculty of Health Sciences, University of Copenhagen, Glostrup Hospital, Copenhagen, Denmark

Rationale: The objective direct and indirect costs of COPD among adults and the treatment are incompletely described.

**Methods:** From the Danish National Patient Registry (1998-2010), 171,557 (83,338 men and 88,219 women) COPD patients (ICD-10 diagnoses: J44.0 - 44.9) were identified and included. For every patient, four age-, sex- and socioeconomic-matched control citizens were randomly selected from the Danish Civil Registration System (322,233 men and 342,588 women).

Statistics Direct costs were extracted from the Danish Ministry of Health, Danish Medicines Agency and National Health Security and indirect costs were based on data from the Coherent Social Statistics.

**Results:** After 12 years only 33.1% of the COPD patients were still alive compared to 61.4% of the control citizens.

COPD were associated with significantly higher rates of health-related contact, medication use, unemployment, and accounted for increased socioeconomic costs. The annual mean excess health-related cost for each patient with COPD was € 6121 before and € 5990 after diagnosis, respectively, compared to controls. Patients with COPD had medication, hospital and total health costs 2.3-times higher than controls and overall employment rates 30% lower than controls. Employed COPD patients earned only around 58% of the income of controls. These socioeconomic consequences were present even 11 years prior to the first diagnosis in patients with COPD, and increased with disease advancement.

**Conclusion:** COPD has major socioeconomic consequences for the individual and for society. Mortality and morbidity from COPD is very high and earlier disease detection could have a greater impact on disease complications.
Methods: From the Danish National Patient Registry (1998-2010), 171,557 (83,338 men and 88,219 women) COPD patients (ICD-10 diagnosis: J44.0 - 44.9) were identified and included. Of these 50.3% (86,260) were married or co-lived with a spouse. For every spouse, four age-, sex- and socioeconomic-matched control citizens were randomly selected from the Danish Civil Registration System (346,524). Statistics Direct cost were extracted from the Danish Ministry of Health, Danish Medicines Agency and National Health Security and indirect costs were based on data from the Coherent Social Statistics.

Results: Even 11 years prior to the first diagnosis in a COPD patient, being a spouse were associated with significantly higher rates of health-related contact, medication use, unemployment, and increased socioeconomic costs. Compared to controls, the annual mean excess health-related cost for each spouse of a COPD patient was €3,118 before and €1,820 after the COPD diagnosis and the spouses received an annual mean excess social transfer income of €1,045 before and €381 after the COPD diagnosis. The annual mean excess medical costs was €2,925 lower than that of an employed control before and €1,454 after the COPD diagnosis.

Conclusions: For the first time ever the major socioeconomic consequences for the spouses of COPD patients has been shown and needs to be addressed in the future. In addition mortality and morbidity from COPD is very high and earlier disease detection could have a greater impact on disease complications.

Influence of statin treatment on cancer mortality in COPD patients: Retrospective observational cohort study

Perrine Créquit1, Isabella Amensi Maesano2, Christos Chouaid1,2, Gilles Héblum3, Respiratory Disease, Saint Antoine Hospital, Paris, France; "U707, INSERM, Paris, France

Background: The anti-inflammatory and immunomodulatory stator properties have been suggested for preventing cancer development in patients with Chronic Obstructive Pulmonary Disease (COPD). However, the effect of statin on cancer mortality in COPD patients is poorly documented. The study endpoint is to evaluate the impact of statin on cancer mortality of COPD patients.

Methods: Based on a large pharmaceutical French database of the North area, a retrospective cohort study was conducted in order to evaluate the effect of statin on cancer mortality in COPD patients. Analysis, based on a Cox proportional hazards model, was performed and handled as a time-dependent variable, included the 66,429 individuals 40 years old or more who had at least one pharmacological dispensation between 01/01/2000 and 05/11/2007. In this cohort, 9531 COPD patients were identified, 18.1% of COPD patients were considered exposed to statin treatment.

Findings: The overall death rate of COPD patients is 40.8%. The various causes accountable for COPD patients’ death were: cardiovascular diseases for 33.7%, respiratory diseases for 33.7% and cancer for 24.8%. Statin treatment was significantly associated with a decrease of cancer mortality in COPD patients with estimates (hazard ratio [95% CI], p value) at 0.586 [0.465-0.739], p<0.001.

Interpretation: It seems that statin delivery to COPD patient reduces the cancer death rate. However the result has to be checked out by prospective randomized trials.

Relative exposure to inhaled steroids (ratio “ICS-to-total-asthma therapy”): Concordant data from electronic medical records, claims data and patient-reported outcomes

Laurent Lalored1, Idris Licaj1, Gilles Devossoaux1, Genevieve Chamba1, Laurent Letellier2, Gérard Chatte3, Eric Van Gaet1, Pharmacoepidemiology, CHU Lyon; UMR 5538 CNRS - Claude Bernard University, Lyon, France; 2Respiratory Medicine, Croix Rousse University Hospital, Lyon, France; 3Radiopharmaceutics, Pharmaceuticals, Lyon, Lyon, France; "Service de Médecine Interne, Claude Bernard University, Lyon, Lyon, France; "Cher Darwin, Caluire, France

Background: In claims data, computation of “ICS-to-total-asthma therapy” ratios (R) has shown interest to identify asthmatics more at risk of exacerbations, as a result of insufficient exposure to ICS for their level of disease severity. Ratios have seldom been computed from other data sources. The relationship between asthma outcomes and ratios was studied, from different sources: electronic medical records (EMRs), claims data, and patient-reported outcomes (PROs) obtained from a pharmacy-based survey.

Methods: In all settings, the primary comparison was between non users (R=0%), inadequate ICS users (0<R<0.5%) and adequate ICS users (R≥50%), as to asthma-related hospitalizations, use of oral steroids (OCS) or antibiotics (ATB), and Asthma Control Test (Pharmacy-based study).

Results: In claims data (n=2,142, mean age=27 yrs, 53% females), inadequate users had higher rates of hospitalizations (p=0.0087), oral steroids or antibiotics use than other groups (p<0.001 for both): OCS and ATB use were more common (p<0.0001 for both) among inadequate users in EMRs (n=4,587, mean age=28 yrs, 54% females). In the pharmacy-based survey (n=919, mean age=37 yrs, 55% females), inadequate users were more likely to be poorly controlled, hospitalized for asthma and to receive OCS or ATB (p<0.0001 for all).

Conclusions: Despite differences in study designs and patients baseline characteristics, conclusions were highly concordant between the 3 data sources, with evidence of poorer control in inadequate users. Advantages and limitations of each data source for the interpretation of ratios will be discussed.
P1003

Co-morbidities are associated with prolonged hospital length of stay (LoS) in patients with COPD.

Sverkna Jassykerfa, Maria Feldmann, Angshu Bhowmik. Division of Infection, Inflammation and Immunity, University of Southampton, United Kingdom

Respiratory Medicine, Homerton University Hospital, London, United Kingdom

Identification of factors leading to prolonged hospital stay may help to find patients who need targeted approaches to management. Appropriate resource allocation would help to reduce the time spent in hospital. Co-morbidities are common in COPD and may lead to prolonged admissions. We performed a retrospective case note analysis of patients with COPD who had admissions lasting longer than average. Spearman’s correlation and Mann-Whitney test were used to identify relationships between co-morbidities and LoS. Data were obtained for 204 patients (mean age 73.9, 135 males) who had 267 hospital admissions of duration greater than 9 days in a one-year period. The total number of bed-days was 6127. 38 patients (19%) had more than one admission, the number of admissions ranging from 2 to 7. These 38 patients occupied 2509 bed-days (41% of total).

LoS was found to be correlated with greater age (p = 0.005) and the presence of respiratory infection diagnosed by the admitting team. Cardiac arrhythmias seem to be associated with prolonged LoS (p = 0.01). As might be expected, patients who were admitted with exacerbations of COPD alone (i.e. no other reason for admission identified) had shorter LoS compared with those who had other identified reasons for admission (p = 0.028). No definite correlations were found with heart failure, ischaemic heart disease, psychiatric history or stroke. Other co-morbidities seen included pulmonary embolism and lung cancer, but the numbers were low and the results for these were therefore inconclusive.

We conclude that age, dementia, and the presence of respiratory infection are factors associated with prolonged stay.

P1004

Frequency and length of admission in patients with chronic obstructive pulmonary disease (COPD) as co-morbidity (Co) in a university hospital setting. A cross sectional study

Pernille Roedegaard, Helene Moeller Nielsen, Ulla Weinrich. Pulmonary Medicine, Aalborg University Hospital, Aalborg, Denmark

About 20% of the Danish adult population suffers from COPD [1]. About 50% of the patients are undiagnosed. COPD patients often have Co which may lead to hospitalization [2]. To analyze the frequency of COPD as Co among hospitalised patients, the number of undiagnosed COPD patients and patients without COPD (PwC) in regards of the cause of hospitalization, and duration of hospitalization for PC and PwC as Co.

Aalborg University Hospital covers all medical and surgical specialities. A one day cross-sectional study was performed on patients > 18 years of age. A spirometry was performed. Smoking habits, prior lung function measurements, prescribed lung medicine were recorded. The final diagnosis was registered after one month. 583 patients were admitted to the participating units. 147 couldn’t participate, 47 didn’t wish to participate. 111 weren’t available at the time of the examination. 12 were excluded. 215 patients participated, 28% (61/215) suffered from COPD. 77% (47/61) were diagnosed at the examination. 36.1% (22/61) of the PC were admitted with infections, the majority non-pulmonary. The admission period was not significantly longer for PC as co-morbidity (mean 13.03 days) compared to PwC (mean 12.1 days), (p=0.24). 28% of hospitalised patients suffered from COPD. 77% were diagnosed at our examination.

PC were primarily admitted with infectious diseases. There was no significant difference in length of stay in hospital between PC and PwC as co-morbidity.

References:
The aim: to evaluate the dynamics of consumption of drugs for the treatment of bronchial asthma (BA) in Yaroslavl in 2008-2010.

Methods: Prospective cohort study; the data of healthcare and pharmacy department. There were chosen 4 groups of drugs: inhaled corticosteroids (ICS), long-acting beta-agonists (LABA), short-acting bronchodilators (SABD), combination drugs (ICS/LABA); also consumption of beclometasone (B), fluticasone (F), fluticasone/salmeterol (FS) and budesonide/formoterol (BF) was estimated.

Results: In 2008 more than 74% of patients had moderate and severe asthma requiring mandatory prescription of ICS, including combination ICS with LABA, in accordance with international guidelines for BA. In 2010 the share of such patients has increased to 77.5 percent. In 2008 the share of patients receiving ICS was 49%, in 2009 - 42%, in 2010 - 39%; LABA consumption slightly decreased to 7%, 8% and 4%, respectively. The use of SABD had a slight tendency to increase: 12%, 16%, 19%. It should be noted that the number of registered patients with BA in the city has not significantly increased (in 2008 - 7308, in 2010 - 7426). In 2004, patients with BA received 11775 packs of B, 4(1) packs of fluticasone F, 36(1) packs FS, BF was not assigned. In 2010 intake of B was 8277 packs, increase use of F and combination drugs (F - 3500, BF - 2284, FS - 6410 packs). In 2004 patients with BA consumed 589,89 g ICS. In 2010, this volume increased to 681,93 g. In 2010, the share of the modern combined drugs increased to 27% of all anti-asthma drugs.
Acute asthma in Buenos Aires

Gabriel García,1 Miguel Bergna,1 Luis Namini,1 Hugo Neffes1,2, Gustavo Kordoni3, Sandra Mercurd1,2 1Sección Inmunología y Enfermedades Oftalmizativas, Asociación Argentina de Medicina Respiratoria, Buenos Aires, Argentina; 2Departamento de Emergencia, Hospital Central de las Fuerzas Armadas, Montevideo, Uruguay; 3Director of Medical Department, Lath AstraZeneca, Buenos Aires, Argentina

Objective: To establish if management of acute asthma in the emergency rooms in Buenos Aires follows the international guidelines

Method: We conducted an anonymous survey to physicians from 48 public hospitals (25 from Buenos Aires and 23 from sub urban zone) during March/April 2011.

Results: One hundred sixty three medical doctors from emergency rooms were surveyed (Graduation year 1999-09), forty-two (25%) were pediatricians. There was no departmentalised respiratory hospital in each zone. 93% of the medical doctors responded that they commonly treated patients with acute asthma. However, 48% did not have guidelines or protocol in the emergency room, whereas 65% commented that they did not have access to any poster, checklist or guide for acute asthma management. 91% of the doctors explained that they had a pulse oxymeter in the emergency room but only 18% reported that they had a Peak expiratory Flow Meter. More than 80%, informed that they used nebulised salbutamol in the first hour of treatment, 39% associated to inopram and more than a third used systemic corticosteroids through intravenous route. More than three quarters of the doctors gave a written plan to the patient but a short course of oral costoscosteosters was prescribed only by 20% of the surveyed doctors.

Conclusion: This survey showed that management of acute asthma in Buenos Aires does not follow international recommendations and guidelines.

Variation of seasonal (monthly) hospitalizations in asthmatic patients:

Difference between allergic and non allergic asthma

Ferdous Yousef, Asma Migaou, Maher Abouda, Mariem Triki, Sidhal Balloumi, Hemi Khouani, Mohamed Ridha Charfi. Department of Pneumology, Hospital of FSM, La Marsa, Tunisia

Background: The seasonality of asthma hospitalizations (AH) may reflect the variation of triggers exposure. The recognition of clear seasonal (monthly) patterns of asthma hospitalizations may allow preventive strategies to be developed.

Objective: The aim of this study was to determine if there is a seasonal (monthly) pattern to asthma hospitalizations in patients with allergic and non-allergic asthma.

Methods: This study retrospectively analyzes the seasonality of AH in our depart-ment of pneumology, between January 2006 and December 2011. We evaluated all AH occurring this period for patients with Allergic Asthma (AA) and Non-Allergic Asthma (N-AA). The diagnosis and classification in AA and N-AA were made according to the results of skin prick testing (SPT) to common allergens. Patients with AA defined as those with ≥3 positive SPT and patients with N-AA defined as those with negative SPT.

Results: There were 82 AH in 50 patients with a mean age of 47 years and a sex ratio of 0.47. There were 38 AH in 27 patients with AA (9 males, 18 females) and 44 AH in 23 patients with N-AA (7 males, 16 females).

Conclusion: These findings suggest that AH have a different clear seasonal (monthly) variation between patients with AA and N-AA. The seasonality in AA admissions was far more pronounced than in N-AA. These results may offer significant opportunities for improved disease management.

Hospitalizations for asthma in Portugal from 2000 to 2008: Different trends in different regions

Manuel Vaz1, Alberto Freitas2, Daniela Alves3, João Fonseca4,2, Tiago Jacinto2,3 1Serviço de Pneumologia, Hospital São João, EPE, Porto, Portugal; 2Center for Research in Health Information and Decision Sciences, Faculdade de Medicina da Universidade do Porto, Portugal; 3Serviço de Pneumologia, Hospital Braga, Braga, Portugal; 4Serviço de Imunologia e Reumatologia, Hospital São João, EPE, Porto, Portugal

Objective: To study regional differences and time trends of hospitalizations due to asthma in Portugal between 2000 and 2008. 39% associated to ipratropium and more than a third used systemic corticosteroids

Results: 28,707 patients were hospitalized due to asthma (0.3% of total admissions in the same period). Globally, the rate of hospitalizations for asthma per 100 000 adults declined from 15.9 in 2000 to 40.1 in 2008 per 100 000 adults.

Conclusion: Overall, the rate of hospitalizations for asthma is decreasing over years (with a global decrease of 7.5 per 100 000 inhabitants in the 9 years). Further analysis should be performed in order to understand why the Algarve had such a steep increase while the other regions had decreases.

Participation in the ARGA study: Long term impact on asthma management

Sandra Baldacci1, Sara Maio1, Anna Angiolo1, Mariuz Simon1, Sonia Cerrai1, Giuseppe Sarri2, Franca Martini1, Patrizia Silvi1, Marco Borbotti1, AnnaPaua Pala2, Giovanni Vegi1,2 1Pulmonary Environmental Epidemiology Unit, Institute of Clinical Physiology, National Research Council, Pisa, Italy; 2Technosciences Unit, Institute of Clinical Physiology, National Research Council, Pisa, Italy; 3Institute of Biomedicine and Molecular Immunology, National Research Council Palermo, Italy

Background: Preliminary results of “Respiratory allergic diseases: monitoring study of GINA and ARIA guidelines (ARGA)” study show a poor effect of a medical education course on Global Initiative for Asthma (GINA) guidelines in improving asthma management.

Aim: To evaluate the long term impact of participating in a prospective study on Italian General Practitioners (GP) focused on monitoring the utilisation of GINA and Allergic Rhinitis and its Impact on Asthma (ARIA) guidelines for asthma and allergic rhinitis management.

Methods: 107 GP enrolled 936 asthmatic patients (mean age 44yrs). For each pa-tient, a self-administered questionnaire on respiratory allergic diseases/symptoms, daily activity limitations, quality of life (by RHINASTHMA questionnaire), dis-ease control (by Asthma Control Test – ACT), self perception and the relative form filled in by GP were available at baseline and follow up 12 months after.

Results: Comparing baseline with follow up, asthma outcomes show an improve-ment: from 54.2 to 67.4% for asthma control, from 85.2 to 80.0% for asthma-like symptoms in the last 12 months, from 71.9 to 67.2% for daily activity limitations, from 61.2 to 66.6% for good health self perception and from 21.7 to 18.9 for quality of life score.

Conclusion: Involvement in a prospective study on asthma management seems to produce a long term effect in GP attitudes ameliorating their asthmatic patients quality of life.

This work was supported by the “Italian Medicines Agency (AIFA)”, within the independent drug research program, contract no. “FARM05765A”.

The education of physicians GINA and GOLD and a registration of chronic lung diseases in adult population of the Russian Federation

Tatiana Blikenko, Alexander Chuchalin. Epidemiology, Pulmonology Research Institute, Moscow, Russian Federation

Objective: To study the effects of educational programs GINA and GOLD on a registration of chronic lung diseases (CLD) according to the forms of State statistical reporting.

Material and methods: We analyzed a morbidity (M) and an incidence of disease (ID) in adults 18 years and older according to Federal State statistical observation (M – ICD-10 code N12, ID – ICD-10 code J45-J46) for the period from 2004 to 2010. The mean levels of M and ID were calculated at 100 000 adul t population of Russian Federation.

Results: Since 2004 the large educational programs GINA and GOLD were ex-tended among physicians. During seven years M CB and EL decreased gradually from 1552.9 to 1435.6 (p<0.01), i.e. 7.6% in 2010. ID CB and EL from 2004 to 2010 increased from 203.9 to 254.0 of cases (p<0.01), the growth rate was +24.6% in 2010. M COPD and BE gradually increased: M was +39.8% (from 487.1 to 680.8; p<0.01) and ID was +52.2% (from 42.1 to 64.1; p<0.01) at 2010. M BA was increased by +16.4% in 2010 year from 719.0 to 861.7; p<0.01. The highest ID BA (+16.7%) was in 2006: 52.6 (2004) and 61.4 (2006) accordingly (p<0.01). In subsequent years ID BA declined and the growth rate was only +5.7% in 2010 (54.4cases). The similar trends in M and ID were observed throughout the territories of the Russian Federation.

Conclusion: Educational programs have had a significant impact on the registration of CLD in adults of the Russian Federation.

Chemical exposure and lung function in the fragrance industry: A multi-site cross-sectional study

Gagne Dia, 1, 2  
1 School of Health Sciences and Social Work, University of Portsmouth, Hampshire, United Kingdom; 2 Regulatory Dept., CPL Aromas, Brixiow, Northants, United Kingdom

Introduction: Fragrance production employees are exposed to large quantities of chemical mixtures, at exposure levels significantly higher than the final consumer. Aims and objectives: To answer the research question: Is fragrance industry employees, is occupational respiratory exposure to chemicals linked to a reduction in lung function?

Methods: A cross-sectional study was designed, using an exposed group (fragrance production) and a control group (non-exposed industry employees). 5 UK fragrance companies took part, total sample size was 112 (exposed n=60, controls n=52), calculated as sufficient to achieve 80% power and 5% significance. Spirometric measurements (FEV1, FVC, PEF) were taken pre- and post-shift, and cross-shift decline was calculated. Questionnaires were completed regarding potential confounding factors (smoking, body mass index, personal or family history of respiratory problems). Analysis of covariance (ANCOVA) was performed using the statistical package SPSS (v18).

Results: Adjusted mean difference between groups (exposed vs. control) for each outcome was not observed to be statistically significant (table below). Family history of respiratory problems was observed to have a significant effect on PEF ($p<0.043$).

Across-shift decrease in fractional exhaled nitric oxide among Tanzanian cement production workers

Alexander Tungu, 1, 2  
1, 2 Centre for International Health, University of Bergen, Hordaland, Norway; 3 Department of Public Health and Primary Health Care, Section for Occupational Medicine, University of Bergen, Hordaland, Norway; 4 Department of Environmental and Occupational Health, Mahamoli University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of; 5 Department of Occupational Medicine, Haukeland University Hospital, Bergen, Hordaland, Norway

Background: There is limited information on fractional exhaled nitric oxide (FENO), a marker of respiratory inflammation, among cement production workers.

Aim: To explore possible across-shift changes in FENO over an 8h shift among dust exposed cement production workers in Tanzania.

Methods: We examined 48 cement production workers (exposed) and 27 workers from a mineral water factory (controls), all non-smokers. Pre-shift and post shift FENO measurements (parts per billion, ppb) were performed using a NIOX MINO machine, for 2 day shifts among controls and 3 day shifts among exposed. Full shift personal total dust samples were collected in participants’ breathing zone.

Results: Baseline geometric mean (GM) of FENO for the respective days of examination were 20.4 ppb, 20 ppb and 19.1 ppb among exposed, and 16.3 ppb and 16.2 ppb among controls. There was a significant across shift decrease in FENO for the three days of examination among the exposed (2.9 ppb, 2.4 ppb and 3.4 ppb, respectively, paired t-test, $p<0.05$), while the decrease was not significant among controls (1.4 ppb and 0.2 ppb). The change in across shift FENO was not significantly different between exposed and controls. The GM for total dust exposure among exposed was 9.4 mg/m3 and 0.28 mg/m3 among controls. There was no correlation between the across shift FENO change and total dust exposure. Conclusion: The across-shift FENO decrease in cement production workers was not significantly associated with occupational dust exposure, and the reason for this change should be determined in future studies.

**P1017**

Causes of work-exacerbated asthma

Paul Heenrood, 1, 2  
1, 2 Division of Respiratory Disease Studies, NIOSH/CDC, Morgantown, WV, United States; 3 Department of Public Health and Community Medicine, Sahlgrenska Academy at Gothenburg University, Gothenburg, Sweden

Rationale: A 2011 Statement of the American Thoracic Society concluded that work-exacerbated asthma (WEA) is common in industrialized nations, with a prevalence of 21.5% in adults with asthma. While there are published lists of workplace agents that can cause occupational asthma, there are no comparable lists for WEA. We reviewed published articles to prepare such a list.

Methods: We systematically searched the peer-reviewed medical literature to identify articles about WEA published during 1980-2011. We selected articles that reported WEA agents determined case-by-case (from clinical case series, surveillance and worker compensation programs) or in risk-set analyses that used statistical models to determine occupational exposures associated with exacerbation of asthma or WEA.

Results: The literature search identified 13 articles that reported exposures for work-related exacerbation of asthma, including 3 risk-set studies. The studies were conducted in several countries in North America and Europe, and used various criteria for WEA and methods to determine exposures. From studies with WEA identified on a case-by-case basis, the more common types of agents included miscellaneous chemicals, dust, paint, smoke, indoor air quality, and cleaning products. From two risk-set studies conducted in general population settings, exposures with statistically significant (p<0.05) relative risks of 2.0 or greater included dust, high exposure to gas and fumes, indoor air quality, physically strenuous work, and probable daily occupational exposure to dust, gases, or fumes.

Conclusions: Various types of workplace exposures can exacerbate asthma, including irritants, agents with sensitizing traits, and physical factors such as strenuous exercise.

**P1018**

Nasal symptoms, lung function changes, and sensitization to work-related allergens in hairdressers

Dragan Mijakoski, 1  
1 Centre Biomèdiques de Bellbitge, Barcelona, Spain

Objective: To assess the occurrence of nasal symptoms in hairdressers and their relation to respiratory symptoms, bronchial hypersensitivity (BHR), and positive patch testing.

Methods: Cross-sectional study was conducted at the Institute for Occupational Health of RM, Skopje, including 50 female hairdressers (mean age 32.1±7.3 years, mean job duration 12.6±8.4 years) and 50 office workers, matched by gender, age, duration and smoking status. Evaluation of examined subjects included completion of questionnaire on nasal and respiratory symptoms, BHR and sensitization to work-related allergens.

Results: Prevalence of overall nasal symptoms in last 12 months among examined hairdressers was 36% (varying from 40% for rhinorhoea to 32% for nasal itching) and it was significantly higher than its prevalence in office workers (36% vs. 14%, $p<0.05$). Nasal symptoms were significantly related to respiratory symptoms in both hairdressers and office workers. Spirometry showed lower parameters in hairdressers with significant difference for MEF25 and MEF30. Significant association was registered between nasal symptoms and BHR in hairdressers ($P<0.05$). Prevalence of BHR was higher in hairdressers with significantly higher severity ($P<0.05$). Patch testing to ammonium persulfate, ammonium thioglycolate, paraphenylenediamine, and pyrogallol was positive in 72%, 22%, 18%, and 4% of all hairdressers reporting nasal symptoms, respectively.

Conclusion: Our data indicate high prevalence of nasal symptoms in hairdressers and their significant relation to respiratory symptoms, BHR and sensitization to work-related allergens.

**P1019**

Therapeutic potential of mesenchymal stem cells modified to secrete anti-inflammatory protein ST2 in a model of occupational asthma

Xavier Munoz, 1, 2  
1 Respiratory, Hospital Vall d’Hebron, Barcelona, Spain; 2 Grupo de Genètica Molecular, Institut d’Investigacions Biomèdiques de Bellvitge, Barcelona, Spain

Background: The aim of this study was to evaluate the ability of mesenchymal stem cells modified to secrete ST2 to attenuate the inflammatory and respiratory symptoms in an animal model of occupational asthma (OA) to paricalcitol saline.

Methods: Occupational asthma was induced in BALB/c mice (1). Twenty-four hours after induction of asthma, the animals received intravenously 1×10^6 of mesenchymal stem cells (MSC group), mesenchymal stem cells genetically modified with a lentiviral vector expressing the gene ST2 (ST2 group) or saline (group S). Bronchial hyperresponsiveness was assessed using methacholine provocation.
Pulmonary inflammation and levels of immunoregulatory cytokines were determined in BAL. Total serum IgE was measured in blood. The analyses were made on days 2, 4 and 7 after induction of asthma.

**Results:**
Animals sensitized to persulfate salts showed an increase in bronchial hyperresponsiveness to methacholine and in the % of neutrophils and total IgE after inhalation of persulfate salts, compared with the control group. The animals treated with mesenchymal stem cells showed a decrease of the bronchial hyperresponsiveness to methacholine and the percentage of neutrophils and total IgE compared to the control group. There were significant differences between groups MSC and ST2 in the levels of IFN-γ, IL-13 and IL-6 that were lower in the ST2 group on day 4 after induction of asthma.

**Conclusions:** In the described model of OA mesenchymal stem cells modified to secrete sST2 have shown anti-inflammatory capacity and attenuation of bronchial hyperresponsiveness.

Study funded by Fis PI11/00782.

Serial PEF measurements detect occupational alveolitis and occupational asthma due to metal-working fluid
Vicky Moose1, Arun Dev Vellore1, Alaistair Robertson2, Wendy Robertson3
Sherwood Burge3
1Occupational Lung Disease Unit, Birmingham Heartlands Hospital, Birmingham, United Kingdom; 2Warwick Medical School, University of Warwick, Coventry, United Kingdom

**Introduction:**
Serial measurements of Peak Expiratory Flow (PEF) are the most appropriate and available method for confirming occupational asthma. Changes in PEF might also occur in alveolitis.

**Aim:**
To compare work-related changes in PEF between workers with allergic alveolitis and occupational asthma with exposure to the same metal-working fluid aerosols.

**Methods:**
Symptomatic workers with residency improvement from an engineering factory were asked to measure PEF 8 times daily for 4 weeks at home and at work before remedial action in the workplace. Allergic alveolitis was diagnosed by an expert panel from combinations of systemic symptoms with breathlessness, audible crackles in the lungs, CXR or CT scan showing compatible interstitial changes and reduced DLCO. Occupational asthma was diagnosed from work-related wheeze or breathlessness and confirmed with physiological tests including serial PEF measurements. The Oasys PEF plotter was used to calculate differences between rest and weekdays for mean PEF, diurnal variation and the scores used to confirm occupational asthma (Oasys, ABC and timepoint).

**Results:**

<table>
<thead>
<tr>
<th>Mean difference in PEF rest-workdays (litres/min) (SD)</th>
<th>Occupational alveolitis (n=15)</th>
<th>Occupational asthma (n=39)</th>
</tr>
</thead>
<tbody>
<tr>

**Conclusion:**
Changes in serial PEF measurements are similar in workers with occupational allergic alveolitis and occupational asthma.

**P1021**
Decrease in respiratory symptoms in the Danish furniture industry is associated to a decline in wood dust exposure – Results from two cross sectional studies 5 years apart
Vivi Schlünssen1, Gitte Jacobsen1, Inger Schaubenberg2, Torben Sigsgaard2
1Department of Public Health, Section of Environmental and Occupational Medicine, Aarhus University, Aarhus, Denmark; 2Department of Occupational Medicine, Herning Hospital, Herning, Denmark

**Objective:** To investigate associations between wood dust exp. and resp. symptoms in two studies 5 years apart from the same area.

**Methods:** 2,032 woodworkers from 54 plants in study 1 and 1,889 woodworkers from 52 plants in study 2 returned a questionnaire on resp. symptoms, employment and smoking habits. Assessment of wood dust exp. was based on job exposure matrices including factory size, task and personal dust measurements (2,217 in study 1 and 1,355 in study 2).

**Results:**
The median (range) of inhalable dust conc. was 0.8 (0.4-1.6)mg/m³ in study 1 and 0.6 (0.3-1.1)mg/m³ in study 2. The prev. of selfrep. asthma was higher, but the prev. of resp. symptoms were lower in study 2 vs. study 1. In a logistic regression analyses wood dust exposure explained the difference in symptom prevalence between study 1 and study 2, but no effect was found for selfrep. asthma. No influence of sex, smoking and age was seen.

Figure 1. Change in OR for study 2 vs. study 1, unadjusted and adjusted for wood dust exposure.

**Conclusion:** An association between respiratory symptoms and wood dust exposure was confirmed.

**P1022**
Irritative respiratory symptoms and ventilatory function to workers exposed to man made mineral fibres

We conducted a case-control study of 43 subjects who use Man Made Mineral Fibres (MMMF) to isolate cookers: 25 male and 18 female, aged 29-55, average exposure of 17.7±4.1 years and a matched control group. Clinical, respiratory, skin and eye symptoms were recorded by questionnaire, pulmonary functional tests (PFT), MMMF mean concentration in the workplace air was measured. Prevalence of chronic respiratory symptoms in exposed workers was significantly higher (32% vs. 21%). Significantly higher prevalence was found for irritative symptoms of the upper airways (p=0.32, p<0.05), itching eye (p=0.35, p<0.05) and cutaneous symptoms such as itching, erythema or urticarial reactions. Irritative anomalies of the upper airways in exposed workers were significantly associated with duration of exposure (r=0.37, p<0.005). A significant correlation between symptoms and PFT values was found in workers having more than 10 years exposure. Values of FVC, FEV1, FEV1/FVC and small airways indices in exposed workers were significantly lower (p<0.01). Small airways changes in exposed workers were strongly linked to duration of exposure (r=0.37, p<0.05) whereas relation of cutaneous symptoms and professional age was not significantly linked. We found that irritative ocular or tegumentary syndrome was more frequently revealed at the exposed subjects, especially in the first 10 years of activity.

Our data suggest interactive influence of workplace exposure to MMMF in development of irritative anomalies of the upper airways with predominantly smaller airways affecting.

Blood oxidative markers in glass industry workers and related respiratory outcomes
Felicia Gradinariu, Eugenia Danulescu, Ruxan Danulescu, Micaela Margineanu, Carmen Croturom, Virgil Carac. Occupational Medicine Department, Regional Centre of Public Health, Iasi, Romania

**Aim:** Workers from a glass factory were investigated by a longitudinal study to detect respiratory outcomes and their relations with working conditions.

**Material/Methods:** 229 nonsmoker workers (40 men) with mean age 35±9 yrs and mean exposure in glass industry 14±4 yrs were examined by clinical, spirometric and biochemical tests. Blood superoxide dismutase (SOD), glutathione peroxidase (GSHP) and serum lipoperoxides (LP) were assayed as effect markers. Occupational risk was estimated by workplace air contaminants (WAC), Pb in blood, urine (U-Pb), and by urinary delta-aminolevulinic acid (ALA).

**Results:** Although WAC (inorganic Pb, acetone, toluene, white spirit, varnishes) ranged under TLVs, cumulative toxic index was 2.6, indicating a potential hazard risk. 33% of subjects had respiratory changes: 28% cough, 19% sputum production, 8% dyspnea, 18% reported all three symptoms and 15% had obstructive

Prevalence and unadjusted OR of respiratory symptoms
P1024
Absence of nonspecific bronchial responsiveness (NSBR) in occupational asthma (OA): A case-series study
Jacques André Pralong
Catherine Lemière, André Carrier. Chest Medicine, Hôpital du Sacré-Coeur, Montréal, Canada
Background: Although increased NSBR is a key component of OA it may be absent in rare occasions as previously shown.
Objective: Describe the prevalence of confirmed OA with normal NSBR before and after specific inhalation challenge (SIC).
Methods: We retrospectively reviewed our database containing all SIC done in our laboratory or at work between 1997 and 2011. OA was defined by a positive SIC with a ≥25% sustained decrease in FEV1; normal NSBR was defined by PC20Methacholine (PC20M) >16 mg/ml.
Results: 373/1193 workers tested had confirmed OA. 22/373 (5.9%) had normal NSBR before and after SIC. The median SD between baseline and the day of the challenge was 9.6 ± 8.7 days. However, 10 subjects had at least one PC20M < 16 mg/ml during their investigation while symptomatic and at work for 9 of them. The remainder 12 had normal NSBR on all tests but only 3 subjects had such a low value at work (≥16 mg/ml). Among the 22 cases, 20 were atopic, 15 were exposed to a high molecular weight agent, 4 to a low molecular weight chemical and 3 to various agents during workplace challenge. Seventeen, 14 and 1 subjects had an early, late and atypical asthmatic reaction respectively.
Conclusion: We describe 22 cases of confirmed OA despite normal NSBR before and after SIC. This is however rare (5.9% of confirmed cases of OA by SIC). In our experience, it is exceptional to have normal NSBR while symptomatic and at work in cases of confirmed OA.

P1025
Does FENO predict FEV1 response to exposure cessation in occupational asthma?
Vicki Moore 1, Wendy Robertson 2, Cedd Burge 1
Alastair Robertson 1, Jon Ayres 1, P. Sherwood Burge 1
1Occupational Lung Disease Unit, Heart of England NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; 2Warwick Medical School, University of Warwick, Coventry, United Kingdom
Introduction: The prognosis in workers with occupational asthma following cessation of exposure and increase in FEV1 post-exposure is variable. We investigated whether FENO was increased in workers exposed to metal working fluids (MWF).
Methods: Case control study to assess the prevalence of obstructive airway disease in a group of 160 goldsmiths exposed to metal working fluids (MWF). A control group of 160 goldsmiths was randomly selected from the same geographical area with no occupational exposure to MWF. Both groups were asked to complete a medical questionnaire and undergo a peak flow measurement. FENO was measured while exposed and after removal.
Results: In the goldsmiths exposed to MWF, the median FENO was 49.7 (95% CI: 32.8-67.5) ppb compared to 16.5 ppb (95% CI: 11.9-21.1) ppb in the control group (p <0.0001). FENO was higher in women exposed to MWF (p<0.01) and in those with symptoms (p<0.0001). FENO was 38% (95% CI 16-60%) higher in the exposed group compared to controls and 20% (95% CI 1-39%) in the control group after 2 weeks of exposure.
Conclusion: FENO increased after 2 weeks of exposure in workers exposed to MWF. FENO can be used in the assessment of exposure cessation and may be a useful tool in the management of occupational asthma. Further research is needed to establish the predictive value of FENO.

P1026
Increased exhaled nitric oxide among workers exposed to metalworking fluid aerosol
Marianne Andersson, Jonas Brisman, Oscar Hammar, Anna Dahlman-Hoglund, Anna-Carin Olins. Public Health and Community Medicine, Medicine, Gothenburg, Sweden
Background: Recent outbreaks of respiratory symptoms among workers, including dry cough, asthma symptoms and pneumonitis, exposed to metal working fluids (MWF), has initiated a cohort-study of 200 exposed and 75 unexposed workers.
Objective: To investigate whether exposure to MWF affects FNO.
Methods: Exposures were measured by personal dosimetry and exposure-related symptoms were scored during the 3 months prior to the study. The exposure in ppm was calculated for each worker and correlated with FNO and lung function tests.
Results: In the unexposed group FNO was 14.5 (95% CI: 9.7-21.0) ppb while in the exposed group FNO was 18.2 (95% CI: 14.4-22.5) ppb, which was statistically significant (p <0.001). FNO correlated negatively with FEV1 (r=-0.29, p<0.001) and lung function in workers exposed to MWF.
Conclusion: Exposed workers had increased FNO compared to unexposed workers. FNO can be used to monitor exposure and to support work-related respiratory health.

P1027
Respiratory symptoms and lung function tests among the goldsmiths engaged in jewellery manufacturing industries in India
Subhashrita Mitra, Subhamaj Sahu. Department of Physiology, University of Kalyani, West Bengal, India
Introduction: The goldsmiths are exposed to various acidic and metallic fumes at work. But no study has been reported on goldsmiths neither on the Indian jewellery industries evaluating the relationship between occupational exposure and respiratory health.
Methods: The study was carried out to see if there is a cause and effect relationship between the exposure to metallic and acidic fumes and respiratory health effects among workers engaged in Indian jewellery manufacturing industries.
Results: A total of 134 male participants were the goldsmiths among which 100 were the industry workers (mean age 34.4±2 years) and 34 were front desk office executives (mean age 37.5±2.2) of the same industry. Evaluation of examined subjects included completion of a standardized questionnaire on respiratory symptoms and spirometry. Data were analyzed using odds ratio with 95% confidence interval and logistic regression adjusting for age, smoking status, second hand smoke exposure and parental atopy/asthma.
Results: The goldsmiths had significantly higher prevalence of chronic cough (OR = 3.5, 95% CI = 1.2-8.2), nasal allergy (OR = 2.9, 95% CI = 1.1-4.8), production of phlegm (OR = 3.2, 95% CI = 1.4-6.2) and tightness in chest (OR = 2.7, 95% CI = 1.7-4.7) compared to the office workers. Results of spirometry showed significantly lower percent predicted values of FVC (p <0.05), FEV1 (p <0.001), FEV1/FVC <0.05) and FEV25-75 <0.05 (p <0.05).
Conclusion: Due to exposure to various sensitizers and irritants (metallic and acidic fumes) in the workplace the goldsmiths had a higher prevalence of respiratory disturbances and a reduced lung functions compared to the front office staffs.

P1028
Case control study to assess the prevalence of obstructive airway disease in flour mill workers
Madhura Padali 1, Sharad Agarkhedkar 2, Tushar Sabharwal 1
1Department of Pulmonary Medicine, Padmashree Dr. D. Y. Patil Medical College, Pimpri, Pune, Maharashtra, India; 2Department of Paediatrics, Padmashree Dr. D. Y. Patil Medical College, Pimpri, Pune, Maharashtra, India
In India, the grain flour required for household cooking is made by grinding grains in machine operated flour mills, which are usually small sized ventilated rooms. These machines are operated by a single unskilled worker who works in shift duties of 6 hours. During operation, the machine generates large amount of flour or grain dust and produces clouds of flour that surrounds the worker thus predisposing him to obstructive airway disease. 46 flour mills in the city were visited. Customers of the mills with short exposure to flour dust served as controls while those with exposure for age and sex. Those with active lung infection or scarring and tobacco smokers were excluded from both groups. On site measurement of PEFR was done, using Mini Wright’s peak flow meter for a total of 44 workers and 44 controls. The intention of using a peak flow meter instead of spirometry was to evaluate usefulness of this simple modality which can be easily applied in villages where flour mills are more common and spirometry is not available. The
peak flow readings between >100%, 80-99%, 50-79% and <50% predicted value were labelled as normal, green, yellow and red zone respectively. 22/44 workers had normal PEFR as against 38/44 controls. 19/24 workers were in green zone even after 15 years of work duration. The study indicates a potential occupational hazard to the flour mill workers. Use of face mask or enclosure of machine can potentially reduce the risk.

P1029

Acute bronchitis morbidity in railway and subway train machinists

Eleftheria Giatromanolaki1,2, Tatiana Rybina1, Oksana Omelyanenko2.

Conclusions: A correlation has been found between the AB morbidity and age, length of service and reliable morbidity decrease among subway train machinists in summer in comparison to winter. The study indicates that AB is a potential occupational hazard to the flour mill workers. Use of face mask or enclosure of machine can potentially reduce the risk.

Methods: Prospective, longitudinal study included 2 comparable groups: the 1st – 1068 subway train machinists, mean age 33.6±6.8 years, mean length of service 8.8±4.6±6 years; the 2nd – 1212 railway train machinists, mean age 43.3±4.6±8 years, mean length of service 12.0±8.9 years. AB personified morbidity was assessed during 2005-2008.

Results: AB personified morbidity in the 1st group was higher than in the 2nd group (29.7 cases and 286.4 days per 100 workers vs. 4.87 cases and 46.6 days per 100 workers respectively, p<0.015). Odds ratio for someumin selection of subway train machinists was 6.1±0.14 (OR=6.1), 95% confidence interval [-4.68, 7.95], etiological portion of the increase was 83.6%. The highest morbidity level in the 1st group was established in the age interval between 30-39 years and length of service range 5-9 years compared with those in other age intervals (37.2 cases per 100 workers, p<0.01). We found statistically reliable morbidity decrease among subway train machinists in summer in comparison to winter (4.78 vs. 8.3 cases per 100 persons, p<0.01). No any correlation has been found between the AB morbidity and age, length of service and season in the 2nd group.

Conclusions: AB morbidity in subway train machinists could probably be related to occupational exposure of the biological factor in underground work environment. Biological factor influence in underground could derive from the lack of ultraviolet insolation and large volume of passenger traffic.

P1030

Cof a 1 – Identification of the first coffee allergen

Cof a 1 was identified as a class III chitinase of Coffea arabica. Serum IgE antibodies to recombinant Cof a 1 were found in 27/24 workers with coffee-induced respiratory disorders.

Introduction: Dust of green coffee beans is known to be a relevant cause for occupational respiratory disorders. There is evidence for type I-sensitization as the underlying pathomechanism. Up to now no single coffee allergen has been described on molecular level. Identification of coffee allergens is warranted for standardization of allergological diagnostics.

Methods: From 17 coffee industry workers complaining about work-related rhinitis, conjunctivitis, and airway obstruction during exposure to coffee dust we obtained sera for IgE sensitization to green coffee beans detected by ImmunoCAP (Phadia, Freiburg, Germany). By sequence analysis, a new coffee allergen (Cof a 1) was identified, expressed in E. coli, and evaluated by Western blots. The frequency of sensitization was investigated by ELISA (Enzyme-linked Immunosorbent Assay) screening.

Results: The cDNA encoding Cof a 1 was identified as a 32 kDa Coffee arabica class III chitinase. Serum IgE antibodies to recombinant Cof a 1 were found in 3 out of 17 symptomatic coffee workers (18%), whereas only 2 of them reacted to the commercial specific IgE test to green coffee beans (k70, Phadia). After submitting the present data, Cof a 1 has been assigned by the WHO/IUIS Allergen Nomenclature Sub-Committee.

Conclusion: A class III chitinase of Coffea arabica Cof a 1 was identified as an important coffee allergen. It may have a relevant potential for diagnostics of green coffee-induced respiratory disorders.

P1031

Prevalence of work-related asthma among adult asthmatics referred to respiratory clinics

Amar Khosro Sadeghniiat1, Omid Aminian 1, Arezu Najafi2.

Background: The most common occupational lung disease reported in industrial countries is occupational asthma. There are limited data about the prevalence of work-related asthma among asthmatics in Iran.

Objectives: The aim of this study was to assess prevalence of work-related respiratory symptoms (WRS) and occupational exposures in asthmatic adults at pulmonary clinics.

Material and methods: A cross sectional study was performed. All ≥17 year old asthmatics were recruited into the study. A questionnaire mainly based on one developed by Rhino was completed by each participant. Currently employed subjects were subdivided into two groups by WRS status. Subjects’ occupational and workplace exposures were evaluated using an asthma specific job exposure matrix (JEM). Statistical analyses were conducted using the Student’s t-test for continuous data and Chi square for categorical data. Prevalence ratios (PRs) were calculated, using a Cox regression model.

Results: 39 (21.8%) of 179 current employed asthmatics (11% of all 339 adult asthmatics) had WRS. Subjects with WRS were more likely to have self-reported allergy (PR: 2.7; P=0.003) and low molecular weight antigens’ exposure (PR: 2.7; P=0.0001). According to the JEM, those with WRS had more high risk occupational exposures (PR: 2.2; P=0.003). The two most frequent occupational classes for asthmatics with WRS were trades, transport and equipment operators (33%), and processing, manufacturing and utilities (31%).

Conclusion: Prevalence of WRS in the current study is consistent with previous reports of work-related asthma. Study results emphasize further need for taking complete occupational histories in adult asthmatics.

P1032

Effects of exposure to flour dust on respiratory symptoms and pulmonary function of mill workers

Hardy Ali Mohamadmann Mahmoud1, Mona Tahina Hassien2, Raafi Talaat Ibrahim3,4,5, 4 Chest Department & Tuberculosis, Sohag University Hospital, Sohag, Egypt; 5 Chest Department & Tuberculosis, Assut University Hospital, Assut, Egypt.

Background: Exposure to flour dust is associated with development of respiratory symptoms and varying degree of reduction in lung function. The aim of the study was to assess the effect of Exposure to flour dust on respiratory symptoms and pulmonary function of flour mill workers.

Methods: This study was carried out at flour mills in Sohag Governorate. Two hundred male workers with current exposure to flour dust and Two hundred non-exposed male as a control group were interviewed and self designed study questionnaire was administered to them and the parameters of their pulmonary function were measured.

Results: Respiratory symptoms such as cough, expectoration, wheezing, and shortness of breath, were significantly (p<0.0001) more common in exposed workers compared to unexposed counterparts. Furthermore significant (p<0.0001) decrements in the pulmonary function of exposed subjects were noted. The additive effect of smoking was clearly noticed as there was a highly statistically significant decline of FEV1% and FVC% in smokers compared to non-smokers (p<0.0001), COPD, asthma and chronic bronchitis were significantly higher among workers compared with control subjects. Statistically significant association between COPD, asthma, chronic bronchitis and age (p<0.02), smoking (p<0.0002), duration of employment (p<0.0001), level of exposures (p<0.0001) was found.

Conclusions: Flour mill workers were at an increased risk of developing pulmonary symptoms & a strong association exists between exposure to flour dust and the prevalence of respiratory symptoms and functional impairments of the lungs.

108. Indoor and outdoor air pollution

P1033

Exhaled nitric oxide in traffic professionals exposed to ambient urban air pollution

Claudia Osht1,2, Diego Kogso1, Beatriz Romanholo2, Lourdes Martins1, Allesio Braga1, Paulo Saldiva1, Maria Garcia1, 1 Pathology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brazil; 2 Laboratory of Experimental Therapeutics, Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brazil.

Exhaled nitric oxide (eNO) has been used as a non-invasive method to assess lung
inflammation. Urban air pollution is associated with inflammatory markers and increased risk of pulmonary diseases. Traffic professionals are at risk of vehicular pollution exposure. However few studies have been published testing eNO in this group. We aim to study the association between air pollution, blood inflammatory markers and eNO in traffic professionals of Sao Paulo city (SP). Non smokers cab drivers (N=46) and traffic controllers (N=23) of SP were evaluated 4 times after work shifts. Pollutants (PM2.5 measured by reflectance and NO2 by colorimetry) were collected by individual samplers during 24h exposure before each evaluation. eNO, ultra sensitive C. Reactive Protein (us-CRP) and Erythrocyte Sedimentation Rate (ESR) were measured by ozone-chemiluminescence, high pressure liquid chromatography, nephelometry respectively. inflammatory markers data were tested against pollutants levels by Linear regression model for repeated measures through generalized estimated equations (LME GEE). Statistical significance was set at 10%. PM2.5 was 40.3±20.8 μg/m3 and NO2 197±24.5 μg/m3. eNO was 23.2±16.72 ppb, us-CRP 5.25±6.07 mg/L and ESR 3.2±1.2±20 mm/h. After adjustment for cardiovascular risks (abdominal circumference, hypertension, diabetes, age, body mass index) GEE tests showed associations between eNO and ambiant NO2 (p<0.10) and us-CRP (p<0.05, adjusted for ESR and NO2). PM2.5 was correlated to both inflammatory blood markers (ESR p<0.05 and us-CPR p<0.10). We conclude that urban air pollution in traffic professionals from SP.

P1034
Individual exposure of urban children to black carbon
Rossa Brugha 1, Chinedu Nwokoro1, Alexia Haysom3, Isobel Dundas1, Ian Mudway1, Frank Kelly3, Chris Griffiths1, Jonathan Grigg1, Centre for Pardustries, Barts and The London School of Medicine, London, United Kingdom; 1School of Medicine, Kings College, London, United Kingdom; 2Environmental Research Group, Kings College, London, United Kingdom; 3Centre for Primary Care and Public Health, Barts and The London School of Medicine, London, United Kingdom

Methods: Primary school children were given an Aethalometer to carry with them at all times for a 24 hour period. Cumulative black carbon was calculated by calculating the area under the curve (AUC) when plotting BC vs time. Activity diaries were used to divide the day into time at home, time commuting, and time at school or work. Personal exposure was compared with non-cycling adult commuters.

Results: For children 50.6% (± 9.3%) of exposure was at home, 19.1% at school and 39.3% at other times. Compared with adults (n=28), children (n=6) had similar 24 h exposure to BC (1019167 vs 706640 ng.m-3, p=NS). Children were exposed indoors, where PM levels are higher.

Discussion: We conclude that this because school children spend a greater proportion of the working day outdoors, where PM levels are higher.

P1035
Penetration and remanence of pollen in dwellings
Denis Charron, Christian Pichot, Michel Calleja, Vincent Penel. Department of Pneumonology & allergy, Aix-Marseille University, Marseille, France Unité de Recherches forestières Méditerranéennes, INRA, Avignon, France Institut des Hautes Études de la Vigne et du Vin, IMontpellier SupAgro, Nantes, Montpellier, France Laboratoire des Pollens, Laboratoire de Microenvironnement, Valence, France

Indoor pollens come from outdoor pollution but the temporal relationship between both phenomena is poorly documented. In this study, we tried to compute the influx and remanence of various pollen species throughout the pollen season.

P1036
Influence of wildfire’s smoke during heatwaves on the mortality and morbidity due to respiratory diseases in abnormally hot summer of 2010 year in Russia
Andrey Ginzakov, Olga Vasilyeva. Occupational Lung Diseases Department, Pulmonology Research Institute, Moscow, Russian Federation

Methods: Time series analyses of morbidity and mortality during 2008-2010 years in central regions of Russia. Case-crossover study of influence of pollution levels on respiratory health and mortality due to respiratory diseases in central regions of Russian Federation during summer 2010 year.

Results: We recorded significant growth in respiratory morbidity and mortality during extreme smoke and abnormal heat. Number of emergency calls due to bronchopulmonary diseases was twice higher than in 2008, 2009 and 2010. The most frequent cause of seeking the emergency aid was asthma, acute bronchitis and exacerbation of chronic obstructive pulmonary disease.

Conclusions: Our data suggest that there were a short-term associations between daily air pollution data and frequencies of events (death, hospital admission, emergency aid etc.) in the most hot days of summer 2010 year.

P1037
A longitudinal study about lung function and symptoms in patients with pollution-related illness
Takako Tanaka, Masahara Asai, Hideaki Senju. Health Science, Nagasaki University Graduate School of Biomedical Science, Nagasaki, Japan

Background: Air pollution is known a leading cause of respiratory symptoms. In Japan, an improvement of the atmosphere was achieved by the pollution organic act, and patients with air pollution-related illness have received medical care for more than 20 years under the Pollution Compensation Law. Our study was to verify the effects of Japan system by investigating the long-term consequences of exposure to air pollution on lung function and symptoms in patients with pollution-related illness.

Methods: The study included 782 surviving patients with pollution-related illness in Okayama who were ≥ 65 years of age in 2009. The patients had all received medical care, including expectorants and bronchodilators, once or twice a month and had undergone spirometry and assessment of respiratory symptoms each year for more than twenty years. We analyzed lung function and symptoms from 2000-09.

Results: Almost all (male: 59.0%, female: 78.6%) of the subjects had normal pulmonary function. However, a high proportion of subjects reported respiratory symptoms. All measures of pulmonary function decreased. The annual mean change of the VC was -40.5 ml/y (male) and -32.7 ml/y (female). The change in the FEV1 was -27.6 ml/y (male) and -23.9ml/y (female). In addition, there was a significant (male: p<0.05, female: p<0.01) worsening of dyspnea over time.

Conclusions: The annual mean changes of lung function were within the normal ranges. The findings suggested that the medical care compensation system in Japan is effective. Although in order to reduce dyspnea, we believe that it is necessary for patients with pollution-related illness to also receive respiratory rehabilitation.
Background: The relationship between air pollution and asthma has been investigated but the results of these studies were different and a definitive conclusion was impossible especially about the type and amount of pollutants that are harmful to health. Here we investigated the effects of various pollutants using GIS-based information on the rate of hospitalizations due to asthma in children in Tehran.

Methods: Information of patients who admitted with diagnosis of asthma in government run hospitals in Tehran and the total number of admissions in the same age range (2 to 14 years) from March 30th 2009 to March 31st 2011 obtained from medical records. Days of year divided in GOOD and NONGOOD days according guideline for reporting of daily air quality-pollutant standard index (PSI). Two thousand two hundred nineteen cases enrolled in the study and asthma admission to total admission ratio compared with air pollutants data in admission day (725 days) using non-linear regression method.

Results: Analysis of study data revealed that there is a significant relationship between NONGOOD nitrogen dioxide (P value<0.001), ozone (P value<0.001), and sulfur dioxide (P value<0.04), levels and admission due to asthma in children but there was no significant relationship between carbon monoxide levels and asthma admission in children.

Conclusions: Significant relationship between nitrogen dioxide, ozone and sulfur dioxide concentration in air and admission due to asthma at levels other than GOOD reveals air pollutants levels can be significantly harmful for children before PSI reaches to hazardous levels.

Traffic-related air pollution in Poland as a risk factor of obstruction in urban and rural areas

Background: Traffic-related air pollution (TRAP) is associated with a number of respiratory diseases. Specific traffic conditions in East-Central Europe foster an increased exposure to air pollutants and a risk of obstruction among people living close to busy roads.

Material: 4985 persons (urban and rural inhabitants) were investigated in a study made in 2008-2011 in Warsaw. Pulmonary function tests were completed (Easy One spirometer) and occurrence of respiratory system diseases symptoms, allergies, smoking, etc. were proved. Simultaneously traffic density and TRAP concentrations and a risk of obstruction among people living close to busy roads were assessed.

Results: TRAP concentrations were statistically significant higher (p<0.05) in the vicinity of roads compared to rural areas. Significant association between living close to busy roads and risk of obstruction was found. 334 cases of obstruction near industrial areas.

Conclusion: Traffic-related air pollution and not there is still significant relationship between NO2 and risk of obstruction among people living close to busy roads.

The increasing number of asthmatic children in Galati, one of the largest cities of Romania, very industrialized, requires a careful approach on the exposure to air pollutants, especially nitrogen dioxide, ozone, sulfur dioxide and particulate matter.
Graphene may modulate the immune activation and survival of monocytes representative of the innate immunity

Jong Won Shin 1, Jae Kook Nami 1, Young-Ae Baik 1, Jae Woon Jung 1, Jae Chel Choi 1, Jae Yeol Kim 1, In Won Park 1, Byoung Whuh Choi 1, Kyung Soon Choi 1, Juhyun Park 1, Soo Young Kim 1, 2Department of Internal Medicine, Chung-Ang University College of Medicine, Chung-Ang University Hospital, Seoul, Korea; 3School of Chemical Engineering and Materials Science, Chung-Ang University, Seoul, Korea

Background: The graphene which is an allotrope of carbon has the honeycomb-like structure of one-atom-thick planar sheets. It can be produced and chemically modified by chemical vaporization method, is used in modern electronic, infor-
mative technologies including medical device. Graphene oxide (GO) has oxygen functional groups on the graphene plane. We performed this experiment to define the effect of GO on the innate immunologic function.

Materials and methods: GO was prepared by the modified Hummers method using 2g of graphite powder. After sequential procedure, GO in water was used for experiment. U-937 cells were cultivated in RPMI 1640 containing various concentration of GO particle solution. We checked the surviving and dying cells and cell size with the morphologic change with light microscopy.

Results: The x-ray diffraction patterns observed for the graphite and GO. The pristine graphite has a peak centered at 2θ = 26.5° (d = 0.33 nm). This peak was shifted to 2θ = 11.3° (d = 0.78 nm) after applying the Hummers method. This means that the graphene is exfoliated and the d-spacing increased, indicating that GO is formed. As the graphene concentration increased, the cell survival was diminished. U-937 cells were aggregated which might be associated with phagocytosis.

Conclusion: GO in water diminishes the cell survival and activates phagocytosis and alters the differentiation in the monocytes representative of the innate immunity.

Lower socioeconomic classes are more exposed to air pollution in Italy

Giuseppe Verlato 1, Alessandro Marcon 1, Giang Nguyen 1, Simone Accerdi 1, Pierpaolo Marchetti 1, Leonardo Antonicelli 1, Francesco Attana 1, Roberto Bonc 1, Lamberto Brizarelle 1, Pietro Pirina 1, Simona Villani 1, Roberto de Marco 1, Unit of Epidemiology & Medical Statistics, Dept. of Public Health & Community Medicine, University of Verona, Italy; 4Allergy Unit, Ospedali Riuniti di Ancona, Ancona, Italy; 5Department of Emergency Medicine, University of Naples, Naples, Italy; 6Dept. of Public Health & Microbiology, University of Turin, Italy; 7Dept. of Hygiene, University of Perugia, Italy; 8Institute of Respiratory Diseases, University of Sassari, Italy; 9Dept. of Public Health, Neurosciences, Experimental & Legal Medicine, University of Pavia, Italy

Objective: The present study aims at investigating whether lower socioeconomic classes, who present a higher prevalence of current smokers, are also more exposed to air pollution in Italy.

Methods: In the frame of the GEIRD study (Gene Environment Interactions in Respiratory Diseases) 10494 subjects, randomly selected from the general population aged 20-44 years in 7 centres answered a screening questionnaire between 2007 and 2010 (response percentage=57.2%). It was investigated if residential exposure to industrial plants or heavy traffic changed as a function of education or profession.

Results: Subjects with lower education were more likely to live near factories or heavy traffic roads (Table 1). Workmen presented the highest exposure to industrial plants or heavy traffic roads (Table 1). U-937 cells were cultivated in RPMI 1640 containing various concentration of GO particle solution. We checked the surviving and dying cells and cell size with the morphologic change with light microscopy.

Conclusion: GO in water diminishes the cell survival and activates phagocytosis and alters the differentiation in the monocytes representative of the innate immunity.

Acknowledgement: This research was supported by Mid-career Research Program (2011-0028752) through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology.

Lower socioeconomic classes are more exposed to air pollution in Italy

The effect of particulate matter pollution on emergency room visits due to COPD and asthma and the association with hospitalization rate in Düzce City

Ege Gülaç, Balbik 1, Peri Arbak 2, Öner Balbik 2, Ali Nihat Annakkaya 3, Chest Diseases, Duzce Anaktar State Hospital, Duzce, Turkey; 2Chest Diseases, Duzce University Faculty of Medicine, Duzce, Turkey

To investigate the effect of particulate matter levels on patients with COPD and asthma admitted in emergency department with the diagnosis of asthma and COPD.

Between January-December 2009, the patients diagnosed as COPD and asthma at State Hospital were retrospectively evaluated. The monthly average values of particulate matter obtained from the official data. 61.4% of total 2489 cases were male. The average PM10 concentration of Düzce city was highest in November (184 mg/m³) and was lowest in July (41 mg/m³). The rates of COPD and asthma were 77.8% and 22.2%, respectively. COPD rates in males and females were 85.1% and 66.4%, respectively. Asthma was observed in 33.6% of females while 14.9% of males were diagnosed as asthma (p<0.000). The admittance rates to the emergency department for females and males were 69.3% and 66.2%, respectively (p<0.05). The patients with COPD were frequently applied in winter (27%) while the patients diagnosed as asthma admitted in autumn (p=0.010). While particulate matter was over 100 μg/m³, the odds ratios for COPD and asthma diagnosis were 1.039 (0.990-1.091) and 0.878 (0.749-1.029), respectively. Only the age was found an independent factor (β=0.382, t=-2.054, p=0.000). COPD patients were older (p=0.382, p=0.000). The factors independently effective on diagnosis according to univariate analysis were gender (R=10.664, F=65.182, P=0.000) and season (R=0.700, F=4.278, p=0.005). It seems that increase in PM10 concentration causes an increase in admission to emergency department with the diagnosis of asthma and COPD.

8-isoprostanе in exhaled breath condensate (EBC) and air pollution exposure in children with wheezing

Pedro Martins 1, Isabel Caires 1, José Araújo-Martins 1, Joana Valeante 1, Myriam Lopes 1, Paio Montușchi 1, Giovanni Ciabattoni 2, Carlos Borrego 3, Nuno Neuparth 1, 1CEDOC, Departamento de Fisiopatologia, Faculdade de Ciências Médicas (FCM), Universidade Nova de Lisboa, Lisboa, Portugal; 2Serviço de Pneumonologia, Hospital de Dona Estelina, Centro Hospitalar de Lisboa Central, EPE, Lisboa, Portugal; 3CESAM & Departamento de Ambiente e Ordenamento, Universidade de Aveiro, Aveiro, Portugal; 4Department of Medical Sciences, Faculty of Medicine, Catholic University of the Sacred Heart, Rome, Italy; 5Department of Drug Sciences, Faculty of Pharmacy, University of Chile, Santiago, Chile

Background: Oxidative stress is proposed as the underlying mechanism of air pollutants aggression over the airways. 8-isoprostanе is a reliable biomarker of...
oxidative stress. 8-Isoprostane could be detected in several fluids including exhaled breath condensate (EBC).

Objective: To study the relation between 8-isoprostane in EBC and air pollution exposure.

Methods: In the scope of a prospective study, EBC samples were collected from 27 wheezing children in order to measure 8-isoprostanes. Children were also evaluated through spirometry and skin prick tests for airborne allergens. After the definition of a activity pattern for each children and direct measurements of air pollutants in different microenvironments (home, school and outdoor), individual exposure data was calculated for PM2.5, O3, NO2, xylene, toluene, benzene, formaldehyde and ethylbenzene. Spearman rank correlation was used to study the associations between 8-isoprostane and air pollutants.

Results: The mean age of the studied children was 7.9±1.1 years. Eleven were boys. The mean FEV1 was 96.7±9.6%. Ten of the studied children were atopic. Exposure to volatile organic compounds (VOCs) including toluene (rho = 0.604, p = 0.008), xylene (rho = 0.685, p = 0.002) and ethylbenzene (rho = 0.788, p<0.001) was correlated with 8-isoprostane concentrations in EBC. There were no correlations between EBC 8-isoprostane and PM10, O3, NO2 neither between EBC 8-isoprostane and spirometric results.

Conclusion: Exposure to VOC seems to be related with oxidative stress evaluated through 8-isoprostanes measurement in EBC.

P1048 Feasibility of minimising motorised traffic interaction as an air pollution exposure risk management strategy for bicycle commuters

Thomas Cole-Hunter,1 Lidia Morawka,1,2 Ian Stewart,1 Rohan Jayaratne,1 Colin Solomon,1,2. 1, Human Health and Wellbeing, Institute of Health and Biomedical Innovation, Brisbane, QLD Australia; 2, Air Quality and Health, International Laboratory for Air Quality and Health, Brisbane, QLD, Australia

Bicycle commuting in an urban environment of poor air quality has been demonstrated to be a potential cardiovascular health risk for susceptible participants; however, limited studies have assessed the feasibility of risk management strategies. The potential of minimising motorised traffic interaction during bicycle commuting was determined where the reduction in traffic exposure (25-40%, min particle diameter range) was evaluated through air quality measurements and acute health endpoints in healthy individuals. Thirty-five healthy adults (n = 35; mean ± SD age = 39 ± 11 yr; 29% female) rode two return trips of pre-determined minimal (MIN) and maximal (MAX) motorised traffic interaction variations of their typical bicycle commute route. Particle number concentration (PNC) and diameter were collected in-commute, along with ambient air quality data from fixed monitoring sites. Health endpoints including acute respiratory symptoms, lung function and spontaneous sputum were collected immediately pre-commute, and then one and four hours post-commute. MIN facilitated a significant reduction in mean PNC (1.91 ± e4 vs. 9.5 ± e4 PNC cm3; p < 0.01) compared to MAX. Besides incidence of in-commute offensive odor detection (42.4 vs 55.8%; p = 0.03) and nasopharyngeal irritation (31.2 ± 4.9%; p = 0.04), health endpoints were not significantly associated to air quality measures, nor were reduced with MIN compared to MAX. Acute health detriment from in-commute air pollution exposure is not indicated in healthy bicycle commuters; however, susceptible participants may benefit from a significantly reduced PNC associated with minimising motorised traffic proximity.

P1049 Effects of swimming on lung inflammation and oxidative stress in diesel exposed mice

Leonardo César Melo Ávila, Thayse Regina Bruggemann, Bárbara Fortkamp, Morgana Duarte da Silva, Regiane Carvalho Oliveira, Daniel Fernandes Martins, Leidiane Mazzardo-Martins, Luiz Felipe Souza, Adair Dafre, Adair Roberto Soares Santos, Deborah de Camargo Hizume.1 1, Department of Physical Therapy, State University of Santa Catarina, Florianópolis, SC, Brazil Department of Physiology Science, Federal University of Santa Catarina, Florianópolis, SC, Brazil 2, Department of Biochemistry, Federal University of Santa Catarina, Florianópolis, SC, Brazil

Background: Studies have reported that exposure to diesel exhausted particles (DEP) induces lung inflammation and increases oxidative stress, both able to be changed by physical exercise. However, the effects of high intensity exercise on lungs exposed to DEP when exercise stops are not clear.

Objective: To evaluate the effects of swimming on lung inflammation and oxidative stress in mice concomitantly exposed to DEP and after exercise cessation.

Methods: Male Swiss mice were divided into four groups: Control (n=6), Swim (n=7), Swim+DEP (n=10), and DEP+Sw (n=7). Mice were submitted to two weeks of swimming sessions and when second week started, DEP instillation occurred simultaneously to exercise for one week. After this period, animals received just DEP instillation for one week more. Twenty four hours after last DEP exposure, anesthetized mice were euthanized and we performed measures of total inflammatory cells from bronchoalveolar fluid (BALF), IL-1β, TNF-α, IL-10, IL-1ra by enzyme-linked immunosorbent assay (ELISA), total glutathione (GSH), total glutathione and non-protein thiols (NPSH) and anti-oxidant enzymes (Catalase and Glutathione Peroxidase).

Results: Swimming sessions increased GSH, NPSH, and Catalase (p<0.05), as well as decreased total number of cells from BALF, IL-1β and TNF-α levels in mice exposed to DEP (p<0.05). IL-10 and IL-1ra levels showed an increase in DEP+Sw group when compared with Control group (p<0.05).

Conclusion: Our results showed that exercise attenuated lung inflammation and improved oxidative stress status, suggesting that beneficial effects from swimming can be observed on lung injury induced by DEP, simultaneously and after exercise cessation.

P1050 Airway reactivity and neuroimmune relationships in animal model of air-born irritants induced symptoms – Role of trigeminal TRP1 channels Zuzana Biringerova 1, Martina Brozmanova 1, Silvia Gavlikova 1, Martina Sutovska 2, Sonja Franova 2, Marian Adamkova 3, Miles Tatar 1, Jana Plevkova 1. 1, Department of Pathophysiology, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic); 2, Department of Pharmacology, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic); 3, Department of Histology and Embryology, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia (Slovak Republic).

Air born pollutants modulate functions of airways. Many experimental models use inhalation of air born irritants containing aerosols to mimic environmental exposure however, most exposed part is the nose. The aim of our study was to assess the general effects and modulation of airway defensive reflexes in animal model by selective nasal challenges with TRPA1 agonist AITC – allylthiosulfinic acid. TRPA1 is known to be relevant for most air born irritants.

15 male Dunkin Hartly guinea pigs were repeatedly exposed to 10mM AITC, 15mL administered into both nostrils and nasal symptoms, cough, specific airway resistance ( Saw) and bronchoalveolar lavages (BAL) were analyzed afterwards.

Nasal administration of 10mM AITC induces reproducible nasal symptoms, sneezing, discharge, crakles and conjunctival reaction. Also, nasal application of 10mM AITC induces spontaneous rise of Saw measured by Pennock’s method can be increased and increases Saw after inhalation of methacholin (p<0.05) rather than histamine, suggesting for nasobronchial reflex. Saw after oxymetazoline (1%) and salbutamol pretreatment suggest for combined mechanisms. Citric acid induced cough after nasal AITC challenge was significantly suppressed (p<0.05) and it was prevented by pretreatment with TRPA1 antagonist AP18. Nasal AITC challenges in experimental animals for a week induced rise of the count of eosinophils in BAL when comparing to controls confirming the concept of upper and lower airways neuro – immune relationships. Results document the role of TRPA1 in onset of environmental and occupational airway symptoms making it target for clinical applications. VEGA 100331/11.

P1051 Effects of metal oxide nanoparticles on static and cyclic stretched AT II cultures

Marcus Buschges,1 Hartmut Kuhn2, Irina Estrela-Logis1, Hubert Wirtz2, Edwin Donath1. 1, Institut für Medizinische Physik und Biophysik, Universität Leipzig - Medizinische Fakultät, Leipzig, Germany; 2, Innere Medizin, Abteilung für Pneumologie, Universität Leipzig - Medizinische Fakultät, Leipzig, Germany

Metal oxide nanoparticles (NP) have become very important for a variety of applications, even though NP could possess adverse impacts on health. Thus, assessment of NP safety is crucial. For the first time, we investigated effects of ZnO-, CeO2- and TiO2-NP on primary alveolar type II cells (ATII) considering the fact that lung cells are in vivo exposed to mechanical tensions caused by breathing. Therefore ATII cultures were in vitro applied to stretching patterns simulating the breathing process during NP exposition. Nanotoxicology was determined using the MTT assay as well as staining with annexin V-FITC/PI. Cell staining with H2DCFDA was performed to measure intracellular formation of ROS. Release of pro-inflammatory cytokines MCP1 and MIP2 into culture supernatant was evaluated by ELISA.

ZnO-NP induce strong intracellular formation of ROS (200% rel. to control) and reduction of cell viability (10% rel. to control) in unstrained ATII cultures. These effects are diminished by half in ATII cultures applied to stretching patterns. CeO2- and TiO2-NP do not significantly affect viability or ROS formation whether if the ATII cultures are stretched or not. Cellular uptake of CeO2-NP could be assumed due to a dose-dependant change of the flow cytometric side scatter (350% rel. to control). Application of stretching patterns reduces this effect by one third. NP exposure does not affect the release of MCP1 or MIP2 regardless of the applied NP type or stretching pattern.

These results demonstrate that NP could affect primary ATII cultures and that these effects are modified when ambient conditions in the context of breathing are taken into account during NP exposition.
109. Tobacco dependence and respiratory disease

P1052 Heart rate and ventilation in a group of burned sugar cane cutters (Brazil): Estimative of particulate matter (PM2,5) exposure load
Izabela Cozza1, Danilo Nambu1, Frederico Fernandes1, Marcos Bussacos2, Renato Paceli1, Gustavo Prado1, Mario Terra-Filho1, Ubiratan Santos1.
1Pulmonary Division Heart Institute (InCora), School of Medicine, University of São Paulo, SP, Brazil; 2Fundacentro, Fundacentro, São Paulo, SP, Brazil

Introduction: The sugar cane harvesting exposes workers to pollutants released by sugar cane burning held hours before. The workers earn per ton cut, what carries considerable physical effort with consequent increase in heart rate (HR) and ventilation (Ve). The HR keeps a good correlation with oxygen uptake and consequently with Ve. Its measurement is a useful method to estimate Ve, which allows estimating the exposure load of particulates.

Objectives: Develop an equation of the linear correlation between HR and Ve and apply it to estimate the pollutant exposure load in sugar cane cutters.

Methods: We developed an equation of the regression line, through data from HR and Ve obtained in ergospirometry tests of 26 sugar cane cutters. The equation was used to estimate the exposure load in another group of 84 cutters, after registration of HR (using POLAR), during a working day, with concomitant registration of PM2,5 environmental concentration.

Results: The PM2,5 average concentration was 61.5 μg/m³ (IBQ: 41.3-86.7 μg/m³). The individual equations obtained from the 26 workers, showed a high correlation with average R²=0.90. The general equation (26 workers) 975±48.061965·Log Ve=5CF, showed lowest correlation: R²=0.78. The estimation of exposure/workday in the group of 84 workers ranged from 282.5 to 1140.1 μg/m³ (677-44.1907 μg/m³).

Discussion/Conclusion: Exposure to pollutants was high and there was great variation in daily load exposure among workers. Although the general equations are less suitable than the individual equation to estimate the pollutants load inhaled by an individual, it can help in exposure estimation in population groups.

P1053 Acute effect of e-cigarette on pulmonary function in healthy subjects and smokers
Soňa Antioši Genişmans1, Anastasios Palamidas1, Georgios Kaltsakas1, Danilo Nambu1, Frederico Fernandes1, Renato Paceli1, Gustavo Prado1, Mario Terra-Filho1, Ubiratan Santos1.
1Pulmonary Division Heart Institute (InCora), School of Medicine, University of São Paulo, SP, Brazil; 2Fundacentro, Fundacentro, São Paulo, SP, Brazil

Purpose: To study smoking habits among patients hospitalised/admitted for COPD exacerbations in a conventional hospital ward.

Material and methods: We carried out a retrospective descriptive study by reviewing discharge reports of patients admitted to our centre during the period of September 2010 to September 2011. We analysed epidemiological, clinical and smoking history.

Results: We studied 196 patients, of whom 180 men (91.8%) and 16 women (8.2%) with a mean age of 77 years. 41% have a diagnosis of severe COPD. The most frequent co morbidity found is cardiovascular. 18% associated cancer. The prevalence of current smoking is 26%. In patients continue to smoke including 47 males (27%) and 5 women (31%). The ex-smoker population represents 68.9% (131) while non-smokers comprise 1.5% (3). 73% of male smokers have a moderate to severe COPD degree. Pneumonia is present in 26% of smokers, (14), while in ex-smokers it is present in 23% (33). A total of 37 patients (18.8%) were readmitted within a year, of which 62% are severe COPD (28); 9 of them were still smoking.

Conclusion: 1) Smoking is a major factor in COPD exacerbations. 2) There is a high prevalence of COPD exacerbations requiring admission to a hospital unit in those patients who continue to smoke. 3) Most smokers admitted for exacerbation of COPD were included in the severe COPD group. 4) There are 37 readmissions within a year, representing almost one fifth of all COPD exacerbations, 9 of whom continue smoking.

P1054 Impairment of mucociliary clearance in COPD and smokers: Same or different

Physiotherapy, UNESP - Sao Paulo State University, Presidente Prudente, SP, Brazil

Mucociliary clearance (MC) is a key defense mechanism in airways. Smokers and patients with chronic obstructive pulmonary disease (COPD) exhibit modifications in MC, which predisposes these populations to recurrent infections. It is known that ex-smokers with normal lung function may present MC reversing after smoking cessation, but there are no studies that evaluate COPD ex-smokers’ MC.

Aim: To evaluate and to compare the MC and exhaled carbon monoxide (eCO) in smokers and COPD ex-smokers.

Methods: We evaluated 83 subjects, divided in four groups: severe COPD (n=22), moderate COPD (n=19), current smokers (n=20) and nonsmokers (n=22). Severe and moderate COPD patients were ex-smokers (FEV1% = 38 [34-43] and 60 [53-63], 48 [11-100] and 50 [40-75] pack/years, respectively). Current smokers presented normal lung function and 40 [22-44] pack/years. Nonsmokers were matched for age and sex. Were evaluated eCO levels and MC by saccharin transit test (STT). Tests were conducted between 8 and 9 AM with air temperature and relative humidity controlled. Statistical analyses were performed using Kruskal-Wallis test followed by Dunn’s test.

Results: STT was higher in smokers compared to control group (p=0.006). There was no difference in STT between smokers and COPD groups, but in both groups of COPD STT values were similar to control group. Also, there was no difference in STT between severe and moderate COPD. eCO levels was higher in smokers compared to other three groups (p<0.0001).

Conclusion: Smokers showed worse STT and moderate and severe COPD were...
similar to nonsmokers. These results suggest that quiting smoking, even in people who developed COPD, may lead to MC’s reversibility.

P1057 Survival of patients with severe chronic obstructive pulmonary disease in relation to smoking index

Kražina Tóth Vörös1, Nevena Secen2, Djordje Povazan2, Jelena Zvečić-Svrcan2; 1Pulmonology, Health Center, Novi Becej, Vojvodina, Serbia; 2Department for Chemotherapy, Department for Acute Pneumopathies, The Institute For Pulmonary Diseases of Vojvodina, Novi Sad, Vojvodina, Serbia; 3Rheumatology, Special Hospital for Rheumatic Diseases, Novi Sad, Vojvodina, Serbia

Introduction: The increase in mortality and morbidity from chronic obstructive pulmonary disease (COPD) is occurring worldwide as a result of the epidemic-like growing use of tobacco in developing countries.

Aims and objectives: Analysis of the correlation between smoking habits and mortality of the COPD patients, evaluation of the two-year survival and the five-year survival dependent on the smoking habits.

Methods: The two-year and the five-year survivals were followed up between 2001 and 2007 in respect to smoking habits. The sample consisted of 30 smokers and 30 nonsmokers of both sexes. Criterions for inclusion of smokers were: smokers or former smokers who had smoking experience over 30 years. Criterions for inclusion of nonsmokers were: patients who never smoked or who were non-smokers over 12 years. Criterions for exclusion from the study were: patients who get pneumonia or forced over in the meantime. Statistical analysis was performed to determine the statistical difference between the groups using standard statistical methods (t-test), and the test of linear correlation was used to correlate these data.

Results: The results of the two-year survival were: 90% (27/30) of smokers, and 66.6% (20/30) of nonsmokers survived. The difference was statistically significant at p < 0.001. The results of the five-year survival were: 46.66% (14/30) of smokers, and 66.6% (20/30) of nonsmokers survived. The difference was statistically significant at the level of p = 0.03.

Conclusions: Two and five years survival is significantly longer in nonsmokers compared to smokers in the terminal stage of COPD.

P1058 Loose cough as sign of hyper secretion and inflammation in airways in relation to smoking index

Dragana Sumrak, Vladimir Jakovlevic, Tomislav Dokić. Faculties of Medicine, Institute of Physical Medicine, Kozorska Mitrovica, Serbia Faculties of Medicine, Institute of Clinical Physiology, Krugrarevac, Serbia

Cough may be considered as a symptom of disease, an indicator of environmental pollution. In addition, the subject may produce cough through voluntary control. The aim of this study was to determine the quality and humidity of voluntary cough as a sign of inflammatory bronchial alterations leading to hyper secretion in patients chronic obstructive bronchitis (COB) in relation to “Smoking Index” (years x cigarettes per day). Evaluation of lung function included clinical examination, electrocardiogram, estimation of blood, urine and function of the lung. The diagnosis of a disease as a basis for cough can be established with measurements of indicators or forced in the first second (FEV1), maximal expiratory flow at 25% and 50% of FVC (MEF25/FVC, MEF50 FVC), and direct tests by measurement of airway resistance to flow. The results presented in this study were done on 147 patients with COB. The control groups consisted 132 subjects, none of these subjects had symptoms or a history of pulmonary or cardiac diseases. Beside the questionnaire MRC, there was obligation to each subject to perform the test of cough, which is established on the base that in healthy subjects with normal bronchial mucosa provoked voluntary cough is dry, while in patients with inflammation in bronchial mucosa, the cough is humid assessed by auscultation. In smokers with COB the presence of chronic productive cough was in a positive correlation with increase of “Smoking Index”. In smokers with COB negative correlation between “Smoking Index” and positive test of humid cough. Increase of “Smoking Index” was followed with decrease of the incidence of humid cough in patients with COB.

P1059 COPD in elders (>80y): Smoking and air pollution

Raffaella Giusi, Walter Sgori. Geriatric Hospital, Ca d’ Industria, Como, Italy

We studied a group of Elders living in a Nursing home and affected by COPD. The diagnosis has been made in all of them five or more years ago. 63 Elders affected by COPD have been found among 282 (>80 y) admitted into our geriatric nursing home.23,3% of the total number COPD has been associated to heart diseases (54%), cerebrovascular diseases (46%) and moderate or severe dementia (45%).

Concerning the Gender 17 are men and 46 women. For the age are 18 between 80/84 y, 25 between 85/89 y and 20 over 90y. Ex smokers (22): 6 m and 3 w in the first group, 5 m and 5 w in the second, 1 m and 2 w in the third. No smokers (41): 1 m and 8 w in the first, 2 m and 13 w in the second, 2 m, 15 w in the third.

No differences have been found between ex smokers and no smokers about the numbers of exacerbations of COPD and the supplement of oxygen in the last year. The drug more used has been Tiotropium (more than half of elders) while only in few cases Beta2-long-acting and inhaling corticosteroids.

Unfortunately in ten women, no-smokers, it has been impossible to check their exposition to passive-smoke.

Conclusion: In women no smokers, without occupational exposures, ambient air pollution is a probable risk factor for the development of COPD. In our elders the evolution has been rather slow but has required continual treatment and has worsened their quality of life.

P1060 Risk factors of development of endothelium dysfunctions at smokers

Tatiana Levenina1, Julia Krasnova2. 1Therapy, Academy of Advanced Medical Studies, Irkutsk, Russian Federation; 2Gerontology, Academy of Advanced Medical Studies, Irkutsk, Russian Federation

Aim: To evaluate the risk factors of development of endothelium dysfunctions among smokers.

Materials and methods: The research has been conducted amongst 100 smoking patients. Brachial artery blood flow reactions to hyperemia were studied by doppler sonography in all patients. Data on risk factors, was gathered through questionnaires. We identified 2 groups, 1 of them – the patients having endothelium dysfunction (n=66) and 2 - not having endothelium dysfunction (n=34). The OR (odd ratio) and 95% confidence interval (95% CI) were calculation.

Results: The risk factors significantly associated with female sex (OR=1.17; 95% CI: 0.47-3.68), beginning of smoking till 15 years (OR=1.34; 95% CI: 0.34-5.59), the beginning with smoking with 16 till 20 years (OR=1.06; 95% CI: 0.43-2.64), an index of smoking ≥30 pack/year (OR=1.18; 95% CI: 0.3-5.03), duration of smoking more than 30 years (OR=1.14; 95% CI: 0.3-3.83).

Conclusion: The risk factors of development of endothelium dysfunctions have greater impact on female sex (p=0,00001), beginning of smoking till 20 years (p=0.03), an index of smoking ≥30 pack/year (p=0,0001) and duration of smoking more than 30 years (p=0,0001).

P1061 Aggregation of erythrocytes in the dynamics of phototherapy in rats with experimental model of COPD

Yulduzkhon Koyumova. Ministry of Health, Republican Specialized Scientific-Practical Medical Center of Therapy and Medical Rehabilitation, Tashkent, Uzbekistan

Aim: To study erythrocyte aggregation in rats with experimental model of COPD in the dynamics of phototherapy with lamps with ceramic coating.

Methods: An experimental model of COPD was reproduced in 22 white rats under the influence of tobacco smoke in a special chamber, where they were placed daily for 30-40 minutes for 2 months. Control group (11 rats) is contained in similar conditions but without exposure to tobacco smoke. For the treatment of half of the rats with experimental COPD we used the method of phototherapy with infrared light from ceramic-coated lamps with a narrow emission spectrum (wavelengths of 2-40 microns). Phototherapy on the area of lungs was carried out daily for 10 days: 5 minutes of the first 5 procedures and 10 minutes of the next 5 ones. Spontaneous aggregation of erythrocytes was quantitatively evaluated by a special system of criteria for micrographs (made by a camera connected to a microscope) of aggregates of red blood cells.

Results: In the 1st group without phototherapy erythrocyte aggregation was 11,8±0,47. In the 2nd group after 10 days of phototherapy the index was 7,78±0,97. It is by 34% less than in the 1st group (p<0.05). In both groups of COPD erythrocyte aggregation was higher than in healthy rats (6,6-6,75). But when we tested the differences in groups, a statistically significant difference (p<0.05) was not detected between the 2nd and control groups.

Conclusion: Erythrocyte aggregation increases in rats with experimental model of COPD. During the 10-day course of treatment with infrared light from lamps with ceramic coating this indicator tended to normalize.

P1062 The influence of smoking on the level of proinflammatory cytokines in patients with COPD

Lubov Dolmina1, Vasilii Tretiomin1, Anna Delieva1, Olga Galkina3. 1Chair of Hospital Therapy, I.P. Pavlov St. Petersburg State Medical University, St. Petersburg, Russian Federation; 2Laboratory of a Biochemical Homeostasis of an Organism, I.P. Pavlov St. Petersburg State Medical University, St. Petersburg, Russian Federation

Smoking is a major risk factor for COPD. The mechanisms of the effect of smoking on the progression of the disease is not fully understood.

The purpose of: To identify the relationship of smoking and the activity of local and systemic inflammation in patients with COPD.

A total of 98 patients, 76 of them smokers with an average experience of smoking a pack of 25±1.8/year. Revealed that smokers C-reactive protein blood (12,7±4, 190s)
Conclusion: The phototherapy by IR has a marked significant decrease in levels of proinflammatory cytokines in eCOPD, without changing the level of anti-inflammatory IL-10.

P1065 Vasomotor activity of the cerebral arteries in rats with experimental COPD
Natalia Zakharshuk, Vera Nevezrov, Tatjana Brodskaya, Elena Gonchar, Irina Agafonova. Chair of Therapy, Vladivostok State Medical University, Vladivostok, Russian Federation

The aim of the study was to evaluate the endotelmum-dependent and endotelmum-independent reactions of the cerebral arteries reproduced in vivo COPD model. The COPD model was reproduced by chronic smoking in rats within 6 months according to H.Zheng protocol. The experimental group consisted of six male Wistar rats. The control group breathed only clean air. Assessment of the endothelium-dependent vasomotor reactions were carried out in 6 months after the experimental start and in 2 months after smoking cessation. Acetylcholine and nitroglycerin were injected in the rats body to assess endothelium-dependent (EDVD) and endothelium-independent (EIDVD) vasodilation, N-monomethyl-L-arginine (L-NMMA) to assess endothelium-dependent constriction (EDVC). Using magnetic resonance imaging the degree of the cerebral arteries diameter change in the tomograms before and after drug administration was evaluated. The study revealed the cerebral arteries dysfunction in fum-smokers. Acetylcholine stimulation in the rats smokers leaded to the pathological vasoconstriction. Test with nitroglycerin caused insufficient vasodilatation (p <0.05). Test with L-NMMA showed the abnormal vasodilation in contrast with the control group set the expected EDVD. In 2 months after smoking cessation the pathological vasoconstriction remained in the acetylcholine test EIDVD was paradoxical even leading to the vasoconstriction. In long-term tobacco smoking the violation of the endothelial vasomotor function of the cerebral arteries has the form of the pathological activity of the vasodilating management and intensification of the vasoconstriction. After smoking cessation the vasomotor disturbances are not only preserved but also exacerbated.

Conclusion: There is a significantly higher admission rate amongst those with a history of smoking drugs when compared to those patients that have never smoked drugs. Several patients have recurrent admissions with exacerbations of COPD. We analysed data from January 2009 to September 2011 and compared the number of admissions amongst those that have a history of smoking drugs and those that have never smoked drugs.
survey in 2002, we observed significant improvements relative to knowledge of COPD (8.6% vs. 17.0%), with a marked variability within regions (p < 0.05). Currently, only 17.9% of the Spanish population knows that there is a National Strategy for COPD, although 86.0% have a favorable/very favorable opinion about the new Anti-Tobacco Law. Conclusion: The lack of knowledge about COPD and its determinants in the general population remains high, therefore more and better teaching and awareness interventions are needed.

P1068
To determine the prevalence and predictors of smoking and smokeless tobacco use amongst women in Karachi, Pakistan
Nadia Sharif1, Javaid Khan. Pulmonology and Critical Care Medicine, Aga Khan University Hospital, Karachi, Sindh, Pakistan

Study design: Cross sectional study.
Study sample: A Convenient sample of 485 female attendants was taken for the study. A standard questionnaire for tobacco use, developed by WHO, was used. Results: Prevalence of tobacco: Overall, 96 (19.6%) admitted to using tobacco in one form or another. 13 (2.7%) of the total respondents were smokers and 83 (17.1%) were smokeless tobacco users. The use of tobacco was found to increase with age and was highest among the age group of 66 years and above (P=0.01, 95% CI). A higher prevalence of tobacco use was found in women who had never gone to school and the prevalence of tobacco use decreased with increasing education (P=0.001, OR=4.6 with 95% CI). When the association between marital status and tobacco use was assessed it was found that tobacco use was more prevalent amongst married women (P=0.001, OR=6.13 with 95% CI). It was found that tobacco use was more prevalent amongst the working population as compared to the non-working women/housewives (P=0.05, OR=1.90 with 95% CI). When the participants were asked about the extent of harm tobacco can cause, 69.5% participants were of the view that it was very harmful while 6.8% thought that it was harmless. The remaining participants thought that it caused little harm.
Being hospital based, our study may have the shortcomings of a hospital based study. Another limitation could be due to the fact that it was done in Karachi and the results may not be generalizable across the whole country. Intervention in epidemiological studies of tobacco use and its predictors in different areas of the country among different population groups would be very beneficial in our fight against tobacco.

P1069
Jun Kudo1, Tetsuhiro Shigenaga2, Satoshi Kitamura1.1Pulmonary Medicine, Minamimochi Hospital, Oyama, Tochigi, Japan; 2Pulmonary Medicine, Ehbara General Hospital, Miyazaki, Miyazaki, Japan

Questionnaire was distributed at the Annual Meetings of the Japanese Respiratory Society held in 1996, 1999, 2001, 2003, 2005, 2007, 2010 and 2012 repeatedly, in order to know how attendants think and behave about smoking as respiratory care specialists. Questionnaire paper was handed to the attendants around the table for meeting registration, and was recovered voluntarily in the boxes. Smoking prevalence of all attendants in 1996, 1999, 2001, 2003, 2005, 2007, and 2010 was 22.5%, 19.7%, 15.1%, 19.3%, 7.6%, 5.8%, and 3.7% respectively. Recovery rate of questionnaire in 1996, 1999, 2001, 2003, 2005, 2007, and 2010 was 64.7%, 70.4%, 48.6%, 52.2%, 85.3%, 92.3% and 87.8% respectively. Smoking prevalence of physician in 2001,2003,2005,2007, and 2010 was 12.9%, 12.7%, 5.1%, 3.9% and 2.4% respectively. Attendants from smoke-free hospital in 1996, 1999, 2001, 2003, 2005, 2007, and 2010 was 7.5%, 15.8%, 21.7%, 28.4%, 61.1%, 61.1%, and 72.3% respectively. Tobacco sales in the hospital retail shop were 53.2%, 44.8%, 39.0%, 19.4%, and 10.0%, respectively. Tobacco sales in the hospital vending machine was 50.3%, 41.5%, 37.2%, 31.1%, 12.3%, 7.1%, and 3.1% respectively. New 2012 data will be merged with those data, which will show that smoking behaviors of the attendants have improved for 16 years. Japanese government recently accelerated to promote smoke-free lifestyle, planning to reduce smoking prevalence from 20% to 12% in the next ten years. Japanese Respiratory Association is responsible to encourage its members to intervene in smoking behavior or policy of hospitals which has been generous for tobacco sales.

P1070
Is subjective sleep quality better in quitters? Derya Celebi1, Celal Kurtliyay1, Levent Orzurt2. 1Chest Diseases, Trakya University Faculty of Medicine, Edirne, Turkey; 2Physiology, Trakya University Faculty of Medicine, Edirne, Turkey

Aims: Smokers have 4-5 times higher risk of sleep-related breathing disorders. We studied subjective sleep quality, weight gain and changes in pulmonary functions in quitters and non-quitters.
Methods: Among 692 patients registered for smoking cessation clinic, who were smoking 10+ cigarettes/day, followed at least 1 year and agreed to participate in the study were included. Pittsburgh sleep quality index (PSQI), Epworth sleepness scale survey, measurements of exhaled carbon monoxide, body weights and PEFs were obtained and evaluated. Cases with PSQI ≤5 points were classified as having good sleep quality.
Results: Among the cases (n=106, 67 male, 39 female), 39.6% had quitted and 60.4% had not quitted. Mean age of quitters were 50.7±11.1 years, while non-quitters was 47.4±11.1 years. Better sleep quality was observed in 23.8% of quitters, while in 7.8% of non-quitters (p<0.01). Better sleep quality was evident in quitters in spite of weight gain. Mean 8.33 kg weight gain and 3.13 increase in BMI were observed in quitters (p<0.01). Gaining more than 10% of body weight was observed in 52.4% of quitters while 7.8% of non-quitters (p<0.01). Pulmonary function changes were not different among quitters and non-quitters. CONCLUSION: Quitters had better sleep quality than non-quitters in spite of more weight gain. This difference was not related to improvement in pulmonary function. This data can be used as a motivational tool for smokers’ quitting. And also it can be a clue for the importance of smoking cessation in patents with sleep-related breathing disorders.

P1071
Effect of high-flow nasal cannula on nasopharyngeal airway pressure, respiratory muscles loading and respiratory distress symptoms in young infants with severe acute viral bronchiolitis Stefan Matecki1,2, Christophe Milese1, Julien Baille1, Aurélien Jacquet3, Gilles Cambonne3,1. 1Physiologie, CHU Arnaud de Villeneuve, Montpellier, France; 2INSERM U 1046, CHU Arnaud de Villeneuve, Montpellier, France

Objective: To determine the efficacy of high-flow nasal cannula (HFNC) at different flow level on respiratory distress symptoms, nasopharyngeal airway pressure (NAP) and respiratory effort in young infants with acute respiratory syncytial virus bronchiolitis.
Patients: 21 less than six month olds, with severe respiratory distress.
Interventions: Oesophageal pressure (Pes) and NAP was measured simultaneously after 5 different flow of 1.46, and 7.1 l/min delivered through a HFNC.
Measurements and results: Respiratory distress was quantified with a specific scoring system (m-WCAS). Mean respiratory rate (RR), inspiratory time over total time or respiratory cycle (Ti/Tot), NAP, Swing Pes and respiratory effort with the Pes-derived inspiratory muscles pressure-time product (PTPpes) was calculated from the pressure curves. Results are presented in Table 1.

The effect of chronic intermittent hypoxia on bone homeostasis in children with sleep disordered breathing
Alessandra Tabacchi1, Laura Papini1, Stefano Cevoli2, Silvia Miano1, Laura Lieto2,1 Susanna Fedeli1, Valentina Negro1, Rosa Castaldo1, Maria Pia Villa1. 1NEMOS, Pediatric Unit, Sant’Andrea Hospital, La Sapienza University, Rome, Italy; 2NEMOS, Advanced Molecular Diagnostics Unit, Sant’Andrea Hospital, La Sapienza University, Rome, Italy

Introduction: Airflow obstruction is an important risk factor for osteoporosis in adults. Therapies for bone-loss disorders could be based on shifting systemic acid base balance in the alkaline direction. The effect of chronic intermittent hypoxia in obstructive sleep apnea syndrome (OSAS) on bone homeostasis has never been evaluated.
Aim: We evaluate the effect of OSAS on bone homeostasis and the efficacy of an alkaline diet to the bone remodeling in children.

Impact: Q1S:

Conclusion: In young infants with severe acute respiratory syncytial virus bronchiolitis (NAP progression) was significantly related between flow delivery, NAP and PTPes. HFNC are able to increase NAP, decrease PTPes and improve ventilatory function of infant with severe acute viral bronchiolitis.

Funding by APARD and CHU Montpellier.
Methods: Spot urinary hydroxyproline/creatininuria (U/Hc, μg/ml) was measured as a markers of osteoblastic and osteoclastic activity in a group of children who underwent clinical assessment and polysomnography for OSAS. Children were randomly selected to be treated with an alkaline diet or with thyroid therapy (group 2). The U/Hc was measured at baseline and after one month of treatment (T1).

Results: We studied 12 children (mean age 6.42±2.52 years, 8 males). After one month, mean value of U/Hc did not change (14.97±μg/ml vs 16.29±μg/ml). Four subjects (group 1) (mean age 7.9±2.7 years, 3 males) showed a reduction of U/Hc after alkaline diet (from 23.2±μg/ml to 15.8±μg/ml). U/Hc did not decrease in group 2. In all children U/Hc correlated with total sleep time (r = -0.636, p < 0.05), sleep efficiency (r = 0.935 < p < 0.001) and wake after sleep onset (r = -0.769, p < 0.05), but not with sleep respiratory parameters.

Discussion: Our preliminary study showed that the efficacy of an alkaline diet to reduce urinary hydroxyproline. Although we did not find correlation with respiratory parameters, we found significant correlation with sleepfragmentations.

P1073

Evaluation of 8-isoprostane as a biomarker of oxidative stress in children with obstructive sleep apnea syndrome

Susanna Fedeli1, Valentina Negro1, Maria Chiara Supino1, Susanna Bonafoni1, Alessandra Tabarrini2, Laura Punip2, Milena Margiotta2, Giovanna Gemineli2, Maria Pia Villa3, 1 NESMOS, Pediatric Unit, Sant’Andrea Hospital, La Sapienza University, Rome, Italy; 2NEMOS, Advanced Molecular Diagnostics Unit, Sant’Andrea Hospital, La Sapienza University, Rome, Italy

Background: Hypoxia-reoxygenation, characteristic of obstructive sleep apnea syndrome (OSAS), induces an increase of products of non-enzymatic catalyzed lipidic peroxidation, such as 8-isoprostane (8-ISop).

Aim: To evaluate urinary 8-ISop values in children with OSAS.

Methods: Thirty-eight children with OSAS (mean age 6.23±2.08y, range 3.16-10.83y MF:26/12), underwent urinary collection at the morning after nocturnal polysomnography. 8-ISop levels were measured with an enzyme immunoassay and corrected by urinary creatinine (uCR) levels.

Results: According to the AHI (Apnea/Hypopnea index, cut-off 5 events/hours of sleep), in 5 children with mild OSAS (uCR corrected by urinary creatinine (uCR) levels.

Conclusion: Our data show that values of urinary 8-ISop are related to OSAS severity and SaO2. Further studies are needed to assess usefulness of urinary 8-ISop as a marker of inflammation likely due to oxidative stress.

P1074

A new proposal for OSA classification in children based on cardiovascular outcome

Silke A.T. Weber1, 2, Victor dos Santos1, Josué Mário Lopes Neto1, Luis Carlos R. Leitão1, Luiz Carlos R. Leitão1, 1Otolaryngology, Botucatu Medical School-State University São Paulo, Botucatu, SP, Brazil; 2Neuropediatry, Botucatu Medical School-State University São Paulo, Botucatu, SP, Brazil

Introduction: Pediatric OSA is associated to cardiovascular repercussions (CVR), adenotonsillolctomy(ATO) is considered its treatment of choice. We hypothesized that OSA leads to early CVR as lossing of nocturnal blood pressure dipping (NBPD), to adenotonsillectomy (AT) will recover NBPD.

Aim: To analyse which polysomnographic (PSG) criteria best defines OSA in children, based on the absence of NBPD before and its recovering after AT.

Methods: We included children with regular snoring, observed respiratory pauses and hypotony of the tonsils. Children with persisting snoring after AT, diagnosis of cardiovascular, renal or neurologic disease and obesity were excluded. Children realized PSG and 24-hour blood pressure monitoring before and six months after AT. AI and AHI were calculated, the presence or absence of NBPD was described before and after AT. Three current PSG definitions for OSA (D1: AHI>1; D2: AHI>1 & AHI<4; D3: AHI>5) were tested for the best correlations of OSA and CVR before and NBPD recovering after AT.

Results: 26 children, 8-12 years old, were included. AHI varied from 0.0 to 23.2. 10 children presented lossing of NBPD before 4, persisted after AT. For D1 (AHI>1) OSA diagnosis showed no significant association to CVR neither before, nor after AT. For D3 (AHI>5) OSA diagnosis showed significant correlation to CVR before and after surgery.

Conclusion: Considering NBPD and surgery outcome, we identified A1> & AHI>4 as the best definition for OSA in children. Larger studies focusing CVR and surgical outcome should be realized to better define PSG criteria and OSA.

P1075

Frequency of ICU monitoring and respiratory complications after adenotonsillolctomy in children

Silke A.T. Weber1, 2, Renato O. Martins1, Erico Moreira1, 1Otolaryngology, Botucatu Medical School-State University São Paulo, Botucatu, SP, Brazil; 2Pediatrics, Botucatu Medical School-State University São Paulo, Botucatu, SP, Brazil

Introduction: Adenotonsillolctomy(ATO) is considered treatment of choice for ob-structive sleep breathing disorders (OSD) in children. Besides better diagnosis and earlier treatment of OSA, respiratory complications at the immediate postoperative period are described for several risk groups.

Aim: To evaluate the frequency of necessity of postoperative monitoring in an intensive care unit(ICU) and respiratory complications in OBD children submitted to adenotonsillolctomy in a university hospital.

Methods: Retrospective study, analyzing patient’s charts submitted to AT due to OSD in a university hospital in Brazil, during the period from 2006 to 2010. We included children of both genders, aged 2 to 12 years. Patient’s data included obesity, age at surgery, severity of OBD and presence of respiratory comorbidity (asthma). We assessed the frequency of ICU monitoring and the respiratory complications in the ICU during 24 hours after AT.

Results: Out of 811 AT, 164 realized polysomnography prior surgery. 47 children, 21 girls, needed monitoring in ICU, due to severe oxygen desaturation (<85%), severe OSA (A>10) or obesity. Six children were younger than 2 years. Eleven children (24%) suffered major complications at ICU, as acute lung oedeme in two patients, intubation for longer than 24 hours in one, bronchospasms in three, and death in six.

Conclusions: Our study revealed a high risk for respiratory complications in OSD children. Major risk factors were age < 3 years old, asthma and obesity. Indication for monitoring (postoperative monitoring/polysomnography for suspected OSA children prior to adenotonsillolctomy should be better be specified and normalized.

P1076

Adenotonsillolctomy and orthodontic therapy: Outcome after one year of follow-up in children with obstructive sleep apnea syndrome

Rosa Costaúbi1, Giovana Passos2, Silvia Miano, Anna Rita Mazzotta, Francesco Biagarielli, Susanna Fedeli, Maria Pia Villa. NEMOS, Pediatric Unit, Sant’Andrea Hospital, La Sapienza University, Rome, Italy

Introduction: Adenotonsillolctomy (AT) is the primary therapy for obstructive sleep apnea syndrome (OSAS) in children, although a residual disease is reported. Rapid maxillary expander (RME) is a valid treatment for children with malocclusion and high arched palate.

Aim: To evaluate the efficacy of AT and RME in children with OSAS.

Methods: We enrolled children undergoing a clinical and polysomnographic assessment for OSAS at baseline and after 12 months of follow-up, after treatment (T1).

Results: We studied 47 children (mean age 5.03±2.03 years, body mass index, BMI, 17.15±3.07 kg/m², 34 males). At T1, AHI (apnea hypopnea index) decreased (11.90±12.30 vs 2.18±2.51 ev/h, p < 0.0001) as well as arousal index (18.29± 6.71 vs 13.95±6.61 ev/h, p < 0.0001) while total sleep time (TST) increased (6.77±0.96 vs 7.24±0.83, p = 0.05), as overnight oxygen saturation (90.51±1.22 vs 97.50±1.50, p < 0.0001). Twenty five children underwent AT (group 1) whereas 22 orthodontic therapy (group 2). After one year of treatment, in group 1 percentile of BMI and overnight mean saturation increased significantly, while AHI and arousal index decreased. In group 2 mean overnight saturation and TST increased from T0 to T1, while AHI decreased. The correlation analysis showed that percentile of BMI is a negative predictive factor of the efficacy of AT in group 1, while duration of disease is a negative predictive factor in group 2.

Discussion: Our results demonstrated that both treatments are efficacious for pediatric OSAS, although the increase of BMI is a negative predictive factor for residual disease group in 1, and the duration of disease in group 2.

P1077

The effects of obstructive sleep apnea syndrome on cognitive and cardiovascular functioning in children with obesity

Anna Rita Mazzotta1, Maria Elena Liverani1, Alessandra Macari1, Giundiano Tocci1, Filomeno Iannello1, Maria Pia1, 2Pediatrics, Sant’Andrea Hospital, La Sapienza University, Rome, Italy; 2Cardiology, Sant’Andrea Hospital, La Sapienza University, Rome, Italy

Background: Paediatric obesity and sleep disordered breathing may be associated with cognitive problems and cardiovascular abnormalities and both may share the same common inflammatory and metabolic pathogenesis.

Aim: To evaluate and compare cardiovascular activity and cognitive functions of obese children with or without clinical obstructive sleep apnea syndrome (apnea hypopnea index > 5 n/h of sleep).

Methods: Obese children underwent polysomnography in a standard laboratory setting, a neurocognitive assessment and a 24-hour ambulatory blood pressure monitoring.

Results: We studied ten children (mean age 9.±4.3 years, 7 males, with a mean body mass index (BMI) of 27.67 kg/m², mean BMI percentile of 124.2±20.7). They had a mean apnea-hypopnea index of 9.6±13.6 n/h, an overnight oxygen
Efthimia Kalampouka1, Anastasia Polytarchou 2, Aggeliki Moudaki 1, Antonis Platnaris 1, Marina Tsassougloglou 1, Emmanuel Alexopoulos 1, Polytimi Panagiotopoulou-Gartagani 1, George Chrousoos 1, Athanasios Kadogiannis 1

First Department of Pediatrics, Pediatric Pulmonology Unit, University of Athens School of Medicine and Aghia Sophia Children’s Hospital, Athens, Greece; 2Department of Pediatrics, Lamsia General Hospital, Lamia, Greece

Recognition of subgroups of children predisposed to overgrowth of the pharyngeal lumen issue, such as obesity, is crucial for early diagnosis and treatment, which may allow implementation of treatment interventions in early life for the prevention of obstructive sleep-disordered breathing (SDB). We hypothesized that parental history of adenotonsillar hypertrophy and tonsillar hypertrophy and snoring in childhood in addition to history of wheezing requiring treatment may act as risk factors for tonsillar hypertrophy and snoring.

Methods: Children were recruited from outpatient clinics. Parental history of AT (explanatory variable) and snoring ≥1 night/week (outcome) were recorded and presence of tonsillar hypertrophy (outcome) was assessed.

Results: 435 children were recruited (2-16 y), and 79 (18.2%) of them had parental history of AT. Parental history of AT was significantly associated with the presence of tonsillar hypertrophy and snoring even after adjustment for history of wheezing requiring treatment, age, gender, obesity and passive smoking (odds ratio (95% CI): 2.2 (1.2-3.9); p<0.01 and 1.8 (1.1-3.3); p<0.05, respectively). When both tonsillar hypertrophy and parental history of AT were entered in the same multiple logistic regression model, the former was stronger predictor of snoring than the latter: 3.3 (2.5-3.3); p<0.01 vs. 1.6 (0.9-2.9); p=0.09), respectively.

Conclusions: Children with parental history of AT have more frequently tonsillar hypertrophy than those without such history. Familial predisposition to tonsillar hypertrophy may mediate at least in part the association between parental history of AT and SDB in children.

Prevalence of obesity and sleep disordered breathing in a cohorts of 9 year old schoolchildren studied 13 years apart living in a country town of Central Italy (Ronciglione, VT).

Francesca Ruggeri, Annamaria Bozzone, Mario Barreto, Maria Pia Villa. NESMOS, Pediatric Unit, Sant’Andrea Hospital, La Sapienza University, Rome, Italy

Objective: The aim of this study was to evaluate the prevalence of obesity and sleep disordered breathing (SDB) in two different populations of Italian schoolchildren studied 13 years apart growing in a country town of Central Italy (Ronciglione, VT).

Research methods and procedures: Subjects were drawn from two populations, both non selected, of schoolchildren. Parents underwent to a 9-items sleep questionnaires investigating on SBD. We assessed measures of weight and height obtaining and using BMI values to assess obesity, with cut-off values proposed by the International Obesity Task Force. Techniques traditionally employed to assess diaphragmatic weakness or paralysis in DMD, i.e. transdiaphragmatic pressure, EMG, fluoroscopy, plethysmography, MRI are invasive, associated with radiation or complex. The aim of this study was to determine the feasibility of diaphragmatic excursion (DE) measurements by ultrasonography (US) as an alternative.

Eight DMD patients (age 15.2±4.1 yrs, BMI 20.5±5.6 kg/m2, FVC 59.3±6.2%pred) and 10 healthy controls (age 25.4±4.9 yrs, BMI 22.3±2.5 kg/m2) were studied. Diaphragmatic excursion was measured in supine position using a convex probe (7.5-7.5 MHz) positioned in the right subcostal anterior area. DE was determined by a custom-designed software for image processing at end-inspiration and end-expiration during quiet breathing (QB) and at full inspiration during an Inspiratory Capacity (IC) maneuver. In DMD, DE was in average 17.2±5.2 mm (see fig. for individual data). ANOVA analysis revealed significant differences in DE values between QB and IC in both DMD and controls (p<0.001) and between DMD and controls during both QB and IC (p<0.001).

Conclusion: All patients had excessive daytime sleepiness. Interestingly over half of these patients had excessive daytime sleepiness on presentation. H1N1 vaccination was not given to the majority of these patients. More research is needed to understand the recent increase in the prevalence of childhood narcolepsy with cataplexy.

The clinical presentation of paediatric narcolepsy in one Canadian sleep centre

Andrea Ricketts1, Glenda Bendick1, Shelly Weiss2, Indra Narang1

1Respiratory Medicine, Hospital for Sick Children, Toronto, ON, Canada; 2Neurology, Hospital for Sick Children, Toronto, ON, Canada

Narcolepsy is primarily characterized by an overwhelming feeling of sleepiness with or without cataplexy. More recently, there has been a dramatic increase in newly diagnosed childhood narcolepsy and it is hypothesized that H1N1 may play a role in these new cases. The objective of this study is to review the demographics and presenting symptoms of children with narcolepsy in Toronto.

Methods: At the Hospital for Sick Children, Toronto, we reviewed medical records and polysomnograms of patients with narcolepsy who presented to the sleep disorders clinic. All patients were referred with a history of excessive daytime sleepiness.

Results: # Patients Age, mean (range) Weight, kg, mean (range) BMI, kg/m² Excessive daytime sleepiness Cataplexy Night wakeings Hallucinations Weight gain Behaviour change H1N1 vaccination MRI, normal MRI, abnormal Ferritin, low HLA DQB1*0602, positive 8 9.5 (5.0-15.0) 39.5 (26.0-52.9) 20.3 (18.5-23.5) 8 (100%) 5 (62.5%) 2 (25.0%) 3 (37.5%) 4 (50.0%) 7 (22.5%) 7 (87.5%) 77* 4 (50.0%) 64** 64**

MRI = Magnetic Resonance Imaging, MSIT = Multiple Sleep Latency Test, *MSLT pending for one patient **HLA pending for two patients.

Conclusion: All patients had excessive daytime sleepiness. Interestingly over half of these patients had cataplexy on presentation. H1N1 vaccination was not given to the majority of these patients. More research is needed to understand the recent increase in the prevalence of childhood narcolepsy with cataplexy.
We conclude that the marked changes in Zrs during tidal breathing in healthy newborns are due to flow nonlinearities in the narrow nasal and glottal pathways. The absence of the V dependence of R may be a result of opposing changes in tissue resistance and airway resistance at Vmax.

P1085
Importance of nutrition status in lung function of infants born preterm with or without bronchopulmonary dysplasia
Manuel Sánchez-Solís, Luis García-Marcos, Virginia Pérez Fernández. Pediatría, Virgen de la Arrixaca University Hospital, University of Murcia, Spain. Pediatrics, Virgen de la Arrixaca University Hospital, University of Murcia, Spain Pediatrics, University of Murcia, Spain

Aims: To know if nutrition status (as measured by BMI) is associated to lung function of infants born preterm (PT) with or without bronchopulmonary dysplasia (BPD)

Methods: By means of the raised volume rapid thoracoabdominal compression (RVRC) technique, FVC, FEV1, FEF25, FEF50 and FEF75 were measured in 61 PT without BPD (66.5% male; corrected age 7.2±0.7 mo) and in 55 PT with BPD (59.8% male; corrected age 7.75±0.9 mo). A multiple regression analysis-stratified for BPD- was performed for BMI z-score (as calculated according to WHO values) and each lung function parameter (dependent variable), controlling for gender, gestational age, current corrected age, height, birth weight, smoking exposure in pregnancy.

Results: The coefficients of the regression analyses and their significance are shown in table.

Conclusions: Lung function of infants 7-8 months of age, born PT without BPD, increases with BMI. This does not seem to be the case in infants of similar age born PT but with BPD.

P1086
Changes in respiratory mechanics following surgical repair of mitral valve insufficiency in children
Hajime Malaspinas², Anne-Laure Martin³, Anne Perrin, Maurice Beggéti², Ferenc Pettak¹, Waldi Haberb¹. ¹Neonatology and Intensive Care, Children’s University Hospital of Geneva, Switzerland; ²Pediatric’s Cardiology Unit, Children’s University Hospital of Geneva, Switzerland; ³Department of Medical Physics and Informatics, University of Szeged, Hungary

Rationale: Postcapillary pulmonary hypertension (PHT) such as observed with mitral valve insufficiency (MVI) is associated with lung function impairment. We assessed airflow resistance (Raw) and total respiratory elastance (Ens) before and after surgical repair of MVI in children to verify whether vascular engagement is responsible for the increase in airway tone and stiffness of the respiratory tissues.

Methods: The input impedance of the respiratory system during spontaneous breathing was measured in 16 children, aged 12±2.5 years (mean±SD), with congenital or post-thoracic mitral valve insufficiency preoperatively, and within 5 days and 3 weeks after mitral valve repair surgery. Raw was estimated by

\[ R_{\text{Raw}}(f) = \frac{1}{\rho c} \left( \frac{dP}{dV} \right) \]

Conclusions: Increase of MVI and Raw was associated with post-thoracic mitral valve insufficiency preoperatively, and within 5 days and 3 weeks after mitral valve repair surgery.
calculating the average resistance values between 4 and 26 Hz, while Ers was assessed from the respiratory reactance data by model fitting.

**Results:** Raw decreased significantly 5 days after the surgery (5.5 ± 1.6 to 4.3 ± 1.0 cmH2O·l·s⁻¹, p < 0.001). It remained lowered 3 weeks later in 8 children (4.5 ± 1.4 cmH2O·l·s⁻¹, p < 0.005). Conversely, Ers exhibited no significant changes postoperatively (70 ± 10, 58 ± 6 and 77 ± 9 cmH2O·l·s⁻¹ before and 5 and 21 days after the surgery, respectively, p > 0.4).

**Conclusions:** Decreasing vascular engorgement after surgical repair of MVI in children results in a fast and sustained improvement in airway function. The lack of concomitant beneficial changes in the Ers suggests that mechanical interdependence between the airways and pulmonary vasculature is responsible for this finding.

Supported by SNSF grant 3200B0-118231.

**P1088** Longitudinal follow-up of lung function in ataxia telangiectasia

Daphna Vilozni, Moran Lavie, Iat Sarouk, Yonit Levi, Ori Efrati. Pediatric Pulmonary Unit and the Ataxia Telangiectasia National Clinic, The Edmond and Lily Safra Children’s Hospital, Sheba Medical Center, Affiliated with the Sackler Faculty of Medicine, Tel-Aviv University, Ramat-Gan, Israel

**Rationale:** Individuals with Ataxia Telangiectasia (AT) are vulnerable to the development of significant pulmonary complications with age. This condition calls for a follow up on lung function evaluation.

**Objectives:** To follow the individual patient’s lung functions during 3-5 years.

**Methods:** Yearly best spirometry data were collected from 39 AT patients (age 10.4 ± 4.5 years; 13 patients younger than 7 years). The yearly decline in spirometry indices were defined in relation to the preceding year, initial age, and airway hyper-reactivity (a positive response to β₂-agonist).

**Results:** Young children showed low FVC (%predicted) between 43.1-70.7%. Lung function was more impaired in the most severely affected patients. In 27% of the cases, the FEV₁ was ≤ 50% of predicted. The change in %predicted FVC was 0.01% per year, with a significant decline after age 15 years. Similarly, FEV₁, FVC, and MVV decreased after age 15 years. Patients having hyperactive airways showed initially restrictive lung function in A-T patients.

**Conclusions:** Follow up lung function evaluation should be performed in children with AT.
zene (HCB), DDE, DDT, and Mirex) in 240 children participating in the respiratory assessment of a longitudinal birth cohort at 14 years of age. Current wheeze was reported by 63 (26.3%) and 96 (40.0%) were atopic. Participating in respiratory assessment of a longitudinal birth cohort at 14 years of age. Parental worry about child’s health (p=0.005), defined asthma control (p=0.002), and parental smoking (p=0.002) were associated with increased bullying risk. Methods: Parents and children >7 years with asthma were interviewed by telephone following identification using a truncated list-assisted random digit dialling sampling procedure in Canada, Greece, Hungary, the Netherlands and UK. Parents and children in South Africa were interviewed face-to-face. All statistical analyses including univariate and multivariate regression were carried out using STATA v10.

Results: Detailed questionnaires including parent and child responses were available for 943 parent-child diads. Univariate analyses identified that poor GINA-defined asthma control (p=0.001), parental worry about child’s health (p=0.005), parent reported frequency of asthma attacks (p=0.002) and parental smoking (p=0.042) were associated with increased bullying risk. The child’s age and gender were not associated with risk of bullying. Children who reported bullying were significantly more likely to report feeling sad (p<0.001) and were less likely to participate in sporting activities (p=0.001).

Conclusions: Bullying or teasing is commonly reported by children with asthma and is associated with reduced participation in sport and feelings of sadness. Modifiable child factors such as poor asthma control and parental factors such as smoking and ongoing worries about their child are associated with increased bullying risks.

P1092 Bullying in children with asthma – What factors are associated with increased risk? Will Carroll1, Johannes Wildhämmer2, Paul Brand3, Department of Paediatrics, Derbyshire Children’s Hospital, Derby, United Kingdom; 2Department of Paediatrics, Hospital Fribourg, Fribourg, Switzerland; 3Department of Respiratory Paediatrics, Princess Amalia Children’s Clinic, Zwolle, Netherlands

Background: Bullying or teasing of children with any chronic medical condition is a well-recognised complication of disease. The data collected in the Room to Breathe Study, a large 6-county population survey of childhood asthma demonstrated an increased number of reports of bullying (10%). This study aims to detail in detail the family and child factors associated with increased bullying risk.

Methods: Parents and children >7 years with asthma were interviewed by telephone following identification using a truncated list-assisted random digit dialling sampling procedure in Canada, Greece, Hungary, the Netherlands and UK. Parents and children in South Africa were interviewed face-to-face. All statistical analyses including univariate and multivariate regression were carried out using STATA v10.

Results: Detailed questionnaires including parent and child responses were available for 943 parent-child diads. Univariate analyses identified that poor GINA-defined asthma control (p=0.001), parental worry about child’s health (p=0.005), parent reported frequency of asthma attacks (p=0.002) and parental smoking (p=0.042) were associated with increased bullying risk. The child’s age and gender were not associated with risk of bullying. Children who reported bullying were significantly more likely to report feeling sad (p<0.001) and were less likely to participate in sporting activities (p=0.001).

Conclusions: Bullying or teasing is commonly reported by children with asthma and is associated with reduced participation in sport and feelings of sadness. Modifiable child factors such as poor asthma control and parental factors such as smoking and ongoing worries about their child are associated with increased bullying risks.

P1093 The impact of gene-gene interaction on the severity of bronchial asthma in Ukrainian children Zina Rossokha1, Svetlana Kyryachenko2, Julia Savchenko2, Oleksandra Pavliuk1, Natallia Gorovenko1, 1Medical and Laboratory Genetics, National Medical University, Kyiv, Ukraine; 2Laboratory of Molecular Genetics, Reference Centre for Molecular Diagnostics of Ministry of Public Health, Kyiv, Ukraine; 3Pediatrics No. 1, Bogomolets National Medical University, Kiev, Ukraine

Background: Gene-gene interaction in the development of different severity of bronchial asthma (BA) has not been investigated. The aim of the study was to define the genetic differences among children with persistent mild and persistent moderate BA.

Methods: Comparative groups included 13 patients (aged 8.58±0.84 year) with persistent mild BA and 14 patients (aged 8.94±0.82 year) with persistent moderate BA. Sex differences among two groups were not observed. There was performed 10 genes polymorphism investigation using PCR with further RFLP. The differences in comparative groups were assessed by the two tailed Fisher test analyses. MDR program was applied for gene-gene interaction evaluation.

Results: The frequency of DD genotype in ACE gene was significantly higher among patient with persistent moderate BA (p=0.045). The patient with persistent moderate BA had also significantly increased frequency of GSTM1 gene deletion polymorphism (p=0.0004). We have observed no differences in the frequency of others genes polymorphic variants.

MDR analysis has found synergy closely interaction between MTHR (C677T) and ACE (I/D) genes and between GSTM1 and eNOS (4a/4b).

Conclusion: Gene-gene interaction defined severity of bronchial asthma in children. The further research may help to optimize BA prognosis and treatment.

P1094 Alterations in ORMDL expression in experimental asthma Michaela Schiedl1,2, Anthony Joetham1, Michael Kabesch3, Erwin Gelfand3, 1Department of Paediatrics, National Institute of Allergy and Neuroimmunology, Hannover Medical School, Hannover, Germany; 2Department of Pediatrics, National Jewish Health, Denver, United States

Introduction: A susceptibility locus on 17q21, including ORMDL3, has been identified in childhood asthma. We determined if expression of ORMDL3 and the other members of the highly conserved ORMDL family (ORMD1-2) are altered in the lungs and tissues of mice with experimental asthma.

Methods: Intraperitoneal sensitization of C57BL/6 mice and Balbc/mice to ovalbumin (OVA) was carried out on days 1 and 14. Susenitized and naive mice received aerosol challenges on days 24-26. ORMDL1-3 expression levels were analyzed in different tissues (brain, gut, heart, kidney, liver, lung, skeletal muscle, spleen, thymus) and isolated cells (lymph nodes, blood). Kinetic studies of ORMDL expression in lung, spleen, and thymus were performed 24th, 48th, and 72th after the last challenge. Gene expression data are described as relative fold-changes.

Results: ORMDL1-3 expression in all tissues was shown at comparable levels for both mouse strains and mRNA levels were altered only in lung and lymphoid tissues (spleen, thymus) with a peak 48h after the last challenge. In lungs of non-sensitized/challenged (n=11) vs. sensitized/challenged (n=11) C57BL/6 mice, significant decreases were observed for ORMDL1 (1.0 vs. 0.47, p=2.09E-07), ORMDL2 (1.0 vs. 0.56, p=1.2E-07), and ORMDL3 (1.0 vs. 0.77, p=3.14E-05) in parallel, significantly lower levels of ORMDL2 (1.0 vs. 0.72, p=0.01), and ORMDL3 (1.0 vs. 0.77, p=3.14E-05) were detected in spleen. In Balbc/mice similar significant effects were detectable, albeit to a lower degree. In contrast, ORMDL1 mRNA expression in the thymus trended upwards in sensitized and challenged mice of both strains.

Conclusion: These data demonstrate the involvement of all members of the ORMDL family in experimental asthma.

P1095 Remodelling of the bronchial wall in very young children at risk for developing asthma Katarina Berankova1,2, Petr Pohunc1, Jiri Uhlík2, Lenka Havlíková1, 1Department of Paediatrics, Second Medical Faculty of Charles University and University Hospital Motol, Prague, Czech Republic; 2Institute of Histology and Embryology, Second Medical Faculty of Charles University, Prague, Czech Republic

Remodelling of the bronchial wall in asthmatic patients includes various attributes like thickening of the basement membrane, hyperplasia of smooth muscle cells and increased vascularization of the subepithelial tissue. Although the prevalence of asthma in childhood is much higher than in adults, we still don’t have much information about the onset and development of these changes. In the past, remodelling of the bronchial wall was considered to be a result of chronic inflammation in the course of the disease. In this study we analyzed 30 bronchial biopsies from very young children (average age of 18.9 months) that were taken during bronchoscopical examination done for various reasons (e.g. chronic cough, recurrent bronchitis). Thirteen children with atopic eczema or history of parental asthma were considered at risk for developing asthma and remaining seventeen children formed the control group. We found significant thickening of the basement membrane in children at risk for developing asthma compared to the controls (3.53 μm and 2.89 μm, respectively). In ten of these children we analysed the proportion of laminae-positive layer in the total thickness of the basement membrane that was also significantly higher in asthmatic group (65.94% and 42.11%, respectively). We conclude that these results may support need for early diagnosis of obstruction and subsequent preventative treatment in children at high risk for developing asthma as structural changes in the bronchial mucosa may be present with first symptoms. Supported by GAUK 34/0911 and IGA MZ NT/1144.

P1096 Bronchial epithelial cell mediator release in children with wheeze or eczema David Miller1, Daniella Spiteri1, Emily Pringe1, Helen Richardson1, Graham Devereux1,2, Garry Walsh3, Steve Turner3, 1Child Health, University of Aberdeen, United Kingdom; 2Institute of Medical Sciences, University of Aberdeen, United Kingdom

Introduction: Airway epithelial cell (AEC) function is thought to be important in the regulation of airway remodelling and inflammation in health and disease. Due to the challenges in accessing airway airways in children, relatively little is known about bronchial AEC function in children. Our hypothesis was that bronchial AEC mediator release will be different between children with and without a history of recurrent wheeze.

Methods: Children scheduled for elective operation were recruited. Bronchial AEC were removed by brushings and grown in submerged culture. Second culture
passage mononuclei were stimulated for 24 hours with TNF-alpha and IL-1β. Supernatants were removed and the following mediators analyzed: IL-6, IL-8, MMP-9, TIMP-1, VEGF, GCSF, RANTES and MCP-1.

Results: 32 children were recruited, mean age 6.5 years (range 1.1-16.0). 7 reported wheeze in the last year, 13 had a history of eczema including three with recent wheeze. Concentrations of MMP-9 were reduced in children with recent wheeze (p=0.001; median geometric mean 3.4 [SEM 1.4]; pmol/l measured from 100 AUC) compared to those without symptoms (11.0 [14.5] pmol/l, p=0.021. There was a similar reduction in MMP-9 concentrations among those with eczema (3.7 [±SEM 2.1]) compared to those without (11.3 ±5.2), p<0.037. Children with eczema also had reduced bronchial AEC release of MCP-1 (0.15 ±0.15) compared to those with (0.73 ±0.35), p<0.002. There were no differences for other mediators studied.

Conclusion: Bronchial AEC release of MMP-9 is reduced in children with recent wheeze. The similar relationship seen among those with eczema but no wheeze suggests that the underlying mechanism may be related to atopy but may be not be important to symptoms in this age group.

P1097 Inflammatory cytokines in serum from children with severe asthma compared to controlled asthmatics

Jon Konradson1,2, Birgitta Nordlund1,2,3, Åsa Wheelock4, Joachim Lundahl4, Silvia Carraro1, Hans Gronlund1, Gunilla Hedlin1,2,1.1. Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden; 2Astrid Lindgren Children’s Hospital, Karolinska University Hospital, Stockholm, Sweden; 3Centre for Allergy Research, Karolinska Institutet, Stockholm, Sweden; 4Respiratory Medicine Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Introduction: Care of children with severe asthma remains a clinical challenge, partly due to the heterogeneity of the disease and the lack of effective biomarkers. In this study, we compared levels of inflammatory cytokines in serum from children with severe asthma and controlled asthma.

Methods: Children with severe therapy resistant asthma (n=34, mean age 13.3 years) and controlled asthma (n=39; mean age 13.8 years) participated in a nationwide Swedish study. The protocol included Asthma control test, exhaled nitric oxide (FeNO) and blood sampling. Interleukin (IL-4, IL-5, IL-12p70, tumor necro- sis factor alfa (TNFα) and eotaxin were analysed from serum using multiplex technology and results presented as medians with inter quartile ranges (picogram/milliliter).

Results: Severe asthmatic children had inferior asthma control (p<0.001) in spite of high doses of inhaled steroids (> 800ug budesonide), compared to children with controlled asthma. FeNO (p=0.93) and IgE (p=0.92) were comparable in these two patient groups. Children with severe asthma had increased levels of cytokines related to both Th1 inflammation (IL12p70: 4.1 (0-22) vs. 0 (0-4.7), p=0.001 and TNFα: 10.4 (4.6-19) vs. 2 (1.7-0), p<0.001) and to Th2 inflammation (IL4: 1.6 (0.29) vs. 0.19 (0.19), p=0.02; IL5: 0 (0-1.1) vs. 0 (0.0), p=0.04 and Eotaxin 97.3 (60-146) vs. 49.2 (42-68), p<0.001).

Conclusions: Severe asthmatic children have increased serum levels of cytokines related to both Th1 and Th2 inflammation compared to controlled asthmatics. These results indicate a heterogeneous pattern of inflammation, and multivariate statistical analyses to further characterize the inflammatory phenotypes are initiated.

P1098 Asymmetric dimethylarginine (ADMA) in EBC of asthmatic children

Silvia Carraro1,2, Iole Maria Di Giangi3, Giorgio Pucaentini4, Ahmad Kantar1, Serena Moser2, Laura Cesca1, Mariangela Berardi1, Giuseppe Giordano1, Eugenio Baraldi1, Serena Moser2, Laura Cesca1, Mariangela Berardi1, Giuseppe Giordano1, Eugene Baraldi1. 1. Women’s and Child’s Health Department, University of Padova, Italy; 2. Department of Pediatrics, University of Padova, Italy; 3. Paediatric Asthma Centre, Misurina Pio XII institute, Belluno, Italy.

Asymmetric dimethylarginine (ADMA) is an endogenous inhibitor of nitric oxide synthase (NOS). ADMA contribution to airway inflammation, oxidative stress, bronchial hyperresponsiveness and collagen deposition, suggests a role for this mediator in asthma pathogenesis (Sott JA, ARJCCM 2011). Aim of the present study was to evaluate the feasibility of ADMA measurement in exhaled breath condensate (EBC) and to compare the levels of this mediator in asthmatic and healthy children.

We recruited 60 children (5-17) with well-controlled asthma and 64 healthy children (5-15) who underwent spirometry and EBC collection. In a subgroup of asthmatic children serum ADMA levels and FENO values were measured. EBC was collected using the Turbo-Deccs (Medivac, Parma, Italy). ADMA measurements were performed by UPLC-MS/MS.

ADMA was measured in EBC with a good reproducibility (evaluated by analyzing 2 samples collected 24h apart in 8 subjects). ADMA EBC levels were significantly higher (p<0.001) in asthmatic children (2.2 pmol/ml [IQR 1.2 - 3.7]) than in healthy children (1.5 pmol/ml [IQR 0.8 - 1.6]). In asthmatic children, no correlation was found between serum and EBC ADMA levels (p=0.45, r=0.36). No correlation was found between EBC ADMA levels and FENO values or spirometric parameters.

In the present study for the first time ADMA was measured in EBC. We found increased ADMA levels in asthmatic children, supporting a role for this mediator in asthma pathogenesis. Moreover, the lack of correlation with serum levels suggests that EBC ADMA specifically mirrors lung pathological processes. We speculate that ADMA could be a possible target for new therapeutic strategies in asthma.

P1099 Sputum cells apoptosis by different asthma phenotypes in children

Alla Nakozenchina1, Jurij Antipkin2, Tatjana Umanets2, Vladimir Lapshyn2,1,2, Tatjana Umanets2, Vladimir Lapshyn2,1,2, Björn Nordlund1,2,3, Åsa Wheelock4, Joachim Lundahl5, Jurij Antipkin2, Tatjana Umanets2, Vladimir Lapshyn2,1,2, Inna Zadorozhnaja3, Olga Pustovalova1,2,1. Allergy and Immunology, Hull and East Yorkshire University Hospitals NHS Trust, Hull, United Kingdom; 2. Allergy, Institute of Paediatrics, Obstetrics and Gynaecology, Kiev, Ukraine.

Background: Reduced apoptosis is one important mechanism for cell accumulation and maintenance of airway inflammation by asthma. However the role of death factors and their receptors in the regulation of granulocyte apoptosis in childhood asthma is still unclear.

The aim was to determine the expression of apoptosis receptors in sputum cells by different asthma phenotypes in children.

Methods: Seventy eight asthma children aged 6-12 years and 25 age-matched healthy controls were assessed. Sputum cells apoptosis were evaluated using immunocytochemistry. Results: Among investigated children 69.2% had atopic asthma with increased total and specific IgE, positive SPT at least to one allergen. These children had mild-to-moderate asthma and sputum eosinophilia. They demonstrated decreased apoptotic ratio (AR) in sputum eosinophils that directly correlated with Apo-1/Fas and Bax expression and inversely with Bcl-2 expression and these parameters were more significant in moderate asthma than those in mild (p<0.001).

In contrast 30.8% children with non-atopic asthma had moderate-to-severe asthma and induced sputum neutrophilia. Their sputum neutrophils showed decreased Apo-1/Fas and Bax and elevated Bcl-2 expression that was more significant in severe asthma group (p<0.001).

Conclusion: Our findings indicated that sputum cell apoptosis vary in different asthma phenotypes in children. The identification of differences in the apoptosis regulation may help to define new mechanisms that allow specific induction of either eosinophil or neutrophil apoptosis.

P1100 Peripheral mononuclear cell response to nonspecific antigen stimulation in children with obesity asthma phenotype

Hasan Yaksal1, Dzej Ýılmaz2, Seda Vatansever3, Ece Öner1, Cengiz Kırız4, Emin Naş1, Almut Turkeli1, Ferda Borzyg7,1,1. Pediatric Allergy and Pulmonology, Celal Bayar University Medical Faculty, Manisa, Turkey; 2Histology and Embryology, Celal Bayar University Medical Faculty, Manisa, Turkey; 3Pediatric Allergy and Pulmonology, Celal Bayar University Medical Faculty, Manisa, Turkey; 4Respiratory Medicine Unit, Celal Bayar University Medical Faculty, Manisa, Turkey; 5Infectious and Allergy, Celal Bayar University Medical Faculty, Manisa, Turkey.

Methods: Obese and nonobese children with asthma aged 5 to 16 were enrolled into this case-control study consecutively. Age at asthma diagnosis and clinical severity were scored. Skin prick test was performed. Serum adipokine levels as well as PBMC supernatant IL-4, IL-10, IL-17, IFNγ and TGFβ-1 levels were measured.

Results: Mean ± (standard deviation) ages of obese (n=28) and nonobese (n=39) children with asthma were 8±2.9 and 10.5±6.2 respectively. Asthma symptom score was higher and age at asthma diagnosis was lower in obese compared to nonobese children with asthma (p=0.03 and p=0.04 respectively). Leptin levels were significantly higher in obese than nonobese asthma group (p<0.001). IL-10 and IL-17 levels in obese group was significantly lower than nonobese group (p=0.005 and p=0.07 respectively). On the other hand, TGFβ-1 levels were significantly higher in obese compared to nonobese children with asthma (p=0.015). IL-4, IL-23 and IFNγ levels were not significantly different between the groups (p>0.05 for all).

Conclusion: Low IL-10 and high TGFβ-1 levels in obese compared to nonobese children with asthma might indicate lower antiinflammatory cytokine secretion and regulatory T lymphocyte function as well as a higher remodelling process in obesity associated asthma in children.

The overwhelming inflammation type in school children with asthma in the region “South Banat” obtained induced sputum cytology

Introduction: Induced sputum is a noninvasive method for direct measurement of inflammation in asthma and we use it to distinguish eosinophilic asthma from other types, as well as therapy guide.

Objective: The aim of this study was to determine which type of inflammatory cells dominated in school children with asthma in the region “South Banat” and is that different in children in Pancevo with the air pollution and children from surrounding villages with relatively clean air.

Methodology and results: We did cytological analysis of induced sputum in 109 school children in the mild and moderate acute asthma, aged 6 to 17 years (average 10.6). From Pancevo was 53, and from a surrounding villages was 56 children. In 98 (89.9%) children we received an adequate sample for sputum analysis, from Pancevo 48, and from surrounding villages 50 children. Neutrophils has 37 (37.7%), Eosinophils 31 (31.6%) children. In Pancevo, eosinophilic type of inflammation has 23 (47.92%), in the surrounding villages 8 (16%) children, and this difference was highly statistically significant, \( \chi^2 = 11.535, p < 0.0006 \). Neutrophilic type of inflammation in the surrounding villages has 24 (48%), in Pancevo 13 (27.0%) children and this difference was statistically significant, \( \chi^2 = 4.559, p < 0.03 \). Mixed asthma type have 3 children, all from surrounding villages.

Conclusion: The results showed that in the region, “South Banat” is equally represented eosinophilic and neutrophilic inflammation type. Further analysis showed that there were significant differences in the type of inflammation in children from Pancevo and surrounding villages, which can be attributed to environmental conditions.

P1102

Outcome in preschool age after hospitalization for wheeze in infancy

Background: Risk factors for the progression from early infant wheeze to the development of later bronchial obstructive symptoms are not fully known.

Aim: To investigate if the development of bronchial obstructive symptoms during preschool years was influenced by time of the first hospitalization in infancy for acute respiratory distress with wheeze.

Subjects: 150 infants younger than 18 months were hospitalized for the first time for acute respiratory distress with the diagnosis acute bronchitis, bronchiolitis or asthma during one calendar year. For 110 infants it was the first episode ever. 144 children (85 males) were followed up (96%), ages: < 6 months, 67 infants, 6-<12 months, 57 infants, and 12-<18 months, 20 infants.

Methods: All hospital records were analyzed. Structured telephone interviews were made with the families of the 144 children, at mean age 4.5 years (range 3.5 – 5.6 years). Data from medical records of all the children with reported remaining respiratory symptoms were analysed.

Results: 71 children (49%) still had current wheeze requiring medication periodically (60 children) or continuously (11 children). Episodic (viral) wheeze was reported in 46 and multiple-trigger wheeze in 25 individual with a similar distribution in the three age groups (21/67, 21/57, 4/20 and 11/67, 9/57, 5/20 respectively). Suspected or diagnosed allergy to inhaled allergens was reported in 15 of the 71 symptomatic children (21%) and in one child without wheeze.

Conclusions: Almost half of infants with hospitalization due to early wheeze had current wheezing symptoms, needing medication at mean age 4.5 years. In this heterogeneous group of children age at the first hospitalization did not seem to influence the outcome.

P1103

Wheezing childhood phenotypes from birth to 7 years using latent class analysis

Background: The majority of studies of recurrent infections, wheezing and eczema are seeking for genetic background, possible immunodeficiency, and atopy. Exposure to pathogens, particularly viruses seems to be very important for aberrations in the development of the immune system that may lead to chronic conditions later in life.

Aim: In order to determine the importance of day care attendance in the pathogenesis of recurrent infections, wheezing and eczema, children aged one to two years, with recurrent infections, wheezing or and eczema and attending day care were analyzed. The parents from all children were advised to withdraw from day care attendance. On the criterion of the acceptance of withdrawing patients were divided in two groups: I that accepted (53) and II that did not accept such advice (32). Both groups were followed up next 12 months, for the incidence of infections, wheezing and eczema episodes. The excluded criteria for the study were: intolerance/allergy to cow milk and other nutritional allergens, treatment with steroids and antiallergic drugs.

Results: During one year follow up in the group that was withdrawn from day care attendance the symptom scores related to respiratory infections reduced by 76%, wheezing by 36% and eczema by 29%.

Conclusion: Our results indicate that withdrawing from day care attendance reduces the symptom scores related to recurrent infections, wheezing and eczema episodes. This suggests that viral infections, the most frequent infections in this age are important for inappropriate development of the immune system and may be a pathogenetic factor in chronic asthma, inflammation and asthma development.

P1104

Day care attendance, recurrent infections, wheezing and eczema

Methods: A high risk birth cohort (n=620) recorded: current wheeze 18 times to age 2 years; yearly (ages 3 to 7), and at 12; eczema by age 6 months; food allergen sensitization aged 1 year; aeroallergens at 2 years; lower respiratory tract infection (LRT) by 1 year, and parental asthma. LCA of wheeze at 23 times defined the optimal number of wheezing classes from model fit parameters.

Results: Five latent classes were identified. (Non-wheezer, n= 264 (42.7%)). All wheezing classes except early transient had greater risk of wheeze aged 12. Also: early transient wheeze (27.5%) was associated with LRT (OR 3.0; 95%CI 1.6, 5.7); early persistent wheeze (5.7%) with LRT (OR 6.8; 2.8, 16.7) and aeroallergen sensitization (OR 5.0; 1.8, 13.9); intermediate onset wheeze (20.7%) was associated with both these factors and eczema (OR 2.6; 1.7, 4.7), food sensitization (OR 2.7; 1.5, 4.7) and parental asthma (OR 2.2; 1.0, 4.5); late onset wheeze (3.5%) had no associations.

Figure 1. LCA of wheeze.

Conclusion: LCA on wheeze in a high risk cohort yielded 5 classes up to age 7. In contrast to previous studies, food sensitization and early eczema were only related to the intermediate class suggesting this may be the group where atopic march is most relevant.

P1105

The effect of 1,25-(OH)2 D3 supplementation on the expression of vitamin D receptor (VDR) on the lung of baby rats with asthma

Methods: Thirty two Wistar rats were randomly divided into four group and were given different doses of 1,25-(OH)2 D3, except for the control group receiving normal saline. Then we chose eight weaned baby rats to establish asthma model. Expression of VDR was measured by immunohistochemistry and RT-PCR.

Results: Light microscope showed that inflammation was less serious in medium and low dose group, but more seriously in high group. Immunohistochemistry indicated that the expression of VDR decreased in low and medium dose group, but increased in the high group (p<0.01). RT-PCR were consistent with immunohistochemistry.
Conclusions: Appropriately 1,25-(OH)2D3 supplementation decrease VDR expression in the lung of astmatic rats of different groups. Low dose group 8 0.6094 Control group 8 1

P1106 Respiratory symptoms during double blind placebo controlled food challenges in children in a general paediatric clinic

Cirsten Groen, Paul Brand
Princess Amalia Children’s Clinic, Isala Klinieken, Zwolle, Netherlands

Although double blind placebo controlled food challenges (DBPCFC) are the gold standard for the diagnosis of food allergy, a risk factor for severe asthma, studies examining respiratory symptoms during DBPCFC have come from children with severe eczema in specialized allergy centres. We examined the occurrence of respiratory symptoms during DBPCFC in children referred for evaluation of food allergy to a paediatric department in a general teaching hospital. Between 2006 and 2011, we performed 234 DBPCFCs to cow’s milk, hen’s egg, peanut, hazelnut, and soy in children 2 months-17 years of age (median 22 months). 85 tests were positive (36.3%). The symptoms on which food allergy suspicion was based included respiratory symptoms in 55 cases (23.5%), and were accompanied by symptoms from other organs in 54. Respiratory symptoms were seen on the placebo day in 8 patients (3.4%) and on the verum day in 23 patients (9.9%, p<0.001): rhinitis in 11, stridor in 3, wheeze in 6, and dyspnoea and cough in 16. None of these 23 patients had respiratory symptoms on the placebo day; 22 also had symptoms of other organ systems. The only patient with only respiratory symptoms (dyspnoea without wheeze) on the verum day had a negative DBPCFC to cow’s milk, because his symptoms on the verum day did not match the symptoms at referral (rhinorrhea, vomiting, diarrhoea): Only 4 patients required bronchodilator treatment.

In a general paediatric clinic, respiratory symptoms rarely occur in DBPCFC, and respiratory symptoms are never the only manifestation of food allergy in children.

P1107 Peanut allergy and asthma: A dangerous liaison?

Wilma van Veen1, Paul Brand1
Children’s Clinic, Isala Klinieken, Zwolle, Netherlands

Objectives: Peanut allergy (diagnosed by sensitization to peanut) has been associated with increased risk of severe asthma and anaphylaxis in tertiary care centres. We determined the association between the severity of asthma and peanut allergy diagnosed by standardized food history and food challenges in children from primary and secondary care.

Methods: We conducted a prospective cohort study among 280 peanut-sensitized children (0-18 yrs of age), referred for sensitization testing by general practitioners and paediatricians between 2003 and 2010. Diagnosis of peanut allergy was made or rejected in a stepwise fashion. Children who reported ingestion of peanut and no symptoms in a food allergy history questionnaire were classified as peanut allergy. Asthma was assessed by ISAAC and asthma control questionnaires, and skin-prick testing.

Results: Peanut allergy (diagnosed by sensitization to peanut) has been associated with increased risk of severe asthma and anaphylaxis in tertiary care centres. We determined the association between the severity of asthma and peanut allergy diagnosed by standardized food history and food challenges in children from primary and secondary care.

Methods: We conducted a prospective cohort study among 280 peanut-sensitized children (0-18 yrs of age), referred for sensitization testing by general practitioners and paediatricians between 2003 and 2010. the lungs a few hours before birth, a process that continues until two weeks after birth. The hemozyotic process to the lungs is independent of GM-CSF or TLR4. Upon entering the lung neonatal CD11b+Ly6Chigh, but not CD11b+Ly6G+ cells gain suppressive capacity. This suppressive capacity, as measured by suppression of T cell proliferation in vitro, is arginase-1 dependent. Neonatal lung CD11b+Ly6Chigh cells can therefore be classified as myeloid derived suppressor cells. The cells do not proliferate locally, but keep entering the growing lungs until the age of two weeks. Within the first week the Ly6G+ cells become apoptotic and the Ly6Chigh cells differentiate into dendritic cells and M1 and M2 macrophages. M2 macrophages, consequently peak in numbers between 7 and 14 days after birth. The high frequency of suppressive CD11b+Ly6Chigh cells in the neonatal lung do not suppress but rather potentiate sensitization to house dust mite by differentiating into ST2 expressing CD11b+ dendritic cells.

112. Cystic fibrosis (adults and children): risk factors and clinical problems

P1111
Cystic fibrosis registry: A preliminary report of CF patient from NRITLD

P1112
Early deaths in cystic fibrosis: Analysis of causes and risk factors in a pediatric cohort

P1113
Early deaths in cystic fibrosis: Analysis of causes and risk factors in a pediatric cohort

P1114
Early deaths in cystic fibrosis: Analysis of causes and risk factors in a pediatric cohort

Conclusion: Severity of symptoms and rate of disease progression varied widely; and early death was mainly influenced by poor socioeconomic status and presence of del F508 mutation.

With current treatment strategies, specialized care, the majority of patients should reach adulthood with good quality of life. This could be achieved in developing countries too through involvement of more dedicated clinicians and funding directed to organizing of care.

Introduction: Our CF center performed a quality improvement project to improve identification and treatment of CFRD. Our primary goal was to screen at least 80% of patients ≥8 years of age with oral glucose tolerance testing (OGTT) in 2011. Our secondary goal was to improve the mean HbA1c of CF patients.

Methods: With CF family and staff involvement, we identified barriers in our existing screening process and after multiple PDSA (Plan, Do, Study, Act) cycles implemented new processes:

Screening:
1) Changed lab protocol for patients receiving OGTT to improve screening efficacy
2) Scheduled annual labs at the first clinic visit of the year
3) Improved messosystem relationships via weekly huddles between pulmonary and endocrine teams
4) Developed protocol for follow-up of identified patients with CFRD Protocol Design to Improve HbA1c
1) Plan endocrine consult and transition to endocrine clinic using principles of clinical Microsystems
2) Implement system to contact families who failed clinic appointment
3) Provide additional education of staff and families

Results: Screening of outpatients with OGTT improved from 2010 (66%) to 2011 (99%). The mean HbA1c in patients with CFRD in 2010 was 7.0 (n=44). Their levels improved to 6.6 in 2011, and the mean for all patients including newly identified patients with CFRD in 2011 was 6.0 (n=47).

Conclusion: The development of an outpatient screening process successfully identified patients with CFRD. We successfully screened 99% of our patients with OGTTs, and reduced the mean HbA1c in CFRD patients.

Introduction: Early deaths in cystic fibrosis are frequent, and at least 30% of deaths occur within the first year of life. These early deaths are associated with several factors, including poor nutrition, respiratory problems, and infections. Studies have shown that early deaths in cystic fibrosis are often due to respiratory failure, and that early intervention can improve outcomes. Early deaths in cystic fibrosis are also associated with poor socioeconomic status, with patients from lower socioeconomic backgrounds being more likely to experience early death. The aim of this study was to identify risk factors for early death in cystic fibrosis and to develop strategies to prevent these deaths.

Methods: A retrospective cohort study was conducted on patients with cystic fibrosis who were followed up at our hospital for at least 1 year. Patients with early death were compared to those who survived to adolescence. Demographic and clinical data were collected, including age at diagnosis, socioeconomic status, nutritional status, and respiratory status. Logistic regression analysis was used to identify risk factors for early death.

Results: A total of 120 patients were included in the study, with 40 patients experiencing early death. The median age at diagnosis for early deaths was 3.5 years, compared to 7.5 years for survivors. Early deaths were more common in patients from lower socioeconomic backgrounds, with 80% of early deaths occurring in patients with a low socioeconomic status. Early deaths were also more common in patients with severe nutritional deficiencies, with 80% of early deaths occurring in patients with a BMI less than 15. Respiratory failure was the most common cause of death, occurring in 90% of early deaths. Logistic regression analysis identified low socioeconomic status, severe nutritional deficiency, and respiratory failure as independent risk factors for early death.

Conclusion: Early deaths in cystic fibrosis are frequent and are associated with poor nutrition, early lung involvement, and respiratory failure. Low socioeconomic status is a major risk factor for early death, and interventions to improve socioeconomic status and nutritional status are needed to improve outcomes.

The study was funded by the National Institute of Health and the Cystic Fibrosis Foundation. The authors declare no conflicts of interest.

Cystic fibrosis: Heartburn and lung function – “Too hot to handle”

Aim: Assess prevalence of GORD in CF adults, and study possible associations with genotypes, specific colonizations, lung disease severity and GORD treatment.

Methods: Retrospective study conducted in 23 CF patients attended at Pneumology Unit of Combrbia University Hospital, through a direct questionnaire (adapted from Mayo GER Quo list) recieving at least once GERD symptoms in previous 12 months.

Results: Of 23 studied patients, mean age 30±7.6, 70% female; DFS08 homony- gote was the most frequent genotype. P. aeruginosa and S. aureus organisms were the most prevalent secondary colonization. In 48% lung function was severely depressed. 21 patients (91%) experienced at least one GERD symptom, 12 (57%) referred the occurrence of 5 or more. Concerning lung function severity, we established significant statistical difference between groups under treatment versus un- treated group, being the first the one that presented the worst CVCF values (p=0.032).

Conclusions: Despite the limited evidence that GERD adversely impacts lung function, the possibility that acid suppression improves the outcome of this pa- tients, leads to a strong recommendation for aggressive treatment of GERD. However, according to our study, acid suppression treatment might be insufficient, turning it in a contemporary and scientifically important subject.

Dynamic hyperinflation in cystic fibrosis

François Tremblay, Julie Morisset, Claude Poirier. Pulmonary Division, Centre Hospitalier de l’Université de Montréal, Montréal, QC, Canada

Introduction: Cystic fibrosis (CF) is the most common life-limiting autosomal recessive disease. CF affects the exocrine glands of lungs, pancreas, intestines and liver. Lungs are usually affected more critically. Exercise tolerance is reduced in patients with CF. It has been shown that pulmonary function weakly correlates with peak exercise capacity. Furthermore, it has been demonstrated that oxygen desaturation during exercise is present in severe lung involvement, but not in mild to moderate disease. Peripherial muscle dysfunction has been demonstrated to be related to the presence of hyperinflation. Thus, the presence of dynamic hyperinflation has been looked at as a factor of exercise tolerance.

Objectives: The aim of this study was to evaluate the relationship between dynamic hyperinflation in CF during exercise. This provides a better understanding on exercise limitations in CF.

Results: Six patients with mild to moderate CF (FEV1 45 to 79%) were studied during incremental treadmill exercise and changes in inspiratory capacity (IC) were obtained to measure dynamic hyperinflation. During the exercise, dyspnea was assessed by Borg scale. Of the 6 CF patients, 5 patients showed a decrease in IC (dynamic hyperinflation). Furthermore, there was a direct relation between dyspnea assessed by Borg scale and change in IC (r = 0.38).

Conclusions: This is the first demonstration of dynamic hyperinflation in mild to moderate CF and a direct relationship between dyspnea and IC in CF during exercise. This provides a better understanding on exercise limitations in CF.

Factories predicting mortality in cystic fibrosis where lung transplantation can not be performed

Yasemin Gökdemir1, Elif Erdem1, Fazilet Karakoç1, Bulent Karadag1, Iszan Nur Akpinar2, Retika Erzu1. Pediatric Pulmonology, Marmara University Medical Faculty, Istanbul, Turkey

Introduction: Cystic fibrosis is the most common lethal genetic disorder affecting the Caucasian population. Severe pulmonary disease is responsible for over 80% of deaths associated with cystic fibrosis. Patients with less than 2 years life expectancy and with reduced quality of life are candidates for lung transplantation.

Aim: To evaluate the risk factors of mortality in moderate to severe cystic fibrosis lung disease that doesn’t go to lung transplantation.

Material and methods: We follow up 206 cystic fibrosis patients in our clinic and 35 of them with FEV1 <60% were enrolled to the study. Demographic data, pulmonary function test, high resolution computed tomography modified Bhalla score, blood gas analysis and nutritional status of patients were evaluated.

Results: The requirement was frequent in severe to moderate to severe lung disease (31.4%). Low pulmonary function, non invasive ventilation requirement, having diabetes mellitus, β2-agonist saturation <95%, P<50 mm Hg and frequent IV antibiotic treatment were significantly related with increased mortality (p<0.05).

Conclusion: This is a single centre study of cystic fibrosis patients with moderate to severe lung disease that did not go to lung transplantation. We evaluated the clinical going and factors that were associated with mortality. We think that it is important to do similar multicentre studies to discover Turkish CF patients information that have different genetics and phenotype.

Genotypic diversity of Pseudomonas aeruginosa in cystic fibrosis patients with the CFTR 11234V mutation in a large kindred family

Background: Pseudomonas aeruginosa is one of the primary pathogens within Cystic Fibrosis (CF). Despite the cystic fibrosis (CF) gene defect being a cause of morbidity and mortality, Reports of cross infection and epidemics with this pathogen within and across CF centers raised the possibility of clonal spread among siblings with CF. Aim: To genotype P. aeruginosa by amplified fragment-length polymorphism (AFLP) analysis in CF patients with the CFTR 11234V mutation belonging to a large kindred tribe, and to determine whether the genotypes are identical among CF siblings and among different families with the same mutation.

Methods: Sixty seven P. aeruginosa isolates from sputa of 27 CF patients were studied at Hamad General Hospital, Qatar. Genotypic relatedness was assessed using AFLP, and compared with 33 P. aeruginosa isolates of a known genotype from the Netherlands.

Results: Twenty seven CF patients were from 17 families, 16 males with a median age of 15 years (range 4 years-34 years). Twenty-two CF patients (12 families) with the CFTR 11234V mutation arising from a single large kindred trib bourhoped chron P. aeruginosa colonization. Twenty three unique genotype of P. aeruginosa were identified and different from CF patients. Ten families each had one unique genotype which were different from each other. Four of these families harboured 2 different genotypes, one family 3 genotypes and two families had 4 genotypes. CF siblings within one family harboured the same genotypes of P. aeruginosa.

Conclusions: This study demonstrated genotypic diversity of P. aeruginosa isolates between families and established cross-infection among CF siblings.

Nebulised antibiotics with the I-neb adaptive aerosol delivery (AAD) system: Impact on adherence in cystic fibrosis (CF) patients

Sülyesi Güneyi1, Carlos Martin1, Pilar Vallejos2, Antonio Moreno1, Ines de M1, Alba Torrent1, Marcelo Raquín1.1Pediatric Pulmonology and Cystic Fibrosis Unit, Hospital Universitari Vall d’Hebron, Barcelona, Spain; 2Medical Department, Praxis Pharmaceutical, Madrid, Spain

Purpose: To assess the adherence and compliance to prescribed treatment of CF patients to nebulised antibiotic utilising the AAD system.

Methods: 17 cystic fibrosis patients with regular treatment for a period of time (range 8-18 years) infected with Pseudomonas aeruginosa and treated with aerosolised colistin twice a day using the AAD were included. Data were downloaded during a clinic visit 3 months later and in 7 patients, a second downloaded after year. None of the patients were aware that the data were recorded.

Results: Mean overall adherence over the 3 months of treatment (number of recorded doses/number of prescribed doses x100) was 90.73% (SD: 26.37%) with 2 out of 17 patients having an overall adherence below 75%. The mean percentage of days each patient fully adhered was 78.48% (SD: 17.5%) and the mean of fully completed was 84.90% (SD: 28.27%). Overall mean values adherence was 85.10% and was not, to the first to demonstrate dynamic hyperinflation in mild to moderate CF and a direct relationship between dyspnea and IC in CF during exercise. This provides a better understanding on exercise limitations in CF.

The prevalence and characteristics of intravenous (IV) antibiotics allergy in adult patient with cystic fibrosis (CF)

Ravi Bijel1, Reema Jassal1, Deep Shah1, Waeil Bashari1, Sarah Whewall1, Angela Norcup1, Albert Yick-Hou Lim1,2.1 Department of Respiratory Medicine, University Hospital of North Staffordshire; Stoke on Trent, United Kingdom; 2North West Midlands Cystic Fibrosis Centre, University Hospital of North Staffordshire, Stoke on Trent, United Kingdom

Background: CF patients have increased risk of antibiotics allergy. There is little information on the prevalence and characteristics of IV antibiotics in adult CF patients.

Objectives: To determine the prevalence and the role of CFTR genotype in IV antibiotics allergy, and to describe the characteristics of allergy.

Methods: A retrospective study on all CF patients attending the regional adult CF centre at University Hospital of North Staffordshire between January 2009 and December 2010. Age, sex, CFTR genotype, BMI, spirometry, sputum microbiologi- my/mycology, Aspergillus serology, allergic reactions, the type and the number of courses of IV antibiotics administered were recorded.

Results: 39 of 54 patients received at least 1 course of IV antibiotic were studied. 16 patients with allergy (mean ±S.E) age 28.5±2.6, 10 female) and 23 without (mean ±S.E) age 28.5±2.6, 10 female). The 2 groups had similar spirometry
Acrodermatitis enteropathica-like skin lesions can be seen in CF because of malabsorption and insufficient nutrition that lead to hypoproteinemia, zinc and essential fatty acids deficiencies. In patients with these skin lesions, CF must be kept in mind and sweat test must be repeated after the resolution of edema.

**P1122**

**Acrodermatitis enteropathica-like skin eruption in cystic fibrosis patients**

Grunz Canöl1, Selin Yakarisk2, Ebub Yalın1, Deniz Dogru1, Ugur Ozcelik1, Nurul Kiper1

1Department of Pediatrics, Hacettepe University, Ankara, Turkey

**Background:** Cystic fibrosis patients are predisposed to pulmonary infections. Conditions associated with CF like underweight, diabetes mellitus (CFRD), liver disease (CFLD) are favoring factors for tuberculosis (TB). The hypothesis of a potential comorbidity of TB in CF children occurred. The aim of the paper was to evaluate the prevalence of TB in children with complicated CF.

**Methods:** Three-two patients with typical CF, associating complication like CFLD(27 pts), diabetes(3 pts) and 2 with both complication were considered for a prospective five years study. Bitemoc bacteriali exam (TB specific) also were included, in addition to clinical examination and annual CT, to the patients evaluation.

**Results:** Tuberculosis occurred in 6.25%(2 patients), both F508 del homozygous, with CFLD and poor nutritional status; one patient had also CFRD. His evolution was unfavorable; he developed portal hypertension and died from respiratory failure. The other patient was diagnosed with active TB, Pseudomonas positive and poor nutritional status, but good evolution after treatment. The rest of CFLD patients had a stationary evolution, except 4 of them (15.38%) developed diabetes. Tuberculosis skin test was positive in 4 patients (12.5%), 3 of them received TB vaccine. Despite the mandatory vaccination for TB in our country, only 84% pts were vaccinated. 18% of patients pts were CF patients with CFLD and treated as TB cases, without bacteriological confirmation, before being diagnosed with CF.

**Conclusion:** Although TB is a frequent condition in our area, the prevalence among CF children is not as high as expected. It is possible that other factors, unknown so far, are implicated.

**The use of Pezzer catheter in cases of persistent airleak in advanced cystic fibrosis**

Kalilopi Athanassiadi1, Ioana Cinci1, Liviu Pop1, Zagorea Popa1, Voicu Tudorache2, Simona Turcu1, Ioan Popa1

1Pediatric II Department, University of Medicine and Pharmacy
2Victor Babes Institute, Timisoara

**Objective:** Spontaneous pneumothorax with persistent airleak is a complication that is commonly reported in patients with cystic fibrosis (CF). There is an attributable mortality and considerable morbidity to the complication, resulting in increased health-care utilization and a measurable decline in lung function. We present a series of 11 patients with CF presenting with recurrent pneumothoraces and persistent airleak treated with a Pezzer catheter.

**Material & method:** All 11 patients presented with large pneumothoraces; a 28 French Argyle intercostal catheter was inserted in the 5th or 6th intercostal space, mid axillary line, and connected to an underwater seal drain, resulting in re-expansion of the lung. However, there was persistent air leak on coughing in 7 cases while in the rest 4 cases, the intercostal tube became inactive and smaller pneumothoraces presented as local ones, impossible to be drained by the already in place intercostal catheter. In both groups either with persistent pneumothoraces or recurrent ones we decided to use Pezzer catheters made of Latex instead of Argyle ones.

**Results:** All pneumothoraces were resolved within 3 days after the insertion of a Pezzer catheter. There were no complications recorded and in a follow up of 2 years no recurrence was observed.

**Conclusion:** Our experience supports the use of Pezzer catheter connected to water seal in cases of advanced cystic fibrosis with prolonged air leak, since it promotes pleurisy. It reduces significantly the duration of the intrapleural drainages and the length of the in-hospital stay. The procedure is cost-effective, safe, and easy to perform.

**Rate of change of FEV1 and VC in adults with chronic airflow obstruction**

Andrew Robson1,2, Alastair Innes1,2, Respiratory Function Service, Western General Hospital, Edinburgh, United Kingdom; 2Respiratory Function Service, Royal Infirmary of Edinburgh, United Kingdom

We have investigated the rate of change in post-bronchodilator FEV1 and VC in patients with chronic airflow obstruction by retrospective analysis of data in our clinical database. One thousand and forty-four patients (633 females) fulfilled the study criteria, namely two sets of measurements with a minimum of six calendar months between measurements. Measurements of FEV1, and VC were made before and 20 minutes after administration of 2.5 mg nebulised salbutamol. Only patients with an FEV1/VC ratio below the lower limit of normal after administration of 2.5 mg nebulised salbutamol were included in the study. Rate of change in FEV1 was calculated in litres/year. Smoking status (smoker, ex-smoker or non-smoker) was recorded at each visit, but the number of cigarettes smoked was not recorded. Patients were only identified as smokers if the same status was recorded at both measurement. The rate of change in post salbutamol FEV1 and VC in all patients and in the subgroup of smokers are shown in Table 1. Values shown are mean ± SD.

**Economic impact analysis of a tele-medicine program to improve the quality of spirometry in primary care**

Maria Margali1, Elena Lopez de Santa Maria1, Asuncion Gutierrez1, Juan Carlos Bayon2, Larratza Garcia3, Juan B. Galdiz4, Respiratory Function Laboratory, Cruces Hospital, Barakaldo, Spain; 2Health Technology Evaluation Service, Basque Government, Vitoria, Spain; 3Respiratory Function Laboratory, CIBERES, Cruces Hospital, Barakaldo, Spain

**Introduction:** The tele-spirometry (TS) procedure consists in a computer application (expiro,Osasunet) which allows the control and improvement of the quality of the spirometry (S) carried out in primary care centers (PCC), leading a continuous training of professionals that perform the technique.

**Aim:** To calculate the economic impact of a procedure of TS in the Basque Health Service.
Methods: The study was based on the impact in the funder of the Public Health System and a time horizon of 5 years: 2010-2014. We compared the TS with the usual procedure and calculated the direct costs of the test, the computer platform, training, and staff for their handling. The population was calculated using the prevalence of COPD in Spain (Soriano EIR 2009). Effectiveness was measured as the average of S with quality A+B (ATS).

Results: The COPD population who will perform a S goes from 32,850 to 35,207 (2010-2014). At present (2011) 53 PCC have been involved and 1500 S have been done. At the end of 2014, 275 will be included and, with initial data (Marina 2011 ERS Congress) 3500 S will be done yearly. The cost of one S for the procedure of TS, in 2010, was 48,1€ with an effectiveness of 83%; while for the usual procedure was 37,9€ and 57%. The budget impact analysis, at the end of the year 2014, reflected a decrease of 132,438€, with the assumption that the S of poor quality should be repeated.

Conclusions: The TS procedure involves an increase in the initial budget but produces a saving of the 6.3% (€132,438) in the medium term. For subsequent studies we will have to know the economic impact that this improvement in the quality of the S may have on the diagnosis and prognosis of COPD patients.

P1126
Telemedical care concept for patients with advanced chronic obstructive pulmonary disease (COPD)

Keywan Ali Sohrabi1, Andreas Weissofl3, Michael Scholtes1, Lothar Leiches3, Henning Schneiders3, Ulrich Koehler4, Volkger Gross5, ITH-Mittehessen University of Applied Sciences, Biomedical Engineering, Giessen, Germany; 2ITH-Mittehessen University of Applied Sciences, Medical Informatics, Giessen, Germany; 3ThoraTech GmbH, Research, Giessen, Germany; 4Philippus University of Marburg, Interdisciplinary Sleep Disorders Centre Hessen, Marburg, Germany; 5Ingenieurbuero fuer Medizintechnik GmbH, Research, Wittenberg, Germany

Providing health care services via telemedicine opens new possibilities and offering cost efficient solutions for monitoring, assistance, and even training for COPD patients. An acute exacerbation is a sudden worsening of COPD symptoms. As the disease progresses, exacerbations tend to become more frequent. For the successful long-term treatment of COPD, it is necessary to optimize the management of acute exacerbations.

Patients with severe COPD benefit physical and physiological from moderate fitness training, as it is shown in our rehabilitation program for COPD patients in Marburg. A good understanding of their disease and communication from and to the therapist will improve therapy compliance and patients self-management abilities. Finally patients get more sensitive for symptoms of early stages of exacerbations. The new telemedicine concept of the Tele-Therapist and the innovative locomotion recognition system will be a part of the Tele-Therapist and allows the monitoring of rehabilitation & training@home, and furthermore it will improve therapy compliance and patients self-management abilities. Finally patients get more sensitive for symptoms of early stages of exacerbations. The new telemedicine concept of the Tele-Therapist and the innovative locomotion recognition system will be a part of the Tele-Therapist and that allows to identify the BD response in COPD patients.

Elena Lopez Santa Maria, Nuriis Narima, Ruth Diez, Grupo Atencion Primaria, UrbeCosta, Ezkerketarea, Juan Gallid1, 1Pneumology, Cruces Hospital, Barakaldo, Bizkaia, Spain; 2Pneumology, Cruces Hospital Cibones, Barakaldo, Bizkaia, Spain

Spirometry can be considered a key element in the assessment of COPD patients in primary care centers (PCC). The slow maneuver is not a common practice in such environment. Bronchodilator response (BD) could be understimated if IC is not evaluated.

Aim: Assessing the usefulness of the measurement of inspiratory capacity (IC) in the evaluation of bronchodilator response in COPD patients

P1127
Inspiratory capacity measurement in primary care centers to evaluate bronchodilatation response in COPD patients

Elena Lopez Santa Maria, Nuriis Narima, Ruth Diez, Grupo Atencion Primaria, UrbeCosta, Ezkerketarea, Juan Gallid1, 1Pneumology, Cruces Hospital, Barakaldo, Bizkaia, Spain; 2Pneumology, Cruces Hospital Cibones, Barakaldo, Bizkaia, Spain

Spirometry can be considered a key element in the assessment of COPD patients in primary care centers (PCC). The slow maneuver is not a common practice in such environment. Bronchodilator response (BD) could be underestimated if IC is not evaluated.

Aim: Assessing the usefulness of the measurement of inspiratory capacity (IC) in the evaluation of bronchodilator response in COPD patients in primary care centers.

Material and methods: Transversal, multicenter, descriptive study performed in eight PCC. 113 COPD patients were included. Spirometries were carried out by eight technicians who performed a two days training program in the slow maneuver (IC). We considered as acceptable maneuvers a coefficient of variation in the CI lower 10% and 150 ml in two maximum values of S with a maximum of eight maneuvers in one day. The slow maneuver was performed prior to the forced maneuver (FC). We considered as acceptable maneuvers a coefficient of variation in the CI lower 10% and 150 ml in two maximum values of S with a maximum of eight maneuvers in one day. The slow maneuver was performed prior to the forced maneuver (FC).

Results: 113 patients, 99 H and 14 M, age 65±14.6 years (SD 17.5), and 43% were female. Mean BMI was 27.3 kg/m2 (SD 6.3), and 24% were smoking. The following results are presented as the percentage of all tests meeting the goals per centre: Start of test: BEV <150 ml, varied from 74% to 95% (mean 86%); end of test; PET >6 s, from 23% to 90% (mean 66%); Repeatability of FEV1, pre bronchodilator (<150 ml) varied from 73% to 97% (mean 89%), and post bronchodilator from 79% to 98% (mean 91%).

Conclusion: Achievement of quality goals varied considerably between the centres. These data will be further analysed and established an initial status to compare quality of spirometry after a Spirometry Driving License training.

P1129
Spirometry training courses are not enough to achieve quality spirometry in the community

Maureen P. Swanney, Josh D. Stanton. Respiratory Physiology Laboratory, Christchurch Hospital, Canterbury District Health Board, Christchurch, New Zealand

Community diagnostic spirometry should be performed at the same standard as a respiratory laboratory. In 2008 our 10-year-old training course was altered to include a post-course quality review to qualify for spirometry certification.

Aim: To review the effectiveness of a quality review after spirometry training.

Methods: We audited attendees at our spirometry courses and portfolio submissions. The portfolio required 10 tests and technical comments; spirometry pattern, and quality control logs. We required 90% in all criteria and those who failed could resubmit.

Results: 2-day and refresher spirometry courses were reviewed including 107 practice nurses, 59 occupational health nurses and 27 regional hospital technicians. We found similar trends for the three groups. The portfolio first submission (22%, 30%) and pass rate (33%,62%) for the 2- and 1-day courses respectively were low.

Discussion: The number seeking feedback on spirometry practice was low with 24% submitting portfolios. Poor compliance was probably because spirometry certification is not compulsory in New Zealand. This review suggests a spirometry course alone is insufficient to achieve quality spirometry, or there are deficiencies in our course content or delivery. A failed portfolio provided additional learning because some resubmissions were successful. The low submissions and passes for the portfolios are a concern. We need to encourage excellence in community spirometry and maybe legislation to make spirometry certification compulsory is the way forward.

Physician's mistakes in the interpretation of spirometry

Claudio Sorino 1, Nicola Scichilone 1, Annarosa Maspero 1, Vincenzo Bellia 1.
1PRE DI C A.R.E., Associazione per la Prevenzione, Diagnosi e Cure delle Affezioni Respiratorie ONLUS, Palermo, Italy; 2DI.BI.M.I.S., Università degli Studi di Palermo, Italy; 3U.O. Pneumologia, A.O. Sant’Anna, Como, Italy

Background: The most recent ATS/ERS recommendations on lung function testing include a definition of airflow obstruction based on lower limit of normal (LLN) of FEV1/FVC and suggest to measure total lung capacity (TLC) in suspected cases of “pseudo-restriction” (normal FEV1/FVC ratio but concomitant reductions in FEV1 and FVC), that can conceal airflow obstruction if the subject does not exhale long enough.

Aims: To evaluate the skill of physicians in the interpretation of spirometry.

Methods: A questionnaire focusing on the interpretation of five spirograms was administered to 127 physicians (aged 25-67yrs; 39% pulmonologists, 20% geriatrics). The day was advertised in the Trust Talking Point and the Trust Press

Results: Overall, 31% of physicians made at least one mistake in the interpretation of the spirograms administered. The percentage decreases to 15% among physicians and asthma patients visited in the last year.

Conclusions: Inappropriate spirometric interpretation is not rare among physicians and produce overdiagnosis among elderly. Diagnosis by pulmonologists and scientific update of physicians allow to reduce spirometric interpretative errors.

P1132
Finding the missing millions with COPD – Does it work?
Rehan Mustafa, Fiona Bates, Angela Charlesworth, Tina Stallard, Rosie Watts, Joan Summersgill, Cindy Lightowler. COPD Outreach Service, JamesCook University Hospital, Middlesbrough, Cleveland, United Kingdom

Introduction: Many COPD patients do not receive a diagnosis until it is relatively advanced. It is estimated that for every one patient that has been diagnosed there are four that are not known to the health service. In conjunction with World COPD Day in 2011, our COPD Outreach team promoted this event by performing spirometry on patients, staff and visitors at the main hospital entrance, to raise public awareness and to find the ‘missing millions’.

Aims and objectives: To raise public awareness of COPD and to detect people with undiagnosed COPD.

Method: The day was advertised in the Trust Talking Point and the Trust Press release. Flyers were posted around the hospital. 4 stands were set up in the main atrium of the JCUH, with spirometers and COPD nurse specialists to perform spirometry. Volunteers completed a questionnaire focusing on their smoking history, symptoms of COPD, history of comorbidities and concomitancies to perform spirometry. Individuals with abnormal spirometry were provided a letter for their primary care physicians, to undergo repeat testing or further investigations if appropriate.

Results: Out of the 75 volunteers tested, only 9% (n=7) were noted to have abnormal spirometry results. 5% (n=4) of the volunteers had a prior history of airflow obstruction. Therefore only 4% (n=3) of the volunteers screened were found to have abnormal recordings.

Conclusion: Random screening doesn’t capture a large population of people with abnormal spirometry. Screening needs to be more selective e.g.individuals over the age of 35 with a smoking history or symptoms suggestive of COPD. Where our screening did raise awareness of COPD within the general public, it didn’t diagnose a large number of people with COPD.

P1133
Irreversible airways obstruction on spirometry, does it equate to a diagnosis of COPD?

Dennis Wat, Sarah Haynes, Linda Lukehurst, Joan McWean, Omnor Hampson, Kamlesh Mohan. Community COPD Service, Liverpool Heart and Chest Hospital, Liverpool, United Kingdom

Introduction: Irreversible airways obstruction and a post-bronchodilator FEV1/FVC ratio of <70% on spirometry is diagnostic of chronic obstructive airways disease (COPD). Using the above criteria to make clinical diagnosis may potentially overlook other obstructive lung diseases.

Aims: To study the prevalence and characteristics of lung diseases in patients with irreversible airways obstruction.

Methods: The diagnosis of all patients with irreversible airways obstruction seen in our service between August 2011 and January 2012 seen respiratory physicians was retrospectively reviewed. Respiratory diagnosis was made based on clinical history, physiology testing and radiology.

Results: There were a total of 486 referrals; 446 (92%) have COPD and 40 (8%) have bronchiectasis. No other obstructive lung diseases were diagnosed. There are no significant differences between the demographics of the COPD and bronchiectasis groups.

All data expressed as means.

Conclusions: Current guidelines define irreversible airways obstruction as COPD and many of the therapeutic management strategies for COPD are based on the degree of airway obstruction. We have shown that a proportion of patients with irreversible airways obstruction have bronchiectasis. Hence any patients with irreversible airways diseases who are refractory to maximised COPD management should prompt a review of the diagnosis.

P1134
The value of additional testing in physician diagnosed asthma: A prospective pilot study

Dinike Bruss, Steven Uil, Irene Steenbruggen, Jan Willem van den Berg. Department of Pulmonary Diseases, Isala Klinieken, Zwolle, Netherlands

Introduction: Asthma is a common, chronic inflammatory airway disease. Signs and symptoms of asthma are not specific, leading to under and overdiagnosis.

In the Zwolle area, general practitioners can refer patients suspected of asthma to the Isala klinieken for spirometry or methacholine provocation testing. However any patients with irreversible airways disease who are refractory to maximised COPD management should prompt a review of the diagnosis.

Aims: To investigate whether in patients with physician diagnosed asthma, a negative methacholine provocation test, additional tests were valuable to establish asthma.

Methods: Primary care patients with a physician diagnosis of asthma but a negative methacholine provocation test, additional tests were valuable to establish asthma.

All data expressed as means.

nitric oxide (FeNO) was measured. A priori, a diagnostic yield of ≥20% was considered as valuable. The study was approved by the local ethics committee (NL57709.711).

Results: 160 patients were eligible and 51 were interested. Eventually, 36 subjects underwent the research protocol. Three participants had a positive mannitol provocation test (3.8%). Only one (2.8%) subject had a FeNO-value of >30 ppb. Mean sum scores for the BPH were 30.0±(4.0-8.0). After assessment of the results, three participants received the diagnosis of asthma.

Conclusion: In view of the low diagnostic yield found in this study, additional tests did not seem to have significant impact on the diagnosis of asthma.

P1135
Bronchial asthma: New approach to airways functional diagnostics
Vitaliy Mishalov, Andrey Zuev. Propedeutic of Internal Diseases Department, Perm State Medical Academy, Perm, Russian Federation Laboratory of Hydromechanics, Institute of Continuous Medium Mechanics of Ural Branch of Russian Academy of Science, Perm, Russian Federation

It’s known that bioelectrical impedance value depends on electrical current path length and diameter. The aim of the study was to investigate electrical impedance of airways and lung by new technique of polyfrequent electrical impedance analysis using “BIA-lab” software. 39 asthmatics and 20 healthy people at the age of 19-45 years old were examined. There were 24 females in asthmatic group and 11 ones among healthy people. Of the asthmatic patients 10 had a severe asthma, 15 suffer from moderate and 9 ones were with mild form of disease. All patients were examined with physical methods and spirometry tests performed. The polyfrequent electrical impedance technique demanded of 0.9% NaCl airsole inhalation for 1-2 minit to load the airways. The results revealed elevated electrical impedance module values on diapasons of frequencies: 20, 98, 1000, 5000, 10000 and 20000 Hz in asthmatic patients. But we didn’t registered angle ϕ changes. There was a significant correlation between FEV1 and electrical impedance module ζ of airways (r=-0.57; p=0.032).

Conclusion: Polyfrequent electrical impedance analysis, which characterizes the diameter of airways as the main electrical current conductor loaded by 0.9% NaCl airsole, get adiquit esessment of bronchial obstruction in any severity asthmatic patients.

P1136
Acoustic analysis of respiratory sounds in infants with wheezing
Irina Melnikova, Vasillina Grigoreva, Yuri Mizemitski. Dep. of Pediatrics, Yaroslavl State Medical Academy, Yaroslavl, Russian Federation, Dep. of Pediatrics Yaroslavl State Medical Academy, Yaroslavl, Russian Federation. Dep. of Pediatrics, Yaroslavl State Medical Academy, Yaroslavl, Russian Federation. Dep. of Pulmonology, Institute of Pediatrics & Child Surgery, Moscow, Russian Federation

The aim of the study was to determine functional acoustic characteristics of breath by bronchophonographic method (BPG) in infants with wheezing.

Methods: We observed 24 children (2 month-3 years) with wheezing. The patients were divided into two groups (Gr), the Gr1 (n=14) - atopic children and Gr2 (n=10) - non-atopic children. The control group (C) included 27 healthy non-atopic children (2 month - 3 years of age). Computed BPG by computer diagnostic complex “Pattern” (MEI, Russia) (0.2-12.6 kHz) before and after inhalation of salbutamol (BTS) was provided all patients after the disappearance of wheezing. It was used coefficients of general acoustic breath work (ABW) = φ (0.2-1.2 kHz), φ2 (1.2-5.0 kHz), φ3 (5.0-12.6 kHz), representing relation of level ABW in a given frequency range of the level general ABW.

Results: There were significantly more high parameters of general ABW, φ2, φ3 in the patients of Gr1 and Gr2 in comparison with GrC (p<0.05). Patients of Gr1 showed more general ABW then Gr2 (φ2 =<0.01). The parameters of Gr1 and Gr2 also showed the most high amplitude of sounds in high frequency zone (5.0-12.6 kHz) in comparison with GrC (p<0.05). After BTS for the most part of children of the Gr1 (2/3) and 1/2 of the Gr2 showed significant decreasing φ3; the level of φ3 in the Gr1 decreased significantly more in comparison with Gr2 (accordingly 64.4±10.7%; 40.4±10.3%; p<0.05).

Conclusion: These preliminary results showed that the infants after the disappearance of wheezing still demonstrate the significant functional acoustic disorders. It was more expressed at atopic children then non-atopic. It can be important in relation of early debut of bronchial asthma.

P1137
Effect of patient age on response to nebulised salbutamol or ipratropium bromide
Andrew Robson1,2, Alastair Innes1,2, 1Respiratory Function Service, Western General Hospital, Edinburgh, United Kingdom; 2Respiratory Function Service, Royal Infirmary of Edinburgh, United Kingdom

In order to investigate the effects of a patient’s age on their response to nebulised bronchodilators we have carried out a retrospective analysis of our clinical results database. Inclusion criteria for the study were: Age >20 at time of measurement and the presence of airflow obstruction (FEV1/N/C ratio below the lower limit of normal) at baseline measurements. Patients were excluded from the analysis if they were hospital inpatients at the time of measurement, or if they were on oral steroid treatment. After baseline spirometry had been measured, patients received either 2.5mg of salbutamol (SALB) or 0.25mg ipratropium bromide (IPB) via a nebuliser. Spirometry measurements were repeated at 20 minutes (SALB) or 60 minutes (IPB) post administration of bronchodilator. A patient was considered as having a positive response to a bronchodilator if there was an increase in FEV1 >200ml above baseline which was also an increase of ≥12%. Patients were divided into four age groups, shown in Table 1. A total of 11560 patients fulfilled the entry criteria. Of these, 3759 (33%) showed a positive response to a bronchodilator (Table 1).

Table 1. Change in FEV1 expressed as a percentage of the patient’s predicted FEV1.

There were no statistically significant differences between responses to SALB or IPB in any age group. These results demonstrate that increasing patient age does not diminish the magnitude of a patient’s response to nebulised SALB or IPB.

P1138
Characterization of bronchodilator response by spirometry and plethysmography
Raquel Barros1, Paula Pinho1,2, Cristina Bárbara1,2, 1Pulmonology II Department, CHLN - Hospital Padulo Valente, Lisboa, Portugal, 2Medical Science Faculty, Universidade Nova de Lisboa, Lisboa, Portugal

Background: The bronchodilator response criterion is defined by ATS/ERS as an increase of FEV1 and/or FVC ≥12% and 200 ml, respectively, after the inhalation of a bronchodilator. The aim of this study was to determine lung function (LF) parameters obtained by spirometry and plethysmography, that have significant changes with the administration of bronchodilator, to quantify changes of LF parameters between pre and post bronchodilator, to characterize the response to bronchodilator according to different criteria.

Methods: We studied 52 consecutive subjects who performed LF tests, in which was detected airway obstruction with subsequent administration of bronchodilator. The sample was divided in accordance with the presence or absence of pulmonary hyperinflation (PL).

Results: All parameters increased or reduced after administration of the bronchodilator (p<0.05). Raw and the FEV1 had the largest percentage of differences between the pre and post bronchodilator. For the totality of the sample, the criteria which were able to detect the largest number of subjects with a positive response to the bronchodilator were the increase of FEV1≥12% (63.5%), FEV1/FVC≥20% (46%), Raw>10% (34.6%) and the reduction of Raw>10% (32.7%). For the group without PL the best criterion was the increase of FEV1≥12% (62.2%) and in the group with PL, the increase was in FEV1≥12% (66.7%) and the reduction of RV>10% (66.7%).

Conclusion: This study couldn’t define a specific parameter that was considered “the best” to characterize a positive bronchodilator response, but suggested a combination of several parameters for a correct characterization of airway reversibility.

Pressure supported nasal inhalation improving penetration of particles into the human lung
Keywan Sohrabi1, Damian Liberzetti1, Abas Sobrabi2, Michael Scholtes1, Helmut Hoeftken3, Ullrich Koecher2, Volker Gross1, 1Dept. Biomedical Engineering, TH Mittelhessen University of Applied Sciences; Gießen; 2Interdisciplinary Sleep Disorders Centre Hessen; Philipps University of Marburg; 3Dept. Nuclear Medicine, Philipps University of Marburg, Germany

We here report on a new method to facilitate the pressure supported nasal long-term inhalation. The method is developed and technically realized by company NLI GmbH, Germany. We examined the efficacy of the method by measuring the deposition in nasal and thoracic airways. We used 99mTC-nanocell to identify the activity scintigraphically in various respiratory sections. This study included 10 patients (5 ± 5, s ± age, range 49 to 75 years, presenting several COPD stages (GOLD I-III). The NLI system generated particle sizes from 1-2 µm. The pressure support was adjusted to 10 mbar.

We could show that deposition in the lung periphery by using the pressure supported transnasal method is significantly increased compared with conventional methods. The usual method produced an average nasal deposition of 5.9 MBq and a periphery deposition of 9.6 MBq, whereas NLI method results in an average nasal deposition of 4.2 MBq and a periphery deposition of 12.9 MBq, respectively.

Our study showed that it was possible to penetrate even in peri-inhalatory pulmonary tissue in COPD patients by using the NLI system. In addition, we achieved an enhancement of the thoracic deposition of 99mTc-nanocell, when recorded a reduction of activity in the nasopharyngeal zone. Further clinical trials with drug applications will be necessary to confirm the clinical relevance.

P1140
Is the portable NIOX MINO reliable for screening nasal nitric oxide levels in primary ciliary dyskinesia?
Amanda Harris1, 1Department of Respiratory Medicine, University Hospitals, Southampton, Southampton, United Kingdom; 2NIHR Respiratory Biomedical Research Unit, University Hospital Southampton Foundation Trust, Southampton, United Kingdom; 3NIHR Respiratory Biomedical Research Unit, University of Southampton, Southampton, United Kingdom; 4Primary Ciliary Dyskinesia Research Group, Faculties of Medicine, Clinical and Experimental Sciences, University of Southampton, Southampton, United Kingdom

Background: Nasal nitric oxide (nNO) levels are very low in patients with PCD. nNO is used as a screening test for PCD. The portable NIOX MINO (Aerocrine, Sweden), is now able to make nasal measurements. This study aimed to assess the usability and reproducibility of the NIOX MINO measurements and comparison of MINO and ‘standard’ NIOX flex.

Methods: Paired MINO and Flex readings were taken from 22 participants (3 PCP, 5 asthma ± rhinitis, 12 healthy, 1 CF, 1 nonCF/nonPCD lung disease; age 5-66year) nNO was measured using Flex during breath holding, and using the Nios MINO using nasal aspiration at 2 and 5ml during mouth breathing, three times for each measurement.

Results: One participant was unable to use Flex or MINO, one participant was able to obtain acceptable readouts using the MINO at 5ml/sec but not at 2ml/sec nor Flex. Younger children were able to obtain measurements at 5ml/sec but not 2ml/sec. Within-method there was good inter-participant reproducibility using the Flex and MINO. Between method, nNO levels using the MINO at 2ml/sec were comparable with Flex (p=0.098) but readings using the MINO at 5ml/sec were significantly lower than Flex (p<0.001). PCD patients had extremely low levels of nNO (<50ppb) independent of method. A patient with CF had very low nNO (<50ppb) using Flex and MINO (5ml/sec).

Conclusions: Patients who were able to use Flex could also provide nNO measurements using the MINO at 5ml/sec; younger children were unable to use it at 2ml/sec. Reproducibility of nNO within method was acceptable. Measurements using the MINO at 5ml/sec were low in comparison to Flex, but would still differentiate patients with PCD from healthy controls.

P1141
Effect of airflow obstruction on the measurement of lung volumes
Tara Goddard1, 1Respiratory Research, Respiratory Research Unit, University Hospital, Bristol, United Kingdom

Effective alveolar volume (VA) is considered as a representative of Total Lung Capacity (TLC) in subjects without airflow obstruction. In the presence of airflow obstruction, physiological changes can give rise to discrepancies between TLC and VA.

Aim: To assess whether VA correlates with TLC and ascertain whether these differences are amplified in relation to the increase in severity of airflow obstruction.

Method: Data was analysed retrospectively and divided into 2 groups based on TLC measured by either body plethysmography (pleth) or helium dilution (He). Results were classified by FEV1, using the NICE COPD guidelines 2010. Data was analysed using regression, Bland-Altman and ANOVA.

Results: The magnitude of TLC - VA increased significantly (p<0.001) in relation to the severity of airflow obstruction. Bland-Altman gave a bias of 1.38 and 1.39 for helium and plethysmography respectively. A single equation was derived to predict the differences between TLC and VA:

\[(TLC_{XX} - VA) = 2.98 - 0.024 FEV1%Pred\]

Table 1. TLC and VA difference in relation to severity of airflow obstruction as classified by the COPD guidelines

<table>
<thead>
<tr>
<th>Severity</th>
<th>N</th>
<th>5</th>
<th>25</th>
<th>28</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLCpleth-VA (L)</td>
<td>0.8±0.3</td>
<td>1.3±1.1</td>
<td>1.8±1.1</td>
<td>3±1.6</td>

<td>0.9±0.4</td>
<td>1.5±0.9</td>
<td>1.8±0.1</td>
<td>2.9±1.3</td>
<td></td>
</tr>
</tbody>
</table>

Conclusion: 1. VA underestimates TLC
2. As severity of airflow obstruction increases, the magnitude of discrepancy between TLCpleth and VA and TLCHe, and VA increases
3. Overall, VA is unable to substitute TLC in subjects with COPD, particularly those with more severe airflow obstruction

P1142
Rate and depth of breathing affect multiple-breath N2 washout (MBNW) indices
Noor Al-Khathlan1, 2, Erol Guillard1, Maria Viskaduraki1, 1Kathleen O’Donoghue, 1Respiratory Care, Derriford Hospital, Plymouth, England; 2Research Group, Faculty of Medicine, Clinical and Experimental Sciences, University of Plymouth, Plymouth, United Kingdom

Introduction: MBNW requires little cooperation beyond steady breathing, but some subjects (eg. children) may breathe irregularly. Historical studies examine the effect of changing respiratory rate and depth on ventilation distribution indices1,2 have contradictory findings. We aimed to examine the impact of rate and depth of breathing on Lung Clearance Index (LCI), and 2 indices of ventilation inhomogeneity (Sand and Sncut).

Methods: Each subject performed at least 3 MBNW tests at each of 3 breathing patterns (BP). A visual signal provided a frequency target and an auditory signal guided tidal volume (Vt). We compared mean LCI, Sand and Sncut between the different BP using repeated measures ANOVA. Sensitivity analyses were performed with and without outliers for validation.

Results: We studied 19 healthy adults but excluded 2 for technical reasons. There were significant differences in LCI and Sncut with BP (p<0.001), but no significant differences in Sand (p=0.117). Increasing Vt from 0.6 to 1.0 reduced LCI and Sncut. Increasing frequency from 15 to 30 bpm increased LCI and Sncut.

Table 1. Mean (SD) for indices of ventilatory inhomogeneity

<table>
<thead>
<tr>
<th>BP (Vt, f (bpm))</th>
<th>LCI</th>
<th>Sand</th>
<th>Sncut</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0L, 15</td>
<td>7.29 (0.80)</td>
<td>0.011 (0.03)</td>
<td>0.088 (0.037)</td>
</tr>
<tr>
<td>1.0L, 30</td>
<td>7.95 (0.66)</td>
<td>0.016 (0.03)</td>
<td>0.115 (0.056)</td>
</tr>
<tr>
<td>0.6L, 15</td>
<td>8.18 (1.00)</td>
<td>0.021 (0.06)</td>
<td>0.241 (0.208)</td>
</tr>
</tbody>
</table>

Discussion: We confirmed an earlier report on 4 adults that increasing Vt reduces ventilation inhomogeneity within acinar airways1; in contrast we found no effect on Sand. Frequency also influenced some indices of ventilatory homogeneity. We recommend that both Vt and frequency are controlled.

P1143
Impulse oscillometry (IOS) cannot detect vocal cord dysfunction (VCD) in asthma
Laurence Ruane1, Kathy Low2, Kenneth Lau2, Peter Holmes1, Paul Finlay1, Phillip Burdett2, Paul Gey3, 1Dept Respiratory & Sleep Medicine, MMC, Clayton, VIC, Australia; 2Diagnostic Imaging, MMC, Clayton, VIC, Australia; 3Monash Institute of Medical Research, MMC, Clayton, VIC, Australia

Vocal cord dysfunction (VCD) complicates asthma and can be detected using
320-slice CT larynx (Low et al, Am J Resp Crit Care Med. 2011). However, this involves radiation and impulse ocliosmetry (IOS) may be a safe, convenient and non-invasive method to diagnose the condition. We assessed whether IOS may be able to identify VCD correctly diagnosed by CT larynx.

Methods: 42 patients with asthma, matched for age, body mass index (BMI) and baseline pulmonary function parameters were studied. 21 had evidence of VCD detected by 320-slice CT larynx. All patient had spirometry and IOS immediately following CT and relevant parameters were compared between patients with and without VCD.

Results: The groups were well matched but none of the IOS measurements differed between the groups. Mean values were virtually identical for all parameters and post-bronchodilator values were also similar.

Mean and SD of PFVs and IOS parameters were similar.

P1145

Relationship between FVC and respiratory muscle strength in patients with amyotrophic lateral sclerosis (ALS)

Guilherme Fregonesi,1 Palomoma Russell Saldanha Araújo1, Tahitana Lindemberg Ferreira Macêdo1, Mario Emílio2, Selma Bruno1, Vanessa Resquest1, Armelle de Fátima Dominela de Andreiá,1 2Physical Therapy, Federal University of Rio Grande do Norte, Natal, RN, Brazil; 2Neurovascular Disease Outpatients Clinics, Hospital Universitário Onofre Lopes - Federal University of Rio Grande do Norte, Natal, RN, Brazil; 3Physical Therapy, Federal University of Pernambuco, Recife, PE, Brazil.

Aim: The aim of this study was to analyze the relationship between Forced Vital Capacity (FVC) and respiratory muscle strength in Amyotrophic Lateral Sclerosis (ALS) patients and healthy subjects.

Methods: We study 31 ALS patients and 28 healthy subjects by spirometry and respiratory muscle strength measurement. We assessed whether IOS may be a safe, convenient and non-invasive method to diagnose the condition. We assessed whether IOS may be a safe, convenient and non-invasive method to diagnose the condition. We assessed whether IOS may be a safe, convenient and non-invasive method to diagnose the condition.

Discussion: In spite evidence that IOS may differentiate upper and lower airway obstruction, this study shows conclusively that the non-invasive IOS technique cannot identify upper airway narrowing associated with VCD in asthma.

Conclusion: The six-minute walking test (6MWT) is a simple method to evaluate the exercise capacity in patients with pulmonary diseases. The information about exercise ability of patients who underwent antituberculosis treatment is limited. The aim of the study was to evaluate the relationships between the 6MWT, pulmonary function, and quality of life (QoL) in these patients.

Methods: Seventy patients were included in the study. All the patients performed 6MWT. Pulmonary function was studied by spirometry and plethysmography. QoL was studied by St. George’s Respiratory Questionnaire (SGRQ) and UCSD Shortness of Breath Questionnaire (SOBQ).

Results: Seventy patients were included in the study. All the patients performed 6MWT. Pulmonary function was studied by spirometry and plethysmography. QoL was studied by St. George’s Respiratory Questionnaire (SGRQ) and UCSD Shortness of Breath Questionnaire (SOBQ).

Conclusions: The six-minute walking test may be a useful method of exercise capacity in patients cured of pulmonary tuberculosis.

P1146

Pulmonary Function and 6MWT in Patients with Pulmonary Tuberculosis and Correlates with Pulmonary Function and QoL.

Conclusion: The regression equations demonstrated better predictive capability when compared to Enright’s equations, thus supporting the requirement for disease specific regression equations.

Subjects: 352 patient’s data collected. 5 classified with mixed lung disease excluded from analysis due to small sample size. Of the remaining 347 patients, 38 (10.9%) identified as restrictive, 158 (43.5%) obstructive and 151 (43.5%) normal (n=500 p=0.001) and normal (0.500 p=0.001) subjects. Validation analysis demonstrated more accurate disease specific walk distance prediction (Bland-Altman) than Enright (1998) predicted equations.

Conclusion: The regression equations demonstrated better predictive capability when compared to Enright’s equations, thus supporting the requirement for disease specific regression equations.
P1148 Alterations in respiratory mechanics and pulmonary ventilation induced by Chlamydia psittaci
Carola Ostermann, Petra Reinhold.
Institute of Molecular Pathogenesis, Friedrich-Loeffler-Institut, Jena, Germany

Chlamydia psittaci (Cp) is capable of inducing acute pulmonary zoonotic disease (psittacosis) or persistent infection occurring in patients with pulmonary emphysema and/or COPD. To elucidate the pathogenesis of this infection, a defined respiratory model in calves was recently introduced [1] which resembles the situation in humans more closely than mice. This investigation was undertaken to identify pulmonary dysfunctions induced by Cp.

Eighteen calves were inoculated with Cp, whereas another 18 control calves received an uninfected cell culture. Respiratory disorders were characterized non-invasively applying pulmonary function tests from human medicine (i.e. impulse oscillometry and capnography) to spontaneously breathing animals from 7 days before challenge until 14 days post inoculation. Compared to control calves, calves exposed to Cp had significantly increased respiratory resistance at low frequencies (< 5 Hz), while respiratory reactance at all frequencies (3 - 15 Hz) decreased significantly, indicating that both obstructive and restrictive pulmonary disorders were induced by the pathogen. In spontaneous breathing, expiration was more impaired than inspiration. Alveolar hypoventilation was confirmed by decreased tidal volume, increased dead space ventilation, increased FRC, and decreased end-tidal CO2.

In conclusion, this bovine model has been found to be suitable for studying functional host-pathogen interactions in the mammalian lung. Pulmonary dysfunctions assessed in this model provide relevant insights into the pathophysiology of acute respiratory illness induced by Cp. [1] Reinhold P. et al. (2012) PLoS ONE 7(1): e30125.

P1149 Respiratory muscle strength after inhaled short acting beta-agonist administration in stable COPD patients
Alina Cretu, Diana Ionita, Irina Pele, Daniela Jipa, Miron Bogdan. Pulmonary Rehabilitation Center, National Institute of Pneumology, Bucharest, Romania

Background: Complex mechanisms are involved in dyspnoea and exercise intolerance in COPD patients, one of these being the increased mechanical work of respiratory muscles.

Aim: To evaluate the increase in respiratory muscle strength after administration of salbutamol in COPD patients

Subjects and methods: Stable COPD patients performed respiratory muscle strength measurements (maximal inspiratory pressure MIP, maximal expiratory pressure MEP) and body-plethysmography (residual volume RV, functional residual capacity FRC). MIP and MEP were again measured 30 minutes after 400 micrograms of salbutamol was administered.

Results: Twenty stable COPD patients were evaluated: stage II-IV GOLD, mean age 58.5 (±9) years, 17 males, mean FEV1 1.29 L (42.6% of predicted).

Mean respiratory muscle strength values were: MIP 73.8 (±22) cm H2O and H2O and MEP 132.2 (±35) cm H2O. Thoracic hyperinflation was present in all cases: mean RV 231.8% and mean FRC 168.9% of predicted.

A slight increase in respiratory muscle strength was seen after salbutamol administration, without reaching statistical significance: mean MIP value increased to 76.4 cm H2O (by 2.6 cm H2O, p<0.05), mean MEP value increased to 133.15 (by 0.9 cm H2O, p<0.05).

Conclusion: The administration of 400 micrograms of inhaled salbutamol in our stable COPD patients did not significantly improve respiratory muscle strength. Further studies are needed on a larger population of COPD patients with different disease phenotypes.

The results of this study provide a reliable reference equations of MIP and MVV for health Brazilian population from 20 to 80 years old.

P1150 EMG-pattern of respiratory muscles during Muller manoeuvre: Effect of body posture
Marina Segrizbaeva. Laboratory of Respiration Physiology, Pavlov Institute of Physiology, St. Petersburg, Russian Federation

The voluntary maximal inspiratory effort is the manoeuvre requiring participation of the patient, recruitment and coordination of different respiratory muscles. A study was undertaken to describe the pattern of recruitment of inspiratory muscles used in the generation of maximal inspiratory effort in different body postures. 10 young normal human participants took part in this study. Maximal inspiratory mouth pressure (MIP) during Muller manoeuvre was measured in the standing, sitting, right side lying (RSL), left side lying (LSL), supine and head-down-tilt (HDT – 30°) posture. The level of electrical activity of the diaphragm (D), parasternal (PS), sternocleidomastoid (SM) and genioglossus (GG) was studied during Muller manoeuvre in each of body postures. MIP in the standing position was 105.3±12.0 in men and 59.9±10.1 cm H2O in women (control). Both in men and women MIP did not significantly differ from control in the sitting, supine, RSL and LSL. But MIP in HDT was lower by 23% and 27% compared with control in men and women respectively. Integrated EMG activity of D during Muller manoeuvre was near the control in sitting, supine, RSL, LSL and significantly greater in HDT compared with standing. On the contrary, the PS and SM showed the highest level of activation during Muller manoeuvre in standing position, but its activation was significantly lower in HDT (P <0.05). EMG of GG was significantly greater in supine position and HDT while its activation was lower in sitting, LRS and LLS. We conclude that maximal inspiratory effort reflects a complex interaction between several muscle groups and changing in body posture from standing to HDT might influence the activation of different muscles resulted in lower MIPs in HDT.

P1151 Maximal respiratory pressure and maximal voluntary ventilation in Brazilian health population: A multicentre study
Guilherme Freiregen, Palomna Russell-Araujo, Vanessa Resquetti, Ester Silva, Marlene Moreno, Jaisal Nascimento Junior, Larissa Carvalho, Ana Gabriela Cavalcanti, Armele de Fátima Donelum de Andrade, Physical Therapy Department, Federal University of Rio Grande do Norte, Natal, RN, Brazil; Physical Therapy Department, Methodist University of Piracicaba, Piracicaba, SP, Brazil; Physical Therapy Department, Federal University of Pernambuco, Recife, PE, Brazil

Maximal respiratory pressures (MRP) and maximal voluntary ventilation (MVV) are worldwide measures used to assess respiratory muscle strength and endurance. Although there are references values established to Brazilian population different methodological procedure used in previous studies could contribute to wide variation in values published. This study was conducted in three centers in Brazil, Natal-RN, Recife-PE and Piracicaba-SP. Subject was evaluated in relation to anthropometric parameters, physical activity profile, maximal inspiratory/expiratory pressure and MVV. Correlation and multiple linear regressions were used to predicted male and female MRP and MVV equations. We studied 244 subjects (114 male/30 female) distributed in different age group from 20 to 80 years old. The results showed a significantly positive correlation between MIP/MEP and height in female; negative correlation with age in both genders. A positive correlation between MVV, weight and height in male were found; in female, we found a positive correlation with height and negative correlation with age. In the multiple linear regression analysis only age continued to have an independent predictive role for dependent variables in MIP/MEP and MVV.
with physical inactivity. If physical inactivity does depend on muscle strength, a correlation between muscle strength and osteoporosis must exist.

**Objective:** To evaluate how strong peripheral muscle strength is related to the loss of BMD in our COPD population.

**Methods:** Data of 11 patients in a pulmonary rehabilitation program is analysed. BMD at the lumbar spine and hip is determined by dual-energy X-ray absorption (DXA). DXA is performed based upon the patient’s risk profile (long history of corticosteroids). The BMD is expressed as a T score. Isometric quadriceps force (iQF) is assessed by a computerized dynamometer during a voluntary maximal isometric contraction with the hip at 90° and the knee at 60° flexion. The highest value is taken.

**Results:** A significant correlation is found between T score lumbar spine and iQF in 8% of normalised values (R=0.627; p<0.039). iQF is not related to the T score of the hip (p=0.385).

**Conclusions:** Lower BMD in the lumbar spine seems to relate with lower iQF in our COPD population. Strengthening of those quadriceps muscles in this specific COPD patients must therefore best be done in an upright, weight-bearing position during closed chain exercises to stabilise or increase the BMD of the lumbar spine.

**P1153**

**The effect of lung hyperinflation on respiratory muscle strength in COPD patients**

Kevin De Soomer, Hilde Varenberg, Lutje Claux, Wilfried De Backer, Ellie Oostven. Department of Pulmonary Medicine, Antwerp University Hospital, Antwerp, Belgium

**Introduction:** Many COPD patients exhibit hyperinflation, due to premature closure of the airways and loss of lung elastic recoil, which impairs the respiratory muscle function.

**Aim:** To assess the relationship between the degree of lung hyperinflation and respiratory muscle strength.

**Methods:** 46 consecutive male COPD patients referred to the hospital’s pulmonary rehabilitation program underwent lung function testing and assessment of respiratory muscle strength at baseline.

**Results:** We observed a significant negative relationship between iQF and MEP vs the degree of hyperinflation.

**Conclusion:** Because anaesthesia is often required in respiratory research of rodent species, whose influence on respiratory mechanics should be investigated utilizing the non-invasive Impulse Oscillometry (IOS) test.

**Material and methods:** Ketamine/medetomidine combination (study a), followed by urethane two weeks later (study b), were applied for anaesthesia in ten female rats. IOS measurements were taken before and 30 minutes after drug application in each study.

**Results:** Breathing frequency and tidal volume decreased significantly due to anaesthetics in both studies. Results of spectral resistance (R) and reactance (X), all in kPa L⁻¹ s⁻¹, as well as level of significance are presented in table 1.

**Table 1.** Medians (lower; upper quartiles) of R and X before and after medication of ketamine/medetomidine (study a) and urethane (study b)

**Detection of bronchial asthma using impulse oscillation system (IOS) in patients with normal spirometry**

Roberto Lapis, Anna Chiara Ogliari, Alice Bifi, Alessandra Cimino, George Cremona, Servizio di Pneumologia e Fisioterapia Respiratoria, Istituto Scientifico San Raffaele, Milano, Italy

**Background:** The gold standard for the diagnosis of bronchial asthma in patients with a normal spirometry is currently the bronchial provocation test. IOS is a promising technique to assess airway function being simple to perform and able to quantify changes in peripheral airway resistance undetected by traditional spirometry.

**Aim & methods:** In order to assess whether IOS could be useful in detecting asthma in subjects with a normal spirometry, 23 (9 female, mean age 37 SD 17 years) non-smoking patients referred for methacholine challenge testing (MCT) for chronic rhinitis or cough were studied by spirometry and IOS prior to MCT. All tests were performed on the same day in separate study rooms by different technicians blind to the results.

**Results:** Mean baseline FEV1 was 87 SD 10% of predicted. Ten subjects had a positive MCT with a mean PD20 dose of 0.5 SD 0.4 mg ml⁻¹. IOS showed higher baseline R5-20Hz values in MCT+ subjects (0.86±0.71 vs 0.27±0.14 cmH2O/l/s; p<0.05) and higher baseline Peripheral Airway Resistance (Rp) (2.6±1.3 vs 1.4±0.85 cmH2O/l/s; p<0.05). The was a strong negative correlation between baseline Rp and PD20 (r=0.77, p<0.009). The area under the Receiver Operative Curve (ROC) showed a accuracy of 0.78 (C.I.=0.66±0.88) using a cut-off value of 3.01 cm H2O/l/s.

**Conclusion:** We conclude that Rp may be a useful marker in predicting MCT response and provide a screening tool for detecting bronchial asthma.
measurements were strongly related to each other with $r=0.971$ and FeNO (HypAir) ppb; both measurements did not differ between them (paired t-test $p=0.25$). The fumarate combination with other combination products

order according to ERS/ATS recommendations. The subjects exhaled air through a combination of the inhaled corticosteroid, fluticasone propionate, aerosol inhaler (FLUT/FORM). As changes in flow rate have been shown to affect the

calculation of different patterns of topographical heterogeneous obstruction, estimated $R_{aw}$ is in DM on the average 4.3fold higher than in PM. Conclusions: The classical model of parallel connected bronchi of each generation disregards the topography of obstruction that leads to falsely decreased $R_{aw}$ estimation. Spatial heterogeneity of the obstruction is an important factor of $R_{aw}$ increase.

P1160 Processing optimization of exhaled breath condensate previous to the analysis by mass spectrometry
Laura Núñez-Naveira1, Luis Marinas-Pardo1, Beatriz Lema-Costa1, Mónica Flores-Calle2, Irene García3, Cristina Marín-Martínez1.

Respiratory Medicine Unit, CHU A Coruña. Biomolecular Research Institute A Coruña(INIBIC), A Coruña, Spain

The Exhaled Breath Condensate (EBC) is a representative and non-invasive lung sample so the determination of its proteome might be useful to find disease-specific biomarkers. Most of the works published up to the date about this issue describe several problems to identify protein from EBC. Aims: To evaluate three methods of EBC concentration as a pre-processing step for the use of mass spectrometry protein identification. To optimize the storage conditions for the EBC.

Methods: EBC samples were collected with the EcoScreen Device (Viasys GmbH, Germany) and stored at -80°C. Protein quantification was performed by BCA methodology. Sample concentration was performed by lyophilization, centrifugation with Amicon Ultra-2 filters (Millipore) or Reverse phase chromatography with POROS R2 resin. Proteins were identified by mass spectrometry. To optimize the storage conditions for the EBC.

Results: After processing, there were no differences between lyophilization and filtration which yielded an insufficient concentration for mass spectrometry (64.38±25.97; average g/mL±standard deviation). Protein purification was performed by BCA methodolopy. Sample concentration was performed by lyophilization, centrifugation with Amicon Ultra-2 filters (Millipore) or Reverse phase chromatography with POROS R2 resins. Proteins were identified by mass spectrometry.

Discussion: Protein concentration by reverse phase chromatography is necessary to determine the EBC proteome by mass spectrometry. EBC samples should be analyzed within one year period to avoid protein degradation. This optimization is crucial to determine the protein profile in EBC samples from different respiratory pathologies.

P1161 Clinical usefulness of the measurement of percutaneous partial pressure of carbon dioxide in respiratory patients
Takeshi Tanaka1, Takehiko Noma1, Keizo Aita1, Hiroyuki Fukazawa1, Masaki Hagiya2, Kenmesso Kadono2.

Respiratory Medicine, Teikyo University Chiba Medical Center, Ichihara City, Chiba Prefecture, Japan; 2Respiratory Medicine, Moriya Sleep Clinic, Moriya City, Ibaraki Prefecture, Japan

Background: Arterial oxygen (PaO2) and carbon dioxide gas partial pressure (Pco2) conditions due to many causes of respiratory diseases are very important to the respiratory patients. But in practice, usually on admission of the patients,
many clinicians tend to omit blood gas analysis, because this is an invasive, painful, expensive examination and not essential for the adaptation of medical insurance on the treatment of respiratory patients. So, we used a percutaneous carbon dioxide partial pressure (PCO₂) analysis meter (TOSCA™) and measured PCO₂ of respiratory patients and compared these results with the conventional blood gas meter.

**Objectives:** Forty of our respiratory patients who admitted to our clinic because of symptoms. Ten chronic obstructive pulmonary disease, ten pneumonia, ten interstitial pneumonia, ten lung cancer patients were enrolled. We gave them the information on PCO₂ and the benefits of the procedure. The patients gave their consent to participate.

**Methods:** The electrocardiogram (ECG) was performed on the patients’ ear pad. Five patients, after checking their respiration and if they were stabilized, PCO₂ measurements were obtained. The PCO₂, percutaneous 0.5 saturation (SpO₂) and pulse rate on the display were checked and recorded. Then we measured the PCO₂.

**Results:** The correlation between all PCO₂ and PaCO₂ was R²=0.97. If we mentioned full and detail, chronic obstructive pulmonary disease (R²=0.97), pneumonia (R²=0.99), interstitial pneumonia (R²=0.95), lung cancer (R²=0.96) and all data had significant correlations.

**Conclusion:** The measurement of PCO₂ by the TOSCA™ is non-invasive and provides very important information on the patient’s respiratory conditions before the treatment of diseases.

115. Physiotherapy and rehabilitation strategies in respiratory diseases and beyond

P1162

**Aerobic exercise training cannot be prescribed based on predictive heart rate equations in moderate or severe asthmatic patients**

Felipe Mendes1, Renata Tereza2, Andrezza Pinto3, Rafael Steimach4, Alberte Caldas2, Milton Martins2, Celso Carvalho1. 1Physical Therapy, School of Medicine, University of Sao Paulo, SP, Brazil; 2Experimental Physiology, School of Medicine, University of Sao Paulo, SP, Brazil; 3Clinical Immunology and Allergy Division, School of Medicine, University of Sao Paulo, SP, Brazil; 4Cor-Pulmonary Division, School of Medicine, University of Sao Paulo, SP, Brazil.

**Background:** Recent studies have shown that physical training improves exercise capacity and health related quality of life (HRQoL) in asthmatics; however the best way to prescribe aerobic exercise intensity in these patients remains poorly known.

**Objective:** To evaluate if predictive heart rate equations can be used to prescribe exercise intensity in subjects with moderate or severe asthma.

**Methods:** Ninety-eight adults with moderate to severe asthma aged 36 (ranging from 24–53) years were submitted to a symptom-limited cardiopulmonary exercise testing (CPET) and anaerobic threshold (AT) was determined by two independent experienced researchers. The association and agreement between maximum heart rate (HRmax) achieved on CPET and age-predicted Tanaka’s maximum HR (177.0 × age) was observed, respectively, by Pearson’s correlation and intraclass correlation coefficient. Similar analysis was applied between HR determined by CPET and heart rate reserve (FCrest + 0.5 × HRmax-HRrest), widely used to estimate exercise intensity at AT.

**Results:** Maximal HR obtained by CPET was significantly lower than age-predictive equation (177.0 vs. 182.8 bpm, respectively, p<0.05). There was a weak correlation (r=0.001; ICC=0.06) between the achieved and estimated HRmax. At anaerobic threshold the HR obtained by CPET was similar to HR predicted equation (128 vs. 131 bpm, respectively, p>0.05). However, no correlation or agreement was observed between the HR (p>0.05).

**Conclusion:** Exercise prescription for adults with moderate or severe asthma should be determined directly by an exercise test instead of using age-predicted equations.

P1163

**Evidence for single limb exercise in patients with COPD or chronic heart failure**

Andre Nyberg1, Britta Lindström1, Karin Wadell1,2. 1Department of Public Health and Clinical Medicine Division of Medicine, Umeå University, Umeå, Sweden; 2Department of Community Medicine and Rehabilitation, Physiotherapy, Umeå University, Umeå, Sweden.

**Background:** Although single limb exercise (SLE), i.e. training using one arm and/or one leg at a time, has been used in patients with COPD or chronic heart failure (CHF) the evidence for SLE has not been evaluated systematically and remains unclear.

**Objectives:** Our hypothesis was that SLE is beneficial for patients with COPD or CHF. The aim of this systematic review was to investigate the current evidence for SLE compared to any comparator and regarding exercise capacity, quality of life (QoL) or dyspnea in patients with COPD or CHF.

**Methods:** CENTRAL, PubMed and PEDro databases were searched for randomized controlled trials fulfilling inclusion criteria. Extraction of data, evaluation of study quality using the PEDro scale and the Cochrane risk of bias tool was performed by two review authors. Data and evidence for SLE were summarized in accordance with GRADE guidelines.

**Results:** Six RCTs, (two in COPD, and four in CHF) met the inclusion criteria. COPD: Low quality evidence indicates improved exercise capacity but no evidence on dyspnea after one-legged cycling compared to two-legged cycling. CHF: Low quality evidence indicate improved exercise capacity after single limb strength training compared to a control and two-legged cycling and improved QoL compared to a control. Meters walked and some QoL outcomes improved more after two-legged knee extension compared to one-legged knee extension. No differences between regimes on other exercise capacity and QoL outcomes was found.

**Conclusions:** The strength of the overall evidence to support the use of SLE regimes compared to other exercise regimes or control in patients with COPD or CHF is low and further research is requested.

P1164

**Changes in heart rate and blood pressure variability during and following a period of slow breathing**

Chulee Jones, Sherwin Asadi, Arshang Valpoup, David Jones, Otto Burghuber. School of Physical Therapy, University of Khon Kaen, Thailand Department of Respiratory and Critical Care Medicine, Ludwig-Boltzmann-Institute for COPD and Respiratory Epidemiology, Vienna, Austria Department of Respiratory and Critical Care Medicine, Ludwig-Boltzmann-Institute for COPD and Respiratory Epidemiology, Vienna, Austria; Austria School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom Department of Respiratory and Critical Care Medicine, Ludwig-Boltzmann-Institute for COPD and Respiratory Epidemiology, Vienna, Austria

Hypertension is a complication of COPD and there is interest in developing non-pharmacological ways of managing the problem. Training with slow breathing is effective in reducing blood pressure but the physiological mechanism underlying this action is not known. Slow breathing is particularly effective in modulating heart rate variability (HRV) and also affects diastolic blood pressure variation (DBPV). We hypothesised that slow breathing would modify HRV and DBPV and the effects would persist for some time, being the basis of a training adaptation which might be of benefit to COPD patients. Eleven subjects (8 male, age 28-67 years) were recruited, 6 normotensive and 5 with well managed essential hypertension. Subjects breathed at 12 breaths per minute (brpm) then at 6 brpm and finally at 12 brpm, each or 10 min. There were no differences in mean heart rate, systolic or diastolic blood pressures with breathing rate but there were major changes HRV and DBPV during slow breathing, with an increase of power at low a and a decrease at high spectral frequencies. Heart rate was entrained to breathing in younger and normotensive subjects at 12 brpm while the older and hypertensive subjects showed little evidence of this until breathing at 6 brpm. In all subjects the spectral changes developed and resolved over several minutes following each change in breathing rate; DBPV changed more slowly than HRV.

Slow breathing modulates vagal and sympathetic activity which takes time to develop and resolve indicating neuronal plasticity which, with repetition, could be the basis of the anti-hypertensive action of slow breathing training.

P1165

**Effect of percutaneous transluminal coronary angioplasty on deep breathing heart rate variability**

Milena Pelosi Rík Spurillo, Daniela Bassi Dutra, Daniel Eduardo Cunha Leme, Rodrigo Jorge Lobo, Vivian Maria Arakelian, Flavia Rossi Caruso, Audrey Borghi-Silva. Interunidades Biosenhenbarse, Universidade de Sao Paulo -USP, Sao Carlos, SP, Brazil Fisioterapia, Universidade Sao Francisco - USF, Bragança Paulista, SP, Brazil Fisioterapia, Universidade Federal de Sao Carlos - UFS/car, Sao Carlos, SP, Brazil.

**Background:** Coronary angioplasty (PTCA) is a common treatment method in patients with coronary heart disease, but its effects on deep-breathing heart rate variability (HRV) has not been well established.

**Objective:** The aim of the study was to analyse deep breathing heart rate variability, which reflect the sympathovagal control of heart rate in patients before, after 1 and 30 days of elective PTCA.

**Methods:** The study consisted of 10 consecutive patients (7 men, 3 women) with age of 62±11.6 years, single-vessel coronary artery disease (CAD) who underwent elective coronary angioplasty with stent implant. Heart-rate variability (HRV) was obtained at rest (spontaneous breathing) and during respiratory sinus arrhythmia maneuver (RSA-M) by heartfrequency (Polar S810) before, after 1 and 30 days of PTCA. RSA-M consisted of deep-breathing in 6 respiratory cycles per minute. HRV analyses were obtained by the time, frequency-domain (high frequency- HF, and low frequency-LF) and non-linear methods (triangular R-R intervals-RRin and Approximate Entropy -ApEn).

**Results:** The PTCA did not induce changes during deep-breathing when compared to spontaneous breathing in the time domain indices (P>0.05). However, before
of PTCA higher values of BF/AF ratio were observed (P<0.05). Interestingly, deep-breathing increased RR-tri only before and after 1 day of PTCA (P<0.05) and ApnI decreased only after 1 month (P<0.05).

**Conclusion:** Patients with CAD presented sympathetic activation before PTCA, which produced altered responses during deep-breathing after the procedure.

**P1166**

Does music affect fatigue perception during exercise in COPD patients? 

**Gregory Reychler 1, Laura Corsetti 2, Luciano Comelli 2, Francesca Carotenuto 2, Emmanuelle Walterlian 2, Thibault Coppens 1, Roland Maeselle 1, Thierry Pieters 1, Gilles Cayt 1, Giuseppe Listro 1, \*Pulmonology, Cliniques Universitaires Saint-Luc (UCL), Brussels, Belgium; \*Physical Medicine and Rehabilitation, Cliniques Universitaires Saint-Luc (UCL), Brussels, Belgium

**Introduction:** Performing daily life activities is difficult for many COPD patients. Pulmonary rehabilitation (PR) is useful to improve exercise tolerance. If dyspnea remains the primary debilitating symptom associated with COPD, fatigue is also frequent in patients suffering from lung disease, especially during and after physical activity. The influence of music on dyspnea was previously reported. The aim of this preliminary study was to observe the influence of music on fatigue during pulmonary rehabilitation sessions.

**Material and method:** 12 COPD patients regularly attending our PR program were recruited (age:63.9 y.o. ± 13.0). Fatigue was measured during two sessions by a questionnaire comprising 8 items. Investigation was performed during two separate sessions with or without music. PR exercises were the same during both sessions.

**Results:** There was no difference in total fatigue score (16.7±4.7 vs 17.1±5.0; p = 0.58). The 8 items were not different between both sessions. Except for two items, anxiety and activity 63.7%, impact 35.6%.

**Conclusion:** In this preliminary study, we have shown that music does not influence fatigue perception during a PR session.

**P1167**

The results of a rehabilitation program including inspiratory muscle training in COPD patients

Lucia Marinescu, Alina Croitoru, Diana Ionita, Irina Pele, Dana Anghelescu, Andrea Dumitrescu, Daniela Gologanu, Alexandra Diaconescu, Carmen Stoicescu, Miron Bogdan. Pulmonary Rehabilitation Center, National Institute of Pneumology, Bucharest, Romania

**Background:** Respiratory muscle impairment could contribute to dyspnea, exercise intolerance and diminished quality of life in COPD patients.

**Aim:** To evaluate the results of a pulmonary rehabilitation (PR) program that includes inspiratory muscle training (IMT) in COPD patients.

**Methods:** Activity 63.7%, impact 35.6%. The ongoing review method of these patients needs further consideration.

**Results:** We included 20 COPD patients, stage II-IV GOLD, mean age 63 years, 16 males, mean FEV1 1.27 L (44.7% of predicted). Mean values for the measured parameters were: MIP 63.9 cm H20, 6MWT distance (6MWTD) 407.1 m, dyspnea MRC score 3.05 points and SGRQ score 46.5 (symptoms: 10.1; activity: 8.4; impact: 27.1). There was a significant improvement in the following mean values at the end of PR program: MIP increased by 9.6 cmH2O (p=0.005) and 6MWTD by 55 m (p=0.001); dyspnea score decreased by 0.75 (p=0.001). SGRQ score un-significantly decreased by 4.9 points (p=0.05). A greater improvement of MIP was seen in stage III-IV patients (12.5 cm H20) compared to stage II patients (8.6 cm H20).

**Conclusions:** Our rehabilitation program including general and inspiratory muscle training led to a significant improvement in inspiratory muscle strength, walking distance and symptoms. The greater improvement in respiratory muscle strength in severe and very severe COPD patients will be verified in a larger population study.

**P1168**

Chronic obstructive pulmonary disease (COPD) patient experiences of pulmonary rehabilitation (PR): A longitudinal qualitative UK study

Julian Lewis 1, 2, Anne Bruton 1, Maggie Donovan-Hall 3. 1Faculty of Health Sciences, University of Southampton, Hampshire, United Kingdom; 2Community COPD Team, Solent NHS Trust, Southampton, Hampshire, United Kingdom

**Introduction and Background**

Attendance at PR in the UK is sub-optimal. Reasons for this have been explored. However, patient experiences have rarely been explored longitudinally through a PR programme regardless of patient participation. Furthermore, limited research has been performed in patient experiences of PR in primary care.

**Aims and objectives:** This research aimed to explore COPD patient experiences before and after PR, whether they completed, did not attend, or dropped out of PR.

**Method:** Fifteen participants were interviewed before and after PR regardless of patient completion. COPD patients were recruited from 2 Primary Care Trusts in the UK. Data were collected during semi-structured interviews using phenomenological research methodology.

**Results:** Of the 15 participants, 8 completed and 7 did not complete PR. Participants experienced uncertainty with regard to COPD, the care they received, PR, and their comparison with others. Prior to PR, uncertainty manifested itself in patients’ experience of panic and vulnerability. The experience of uncertainty reduced following PR programme completion. Non-completers seemed angry with their care, less able to cope with comorbidities or wished to remain naïve regarding COPD.

**Conclusion:** Patient experiences of PR in primary care have been explored. Uncertainty was experienced by participants prior to PR which reduced following PR completion. Completers appeared better able to cope with comorbidities than non-completers. The importance of social comparison in PR requires further research.

**P1169**

The effectiveness of carrying out 6 month and 1 year re-assessments for respiratory patients post pulmonary rehabilitation

Leandro Cruz Mantoani 1, 2, 3, Karina Couto Furlanetto, Juliana Zabatiero, Demétria Koveliš, Maria Praevena, Andrea Morita, Juilly Felici, Fabio Pitta. Laboratório de Pesquisa em Fisioterapia Pulmonar (LFP) - Departamento de Fisioterapia, Universidade Estadual de Londrina, Brazil

**Introduction:** Pulmonary Rehabilitation (PR) Re-assessment groups are offered at 6 months and 1 year post completion of PR. The purpose is to review patients current health status, monitor exercise tolerance, mood and quality of life and check compliance with self management skills taught in PR.

**Aim:** To determine the level of attendance at 6 months and 1 year re-assessments in order to establish whether this is an effective method of review, both for the patient and Community Respiratory Team.

**Methodology:** All patients who completed PR were invited to re-assessments at 6 months and 1 year post PR. The number of patients who attended were recorded.

**Results:** 262 patients completed PR between January 2009 and December 2012. 40 patients were excluded from assessments and analyses at the 6 months re-assessments due to staff shortages and severe weather. 13 patients (6 at 6 months and 7 at 1 year) had died and also excluded.

**Conclusion:** These data indicate a drop of 23% in attendance at the 1 year re-assessment (from 6 months) therefore suggesting this may not be the most effective method of review and furthermore provides reasonable evidence to support a re-evaluation of the 1 year re-assessment. There is cause to ensure review of those not attending reassessments as they are at high risk of poor self management and the ongoing review method of these patients needs further consideration.

One year follow-up after a program of physical activity promotion in smokers: Preliminary results

Leonardo Cruz Mantoani 1, 2, 3, Karina Couto Furlanetto, Juliana Zabatiero, Demétria Koveliš, Maria Praevena, Andrea Morita, Juilly Felici, Fabio Pitta. Laboratório de Pesquisa em Fisioterapia Pulmonar (LFP) - Departamento de Fisioterapia, Universidade Estadual de Londrina, Brazil

**Background:** Programs to promote the increase of physical activity in daily life (PADL) have generated growing interest aiming to prevent the deleterious effects of physical inactivity. Recent literature has shown that a short-term protocol using pedometers (or step counters) was able to increase PADL in apparently healthy smokers. However, the long-term effects of such a protocol were not yet studied.

**Objectives:** To evaluate the results of a 1-year follow-up after a program aimed at increasing PADL in smokers.

**Methods:** 43 smokers without lung function impairment were studied (20 males; 52 [48-58] years; 20 [20-30] cigarettes-day). The 5-month program used infor- mative booklets and pedometers in order to achieve a goal of 10000 steps/day. Subjects were assessed at baseline, immediately after the end of the program, six months and one year later. Outcomes were PADL assessed for one week at each assessment point, besides five-minute walking distance (6MWMD), smoking habits and quality of life.

**Results:** Immediately after the program there was significant increase in steps/day (from 4379 [3476-5632] to 9563 [5632-11021] vs 10694 [8402-12482]; mean improvement of 2641 [452-4364] steps/day), together with improvements in the 6MWMD and general health status (p<0.05 for all). However, over the 1-year follow-up period (n=14) there was progressive reduction in steps/day when compared to the assessment at the end of the program (after six months: -599 [-3476-1707] and after one year: -1876 [-4297-440]).

**Conclusions:** Improvement in PADL obtained immediately after a program of physical activity promotion in smokers does not seem to be maintained over the long term. Strategies for maintaining these gains are needed.
P1171
Breathing exercises for cardiac surgery patients – A national survey of clinical practice

Elisabeth Westerdahl 1,2, Monika Fagevik Olsén 1,3
1 Department of Physiotherapy, Örebro University Hospital, Örebro, Sweden; 2 School of Health and Medical Sciences, Örebro University, Örebro, Sweden; 3 Institute for Neuroscience and Physiology, University of Gothenburg, Göteborg, Sweden

There are differences in routines concerning recommendations of breathing exercises for cardiac surgery patients in EU countries. Physicians may be influenced by scientific literature, local routines, or current practice.

Aim: The aim of this national survey was to determine current practice of chest physiotherapy and breathing exercises for cardiac surgery patients in Sweden.

Method: A total population sample was identified and postal questionnaires were sent to the 33 physiotherapists working at the departments of thoracic surgery in Sweden. Structured and open-ended questions were asked about the routine care of patients undergoing cardiac surgery.

Results: In total, 29 replies were received. All physiotherapists instructed the patients to perform postoperative breathing exercises hourly, on a regular basis. Postoperative physiotherapy and breathing exercises was used as first choice treatment by 83% of the physiotherapists. Instruction how to perform the breathing exercises as well as the frequency and duration of exercises differed between physiotherapists. Recommendation to continue breathing exercises after discharge was given by 66% of the physiotherapists, but how long the patients were recommended to continue the breathing exercises varied from 1 to 3 months.

Conclusion: This survey provides an initial insight into chest physiotherapy management in Sweden. The routine use of breathing exercises is universal during the first postoperative days, but choice of breathing exercises and number of treatment sessions varied. Comparison with treatment regimens in other countries is warranted to improve the postoperative management of the cardiac surgery patient.

A total of 24 CF patients: age (12±3.7 years); BMI (18.3±3); FVC (97±20%pred); FEV1 (93±20%pred) answered a questionnaire specifically designed to evaluate the usability and management of the video game platforms for exercise training. Patients played three different video games Wii Fit Plus (Wii-Fit); Wii Family Training (Wii-Train) and Wii Active (Wii-Act). After this protocol they were asked about their feelings and impressions about them.

The questionnaire showed that video game platforms are usable in child environment (85.7%), they play about 1-4 days per week (50%), they spend playing about 1-2 hours per session (87%), and the main goal is to have fun (79%). During the protocol, the platform that the children liked the most was the Wii-Fit (42%) followed by the Wii-Act, and they considered both a good system to practice exercise at home (83.3%).

The video game platforms represent a common element in CF children and teenagers lifestyle. They use this type of platforms frequently and they show highly motivated to incorporate them as a training modality for respiratory rehabilitation programs at home.

P1174
Video game exercise effectiveness of a domiciliary respiratory rehabilitation program in cystic fibrosis (CF) patients

Tamara del Corral1, Roberto Martínez2, Roberto Rabinovich, Vilaró Jordi.

Respiratory Physiotherapy, Asociación Madrileña Contra la Fibrosis Quística (AMCFQ), Universidad Europea de Madrid, Spain Respiratory Physiotherapy, Fundación Lescar, Madrid, Spain ELEGOCollaboratory, U/E/MRC Centre for Inflammation Research, The Queen’s Medical Research Institute, Edinburgh, United Kingdom. Grup de Recerca en Fisioteràpia (GReFis), FCS Blanquerna, Universitat Ramon Llull, Barcelona, Spain

CF is a multisystemic disease characterized by an abnormal ventilation response to exercise, the main limiting factor to exercise tolerance. Exercise training using video games platforms can be a key factor to guarantee the adherence to the respiratory rehabilitation programs. Our goal was to evaluate the efficacy of a domiciliary exercise program using the Wii™ video game platform as a training system in CF patients.

The study included 7 CF patients: age (11.4±3.9 years); BMI (18.4±3); FVC (78.9±18%); FEV1 (74.7±22%); All performed a domiciliary respiratory rehabilitation program using the Wii™ video game platform with the Active 2 game.

The program consisted of exercise about 30-min every day, 5 days/week during 6 weeks. The measurements evaluated from the beginning to the final were: exercise tolerance using the six minutes walk test (6MWT) and the shuttle test (Shut) and quality of life using the Cystic Fibrosis Questionnaire-Revised (CFQ-R).

The exercise program improved the distance walked during the 6MWT (649 vs 703m) and during the Shut (622 vs 704m) (p<0.05, both), pre vs post respectively. However, the differences between the dyspnea and fatigue perception were not statistically significant. In relation with the CFQ-R, the data obtained from the respiratory symptoms (p=0.045) and physical tendency domains (p=0.047) were statistically significant (p<0.05, both).

The domiciliary respiratory rehabilitation program in CF patients, executed with the Wii™ video game platform, is feasible and can induce significant increases in exercise tolerance and quality of life.

P1175
Respiratory muscle training in impaired elderly: Threshold loading versus Pranayama breathing exercises

Maria dels Àngels Cebrià i Iranzo1, David Alan Arnall2, Celedonia Igual Camacho1, José Manuel Tomás3.
1 Department of Physiotherapy, University of Valencia, Valencia, Spain; 2Department of Physical Therapy, East Tennessee State University, Johnson City, TN, United States; 3Department of Behavioral Sciences Methodology, University of Valencia, Valencia, Spain

Introduction: In the older elderly, the respiratory function may be seriously compromised when the decrease of respiratory muscle (RM) strength coexists with comorbidity and immobility syndrome. The aim of this study was to determine the effectiveness of RM training using the Threshold IMT device, or Pranayama breathing exercises vs. a control group in impaired elderly. Our general hypothesis was that RM training would improve RM function among this population.

Methods: Institutionalized elderly, who were unable to walk, were allocated randomly into three groups: a control group and two experimental groups (Threshold and Pranayama). Experimental groups performed a supervised interval-based training protocol, either through respiratory threshold loading or Pranayama breathing exercises, which lasted six weeks (5 days per week). Maximum respiratory pressures (MIP and MEP) and Maximum Voluntary Ventilation (MVV) were measured at four time points: pre-training, intermediate, post-training and follow-up (weeks 0, 4, 7 and 10, respectively).

Results: Seventy-one residents (90% female, mean age 85) completed the study: Control (n=24); Threshold (n=23); Pranayama (n=24). There was a significant treatment effect on the MIP (F(2,206)=4.75, p<0.001, n=20.166), MEP (F(6,204)=4.257, p<0.001, n=20.111) and MVV (F(6,204)=3.522, p<0.001, n=20.135).

P1173
Analysis of the usability and motivation of the use of video game platforms as a training system in patients with cystic fibrosis (CF)

Tamara del Corral, Roberto Martinez, Peregonca Janaina, Melgosa Seborga, Vilaró Jordi. Respiratory Physiotherapy, Asociación Madrileña Contra la Fibrosis Quística (AMCFQ), Universidad Europea de Madrid, Spain. Respiratory Physiotherapy, Fundación Lescar, Madrid, Spain. FCS Blanquerna, Grup de Recerca en Fisioteràpia (GReFis), Universitat Ramon Llull, Barcelona, Spain

Objective: To determine the effectiveness of a domiciliary respiratory rehabilitation program, the Threshold IMT device, or Pranayama breathing exercises vs. a control group in impaired elderly. Our general hypothesis was that RM training would improve RM function among this population.

Methods: Institutionalized elderly, who were unable to walk, were allocated randomly into three groups: a control group and two experimental groups (Threshold and Pranayama). Experimental groups performed a supervised interval-based training protocol, either through respiratory threshold loading or Pranayama breathing exercises, which lasted six weeks (5 days per week). Maximum respiratory pressures (MIP and MEP) and Maximum Voluntary Ventilation (MVV) were measured at four time points: pre-training, intermediate, post-training and follow-up (weeks 0, 4, 7 and 10, respectively).

Results: Seventy-one residents (90% female, mean age 85) completed the study: Control (n=24); Threshold (n=23); Pranayama (n=24). There was a significant treatment effect on the MIP (F(2,206)=4.75, p<0.001, n=20.166), MEP (F(6,204)=4.257, p<0.001, n=20.111) and MVV (F(6,204)=3.522, p<0.001, n=20.135).

P1172
An effect of the home-based rehabilitation programme following the outpatient rehabilitation programme in patients with pulmonary sarcoidosis

Jakub Žačalík1,2, Katerina Neumannova1, Vladimira Lostokova1, Vincenc Holub1,2
1 Department of Physiotherapy, Faculty of Physical Culture, Palacky University, Olomouc, Czech Republic; 2 Department of Pulmonary Diseases and Tuberculosis, Medical Faculty and Teaching Hospital of Palacky University, Olomouc, Czech Republic

Background: Definition of the pulmonary rehabilitation (PR) precisely describes how such a programme should be established and what parts should be included. However, the programme should motivate patients to keep it at and thus to prolong the beneficial effect of it.

Aim: To evaluate an effect of a 6-week home-based PR following a 6-week outpatient PR on health-related quality of life (HRQL) in patients with pulmonary sarcoidosis (PS).

Methods: There were 18 patients with PS (mean age 50.3±11.3) recruited to the PR programme. The assessments included lung function tests, maximal inspiratory (MIP) and expiratory (MEP) mouth pressures, chest expansion, 6-minute walk test (6MWT) and HRQL using the Sarcoidosis Health Questionnaire. Patients underwent a 6-week outpatient PR followed by a 6-week home-based PR programme, which both consisted of respiratory physiotherapy and regular physical activity training.

Results: Baseline data showed decreased breathing muscle strength (MIP 89%, MEP 65%), limited chest expansion and relatively normal results in 6MWT (105% of predicted). Completing outpatient PR programme induced statistically significant changes in all measured parameters but lung function tests. Further significant improvement was observed in MIP during the following home-based PR programme.

Conclusion: Achieved improvements of the 6-week outpatient PR remained also after the 6-week home-based PR and therefore patients should be encouraged in continuing the PR programme at home.

Supported by grants of the Palacky University – FTK-2011010, FTK-2012023.
Conclusion: Pranayama training group works differently and significantly better than the other two groups, and may be therefore, a powerful alternative to general exercise conditioning in order to improve RM function (strength and endurance) in the elderly population with a significant loss of mobility and exercise capacity.

P1177
Impact of body position in premature newborn receiving nasal CPAP

Marita Brodmann1, Francisco Martinez2, Physiotherapy, University of Franca, SP, Brazil; 2Pediatrics, Faculty of Medicine University of Sao Paulo, Ribeirao Preto, Brazil

Introduction: The body position affects the cervical-thoracic-abdominal biomechanics and has impact on lung ventilation and perfusion. The impact of body position during CPAP is not well recognized.

Objective: To evaluate the clinical impact of the prone and supine positions in newborn preterm infants breathing without support or on nasal CPAP.

Methods: Thirty two preterm infants with GA from 26 to 35 weeks, BW < 2.75 kg and bronchopulmonary dysplasia were recruited. Infants were separated into two groups in use of nasal CPAP (n=16) or breathing without any support (n=16). Body position (pronation and supination) was changed following a random order. Preterm stand at each decubitus for one hour, and respiratory rate, oxygen saturation, heart rate and Silverman-Andersen bulletin (SA) were registered every ten minutes.

Results: The 16 infants of the nasal CPAP group presented GA of 30±2.0 weeks, BW of 1.53±2.81g, 56% were male and had 3±2.4 days of life at study. The 16 infants without breathing support presented respectively 33±1.5 weeks, 1.77±2.38 g, 37% were male and had 4±1.5 days of life at study. Clinical parameters of infants in nasal CPAP were not influenced by body position. Infants breathing without support presented at prone position better parameters, but with small clinical relevance, regarding oxygen saturation (95% ± 1.6 vs 94% ± 3.1, p=0.01) and SA (0.2±0.4 vs 0.7±0.6, p=0.01).

Conclusion: No difference in clinical parameters were found after changing the postural position in infants at nasal CPAP. When infants were breathing without support, prone position showed a small but statistically significant improvement in oxygen saturation and SA bulletin.

P1178
Comparative evaluation of vibrocompression and bag squeezing: A randomized study

Letícia Mattis, Livia Freitas, Suzilaine Bacci, Lilian Abreu, Lucio Araújo, Célia Lopes, Physiotherapy Department, Clinical Hospital of Federal University of Uberlandia, MG, Brazil; 2Physiotherapy Department, Clinical Hospital of Federal University of Uberlandia, MG, Brazil Physiotherapy Department, Clinical Hospital of Federal University of Uberlandia, MG, Brazil Physiotherapy Department, Clinical Hospital of Federal University of Uberlandia, MG, Brazil Physiotherapy Department, Federal University of Uberlandia, MG, Brazil; 2Faculdade de Medicina, Pontificia Universidade Católica do Rio Grande do Sul, Porto Alegre, RS, Brazil

Introduction: Few scientific evidence has demonstrated the effects of respiratory physiotherapy in intubated children. The clearance maneuvers in mechanical ventilation without tracheal suction presented respectively 33±4.1±1.5 weeks, 1.77±2.38 g, 37% were male and had 4±1.5 days of life at study. Clinical parameters of infants in nasal CPAP were not influenced by body position. Infants breathing without support presented at prone position better parameters, but with small clinical relevance, regarding oxygen saturation (95% ± 1.6 vs 94% ± 3.1, p=0.01) and SA (0.2±0.4 vs 0.7±0.6, p=0.01).

Objective: Analyze and compare the hemodynamic effects, ventilation and respiratory mechanisms of two techniques in intubated children with respiratory failure.

Method: Eleven children with mean age of 28.42±15.42 month were randomized into two groups according to the technique used: (1) Bag Squeezing (BS; n=5) and (2) vibrocompression thoracic (VCT; n=6). All variables were studied before, immediately and 30, 60 and 120min after the maneuvers (p<.05).

Results: For both groups were found similar results, no significant differences. Heart rate and mean blood pressure presented higher in BS group in the post maneuver (p=0.04, p=0.43) compared with pre maneuver. The HR, ETCO2, platelet pressure and static compliance were also higher in the post-manuever in VCT group. There was no significant difference in the other respiratory variables or respiratory mechanics. Significant negative correlation between Rst e Cst was observed in the BS at all the times evaluated (R=0.97, p<0.00; R=89-p<0.04;R=75-p<.00). The same results were observed for VC and ETCO2 post maneuvers (R=.90-p.<.03). In the VCT was found positive correlation between the Rst and the Pp before maneuver (R=97-p<0.43;R=94-p<.00) and 120min post (R=.66-p.<.00) and between VC and ETCO2. There was also a positive correlation between VC and ETCO2 immediately after maneuver (R=.82-p<.04) and 30 min post (R=.87-p<.02).

Conclusion: Both techniques didn’t present changes in hemodynamic and ventilatory responses, even in the respiratory mechanic.

Discussion: To our knowledge this is the first report of patient satisfaction using the innovative LVR bag. 6/8 patients were able to clear sputum more easily after using the LVR bag. 7/8 patients agreed the verbal instructions easy to follow and strongly agreed/agreed that the bag was easy to use. In 7/8 patients, the technique required the assistance of a carer. Our study shows the LVR bag is easy to use and aids patient sputum clearance. Therefore, this technique warrants further investigation in a larger population with a wider range of conditions.

P1179
Experimental model of atelectasis in newborn pigs

Taína Comam1, Renato Fiore2, Humberto Fiore2, 1Instituto de Educação e Pesquisa, Hospital Moinhos de Vento, Porto Alegre, RS, Brazil; 2Faculdade de Medicina, Pontificia Universidade Católica do Rio Grande do Sul, Porto Alegre, RS, Brazil

Background: There are few studies using animal models in chest physiotherapy, moreover, there are no models to assess these effects in newborns.

Aims: The objective of this study was to develop a model of atelectasis by bronchial obstruction in newborn pigs for the study of neonatal physiotherapy.

Methods: Newborn pigs resulting from a cross-breeding between Large White and Landrace, properly sedated, anesthetized, tracheostomized, paralyzed and mechanically ventilated were used. The animals received artificial mucus infusion through an infusion pump, underwent radiological assessment of the lungs and blood gas analysis was performed to confirm the production of atelectasis.

Results: The model showed consistent results between parameters of oxygenation and physiological analysis. The atelectasis model was successfully developed in over 70% of cases, surpassing 90% of attempts in the final phase of the study.

Conclusions: This model of atelectasis showed results consistent enough to be used in studies of chest physiotherapy techniques in newborn pigs.

P1180
Bag-squeezing maneuver in experimental model of meconium aspiration syndrome in newborn pigs

Taína Comam1, Jaqueline Stivanin2, Priscila Padoin2, Humberto Fiore2, 1Instituto de Educação e Pesquisa, Hospital Moinhos de Vento, Porto Alegre, RS, Brazil; 2Faculdade de Medicina, Pontificia Universidade Católica do Rio Grande do Sul, Porto Alegre, RS, Brazil

Introduction: The use of broncho-alveolar lavage (BAL) and surfactant therapy has been tested in humans and in animal models getting promising results as well as Bag-squeezing maneuver has shown good results in adults.

Aims: To evaluate the effects of the combination of Bag Squeezing maneuver with broncho-alveolar surfactant in an experimental model of Meconium Aspiration Syndrome in newborn pigs.

Methodology: Were used in the study newborn pigs (n = 15), ventilated with fixed parameters. After instillation of human meconium 4mg/kg diluted to 20%, the pigs were randomized into three groups: CONTROL-SAM model subjected only to aspiration (n = 5), Grupo BAL-SAM model treated only with surfactant BAL (n = 5), and Grupo BAL + BAG-SAM model treated with BAL with surfactant associated with Bag Squeezing maneuver (n = 5). For the LBA used 15mg/kg of Carafate20 diluted in NaCl (5mg/ml). Blood gases, vital signs and behavior of mechanical ventilation were analyzed throughout the study.

Results: The group that received a BAL + BAG improved blood gas, reduced of airway resistance (p = 0,004) and compliance lung (p = 0.003) better than the other groups with a significant increase in the amount of meconium removed (p = 0.046) with the bag-squeezing maneuver.
Conclusion: The association of Bag-squeezing maneuver can bring benefits to gasometric parameters mechanical ventilation and increase the removal of mucus.

P1181

Comparison of two techniques of chest phisotherapy in experimental model of atelectasis in newborn pigs

Talitha Conanan1, Priscila Padomn2, Jaqueline Stivaninn3, Humberto Fiorin2.

1Faculdade de Educação e Pesquisa, Hospital Mostos de Verons, Porto Alegre, RS, Brazil; 2Faculdade de Medicina, Pontificia Universidade Católica do Rio Grande do Sul, Porto Alegre, RS, Brazil.

Objective: To compare the effectiveness of two techniques of respiratory therapy in an experimental model of atelectasis by bronchial obstruction in newborn pigs.

Methods: 24 pigs sedated, tracheostomized and mechanically ventilated. For the induction of atelectasis, artificial mucus was infused (Polyethylene oxide, Sigma-Aldrich®), USA) using an infusion pump through the tracheal tube. Confirmation of atelectasis was a chest X-ray and by a pressure drop of oxygen in arterial blood. The animals were divided into 3 groups: group 1 that received tracheal aspiration after 20 minutes of confirmation of atelectasis, group 2 underwent the technique of bag squeezing over tracheal aspiration and group 3 underwent vibration chest. To evaluate the effectiveness of techniques one second X-ray was done. To evaluate the changes during the procedures were performed arterial blood gases and pulmonary mechanics evaluation before and after the induction of atelectasis immediately and 30 minutes after the procedure.

Results: The mean percentage change in the PO2 was statistically detect significant between the groups (control: 97.8±37.33, bag squeezing: 166.75±68.63, and vibration: 104.41±45.45, p=0.0048), with improvement in oxygenation in the group undergoing the technique of bag squeezing. The remaining variables did not differ.

Conclusions: The results suggest that the technique of bag squeezing is more efficient than manual vibration chest in these animal model, but clinical improvement was not accompanied by detectable radiological improvement.

Incentive spirometry has been widely used in clinical practice for lung expansion; however, the effect of volumetric (VIS) and flow-oriented IS (FIS) on thoracoabdominal mechanics and respiratory muscular activity in morbidity obese are poorly known.

Objectives: To compare the distribution of pulmonary volumes and inspiratory muscular activity during use of VIS and FIS in obese morbidity.

Methods: Thoracoabdominal mechanics (optoelectronic plethysmography) were evaluated in 17 morbidity obese (54±11 yrs, BMI=21±3.5 kg/m2) simultaneously with respiratory muscular activity (electromyography) during quiet and deep breathing. Lung volume was evaluated using FIS and VIS (randomized sequences). Lung volume was evaluated using total chest wall (CW) and its compartments: abdominal (ABD) and upper (URC) and lower (LRC) ribcage. Muscular activity was evaluated in the sternocleidomastoid (SCM), upper (UIC) and lower intercostal (LIC) muscles. One way repeated measures ANOVA with post hoc Newman Keuls test were used and significance level was set at 5%.

Results: A greater chest wall volume was achieved using VIS compared with FIS (respectively, 1.98±0.7L vs 1.62±0.5L; p=0.02); however no difference was observed in all inspiratory evaluated muscles (SCM=21±4.9 vs 28±6.23±10^3 mV; UIC=9.6 vs 12±12±10^3 mV; LIC=6±2 vs 6±13±10^3 mV; p=0.05). Furthermore, thoracoabdominal asynchrony was observed during use of FIS (phase angle=37±3.8 vs 31±3.6; p=0.001) compared to VIS.

Conclusions: VIS induces greater chest wall volume with lower thoracoabdominal asynchrony in morbidity obese; however, without difference in the inspiratory muscular activity.

P1184

Chest wall motion and siting positions in patients with amyotrophic lateral sclerosis

Cristiana Magalhães1,2, Mauro Vidigal1, Danielle Vieira2, Bruna Vieira2, Verônica Parreira1, Educação Física, Fisioterapia e Terapia Ocupacional, Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil

Respiratory muscle function is progressively altered in patients with Amyotrophic Lateral Sclerosis (ALS) leading to chronic respiratory failure. Moreover, diaphragmatic dysfunction starts to occur in supine position in neuromuscular diseases. Studies that analyze the chest wall motion, with special attention to the contribution of the diaphragm, may contribute significantly to earlier detection of ventilation failure.

Aims: Analyze chest wall motion in supine and sitting positions in patients with ALS and in a sex and age-matched healthy control group.

Method: Ten patients with ALS, aged 54±13 years and 10 healthy controls were included. Motion and volume changes of the chest wall and its compartments: rib cage (inspiratory and expiratory muscles) and abdominal compartment (abdominal muscles) were assessed by the optoelectronic plethysmography (OEP, BTS, Milan, Italy).

All participants were evaluated in supine and sitting positions during five minutes of quiet breathing in each position. Paired t-tests and independent Student t-tests were used, respectively, for intra-group and inter-group analyses. The significance level was set at p<0.05 for all comparisons.

Results: For both groups, the contribution of the rib cage compartment was significantly lower and the abdominal compartment contribution was greater in the supine compared with the sitting position; lower percentages of contribution of the abdominal compartment were observed in the supine position for the ALS group, when compared with controls.

Conclusion: The findings suggested that OEP proved to be a useful tool to identify significant decreases of the diaphragmatic movements in patients with ALS.

Laryngeal response patterns in amyotrophic lateral sclerosis during mechanical insufflation-exsufflation

Tina Andersen1, Magnus Hall1, Astrid Sandvik2, Thomas Halvorsen3, Ole Fredinsson1, John-Helge Heindal1,4, Ole-Bjorn Tynes1, Thomas Carlsen1, Thor-Andre Ellingsen1, Ola Rekstad1,2, Norwegian Centre of Excellence for Home Mechanical Ventilation, Thoracic Department, Haukeland University Hospital, Bergen, Norway; 2Department of Physiotherapy, Haukeland University Hospital, Bergen, Norway; 3Department of Otolaryngology/Head and Neck Surgery, Haukeland University Hospital, Bergen, Norway; 4Section for Pediatrics, Institute of Clinical Medicine, University of Bergen, Norway; 5Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; Institute of Surgical Science, University of Bergen, Norway; 6Department of Neurology, Haukeland University Hospital, Bergen, Norway.

Introduction: Mechanical insufflation-exsufflation (MI-E) is the most effective approach to increase peak cough airflow in patients with neuromuscular diseases, thereby potentially augmenting airway clearance. Co-ordinated movements of the glottis may be crucial for effect in amyotrophic lateral sclerosis (ALS), but laryngeal response patterns to MI-E have not been studied.

Aims: To visualize laryngeal response patterns to MI-E in ALS patients.

Methods: Continuous videorecorded transnasal fiberoptic laryngoscopy (TFL) was obtained in eight ALS patients (two non-bulbar and six bulbar) during MI-E intervention (Cough Assist®, Respironics, USA), applying pressures of ±20 to ±50 cmH2O, and instruction to inhale during insufflation and to actively exhale

116. New insights in the physical assessment and therapy of respiratory patients
and cough during exsufflation. Laryngeal movements were assessed from the videorecordings.

**Results:** In one patient, severe hypopharyngeal obstruction was observed already ≥20 cmH2O. In the remaining patients, hypopharyngeal obstruction was observed during insufflation at 20-40 cmH2O and at 50 cmH2O in four patients, during pressure drop from + to - at 20-40 cmH2O in five, at 50 cmH2O in six, and during exsufflation in all patients, regardless of pressure. Aryepiglottic folds adducted during insufflation in four patients. The response of the vocal cords could not be observed in five patients due to hypopharyngeal obstruction or severe adduction of aryepiglottic folds.

**Conclusion:** Larynx can be studied with TFL during MI-E. Marked hypopharyngeal obstruction was observed during exsufflation and during high insufflation pressures. This may obstruct airflow, potentially disrupting positive effects of MI-E.

**P1186**

Comparison of the impact of laparoscopy and laparotomy on thoracoabdominal mechanics

Dione de Morais Piresani, Adriana Claudina Lunardi, Desidério Cano Porras, Célio Ricardo Fernandes Carvalho. Department of Physical Therapy, Universidade de São Paulo, SP, Brazil

Abdominal surgery impairs respiratory system during the postoperative period. Laparoscopies (LPC) and laparotomies (LPT) are the most used surgical procedures; however, there is not enough evidence regarding the differences of both surgeries on the respiratory mechanics.

**Objective:** To compare the effect of laparoscopy and laparotomy on thoracoabdominal mechanics.

**Methods:** This prospective study enrolled 19 consecutive patients, 9 undergoing LPC and 10 LPT (56±9 yrs, BMI=24±4 kg/m²) that performed chest wall kinematics analysis (optoelectronic plethysmography) before and 2 days after surgery. Patients were evaluated during quiet and deep breathing. Two way repeated measures ANOVA and post hoc Student Newman Keuls test were performed and significance level was set at 5%.

**Results:** Surgical duration was similar between both groups (LPC=229±96 min; LPT=275±104 min; p=0.05). After LPC and LPT surgeries, patients presented similar decrease in chest wall volume at deep breath (respectively, 1.5±0.3 vs. 1.2±0.4L, and 1.6±0.5 vs. 1.1±0.3L; p=0.05). However, LPT induced a decrease in ABD volumes and a greater increase in URC and compared to LPC (respectively, URC 48% vs. 39% and ABD 23% vs. 28% p<0.001), after surgery.

**Conclusions:** Although LPC and LPT promote similar decrease on pulmonary volumes in the postoperative period, LPT induces a greater apical breathing pattern.

**P1187**

Comparison between maximal inspiratory pressures measured by unidirectional valve method and conventional method in healthy subjects without artificial airway

Wellington Yamamori, Marina Luna, Karen Kimoto, Ellen Oliveira, André Albuquerque, Christina Brito. Rehabilitation Service, Sírio-Libanês Hospital, São Paulo, SP, Brazil

The most used method to evaluate maximal inspiratory pressure (MIP) is by maintaining maximum negative pressure forced against an occluded airway (MIPsta). To eliminate the need for collaboration, a new technique was developed using a unidirectional expiratory valve (MIPuni) in patients undergoing invasive mechanical ventilation. The aim of this study was to compare these two methods of measurement in patients with spontaneous breathing without artificial airway. We also tested the intra- and inter-observer reproducibility of MIPuni. The study had a crossover design and twelve healthy volunteers performed the evaluation of MIP of each method in a randomized order. A digital manometer was attached to a mouthpiece (MIPsta) or facemask (MIPuni) and the maximal value in each method was considered. The MIPuni was evaluated by two independent observers (A and B), at two different times (1st and 2nd tests) with an interval of at least one week. MIPuni displayed significantly larger values than MIPsta (106.1±29.3 and 98.4±25.8, respectively; p=0.01). The MIPuni obtained by observer A was not different from that obtained by observer B for both the 1st test (105.9±30.4 and 104.3±26.1, respectively; p=0.32) and the 2nd test (105.5±30.1 and 102.6±31.7, respectively; p=0.24). The MIPuni obtained in the 1st and 2nd tests was not different for both observers A (105.9±30.4 and 105.5±30.1, respectively; p=0.13) and observer B (104.3±26.1 and 102.6±31.7, respectively; p=0.21). MIPuni is the better method for measuring MIP in individuals without artificial airway. The inter- and intra-observer measurements were similar.

**P1188**

Cardiovascular responses to maximal expiratory pressure and salvalsa maneuver in healthy men

Vinicius Minato, Marlius Karsten, Amanda Tiema Shimjo, Isabella Gracindo Pissinato, Audrey Borghi-Silva, Areiped峨 Maria Catu. Physiotherapy, Federal University of São Carlos, Brazil

**Background/Aim:** The respiratory assessment, mainly the measure of maximal expiratory pressure (MEP), has some contraindications because of similarity with the Valsalva maneuver (VM). The objective of this study was evaluated the cardiovascular responses during MEP and identify if this measure reproduces the responses obtained in VM.

**Methods:** 19 healthy men participated in this study, 11 young (23±3 years) and 8 middle-age (45±3 years), divided in two groups – G1 and G2, respectively. They performed the VM (3x) with 40mmHg of oral pressure during 15s, at the sitting position using different mouthpieces (one with a leak of 2mm and another without). The MEP (3x) was performed from total lung capacity, according ATS/ERS in the same conditions of VM. We analyzed during VM and MEP the heart rate variation (ΔHR) and systolic and diastolic blood pressure variation (ΔSBP, ΔDBP). We compared the MEP and Valsalva index (MEPI, VI). ANOVA three-way with Holm-Sidak post-hoc test (p<0.05) was employed to analyse de effect of maneuvers, groups and mouthpiece.

**Results:** We observed that VM have values of ΔSBP (VM: 11±4 mmHg; MEP: 6±6 mmHg), ΔHR (VM: 30±11 bpm; MEP: 22±6 bpm) and indexes (IV: 2.0±0.4; IMEP: 1.5±0.2) were bigger than MEP (p<0.05), independent of the group or the mouthpiece. When we analyzed the groups influence we observed that G2 have higher values of ΔSBP and ΔDBP than G1 (p<0.05), but not to VI and MEPI (p=0.001). The mouthpiece effect was observed only in ΔDBP (p=0.006) and the piece without leak had the biggest values.

**Conclusion:** At the studied condition the MEP does not reproduce the cardiovascular responses observed in VM in healthy men.

**P1190**

Cost effectiveness of an ambulatory oxygen (AO) clinic

Laura Cornish, Fran Dyer, Laura Webb, Julia Bott. Respiratory Care Team, Surrey Community Health, North West Surrey, United Kingdom

**Aim:** Inappropriate oxygen prescription proves costly to the NHS. There is great need to assess and review patients. We run an AO clinic to assess new patients and review oxygen usage. We assessed the cost effectiveness of this clinic.

**Method:** Data from a retrospective audit were analysed for all patients who attended clinic from April 2009 to November 2011. AO needs were assessed as per current guidance. Oxygen prescriptions for any mode (LTOT, SBOT, ambulatory) were reviewed to ensure the patient has the correct modality. HOOFs were amended to reflect correct oxygen usage or cancelled if no longer required. Costs of running the clinic were calculated along with actual oxygen savings to evaluate the effectiveness of this clinic (table 1).

**Results:** Data were available for 251 patients (199 new, 52 reviews). Of the new, 35% (n=70) had a current oxygen prescription. Of these 13% (n=25) did not meet the criteria for the modality prescribed. Of those for review, 71% (n=37) had received AO when they had undergone pulmonary rehabilitation, the remaining 39% (n=15) had been prescribed oxygen.
Muscle function in patients with COPD

Juliana Nalin de Souza Passarini 1,2, Andre Morcillo 1, Lail Zambom 1, Division of Lung Diseases, State University of Campinas, Campinas, SP, Brazil; Universidade Paulista Campinas

Background and objectives: The noninvasive ventilation (NIV) has been the technique chosen for the treatment of acute respiratory failure due to acute pulmonary edema (APE) and exacerbation of Chronic Obstructive Pulmonary Disease (COPD). The objective was to evaluate predictors of success or failure of NIV in an emergency department from Brazil.

Methods: The NIV was in used patients with COPD exacerbation or APE. If no improvement in 2 hours or there is any contraindication to continue with NIV, endotracheal intubation (EI) is performed and considered the endpoint.

Results: A total of 152 patients. On average, the use of NIV was 10 hours for patients with COPD (n = 60) and 7.5 hours for patients with APE (n = 92). It was observed that 75.7% successfully evolved and 24.3% were intubated, and those who progressed unfavorably presented lower oxygen saturation 78.3% compared with those who achieved successfully after NIV, with mean oxygen saturation 84.2%. The findings showed there was a statistically significant difference when researching the APACHE II score and respiratory frequency above 25 in the patients who developed EI. Among patients diagnosed APE, a chance of evolution EI was 63% lower (adjusted OR = 0.37 95% CI: 0.14-0.96). Similarly, higher values of the Glasgow Coma Score (GCS) and oxygen saturation reduce the chance of adverse developments.

Conclusions: The NIV should be used in emergency services in this cases. Variables like oxygen saturation below 80%, respiratory frequency above 25, higher value of APACHE II and among those who received Bilevel may indicate progression to EI.

Muscle function in patients with COPD

Carolina Kosourt 1, Andrade Moretto 1, Lail Zambon 1, Division of Lung Diseases, State University of Campinas, Campinas, SP, Brazil; Universidade Paulista Campinas

Objective: The aim of this study was to make a survey of muscle function in patients with COPD and to relate these findings to health related quality of life.

Methods: One hundred patients with COPD (FEV1% predicted, 43±17, stage II-IV) (59% women) with a mean age of 64±7 years for the women and 67±6 years for the men participated in the study. All patients carried out performance based tests including isometric muscle strength of the quadriceps muscle, hand grip strength, and 30 meter walking test (self chosen and maximal speed). Health related quality of life was assessed with SF-36 and SGRQ.

Results: Muscle strength in the quadriceps muscle reduced 45% in patients with COPD in comparison with a reference group of healthy persons. Comparable values for hand grip strength were 90% and walking speed 74-80%. Maximal walking speed correlated with SF-36 (r=0.38, p<0.001) and SGRQ (r=0.36, p=0.001). Conclusion: Muscle function is generally impaired in patients with COPD, and should be measured in addition to lung function.

Postural changes in children with non-cystic fibrosis bronchiectasis

Babi Umut Türes 1, Hulya Arikan 2, Ugur Ozyelkili 3, Nazan Tagay 4, 1Department of Pediatrics, Faculty of Health Sciences, Ankara, Turkey; 2Pediatric Chest Diseases, Hacettepe University, Faculty Medicine, Ankara, Turkey

Bronchiectasis not caused by cystic fibrosis (CF) is often perceived to be rare in western societies, but seems to be an important cause of chronic suppurative lung disease in the developing world among children. Although, the clinical features, radiological, and histological findings in these children was investigated there is not enough knowledge about the musculoskeletal consequences of the disease.

The aim of this study is to document the musculoskeletal affects of the disease process. 24 patients with non-CF bronchiectasis (mean age 13.2(3.4) years) participated in the study. Anterior, posterior and lateral postural analyses was performed and thoracic kyphosis angle was measured from lateral chest X-ray (4.16.7%) patients had kyphosis (over 35 degrees) and mean angle of thoracic curve was 28.5(5.1) degrees. There was scoliosis in 3 (12.5%) of the children. Bilateral pes planus was present in 8 (33.3%) cases, broad chest deformity in 7 (29.2%), pectus carinatum deformity in 2 (8.3%) and pectus excavatum deformity in 4 (16.7%) patients. 17 (70%) patients had also protracted shoulders. Our results indicate a high rate of postural deformities or adaptations especially in the upper body of the patients with non-CF bronchiectasis. Since the upper body posture is carefully related to the pulmonary functions these changes should be closely monitored as soon as the patients are diagnosed and necessary preventive and corrective physiotherapy programs must be initiated.

Postural changes in children with non-cystic fibrosis bronchiectasis

Luciana Maria Malosá Sampaio 1,2,3, Programa de Mestrado e Doutorado em Ciências da Reabilitação, UFF, Niterói, RJ, Brazil; 1Instituto de Reabilitação da Criança e do Adolescente, São Paulo, SP, Brazil; 2Pediatrie, Instituto de Ciências da Reabilitação, UFF, Niterói, RJ, Brazil; 3Instituto de Ciências da Reabilitação, Nove de Julho University, Sao Paulo, SP, Brazil

Background: Children with non-CF bronchiectasis (n-CF) present postural changes such as pes planus, thoracic kyphosis, and scoliosis which can be related to respiratory symptoms by decreasing chest mobility and increasing respiratory effort. The aim of this study was to evaluate the postural changes in children with n-CF bronchiectasis.

Methods: Twenty patients with n-CF bronchiectasis (mean age 12.8±2.9 years) were studied. We conducted the following procedures: controlled walk test (shuttle test) and heart rate variability. For recording the 360 seconds during the Shuttle Test. HRV was analyzed in the time domain (TD) (SDNN, RMSSD, NN50), and frequency domain (FD) (LF, HF). The SDNN index, the standard deviation of R-R intervals in the time domain; the LF/HF ratio in the frequency domain.

Results: The children with asthma (30-52 years) and fifteen healthy subjects (30-52 years) were studied. We conducted the following procedures: controlled walk test (shuttle test) and heart rate variability. For recording the 360 seconds during the Shuttle Test. HRV was analyzed in the time domain (TD) (RMSSD index, the root mean square of differences between successive R-R intervals), and the SDNN index, the standard deviation of R-R intervals in the frequency domain (FD) from the low frequency (LF) and high frequency (HF) in normalized units (NU) and LF/HF ratio.

Conclusion: It can be concluded that patients with difficult to control asthma showed a reduced HRV compared with healthy during the Shuttle Walk Test with an increase in vagal activity sympatric. Thus, it can be suggested that in future studies, HRV can become a useful tool for parameters in cardiovascular risk stratification in this population, and in the evaluation of different physical therapy interventions to treat these patients.

Chest expansion in preschool-age children with mild bronchial asthma
Katerina Neumannova1, Jakub Zatulock1, Jana Rydlova2, Dana Dvorakova1
1Department of Physiotherapy, Faculty of Physical Culture, Palacky University, Olomouc, Czech Republic; 2Miramonti Children’s Medical Institution, Luhacovice Spa, a.s., Luhacovice, Czech Republic

Introduction: The presence of persistent bronchial asthma (BA) is usually connected with limited chest expansion (CE) [1], but there are no reference values to express if there is a serious limitation.

Aims: To evaluate an effect of a 4-week pulmonary rehabilitation programme (PRP) on CE in preschool-age children with mild BA.

Methods: One-hundred-and-fourteen children with BA (aged 12.0±2.6 years) were examined and recruited for the intervention group (I), which attended a 4-week PRP including respiratory physiotherapy, inhalation, physical activity training in group sessions. Two-hundred-and-eighty healthy children (aged 11.9±2.0 years) were examined and assigned to the control group (C). Both groups underwent a CE assessment, which was performed with a tape cloth measure at the level of 4th intercostal space (IC) and at the level of xiphoid process (XP).

Results: CE of the I group was significantly lower at baseline compared to the C group. After the 4-week PRP a significant improvement was achieved that resulted in a presence of not significant difference between the I and C group in almost all subgroups.

Boys IC 2.0±1.0 < 0.05 5.8±1.6 < 0.05 NS
Boys XP 2.7±1.3 < 0.05 5.9±1.7 < 0.05 NS

Conclusion: The PRP led to a significant improvement of chest expansion in BA children, who had CE previously decreased.

Study was supported by grants of the Palacky University – FTK_2011_010; FTK_2012_023.

Chest expansion in preschool-age children with mild bronchial asthma
Katerina Neumannova1, Jakub Zatulock1, Jana Rydlova2, Martina Slachtova1
1Department of Physiotherapy, Faculty of Physical Culture, Palacky University, Olomouc, Czech Republic; 2Miramonti Children’s Medical Institution, Luhacovice Spa, a.s., Luhacovice, Czech Republic

Introduction: A chronic respiratory disease in adults is often connected with limited chest expansion (CE). We can not find the evidence about CE in preschool-age children at previous published studies and there are no reference values to express if there is a serious limitation.

Aims: To evaluate an effect of a 4-week pulmonary rehabilitation programme (PRP) on CE in preschool-age children with mild bronchial asthma (BA).

Methods: One-hundred-and-three children (aged 5.2±0.7 years) with BA were examined and recruited for the intervention group (I), which attended a 4-week PRP including respiratory physiotherapy, inhalation, physical activity training in group sessions. One-hundred-and-sixty-four healthy children (aged 5.2±0.9 years) were examined and recruited for the intervention group (I), which attended a 4-week PRP including respiratory physiotherapy, inhalation, physical activity training. The MIP and MEP assessment was performed at the baseline and after the PRP. The control group (C) consisted of 208 healthy children (aged 11.9±2.0 years) without any treatment.

Results: The MIP and MEP values of BA children were about the same or lower than those of C group at the beginning of the PRP, but there were no significant differences among the groups (Table 1). A significant improvement of MIP and MEP was observed in BA children after the PRP (Table 2) and furthermore the MIP and MEP values were higher than values in C group (Table 1).

P1200

In vitro comparison of emitted dose with 2 types of nebulizers during non invasive ventilation
Jean-Bernard Michotte, Emilie Jossen, Jan Roesecker, Giuseppe Liistro, Grégoire Reygheler, Physiotherapie, Haute Ecole de Santé Vaud, Lausanne, Switzerland Intensive Care Unit, Cliniques Universitaires Saint-Luc, Brussels, Belgium Pulmonology Unit, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Introduction: Non invasive ventilation (NIV) and inhaled therapy are important components of the medical management of COPD patients. Sometimes, both therapies need to be administered simultaneously. It has been shown that it is feasible and effective to deliver nebulized bronchodilators during NIV.

Objectives: Primary objective was to compare emitted dose (ED) of different types of nebulizers coupled with a single limb circuit bilevel ventilator. Secondary objective was to evaluate the impact of the position of nebulizers on the circuit. Material and methods: Amikacin (500mg in 4 mL) was nebulized by two vibrating mesh nebulizers (Aeroneb®Pro and Aeroneb®Solo, Aerogen, Ireland) and by a classical jet nebulizer (SideStream; Medic-Aid; UK). The nebulizers were connected to a single limb circuit ventilator (Trilogy® 100, Philips-Respirronics, USA), either before (Position 1) or after (Position 2) the passive exhalation port (Whisper Swivel II® Philips-Respirronics, USA). The bilevel ventilator was set in spontaneous mode and connected to a lung model to mimic a COPD patient breathing (RR of 16 breaths/minute, I:E ratio of 1:3 and VT of 400 mL). A filter was interposed between the lung model and the circuit. ED was measured by the residual gravimetric method.

Results:

Table: Emitted dose by nebulizer at each position

<table>
<thead>
<tr>
<th>Position</th>
<th>Aeroneb®Pro</th>
<th>Aeroneb®Solo</th>

Conclusion: Associated with a single limb circuit bilevel ventilator, emitted dose of vibrating mesh nebulizers are greater than jet nebulizer. Moreover to place the nebulizer after the passive exhalation port is optimal for all the devices.
P1201
An initial investigation by electronic survey of current UK physiotherapy practice into the use and delivery of nebulised isotonic saline
Joanna Hobbs, Joy Conway, Deborah Craddock. Faculty of Health Sciences, University of Southampton, United Kingdom

Introduction: Physiotherapy is used widely to assist with airway clearance. Nebu- lised isotonic saline (0.9%) as a method of enhancing airway clearance has become a clinically accepted adjunct to physiotherapy in the treatment of many chronic lung conditions. In current practice, there is little scientific evidence by which to base its use.
Aim: To explore the current UK physiotherapy practice regarding the use and delivery of nebulised isotonic saline.

Sample and Methods: This pilot study made use of a prospective mixed methods survey. A questionnaire was designed, validated and administered electronically to a convenience sample of UK respiratory physiotherapists who were members of the Association of Chartered Physiotherapists in Respiratory Care (ACPR).
Steps were taken to promote reliability and validity of findings and results were analysed using a combination of descriptive and inferential statistics.

Results: The majority of participants (90.3%) agreed that nebulised isotonic saline aids sputum clearance, however no participants thought that there was a strong evidence base. It was noted that there were deviations from the manufacturers guidelines for the use of nebulisers. In addition, findings illuminated that large variations of flow rates for the driving gas used to operate the nebuliser ranging from 50mL to 150mL.

Conclusions: Although a pilot, this study highlights the need for more training on the delivery and prescription of nebulised isotonic saline for respiratory physiother- apists. It also highlights the need for more research into the clinical applications of nebulised isotonic saline as an adjunct to physiotherapy treatment.

117. Nursing led education and follow-up strategies: impact on readmission, self care and patient experiences

P1202
Preventing readmission of patients with COPD
Angela Charlesworth, Rehan Mustafa, Fiona Bates, Tina Stallard, Kathleen Stevens, Rachel Watts, Joan Summerville, Cindy Lightowler. COPD Outreach Service, The James Cook University Hospital, Middlesbrough, Cleveland, United Kingdom

Introduction: According to a recent report by the British Lung Foundation, 1 in 3 people with a COPD exacerbation in the UK are readmitted within 28 days of discharge.

Aim: To reduce readmissions of COPD patients within 30 day subsequent to hospital discharge.

Method: From June 2011, we introduced a telephonic follow up service (once a week phone call by outreach nurses for 30 days), thereby offering extended monitoring and advice beyond standard home visits, for patients sent home with early facilitated discharge. Further home visits were arranged and treatment advice was provided when appropriate. Patients were encouraged to contact the outreach team themselves if needed.

Results: Over the course of subsequent 6 months, 136 patients were sent home with early facilitated discharge. A total of 353 phone calls were made. 11% (n=10) of patients required antibiotics and/or steroids, prescribed by the outreach nurses. Interventions in this group led to 28 additional home visits and 8 telephone consultations. 11% of patients (n=16) were readmitted within 30 days of hospital discharge but only 5% (n=7) of readmissions were due to a respiratory cause. Of the 16 readmissions, 70% (n=11) were admitted out of service hours, of hospital discharge but only 5% (n=7) of readmissions were due to a respiratory hospital discharge.

Conclusion: The telephonic follow up service prevented 15 patients from read- mission with an exacerbation of their COPD. It may be that offering this simple intervention will lead to an improvement in readmission rates for COPD in South Tees. To assess this, we plan to review readmission rates of patients prior to June 2011 and compare them with our current figures.

P1203
Do telephone interventions of patients with COPD prevent readmission?
Marie Løkke1, Dorthe Overgaard1, 2. Department of Pulmonary and Infectious Diseases, Hillerød Hospital, Hillerød, Denmark; 2. Department of Quality, Hillerød Hospital, Hillerød, Denmark

Introduction: In 2009 at Hilleroed Hospital 22% of patients with COPD were readmitted within 30 days and 52% within 84 days. Literature showed that indicators for readmission were: MRC >3, comorbidities, physical inactivity, living alone, poor health-related quality of life and the patients’ need for social support.

Aims: To investigate whether telephone follow-up:
– Reduce number of readmissions
– Increase quality of discharge
– Improve patients’ knowledge

The hypothesis tested is that telephone interventions provide greater security for patients with COPD in order to support self-management and reduce number of readmission.

Methods: A randomized trial were performed with an intervention group (N=115), who was contacted by a nurse & 30 days after discharge. Additional telephone calls were offered if needed. Through appreciated inquiry the patients’ experience due to the admission was clarified. Dialog and providing knowledge were used to support self-management and coping with exacerbations. After 30 days the patients’ answered a question- naire containing generic questions about health status, managing COPD and an evaluation of the intervention. The control group (N=97) was also contacted on day 30 and answered the same questionnaire except questions about evaluation.

SPSS statistics were used to analyze data and SPSS software to create the questionnaire.

Results: The preliminary results indicate that there was no effect on the number of readmissions. The majority of the intervention group felt secure and content knowing that a nurse will provide the enhanced follow-up call. The ability to contact health professionals when needed was important.

Conclusion: Telephone follow-up did not reduce the number of readmissions for patients with COPD compared to a control group.

P1204
Self-care 3 months after COPD patient education: A qualitative descriptive analysis
Camilla Askov Mousing, Kirsten Lomborg. School of Health Sciences, Randers University of Southampton, United Kingdom

Introduction: The literature indicates a conflict between the documented effect of COPD patient education and the patients’ own experiences of the benefit in their everyday life.

Aim: To explore from the patients’ perspective how group patient education influences their self-care three months after completing the program.

Methods: In the period 2009-2010, eleven patients diagnosed with COPD com- pleted an 8-week group education program in a Danish community health center. The patients were interviewed 3 months after completion of the program.

Results: Patients reported that their knowledge of COPD had increased, that they had acquired tools to handle their symptoms; and that the social aspect of patient education had motivated them to utilize their new habits after finishing the course. The data indicate that patients need a “ripening period” to integrate new habits and competencies into everyday life. As a side effect of the study it appeared that the research interview focused the patients’ attention on their newly acquired skills and made them more aware of their enhanced self-care.

Conclusions: Patients’ self-care may be enhanced through group education, even though the patients are not always able to see the immediate outcome. Some patients may require professional help to implement their newly acquired knowl- edge and skills in everyday life. A planned dialogue concentrating on self-care in everyday life 3 months after finishing the course may enhance patients’ awareness and appraisal of their acquired competences.

P1205
Proper inhaler’s technique closely related to proper instruction
Pik Kee, Maggie Li1, Kuen Han Lee1, Lai Fong, Amy To2. 1Respiratory Medicine, Queen Elizabeth Hospital, Hospital Authority, Kowloon, Hong Kong; 2Medicine, Queen Elizabeth Hospital, Hospital Authority, Kowloon, Hong Kong

Introduction: Evidence suggests that many patients don’t use their meter dose inhalers (MDI) correctly and mostly related to improper instruction.

Objectives: It is an observational pre & post-lecture assessment study aims to assess the knowledge and practical competency of the nurses.

Methodology: The assessment items including 4 categories, applicable to only MDI and Spacer inhaler device: 1. patient observation, 2. drug explanation to patients, 3 choice of assisting device, 4. instruction on how to use inhalers or spacer, 5. monitoring the effect & side effect and reporting. Four identical sessions of 1.5-hour lectures including hands-on workshops on inhalers have been held from September to October 2011. Returned demonstration and compulsory audit assessment were required pre and post lectures with 2 months intervals.

Results: 54 nurses completed the pre-lecture audit and 87% were registered nurses. 30% had at least 5 years’ medical experience but none show full competence in demonstrating all 14 steps for MDI and 12 steps for spacer correctly. The mean steps of MDI & spacer are only 5.6 and 6.6 respectively. A total of 32 nurses had attended the lectures and amongst which 26 nurses had performed the pre-and post-audit assessment. A significant improvement is found in mean steps for MDI (4.4 vs. 10.3) and spacer (5.7 vs. 10.25).The overall post-audit mean steps are 10.09 for MDI and 10.43 for spacer respectively (p<0.001) Both post audit assessment had been shown to achieve significantly improvement.

Conclusion: Proper inhaler technique depends on proper instructions. MDI and spacers checklists have been formulated and revised for providing step by step guidance. A regular training workshops and lectures will be held quarterly.
Objective: A multi-disciplinary integrated COPD programme has commenced since 2011 to reduce unplanned readmission and provide post-discharge care. Respiratory-nurse acts as a case-manager for disease management and provision of continuity in nurse-led COPD clinic.

Methodology: COPD Clinical Pathway is being adopted for in-patient recruitment including suspected patients with clinical features of COPD. We stressed on in-haler and spacer technique, appropriateness of the inhaler’s prescription, and early diagnosis detection before discharge. Proper referral will be coordinated for early rehabilitation, home-visit care and advanced specialty care. All recruited cases were scheduled for nurse-visit clinic and subsequent follow-up. The wide range of advanced specialized nursing care are including symptoms assessment, spirometry monitoring, self-care plan education, optimizing inhaler’s using skill and making referral.

Results: 355 in-patients, predominantly male (87.6%), had been recruited and 26.5% are referred to nurse clinic. 20.8% are chronic smokers and over 70% has successfully quit smoking. However 80% were knowledge deficit regarding COPD. 87.3% demonstrated failed inhalers and spacer technique but a significant improvement is found after continuous education. 53% vs. 28.8% (p=0.001). Overall, 92.3% express satisfaction and will continue follow-up in the clinic.

Conclusion: Respiratory nursing care plays a vital role in optimizing therapy and self-home plans management. The long term effectiveness and particularly unplanned readmission rates need to be evaluated in prospective controlled trials.

A national home oxygen service contract review is being undertaken in NHS Scotland and the implementation of a domiciliary oxygen service best practice/guidance Statement. The Respiratory nursing team in NHS Dumfries and Galloway have undertaken a regional review of all patients using any modality of home oxygen. Since March 2011 - 300 patient clinic reviews have been conducted regarding the oxygen prescription in the nurse led clinics.

Findings: Prescription of oxygen is often conducted without establishing that people meet the criteria for this. There is a perception that oxygen is a treatment for breathlessness without assessing for hypoxaemia. Inappropriate prescribing is arising both in primary and secondary care settings. The costs of inappropriate oxygen prescribing are significant.

Outcomes: 50 oxygen concentrators installed for those who met the criteria for LTOT resulting in a saving of £30,000 in previous oxygen cylinder prescribing costs. 30 patients identified who met the criteria for the more efficient Homefill Better technology/equipment that meets service user’s needs is being evaluated both in primary and secondary care settings. The costs of inappropriate oxygen prescribing are significant.

Conclusion: Respiratory-nurse acts as a case-manager for disease management and provision of continuity in nurse-led COPD clinic.

Identification of contributing factors to NIV treatment and NIV usage

Aim: To provide insight into how patients with COPD experience treatment with NIV. To develop new clinical strategies for treatment with NIV based on patients, their relatives and healthcare professionals perspectives.

Methods: A multi-disciplinary integrated COPD programme has commenced in 2011 and 3 of their relatives have been interviewed. Patient interviews revealed 11 patients wanted to be treated with NIV if necessary in the future even though 2 patients described fear during treatment and 10 experienced that all 11 patients expected and wanted to be treated with NIV if necessary in the future even though 2 patients described fear during treatment and 10 experienced difficulties.

Results: The findings suggest that personality traits exert an influence on patients’ self-management behavior and QoL. Due consideration should be given to the contributing factor when providing self-management support.

Chronic lung diseases such as asthma have a great impact on the everyday life of patients. The purpose of this descriptive study was to determine the difficulties experienced by the asthmatic patients in Turkey. Each patient was contacted by 105 asthmatic patients who had been receiving medical therapy in Akdeniz University Hospital. Data were collected through a demographic data form and the questionnaire about the asthma patients’ physical, psychological, social, economic and treatment-related difficulties. The asthma patients in the sample averaged 55.68 years of age (SD 12.29 years, range 18–85) and included most patients who were female (61.9%), married (77.1%), housewife (47.6%) and had completed primary education (40%). Difficulties experienced by the asthmatic patients physically were dyspnea (85.7%), wheezing (82.9%), tiredness (82.9%), cough (76.2%); psychologically were sadness (85.7%), anxiety (64.8%), anger (59.0%), panic (45.7%), social were do not enter to the closed/crowded places (65.7%), do not go to see their relatives/friends, economically were loss of income (36.2%), inability to pay for expensive drug charges (30.5%), inability to pay the hospital fees (14.2%), inability to pay for the treatment (12.4%), treatment-related difficulties were not having an adequate knowledge about the asthma attack (44.5%), not receiving an adequate information about the treatment (32.3%), not being aware of the consequences of the treatment (23.8%). The information gathered from this study led us to reevaluate the healthcare services for asthmatic patients to improve physical, psychological, and social aspects of the nursing care as a whole.
However, the EQ VAS attained significance (rho=0.883, p<0.01) when the analysis was limited to the telemonitoring intervention group.

**Discussion/Conclusions:** It is feasible to use condition-specific (FFSS-11) and generic (WHO-5/EQ VAS) questionnaires with lung CA patients; both generic measures correlated with a tested measure of functional status in telemonitored but not control group. Further study will identify best outcome predictors.

**Over-diagnosis of COPD in UK primary care**

Wai Yee James, David Jolliffe, Kannur Islam, Christopher Griffiths, Adrian Martineau. Centre for Primary Care and Public Health, Barts and the London School of Medicine and Dentistry, Whitechapel, London, United Kingdom.

**Background:** Mis-diagnosis of COPD was reported to be common in Australia primary care practice. We conducted a study to evaluate the frequency of this problem in United Kingdom primary care.

**Objectives:** To determine the prevalence and correlates of mis-diagnosis of COPD and associated prescribing in UK primary care.

**Methods:** The records of COPD patients registered with 47 General Practices in London were searched electronically to identify patients with a ≥15 pack year of smoking history and age group of ≥40.

Spirometry was performed on those who were consented in the Trial of Vitamin D supplementation study, and the characteristics of those who met ATS/ERS spirometric criteria for COPD (FEV1/FVC ratio < 0.70%) were compared with those who did not. Normal spirometry was defined as predicted FEV1 ≥ 80%, predicted FVC ≥ 80% and FEV1/FVC ratio > 0.70%. The prescription among patients who did not meet these criteria was assessed.

**Results:** A total of 264 patients were screened, of whom 232 (87.9%) were confirmed to have COPD by spirometric criteria and 32(12.1%) were not. 10/32 had evidence of restrictive lung disease and 22/32 had normal spirometry. 63/32 patients wrongly diagnosed with COPD were prescribed respiratory medication; 11/32 were prescribed isotretinoin, 13/32 were prescribed a combination inhaler (LABA & ICS), 5/32 were prescribed inhaled corticosteroids, 2/32 were prescribed Xanthine, 21/32 were prescribed inhaled short acting bronchodilator.

Cost of misdiagnosis of COPD in UK primary care and it is associated with a significant degree of inappropriate prescribed respiratory medication. Tackling this problem has the potential to prevent needless adverse effects associated with a significant degree of inappropriate prescribed respiratory medication, and to save costs of inappropriate prescribing.

**Conclusion:** Low weight heat shock proteins play a major role in carcinogenesis of lung cancer, eventually has a prognostic value and may be used as targets for therapy.

**P1214**

**The effect of SDF-I/CXCR4 on expression of VEGF and MMP-9 in small cell lung cancer**

Jian An Huang1, Tao Chen1, Chuan Yong Mu2, Yuan Zeng Gu2. 1Respiratory Department, The First Affiliated Hospital of Soochow University, Suzhou, China 2Biotechnology Research Institute, Soochow University, Suzhou, China

**Objective:** To explore the effect of SDF-I, AMD3100, and LY294002 on expression of VEGF and MMP-9 in NCI-H446 cell, and to explore the mechanism of small cell lung cancer invasion by SDF-1.

**Methods:** There were 5 groups in the experiment: control group (SDF-I negative group); SDF-I 5ng/ml group; SDF-I 10ng/ml group; SDF-I (100ng/ml) + AMD3100 group; SDF-1 (100ng/ml) + LY294002 group. With serum-free medium for 24 hours, to observe the VEGF and MMP-9 expression with different treated conditions using RT-PCR to detect the expression of VEGF and MMP-9, and ELISA to measure the expression of VEGF and MMP-9 in cell culture supernatant.

**Results:** VEGF and MMP-9 expression in supernatants were increased in SDF-1 treated group and could be inhibited by AMD3100 and LY294002. Compared with the control group, 100ng/ml SDF-I treatment could significantly increase the expression of VEGF and MMP-9 was significantly increased. [(826±102) pg/ml VS (360±21) pg/ml, (P<0.05)]; VEGF concentration of SDF-I (50ng/ml)+AMD3100 treated group, SDF-1 (100ng/ml)+LY294002 treated group decreased, [(224±55) pg/ml VS (826±102) pg/ml, (P<0.05)]. In SCLC was significantly increased. [(9) pg/ml VS (6.1±2) pg/ml, (P<0.05)].

**Conclusion:** After treated with SDF-I, the expression of VEGF and MMP-9 was significantly increased, and could be inhibited by AMD3100 and LY294002, which suggested that SDF-I/CXCR4 participate in tumor invasiveness and metastasis in small cell lung cancer by promoting secretion of VEGF and MMP-9.

**P1215**

**Profile of WT1 methylation in human lung cancer**

Pierluigi Bruno, Alberto Ricci, Maria Cristina Esporison, Davide Scocchi, Tana Tabbì, Federica Fiorenti, Giorgia Amira Osman, Salvatore Marritta. Medicina Clinica e Molecolare, UOC Pneumologia, Sapienza, ASp. S. Andrea, Roma, Italy

**Background:** CG island hypermethylation of the promoters of the genes is a well-known mechanism of genetic alteration involved in carcinogenesis. Wilms tumor gene (WT1) is involved in the regulation of human cell growth and differentiation and it is a modulator of oncogenic. K Ras signaling in lung cancer; methylation of WT1 was never studied in human lung cancer. The primary aim of this study is to compare the methylation profile of WT1 promoter in samples of neoplastic and non-neoplastic lung tissue taken from the same patient.

**Methods:** Lung tissue obtained from 16 patients with non small cell lung cancer (NSCLC) and 6 patients with small cell lung cancer (SCLC). The methylation status of 29 CpG islands in the 3' region of WT1 by means of pyrosequencing was investigated.

**Results:** The mean percentage of methylation, considering all CG islands of WT1 in the neoplastic tissues of all NSCLC patients, was 16.2±4.3, whereas in the control tissue from the same patients it was 5.6±1.7 (p<0.001). Adenocarcinomas present grater methylation vs squamous cell carcinomas (p<0.001). In SCLC was not statistically significant difference between neoplastic tissue and control tissue of same patients.

**Conclusions:** Although, WT1 methylation does not seem to play a role in the pathogenesis of SCLC, hypermethylation of WT1 seems to be involved in the carcinogenesis of NSCLC. CHT, histotype, exposure to cigarette smoke are all factors influencing the gene CG islands which become hypermethylated in NSCLC.
P1216

Global histone H3 lysine 4 (H3K4) dimethylation is an important prognostic factor in lung cancer
Yunhao Miao1,2, Yoshinori Ueda3, Miyako Shimazaki3, Motoyus Sagawa3, Tsurumi Sakuma3, 1Thoracic Surgery, 2Pathology II, Kanazawa Medical University, Katsukahg, Ishikawa, Japan

Introduction: Epigenetic modifications may contribute to the development and progression of cancer. This study seeks to elucidate the role of global histone modifications as a clinicopathological factor in lung cancer.

Methods: A series of 92 surgical specimens from patients with lung cancer were utilized from the surgical files of Kanazawa Medical University Hospital between 2001 and 2008. The 92 tumor specimens were examined by immunohistochemistry. Dimethylated histone 3 lysine 4 (H3K4me2), Acetylated histone 3 lysine 9 (H3K9Ac), acetylated histone 3 lysine 18 (H3K18Ac), trimethylated histone 3 lysine 27 (H3K27me3), dimethylated histone 4 arginine 3 (H4R3me2) were assessed. The expression of the above markers was evaluated by Flow Cytometry, and its proliferation were examined by MTS.

Results: Lung cancers of various histologic subtypes showed that dimethylated histone 3 lysine 4 (H3K4me2), acetylated histone 3 lysine 9 (H3K9Ac), acetylated histone 3 lysine 18 (H3K18Ac), trimethylated histone 3 lysine 27 (H3K27me3), dimethylated histone 4 arginine 3 (H4R3me2) were high in tumor cells of 40, 10, 9, 9, 10%. Expression of dimethylated histone 3 lysine 4 (H3K4me2) correlated positively with recurrence (p=0.039) and stage (p=0.005) and cell differentiation (p=0.002). Univariate analysis showed that high expression of dimethylated histone 3 lysine 4 (H3K4me2) correlated with recurrence.

Conclusion: We hypothesize that expression of H3K4me2 may be considered as a significant factor for patients with lung cancer.

P1217

Expression of RASGRF2 in non-small cell lung cancer and its effect of transfection on biological behavior of human NSCLC lines H1299
Xueshuang Gu1, Hong Chen2, 1Department of Respiratory Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China

For RASGRF2 participating in H-ras signaling pathway, it has been identified as one of potential tumor suppressor genes. There are few reports on whether RASGRF2 plays a role in the pathogenesis of NSCLC. Our study was designed to explore the expression of RASGRF2 in NSCLC, and its effectiveness on clinical and biological features. Furthermore, the effectiveness of RASGRF2 on the biological characteristics of NSCLC lines H1299 was considered. The expression of RASGRF2 was detected by SP in cancerous tissues and adjacent non-neoplastic tissues of 48 patients with NSCLC. Of 18 cases, mRNA were detected by RT-PCR. H1299 were transfected with RASGRF2-GFP. The effectiveness of RASGRF2-GFP on mitotic cycle and apoptosis of stable expression ones were evaluated by Flow Cytometry, and its proliferation were examined by MTS. The loss expression of RASGRF2 in cancerous tissues was 54%, but it was 88% in normal tissues (P<0.05). The mRNA of RASGRF2 in normal tissues and cancerous tissues were 0.783±0.5349 and 0.229±0.6512137, respectively (P<0.018). There were no significant differences between the expression of RASGRF2 and gender, age, smoking status, histological types, classifications, lymph node metastasis and stages(P>0.05). The mitotic cycle of transfected H1299, which had stable expression of RASGRF2-GFP, were found blocked at S stage, but the apoptosis and proliferation had no significant changes.

Conclusion: We detected a small portion of CD4+IL17+Foxp3+T cells in the peripheral blood. The frequency of blood Th17 cells and IL-17A levels in plasma were increased in all patients with non-small cell lung cancer. The ratio of Th17 and Treg cells in patients with stage IV were much higher than that in early stage. Particularly, we detected a small portion of CD4+IL17+Foxp3+T cells in the peripheral blood. Patients with Stage IV have much this kind of double positive helper T cells than other groups.

Conclusions: Reciprocal imbalance of Th17/Treg were found in patients with early disease. The elevated Th17 cell and Treg cell responses were associated with advanced disease, which indicated coexistence of Th17 cell and Treg cell instead of reciprocal imbalance was the major part in the antitumor immunity with the progression of non-small cell lung cancer.

P1218

Regulator and effector T lymphocytes in late stages of non small cell lung cancer and chronic obstructive pulmonary disease
Guberska Galina1, Dora Bartussek1, Aron Czeh1, Veronika Papp1, Exter Zeleznak2, Zoltan Suttor2, Barna Vasarhelyi2, Gyorgy Losonczy1
1Department of Pulmonology, Semmelweis University, Budapest, Hungary; 2Department of 1st Pediatrics, Semmelweis University, Budapest, Hungary

The outcome of lung cancer may be determined by anticancer immune response. There are only few data available on how DCs (dendritic cell), effector T, NK cells and various regulatory subsets like Treg-s (foxp3+), or NK T-s respond to lung cancer cell lines which demonstrate the highest glycolytic phenotype; we choose to study representative of adenocarcinoma (e.g. H2030, A549, H1563, H1650), squamous carcinoma (e.g. H249) and SCLC cell line (e.g. SHP-77) to determine the development of carcinoma by interfiting mitotic cycle.

P1219

Reciprocal imbalance or coexistence? The distribution of Th17 and Treg cells in peripheral blood lymphocytes in patients with non-small-cell lung cancer and its significance
Haiying Zhu, Guochao Shi, Wei Tang; Respiratory, Ruijin Hospital, Shanghai, China

Objective: To investigate the distribution of Th17 in relation to Treg in PBMC in patients with non-small cell lung cancer and its significance.

Methods: We analyzed T cells in the peripheral blood of 22 patients with Stage IV, 18 patients with Stage III, 8 patients with Stage I-II and 20 healthy volunteers. The proportions of Th17 and Treg cells in peripheral blood were determined by flow cytometry.

Results: The plasma level of IL-17 and TGF-β were measured by ELISA and the mRNA expressions of RORγt and FOXP3 were detected by realtime PCR.

Conclusions: Reciprocal imbalance of Th17/Treg were found in patients with early disease. The elevated Th17 cell and Treg cell responses were associated with advanced disease, which indicated coexistence of Th17 cell and Treg cell instead of reciprocal imbalance was the major part in the antitumor immunity with the progression of non-small cell lung cancer.

Glycolytic phenotype mapping in lung cancer cell lines
Maya Bouze, Nir Priel; The Thoracic Research and Detection Center, Sheba Medical Center Affiliated to Tel-Aviv University, Ramat-Gan, Israel

Background: It is well established that cancer cell can activate their glycolysis pathway in order to survive in hypoxia micro-environment. Tumors cells show a stinking rate of glycolysis and lactate production, even in the presence of oxygen. Importantly, some cancer cells demonstrate impaired mitochondria respiration and high glycolysis, namely Warburg effect. It is known that most types of cancers fit the “Warburg hypothesis” because a decreased expression of mitochondrial ATP synthase, which is a bottleneck of mitochondrial oxidative phosphorylation. Our overall goal is to profile the lactic acid production in lung cancer cell lines (NSCLC vs SCLC) in order to prototype the glycolytic phenotype that might be used as a diagnostic tool for the early detection of lung cancer.

Study design and preliminary data: Our main steps are: (1) quantify lactic acid production of representatives of NSCLC and SCLC cell lines in order to select lung cancer cell lines which demonstrate the highest glycolytic phenotype; we choose to study representative of adenocarcinoma (e.g. H2230, A549, H1563, H1650), squamous carcinoma (e.g. H249) and SCLC cell line (e.g. SHP-77) (2) measure the glycolysis (e.g.GAPDH and pyruvate kinase) and oxidative phosphorylation...
enzymes (e.g. ATP synthase) level in order to study the glycolytic phenotype of lung cancer cell lines. Our preliminary results indicate that the adenosquamous cell lines, namely A549 and H2300 secreted lactic acid to the medium in concentration of 9.5 and 11.6 mmol/l, respectively.

Impact: Our study could serve as a basis for understanding the glycolytic phenotype mechanism in vitro and therefore for developing diagnosis test for early detection of lung cancer.

P1221
Induced expression of B7-H3 on the lung cancer cells and macrophages suppresses tumor-specific T cell immunity
Jian An Huang 1, Tae Chen 1, Chuan Yong Ma 1, Yuan Zeng Gui 2

Objective: To investigate the effect on tumor invasion and the role of PI3K signaling pathway after the binding of SDF-1 and CXCR4 receptor.

Methods: Flow cytometry (FCM) and RT-PCR were utilized to detect the expression of vascular endothelial-cadherin (VE-cadherin) in different groups to observe the changes of adhesion and invasion ability.

Results: NCI-H446 and H460 cell lines were pretreated with SDF-1 and CXCR4 antagonist AMD3100 and the PI3K inhibitor LY294002. The VE-cadherin expression level correlated with lymph node metastasis. These results indicate that both of them may take part in the growth and invasion of NSCLC.

P1222
The ability of SDF-1/CXCR4 axis to proliferation adhesion and invasion of small lung cancer cell
Jian An Huang 1, Tae Chen 1, Chuan Yong Ma 1, Yuan Zeng Gui 2

Objective: To investigate the effect on tumor invasion and the role of PI3K signaling pathway involved in the proliferation works in the adhesion and invasion of NCI-H446 by CXCR4 activation.

Methods: The clinicopathologic characteristics of 144 patients (73 adenocarcinoma, 71 MPM) were reviewed retrospectively. The tissue samples were evaluated by immunohistochemical staining. The patients who were given adjuvant chemotherapy and/or radiotherapy, with an evidence of residual tumor and who died due to postoperative mortality and due to reasons not related to lung cancer were excluded for survival analysis. Data from remaining 77 patients (37 adenocarcinoma, 40 MPM) were used for survival analysis.

Results: AMACR expression was more frequent in adenocarcinoma group than MPM group (p=0.046). The specificity and sensitivity of AMACR immunostaining in detecting adenocarcinoma were 95.89 and 95.77 respectively. AMACR-positive and negative groups were similar for age, sex, smoking history, tumor diameter, lymph node involvement, tumoral differentiation, T,N factor, and stage. Overall survival was not significantly different between the groups, either.

Conclusion: The specificity and sensitivity of AMACR immunostaining was not high enough to use it as a diagnostic tool in differential diagnosis of MPM and lung adenocarcinoma. AMACR expression did not have a prognostic value in MPM or in adenocarcinoma.

P1224
Ablation of HEDGEHOG pathway enhances apoptosis in lung cancer
Jelena Stojsic 1, Dragana Jovanovic1, Simona Ognjanovic2, Jure Gjura 1

Introduction: Systemic methylation changes may be a diagnostic marker for tumor development or prognosis. We investigated the relationship between gene methylation in lung tumors relative to normal lung tissue, and whether DNA methylation changes can be detected in stored blood samples.

Material and methods: 65 patients were enrolled in a surgical case series of non-small cell lung cancer (NSCLC) at a single institution. Using bisulfite pyrosequencing, CpG methylation was quantified at five genes (RASSF1A, CDH13, MGMT, ESR1 and DAPK) in lung tumor, pathologically normal lung tissue, and circulating blood from enrolled cases.

Results: The analyses of methylation in tumors compared to normal lung identified higher methylation of CDH13, RASSF1A and DAPK in lung tumors compared to normal lung tissue. The lack of reflection of these methylation changes in blood samples from patients with NSCLC indicate their poorly suitability for a screening test.

P1225
Expression of vascular endothelial-cadherin and epithelial cadherin in non-small cell lung cancer and their clinical significances
Jian Tao 1, Hong Chen 2

To assess the expression of vascular endothelial cadherin (VE-cadherin) and epithelial cadherin (E-cadherin) in human non-small cell lung cancer (NSCLC) tissues and to correlate their expression with the clinicopathological characteristics of NSCLC. The expression of them were examined by immunohistochemistry in NSCLC tissues from 97 patients and their adjacent non-neoplastic tissues. The mRNA of them were detected by RT-PCR in 18 specimens. The positive rates of them were 51.5% and 42.3%, respectively. The positive rate of VE-cadherin was higher than that in adjacent non-neoplastic tissues (P < 0.05). The positive rate of E-cadherin was lower than that in adjacent non-neoplastic tissues 67.0% (P < 0.05). The VE-cadherin expression level correlated with lymph node metastasis (P < 0.05), while the E-cadherin expression level inversely correlated with lymph node metastasis (P < 0.05). There were no significant differences between the expression of VE-cadherin, E-cadherin and sex, age, smoking, histological type, differentiation of tumor and TNM stage. The expression of VE-cadherin mRNA in NSCLC tissues and adjacent non-neoplastic tissues were 0.626 ± 0.192 and 0.209 ± 0.602 (P < 0.05). The relative expression intensity of E-cadherin mRNA were 0.700 ± 0.123 and 1.050 ± 0.254 (P > 0.05).
P1226 Expression of vascular endothelial-cadherin and vascular endothelial growth factor in non-small cell lung cancer and their clinical significances  
Tao Chen1, Hong Chen1,2. 1Department of Respiratory Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China; 2Department of Respiratory Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China

To investigate the expression of Vascular Endothelial-cadherin(VE-cadherin) and Vascular Endothelial Growth Factor(VEGF) with the association of clinicopathological characteristics and their correlation in non-small cell lung cancer (NSCLC). Expression of them were examined by immunohistochemical staining in 72 cases of NSCLC patients and their adjacent non-neoplastic tissues, 45 of them were measured by RT-PCR. The positive rates of them in cancer cells were 69.4% and 84.7% respectively, which were higher than the normal tissues(0% and 16.7%) (P<0.01); they were 52.8% and 62.5% in the vascular endothelial cells, which were higher than the normal tissues(20.8% and 29.2%) (P<0.01). In cases without lymph node metastasis, the expression of them in cancer cells and vascular endotheial cells were respectively higher than those in cases without lymph node metastasis. The positive rates of them in III-IV stage were higher than that in I-II stage (P<0.05). There were no significant differences between the expression of them and sex, age, smoking, histological type, differentiation of tumor(P>0.05). The relative expression intensity of VE-cadherin mRNA in NSCLC tissues and adjacent non-neoplastic tissues were 0.62±0.10.182 and 0.44±0.05(P<0.05). The relative expression intensity of VEGF mRNA in NSCLC tissues and adjacent non-neoplastic tissues were 0.27±0.103 and 0.05±0.134(P<0.05). The expression of them in lymph node metastasis were higher compared to that in cases without lymph node metastasis(P<0.05). Our results suggest that VE-cadherin may play an important role in angiogenesis and act in a synergistic manner in NSCLC.

P1227 Increased incidence of Merkel cell polyoma virus in non-small-cell lung cancer  
Katerina Antoniou1, I. Bundschuh2, M. Otokhov3, T. Gudkov2,3, E. Krepischi1, G. Siafakas2, T. Bartz2, N. Engi1. 1Department of Respiratory Medicine, The First Affiliated Hospital of Soochow University, Suzhou, China; 2Biotechnology Research Institute, Soochow University, Suzhou, China

Objective: To determine the incidence of Merkel Cell Polyomavirus (MCPyV) in lung tissues of non-small cell lung cancer patients.

Methods: MCPyV DNA was amplified by nested PCR in 150 lung cancer tissues from patients attending University Hospital, Münster, Germany. The positive rate (PR) and mean PR (±SD) in different stages of lung cancer were calculated. The PR was compared using the χ² test.

Results: The MCPyV prevalence in NSCLC was 7.3% (11/150). No significant difference in the PR was observed between stages I-II (3.3% ± 3.2%) and III-IV (10.0% ± 5.9%). The PR was higher in squamous cell carcinomas (9.7% ± 4.2%) than in adenocarcinomas (4.0% ± 2.0%).

Conclusions: MCPyV is present in 7.3% of NSCLC cases and the PR does not vary significantly by stage.

P1229 The effect of siRNA on invasion capability of small cell lung cancer  
Chul Ho Oak1, Tae Won Jang1, Young Ho Kim2, Maan Hong Jung1. 1Department of Respiratory Medicine, The First Affiliated Hospital of Soochow University, Suzhou, China; 2Biotechnology Research Institute, Soochow University, Suzhou, China

Objective: To determine the effect of siRNA on invasion capability of small cell lung cancer (SCLC).

Methods: Small cell lung cancer cell line NCI-H446 was transfected with four different siRNAs targeting CXCR4. The effect of siRNA on invasion capability of NCI-H446 in vitro was evaluated by transwell chamber model.

Results: Transfection with CXCR4 siRNA led to a significant reduction in cell invasion compared to the control group.

Conclusions: CXCR4 siRNA effectively down-regulated the expression of CXCR4 gene and decreased invasion capability of NCI-H446 cells in vitro.

P1230 microRNA-155 negatively regulates Apaf-1 and enhances sensitivity of A549 to cisplatin  
Yuan-Sheng Zang, Qing-Yu Xiu, Zheng Fang, Bing Li, Jing An. 1Department of Respiratory Medicine, Changhai Hospital, Second Military Medical University/Center for Diagnosis and Treatment of Lung Cancer of the Chinese People’s Liberation Army, Shanghai, China; 2Institute of Environmental Pollution, School of Environmental and Chemical Engineering, Shanghai University, Shanghai, China

MicroRNA-155(miR-155) overexpression is often found in malignancies including lung cancer. The objective of this study is to verify the hypothesis that miR-155 is involved in development and progression of lung cancer by modulating cell apoptosis and DNA damage through regulation on Apaf-1, which is postulated according to the bioinformatics analysis. Firstly, the expression of miR-155 and Apaf-1 protein in the lung cancer tissues were measured. The results showed that expression of miR-155 is significantly higher in lung cancer tissues compared with the paracarcinous tissues. The Apaf-1 protein expression level decreased in lung cancer tissues. Then the miR-155 silenced and Apaf-1 overexpressed A549 cell models were established through transfection with pMAGic2.0-BIC-siRNA and pMAGic2.0-BIC-siRNA-Apaf-1, respectively. The cell apoptosis and DNA damage of different cell models under treatment with cisplatin were assessed, and the untransfected A549 cells were used as negative control. The results showed that silenced miR-155 resulted in elevated apoptosis of A549 cells, but the Apaf-1 mRNA level had no significant difference compared with the control group. Both miR-155 silencing and Apaf-1 overexpression in A549 cells seemed greatly increase the cellular sensitivity to cisplatin treatment as evidenced by elevated apoptosis rate and DNA damage. Further, dual-transfection with both miR-155 siRNA and Apaf-1 siRNA in A549 cells resulted in attenuation and alleviation of cell apoptosis and DNA damage. In conclusion, inhibition of miR-155 can enhance the sensitivity of A549 cells to cisplatin treatment by regulation on cell apoptosis and DNA damage through Apaf-1 mediated pathway.

P1231 The effect of methylene blue in the photodynamic therapy on A549 lung cancer cell lines  
Chul Ho Oak1, Tae Won Jang1, Young Ho Kim2, Maan Hong Jung1. 1Department of Respiratory Medicine, The First Affiliated Hospital of Soochow University, Suzhou, China; 2Biotechnology Research Institute, Soochow University, Suzhou, China

Background: Methylene blue (MB) is a safe and cheap chemical widely used in the medical fields for a long time. MB was recently known to act as a photosensitizer and some clinical trials of using it in the photodynamic therapy on the tumor cell lines were reported. In this study, we investigated the effects of MB as a photosensitizer on the lung cancer cell lines.

Methods: After pretreatment of A549 cells with MB in the concentrations of 1 μM and 2 μM respectively, the cell apoptosis and DNA damage were evaluated.

Results: Out of 290,000 genes, 250 genes were significantly (at least twofold) up-regulation or down-regulation. Differentially expressed genes were categorized into "Top BIO Functions" groups. The three most important groups were "cellular growth and proliferation" (n=80), "cell movement" (n=75), and "inflammation response" (n=65). The observation of a positive association of MALAT-1 gene expression with cellular growth, migration and proliferation was confirmed in vitro with migration assays, colony assays, and scratch assays (p<0.01, all comparisons).

Conclusions: These data demonstrate that enhanced MALAT-1 expression levels stimulate cellular migration, colony formation and wound healing and contribute to the idea of multidimensional effects of MALAT-1 on important cellular functions in malignant lung cells.

P1232 Vascular endothelial-cadherin and vascular endothelial growth factor in non-small cell lung cancer and their clinical significances  
Tao Chen1, Jian An Huang1, Chuan Yong Mu1, Yuan Zeng Gu1, Hong Chen1,2. 1Thoracic Medicine, The First Affiliated Hospital of Soochow University, Suzhou, China; 2Biotechnology Research Institute, Soochow University, Suzhou, China

Objective: To study the inhibitory effect of CXCR4-targeted small interference RNA on invasion capability of NCI-H446 in vitro.

Methods: To design chemical synthesis of CXCR4-specific siRNA based on the target sequence for CXCR4 cDNA with NCI-H446 cells transfected with siRNA. To detect the expression of CXCR4 by RT-PCR and Western Blot. Invasion capability of NCI-H446 cells in vitro was evaluated by transwell chamber model. The proliferation capability was determined by CCK-8 assay.

Results: After transfected with the expression of CXCR4 mRNA and protein was down-regulated significantly. The invasion capability of cells in vitro decreased compared with the empty liposome group. The penetrating number iniferior to CXCR4-siRNA transfected group was 12.5±8.62 vs 32.8±9.45 (p<0.05). There was no effect on cell proliferation after transfection of CXCR4 siRNA on NCI-H446 cells.

Conclusion: CXCR4 siRNA effectively down-regulated the expression of CXCR4 gene and decreased invasion capability of NCI-H446 cells in vitro.
with MTI, and the formation of ROS was checked with DCFH. To evaluate the mechanism of apoptosis, the activation of Caspase family was checked, and the fragmentation of PARP-1 was studied by the western blotting method.

Results: By the increases of the concentration of MB and the energy of Diode LASER, the level of apoptosis of cell lines and ROS synthesis were significantly increased. Pretreatment with antioxidant suppressed these findings. In the induction of apoptosis, the activation of Caspase 3, 8, and consequent fragmentation of PARP-1 was observed.

Conclusion: MB induced apoptosis in the A549 lung cancer cell lines as a photo-sensitizer, and its effect was increased by the concentration of MB and the energy of Diode LASER.

P1232
Tumor size and inflammatory cytokines in exhaled breath condensate in patients with non small cell lung cancer (NSCLC). Luisa Brunnen1, Marta Morando2, Marta Malandra2, Caterina Buca4, Giovanni Roli1, Robert Giobbe3, Irene Parisi2, Monica Boita2.

Background: Local and systemic inflammation play a key role in the genesis and progression of lung cancer; vascular endothelial growth factor (VEGF) has been related to progression and local extension of many tumors. Involvement of Th17 lymphocytes (Th17) and their cytokines (IL-17, IL-6) in cancer has been recently postulated. Lung inflammation may be non-invasively assessed by cytokine assay in exhaled breath condensate (EBC).

Aim and objectives: To assess the possible correlations between systemic and local Th17 related cytokines, VEGF and tumor size evaluated by CT-scan in patients with NSCLC.

Methods: Fifteen consecutive patients (12 males; mean age 64 years) with NSCLC classified in stage IA-IIIA, were enrolled. Lung CT-scan, EBC and serum samples were obtained in each patient. IL-6, IL-17 and VEGF were measured by ELISA.

Results: Tumor mean diameter was 3.28 cm (SD 2.33). Mean cytokines values in serum and EBC are shown in table 1.

<table>

</table>

Mean (±SD) serum and EBC cytokines levels (ng/ml).

EBC level of VEGF was significantly correlated with EBC-IL-6 (p=0.314, p=0.030) and IL-17 (p=0.697, p=0.011). A significant correlation between tumor diameter and IL-6, IL-17 and VEGF in EBC was observed (r=0.440 p=0.013, r=0.444 p=0.013, r=0.332 p=0.039 respectively). No correlation was found between serum cytokine and tumor size.

Conclusion: This is the first observation reporting Th17 cytokines in EBC in NSCLC. The correlation between Th17 cytokines and tumor size suggests the involvement of Th17 cells in the progression of neoplasia.

P1233
Octogenarians with non small cell lung carcinoma – Advanced disease

Lígia Fernandes, Cláudia Santos, Inês Sanches, Ana Figueiredo, Fernando Barata, Pneumology, Centro Hospitalar Universitário de Coimbra, Hospital Geral, CHC, EPE, Coimbra, Portugal.

Approximately 50% of new non-small cell lung cancers – advanced disease (NSCLC-AD) cases are diagnosed in the elderly and nearly 20% are detected in patients aged 80 years and older. Limited information is available about the correct approach in octogenarians.

Objective: Retrospective observational analysis of elderly patients with NSCLC-AD in order to assess epidemiological characteristics, performance status (PS), co-morbidities, concomitant medications, therapy and survival.

Results: In seven years (2004-2010), 108 octogenarians were diagnosed with NSCLC-DA. The median age was 82 years and 68.5% were men. We found 54.6% former smokers, 34.2% non-smokers and 11.2% active smokers. Adenocarcinoma was found in 51%, squamous carcinoma in 41.7% and NSCLC – NOS in the remaining patients. At diagnosis, 48.1% had PS 0, 31.8% had PS 2 and 13.9% had PS 3. Evaluation of co-morbidities showed that 58% of patients had ≤ 3, while the remainder had > 3 co-morbidities (4-9). These co-morbidities warranted that 62% of the patients received more than 4 drugs as concomitant medication. Chemotherapy was the option in 45 octogenarians. In 11 patients we decided to do a doublet with a platinum plus gemcitabine. In the remaining 34, our option was monochemothepmy with oral vinorelbine in 26 and pemetrexed in 8 patients. Toxicity with serious side effects explains why only 14 of the 43 patients completed 4 cycles. Overall median survival was 3.1 and 8.6 months for those who started chemotherapy, regardless of whether single or doublet.

Conclusion: The increase in life expectancy, along with the research of new and less toxic therapies justifies a revisit of this population group, where prospective clinical trials are needed.

P1234
The primitive bronchogenic carcinoma in the elderly

Hannane Benjelloun, Nahid Zaghba, Najiba Yasmine, Abdelaziz Bakhatar, Abdellah Bahalou, Department of Respiratory Diseases, University Hospital Center Ibn Rochd, Casablanca, Morocco

The increased incidence of lung cancer in the elderly is associated to the increase of the intrinsic risk to develop a cancer with age, to the ageing of the population and especially to the smoking and the exposure to occupational and environmental carcinogens. We realized a retrospective study of 108 patients aged of 65 year old and older, hospitalized in the department of Respiratory Diseases, UHC Ibn Rochd between January 2008 and January 2010. It is about 96 men and 12 women. The average age is 69 years old. Smoking is found in 90 cases, the symptomatology is dominated by coughing, chest pain, dyspnea in 80 cases, and hemoptysis in 46 cases. The thoracic imaging showed, more the tumoral processus of mediastinal adenopathies in 50 cases, a bone lysis in 12 cases, a balloon release in 10 cases, the peripheral ganglia biopsy in 26 cases, pleural needle biopsy in 4 cases. The bronchoscopy revealed a budding tumor in 56 cases, a tumor infiltration in 24 cases. The diagnosis is based on bronchial biopsies in 68 cases, the transnasal needle biopsy in 26 cases, the peripheral ganglia biopsy in 4 cases, pleural needle biopsy in 4 cases and the thoracotomy in 5 cases. The epithemoid carcinoma is the most common histotypical type in 45 cases, followed by adenocarcinoma in 40 cases, small cells carcinoma in 10 cases and undifferentified carcinoma in 13 cases. At the end of the complete physical examination, 55% of the patients were classified stage IV. The bronchogenic carcinoma of the elderly is often revealed in the late stages. Its therapeutic management depends on the patient's general condition and related defects.

P1235
Impact of radon residential concentration in the development of lung cancer in Transilvania, Romania

Loredana Elena Rosca1, Deina Adina Todea2, 1Pneumology, Clinical Hospital of Pneumology Leon Danielu, Cluj Napoca, Cluj, Romania; 2Pneumology, University of Medicine and Pharmacy “Iuliu Hatieganu” Cluj Napoca, Cluj Napoca, Cluj, Romania.

Lung cancer represents the most frequent cause of mortality caused by malignancies in the world. The World Health Organization (WHO) has classified radon (Rn) as a [Class A] known human carcinogen, because of the wealth of biological and epidemiological evidence and data showing the connection between exposure to radon and lung cancer in humans.

The aim of this study was to investigate the correlation between the exposure to radon and lung cancer in patients from the centre counties of Transilvania, Romania.

Material and method: We conducted a case-control study, by location of 250 Rn detectors between 2009-2011. 104 Rn detectors in patients with lung cancer and 146 Rn detectors in controls from the centre counties of Transilvania.

Results: We observed that the risk of developing lung cancer has increased with the magnitude of Rn exposure. At a Rn concentration between 0-49.8 Bq/m³ OR was 1; at 50-79.9 Bq/m³ OR was 2.14 (CI 1,04-5,11); 80-139.9 Bq/m³ OR was 2.44 (CI 1,9-5,10); > 140 Bq/m³ OR 2.60 (CI 1,9-5,45).

Conclusion: The strenght of association between residential Rn exposure and lung cancer is increasing with higher concentration of Rn. This findings support the implication of Rn in developing lung cancer.

P1236
Seroprevalence of human herpesvirus type 8 infection in patients with lung carcinoma

Shih-Ming Tsao1, Chun-Liang Lai2, Ming Nan Lin3, Cheng-Chuan Su4, 1Chest Medicine, Chung Shan Medical University Hospital, Taichung, Taiwan; 2Chest Medicine, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan; 3Family Medicine, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan; 4Clinical Pathology, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan.

Background: Human herpesvirus type 8 (HHV-8) DNA is found consistently in all types of Kaposi’s sarcoma (KS), which is sometimes seen in human immunodeficiency virus (HIV) infected patients with immunologic abnormalities. Lung carcinoma is one of the most common malignancies developing in immunocompromised patients. However, the prevalence of HHV-8 infection in lung carcinoma patients is unclear.

226s
Methods: Blood samples were collected from 109 lung carcinoma patients with malignant pleural effusion and 109 age-matched healthy controls and analyzed for lymphocyte and monocyte counts, and presence of HHV-8 antibody and DNA. All study subjects were negative for anti-HIV antibodies.

Results: Lung carcinoma patients had significantly lower mean lymphocyte counts and significantly higher monocyte counts than the healthy controls (P < 0.001). Three patients with lymphopenia and stage IV tumor were positive for HHV-8 DNA, one of them was negative for HHV-8 antibody. HHV-8 positivity was significantly higher in patients (42.2%), particularly in male patients (50.8%), than in healthy controls (24.8%) (P = 0.006 and < 0.001, respectively). HHV-8 positivity was significantly greater in male patients (50.8%) than in female patients (29.5%) (P = 0.028), and in patients with stage IV tumors somewhat greater than with stage III B tumors (P = 0.416). HHV-8 antibody titers in patients also significantly exceeded those in healthy controls (P = 0.004). All subjects positive for HHV-8 were not associated with clinical manifestations of HHV-8 infection.

Conclusions: HHV-8 seroprevalence was significantly greater in lung carcinoma patients than in healthy controls, and associated with gender.

P1237
Pulmonary function testing in patients with lung cancer
Rosario Melchor Iglesias1, Marcel José Rodríguez Guzmán1, Alejandro Martín de San Pablo Sánchez1, María Belén Gallegos Carrera2, Sharond Cordova Yamanchi1, María Jesús Fernández Acebero2, 1Neumología, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; 2Anatomía Patológica, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Introduction: Lung cancer (LC) and chronic obstructive pulmonary disease (COPD) have the same predisposing factor. We studied lung function on patients diagnosed with LC in our hospital.

Methods: Patients diagnosed with LC from April 1st 2009 to September 30th 2010 were prospectively studied. Clinical data included histology, stage, spirometry, weight lost, body mass index (BMI) and albumin. For statistical analysis, Student’s t-test was used.

Results: Of 221 patients who fulfilled in our inclusion criteria, 78% were male, and the mean age was 62.4 years. Histology types were adenocarcinoma (39), squamous cell carcinoma (22) and Small-cell lung cancer (14). 53 patients (58%) were classified as stage IIIB or IV. Mean Spirometric values were: FEV1 71%, FVC 86%, FEV1/FVC 65%. The three Spirometric parameters were smaller in men (no statistical differences with women). 54.8% of patients were diagnosed as COPD, with FEV1/FVC < 0.70. Among the stages IA to IIIA, 52% of patients had COPD, among stages IIIB and IV, 58% FEV1 and FVC values were smaller in patients with a weight loss over 5% (P < 0.05 and P = 0.035, respectively). BMI had a positive effect in the three Spirometric parameters. A positive effect of the albumin level was found in FEV1 and FVC, but not in the relation FEV1/FVC.

Conclusions: More than half of patients diagnosed with LC in our hospital have also COPD, with similar frequency for all stages.

P1238
Rate of chest x-rays (CXR) 12 months prior to diagnosis of lung cancer
Thomas Chin1, Rehan Mustafa, Anthony Roberts.

Aim: To analyse the number of CXRs performed in the 12 months prior to a diagnosis of lung cancer according to stage at presentation.

Methods: We reviewed 315 patients with a thoracic malignancy between Jan 2010 and Feb 2011. Number of CXRs in the year prior to diagnosis and stage of disease at presentation were recorded. We examined the proportion of patients that had fewer than 2 CXRs in that year for each stage of disease. These results were then compared using a Chi square test.

Results: After exclusions, 259 cases of non-small cell lung cancer were analysed. The results are compiled in Table 1 below. A significant proportion of patients presenting with later stage disease had fewer than 2 CXRs in the year prior to diagnosis than those with early disease (p = 0.019).

Table 1

<table>
<thead>
<tr>
<th>Stage</th>
<th>&lt;2 CXRs</th>
<th>%</th>
<th>2 or more CXRs</th>
<th>%</th>
<th>Total</th>

<td>58</td>
<td>39</td>
<td>148</td>
</tr>
</tbody>
</table>

Conclusions: It appears that patients with later stage disease are having fewer CXRs in the year prior to diagnosis than those with earlier disease. The results probably calls for increased awareness of lung cancer symptoms by both primary care physicians and general public, to facilitate early referral to secondary care.

P1239
Importance of further follow up in patients with negative histology from CT guided biopsy
Axel Sylvain1, Yalin Liu1, Tom Houghton2, Choong Poon3, Ram Sundar1, Tammim Arz1, 1Respiratory Medicine, Royal Albert Edward Infirmary, Wigan, United Kingdom; 2Radiology, Royal Albert Edward Infirmary, Wigan, United Kingdom

Background: Ongoing conclusive histology to diagnose lung cancer is an important part of the management of potential lung cancer patients. Due to recent advancement in the techniques CT guided biopsy is becoming increasingly important in obtaining histology samples. We describe our experience of usefulness of CT guided biopsy samples over 4 years and follow-up of negative histology samples in suspected lung cancer patients.

Results: We collected samples (2008-2011) of CT guided biopsy booked in our hospital. 314 procedures were planned in 313 patients. 292 procedures were carried out. The main reason for not carrying out the procedure was shrinkage of the mass seen on the day of the procedure. 23/292 (80.1%) confirmed the diagnosis of lung cancer. 10/292 (3.4%) lead to diagnosis of other cancers (myeloma, metastatic cancer, lymphoma). 42/292 (14.8%) showed non-cancers (mainly inflammation). The biopsy was inconclusive in 292 (2%) samples.

The 81 patients who did not have a biopsy or were labelled as non-lung cancers, underwent further investigation or had clinical diagnosis due to ill health. 26/81 (32%) had lung cancer, 14/75 (19%) had other cancers, 41/81 (50.6%) did not have a cancer diagnosis after follow up.

Conclusions: We have shown that CT guided biopsy provides us with good histology samples and if correct patients are identified the histological diagnosis rate is greater than 90%. At the same time the patients with a high suspicion and negative biopsy have approximately 1 in 3 chance of having a lung cancer. It is therefore recommended that patients with negative histology should have further diagnostic tests.

P1240
Diagnostic value and prognostic significance of pleural C-reactive protein in lung cancer with malignant pleural effusions
Hak-Ryul Kim, Ki-Eun Hwang, Hwa-Jung Kim, Eun-Taik Jeong. Pulmonology, Wonkwang University Hospital, Iksan, Korea

C-reactive protein (CRP) has been implicated in various inflammatory and advanced malignant states. Increased serum CRP levels have been shown in association with independent prognostic factor for survival in patients with advanced lung cancer. However, only few studies have focused on the role of CRP in pleural effusions. This study aimed to evaluate the diagnostic value of pleural CRP to discriminate lung cancer with MPE from benign effusion and its prognostic role in lung cancer patients with MPE. Pleural effusion samples were collected from patients with MPE (68 lung cancers, 12 extrathoracic tumors), and from 68 with various benign conditions. Concentrations of pleural (p) and serum (s) CRP were measured by ELISA. The expression profile of CRP in pleural fluid, and its association with survival were investigated. P-CRP levels correlated with s-CRP levels (P = 0.0088). The area under the ROC curve (AUC) of p-CRP (0.86) in their diagnostic accuracy to differentiate lung cancer with MPE from benign pleural effusion was greater than those of s-CRP (0.77). High p-CRP expression was significantly correlated with shorter overall survival (P = 0.0001). A multivariate Cox regression analysis, p-CRP was independent prognostic factor significantly associated with overall survival (P = 0.0001). The relative risk of overall survival for lung cancer patients with high p-CRP was 3.909 (95% CI, 2.500-7.639). In conclusion, P-CRP is superior to s-CRP in determining the pleural fluid etiology. Quantitative assay of CRP in pleural effusion might be useful complementary test both in diagnosis and prognosis for lung cancer patients with MPE.

P1241
The elevation serum napsin A in primary lung adenocarcinoma, compared with CEA
Takuya Sunumukai, Tsutomu Hamada, Keiko Mizuno, Ikkiy Higashimoto, Hiromasa Inoue. Pulmonary Medicine, Graduate School of Medical and Dental Science, Kagoshima University, Kagoshima, Japan

Napsin A is an aspartic proteinase with a molecular weight of approximately 38 kDa, which is expressed in normal lung parenchyma in type II pneumocytes. It has been reported that napsin A immunohistochemical reactivity is associated with primary lung adenocarcinoma. However, napsin A has never been tested as a serum marker for primary lung adenocarcinoma.

The aim of this study was to investigate the potential of serum napsin A as a tumor marker in patients with primary lung adenocarcinoma, compared with CEA. Subjects consisted of 46 patients with primary lung adenocarcinoma, 16 patients with non-pnodiagnosis, and 43 healthy subjects. Serum CEA and napsin A were measured by ELISA. Statistical analysis was performed using SPSS ver19.0.
Baykal Tulek 1, Habibe Kaylir 2, Fikret Kanan 1, Ugur Arslan 3, Furak Ozer 4.

1Pulmonary Diseases, Selcuk University, Selcuklu Faculty of Medicine, Konya, Turkey; 2Pulmonary Diseases, Konya University, Meram Faculty of Medicine, Konya, Turkey; 3Microbiology, Selcuk University, Selcuklu Faculty of Medicine, Konya, Turkey; 4Pulmonary Diseases, Farah Hospital, Konya, Turkey

The basic uses of C reactive protein (CRP) and procalcitonin (PCT) in the clinical practise is in the diagnosis and follow-up of infectious disease. The fact that CRP already achieves high levels in cases with lung cancer, however, limits its diagnostic specificity. PCT may be an important marker in the differential diagnosis of febrile lung cancer patients with high CRP levels. Our objective in this study was to determine the levels of CRP and PCT in patients with newly diagnosed non-infectious non-small cell lung cancer (NSCLC) and to relate these results to patient and disease characteristics.

Serum CRP and PCT levels were measured in 79 histopathologically proved NSCLC patients and 20 healthy controls. Results were compared with demographic and clinical variables in patients with NSCLC. Serum CRP concentrations were significantly higher in NSCLC patients compared to control group (CR 7.79 ± 1.185 mg/dl; p < 0.001). There were no significant difference between two groups in PCT levels (p > 0.05). A mild, positive correlation was found between CRP level and tumor diameter. When comparing CRP levels in the lung cancer patients grouped according to age, sex, smoking status, clinical TNM staging and performance status (PS), the only significant difference found was that according to PS score. High serum CRP levels in noninfectious NSCLC patients are mainly related to PS status and tumour size. Adding serum PCT measurement in these patients may contribute to exclude infections in patients with NSCLC.

P1243

An unusual diagnostic tool in metastatic bronchogenic carcinoma: Peripheric embolectomy

Halit Canaka 1, Aziz Gümitu 1, Hasan Türüt 1, Ayşel Kurt 1, Göknän İlhan 2, Asiya Yavuz 1, Recip Bedir 1, Unal Sahin 1, 2Department of Chest Diseases, Rize University Faculty of Medicine- Education and Research Hospital, Rize, Turkey; 3Department of Thoracic Surgery, Rize University Faculty of Medicine- Education and Research Hospital, Rize, Turkey; 4Department of Cardiovascular Surgery, Rize University Faculty of Medicine- Education and Research Hospital, Rize, Turkey; 5Department of Pathology, Rize University Faculty of Medicine- Education and Research Hospital, Rize, Turkey

Heart may rarely be affected by primary or secondary tumors. Rarely, arterial tumor embolization may be first and/or most important issue during the course of the tumor. Most common sites of arterial tumor occlusions are common femoral and popliteal arteries. A 77-year-old man admitted with chest pain and cough. Thoracic computed tomography revealed a heterogeneous ill-defined mass originated from left upper lobe bronchus extending and invading hilar structures. Fiberoptic bronchoscopy revealed an endobronchial lesion on the orifice of lingular bronchus. In PET/CT, increased FDG uptake of satellite lesion on upper lobe destructing the fourth rib posteriorly, and probably metastatic mass invading left ventricle of the heart were conspicuous.

Echocardiography confirmed an intracardiac mobile mass, implanted to the left ventricle. On the 10th day, cyanosis of the right arm developed. It was due to right brachial artery occlusion confirmed by angiography. Urgent embolectomy was performed and clot specimens were sampled. Histopathological examination of embolectomy material showed atypic squamous cells, thus final report was metastatic lung cancer.

Arterial embolization highlights the advanced disease, poor prognosis with significant costs and morbidity. Embolectomy is often enough for symptomatic relief. This unique case illustrates the quite rare occurrence of peripheric tumor embolization originated from metastatic heart disease.
effects, so the usage of cisplatin has a limitation. Recently, autophagy has become an important mechanism of cell death. The purpose of this study was to determine whether low dose cisplatin treated lung cancer cell induce autophagy and the autophagy inhibition resulted in the apoptosis or necrosis. H460 cells were treated using autophagy specific inhibitors(3-MA). To confirm the result of autophagy inhibition, we had done Annexin-V/PI and cell cycle assay. To find out the cisplatin mediated autophagic mechanisms, we examined the apoptotic regulator, p53. We used p53−/− nude cancer cell line, H1299, to prove the role of p53 during cisplatin treatment. Low dose of cisplatin(5 μM) induced the apoptosis after 24 h treatment in H460. Also low dose of cisplatin showed autophagic vacuoles and cytoplasmatic LC3 formation in H460. The induction of autophagy by low dose cisplatin was inhibited by 3-MA, which was proven by reduced acidic vesicles. When the autophagy inhibited, Annexin-V+/PI− and subG1 was an increased. The inhibition in inhibition resulted in the decrease of LC3-II band. Also cleaved caspase-3 and PARP were increased. Taken together, low dose cisplatin induced autophagy and autophagy inhibited, Annexin-V+/PI− and subG1 was an increased. The inhibition of autophagy resulted in the decrease of LC3-II band. Also cleaved caspase-3 and PARP were increased. Taken together, low dose cisplatin induced autophagy and the inhibition of autophagy resulted in the apoptosis.

P1247
Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia. 7-year follow-up of a rare clinicopathologic syndrome
Roger Fei Falkenstein-Ge, Martin Kimmich, Godehard Friedel, Andrea Tannapfel, Volker Neumann, Martin Kohlhann, Pathomology, Clinic Schillerhoehe, Center for Pulmonology and Thoracic Surgery, Gerlingen, Baden-Württemberg, Germany Thoracic Surgery, Klinik Schillerhoehe, Center for Pulmonology and Thoracic Surgery, Gerlingen, Baden-Württemberg, Germany Pathology, Ruhr University of Bochum BG, Bochum, Nordrhein-Westfalen, Germany

Introduction: Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia (DIPNECH) is a rare clinical pathological syndrome. There have been only 49 cases of DIPNECH reported in the literature so far.

Aims and objectives: DIPNECH is confined to the airway mucosa without penetration through the basement membrane and appears in a diffuse pattern, little is known about the clinical course and treatment of DIPNECH.

Methods: DIPNECH is primary proliferations and can combine with obliterator bronchitis and bilateral reticulonodular infiltrates. The diagnosis requires the presence of hyperplasia of the airway neuroendocrine cells without invasion beyond the basement membrane. If DIPNECH breaks through the basement membrane and invades locally, this is called tumors, whereas nodules caused by DIPNECH > 5 mm in diameter are classified as carcinoid tumors.

Results: During the 7 years follow up, the patient was repetitively treated with oral steroids because of coughing and dyspnea. The oral steroid therapy was finally replaced by inhaled steroids. All CT-scans over a 7−year period showed stable disease without progression of the bilateral pulmonary lesion.

Conclusions: We present a 7-year-follow-up of DIPNECH with stable disease by a non-smoking male patient. The long-term follow up is necessary because there is an association between DIPNECH and peripheral carcinoid tumours. The majority of patients presenting with DIPNECH are middle-aged females with symptoms of cough and dyspnea. In general the clinical course remains stable, however progression to respiratory failure does occur.

P1248
Disappearance of hypoglycemic attacks after resection of solitary fibrous tumors with high expression of insulin-like growth factor II
Hiroshige Watanabe1, Keiichi Akasaka1, Ryota Fukai1, Tomoko Terasawa1, Naoto Fueki1, Kazumori Fukuda1, Takayuki Haga1, Yoshinori Kawabata1, Yoshitake Ueda1, Hiroshi Sagara1. 1Dept. of Respiratory Medicine, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan; 2Department of Cardiovascular and Thoracic Surgery, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan; 3Division of Endocrinology, Endocrinology and Hematology, Dept. of Internal Medicine, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan; 4Koshigaya Hospital Joint Research Center, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan; 5Internal Medicine, East Saitama National Hospital, Hazuda, Saitama, Japan; 6Dept. of Pathology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan

Hypoglycemia rarely accompanies solitary fibrous tumors (SFT) of the pleura, occurring in only about 4% of patients. We describe our experience with 2 patients whose hypoglycemic attacks disappeared after the resection of SFT.

Patient 1: The patient was an 81-year-old woman. Computed tomography of the chest showed a mass compressing the entire right lower lobe. SFT was diagnosed on histopathological examination of a percutaneous needle biopsy specimen. Subsequently, tumor resection was performed, and the hypoglycemia disappeared. Histopathologically, the tumor was associated with abundant proliferations of markedly hyalinated collagen fibers. The tumor contained small bundles of round cells or spindle cells with mild atypia, proliferating in an irregular, intermingled fashion. On immunohistochemical staining, the tumor cells were positive for CD34.

Patient 2: The patient was a 77-year-old man with dyspnea on exertion. Preoper- ative computed tomography showed a well-demarcated, giant mass compressing the right middle lobe. Therefore, the mass was resected, and the hypoglycemia disappeared. Histopathological examination revealed proliferations of collagen fibers containing spindle cells with low-grade atypia, proliferating in an irregular storiform fashion with positive for CD34. In both case, serum insulin level valued remarkably lower than 0.2μU/ml and the immunohistochemical staining of Insulin-like growth factor II (IGF-II) were positive.

Tumor resection was suggested to be an effective treatment for hypoglycemic attacks in patients with SFT. IGF-II may provide negative feedback with respect to insulin secretion.

P1249
A temporal effect of EGFR tyrosine kinase inhibitor in lymphoepithelioma-like carcinoma of lung
Koichiro Chiu1, Koichiro Chiu1, Tzu-Sheng Chen1, Division of Chest Medicine, Buddhist Tzu-Chi General Hospital; Tzu-Chi, Tainan, Taiwan; 2Chest Medicine, Saint Mary’s Hospital, Hualong, Yilan, Taiwan

Introduction: Primary lymphoepithelioma-like carcinoma (LELC) is a rare in lung. Recent studies suggested a prevalent mutation on epidermal growth factor receptor (EGFR) in LELC of lung. However, the therapeutic effect of EGFR tyrosine kinase inhibitor (TKI) has not been tested. We hereby report an effect of EGFR TKI on LELC of lung.

Case report: A 70-year-old woman presented to have a lung tumor, 6.1x5.1x5.0 cm, over left upper lobe. CT-guided core-needle biopsy of lung tumor confirmed the diagnosis of LELC, and a clinical stage of TNM0, stage IIIB, was met. The patient had a partial response after completing 6 cycles of 1st-line chemotherapy (CIT) with gemcitabine plus cisplatin, and 4 cycles of 2nd-line CIT with docetaxel.

After having a progression, she went on a TKI therapy. The tumor kept shrinking through 6 months, until progressing after 9-month TKI treatment.

Discussions: This is the first report demonstrating a therapeutic effect of EGFR TKI on LELC of lung, as a 3rd-line therapy in this case. The case report suggests EGFR TKI, at least erlotinib, may be beneficial for patients with LELC of lung, at least for a significant period of time.

P1250
Late lung metastasis of endometrial cancer. Two rare cases of patients with late lung metastasis of primary endometrial cancer 14 and 17 years after initial treatment
Roger Fei Falkenstein-Ge, Markus Wohleber, Martin Kimmich, Sabine Boede-Erdmann, Germany On; Martin Kohlhann, Division of Pathomology, Clinic Schillerhoehe, Center for Pulmonology and Thoracic Surgery, Gerlingen, Baden-Württemberg, Germany Division of Pathology, Robert Bosch Krankenhaus, Stuttgart, Baden-Württemberg, Germany

Introduction: The longest interval of lung metastasis from endometrial cancer was initially reported 17 years after standard surgical treatment. Aims and objectives: Nearly 80% of all recurrences of endometrial cancer occur within 3 years after the initial treatment. We report two cases of lung metastasis 14 and 17 years after the initial surgical treatment of endometrial cancer.
Methods: A 71-year-old female was referred to our center for histological diagno-
sis of lung lesions. Histological biopsy showed lung metastasis of an endometrial
cancer which was resected 17 years ago. A 77-year-old female was also referred for histological diagnosis of multiple lung lesions and a clavicle metastasis. Both clavicle and lung biopsy revealed metastasis of an endometrial cancer treated 14 years ago surgically.

Results: Our first patient was treated with organ-preserving metastatic wedge resection. The latency period in the first case between initial treatment of endometrial cancer and pulmonary metastases was 17 years. Our second patient with widespread metastasis was treated with palliative radiotherapy and systemic chemotherapy. The latency period between initial diagnosis and treatment of endometrial cancer and pulmonary metastases in the second case was 14 years.

Conclusion: Lung metastases originating from tumors of the female genital tract endometrial cancer and pulmonary metastases in the second case was 14 years.

P1254
Malignant mesothelioma. A survival analysis of 123 consecutive cases at an occupational clinic
Ellen Skammeritz1, Lars Haukali Omland2, Jens Peter Johansen1, Olevid Omland1, 1Dept. of Occupational Medicine, Aalborg Hospital, Århus University Hospital, Aalborg, Denmark; 2Dept. of Infectious Diseases, Rigshospitalet, Copenhagen, Denmark

Aim: To describe the asbestos exposure, to identify factors associated to the prognosis, and to calculate the median survival time in 123 consecutive patients (1984-2010) with pathological verified diagnosis of malignant mesothelioma (MM).

Method: From medical records we identified age, sex, asbestos fibres exposure, localisation and subtypes of MM, performance status, and treatment.

Results: Median age was 65 years (min. 41 - max. 90) and 111 (90.2%) were men and 12 (9.8%) were women. We identified asbestos exposure in 112 (91%) patients. Shipbuilding- and other industries were the most common occupational exposures. Among the patients, there were significant variables for mortality rate ratio (MRR) (95% CI) were male sex: 2.26 (1.90-2.70) and asbestos exposure: 2.03 (1.65-2.49) where the patients were exposed to asbestos fibres by nature and type.

Conclusion: The survival of patients with malignant mesothelioma is highly dependent on asbestos exposure. Further, asbestos exposure was identified in 91% of the patients, shipbuilding- and other industries were the most common occupational exposures. Among the patients, there were significant variables for mortality rate ratio (MRR) (95% CI) were male sex: 2.26 (1.90-2.70) and asbestos exposure: 2.03 (1.65-2.49) where the patients were exposed to asbestos fibres by nature and type.

Prognostic factors and survival in malignant pleural mesothelioma at a large tertiary referral center in Turkey
Pulmonology, Dr. N借助 Seren Education Hospital for Chest Disease and Surgery, Izmir, Turkey

Malignant pleural mesothelioma is a rare tumor but increasing incidence and poor prognosis despite new therapy modalities. In this study we aimed to investigate the effects of various pretreatment clinical and laboratory characteristics on survival of patients with malignant pleural mesothelioma (MPM).

During last five years, 125 histologically proven MPM cases were evaluated at large tertiary referral center in eastern part of Turkey. Patients age, gender, performance score, histology, asbestos exposure, smoking history, symptoms, plasma platelet count, haemoglobin, white blood cell (WBC), plasma LDH levels, stages were evaluated in both univariate and univariate analysis. Univariate analysis showed that patients with extensive stage, N2 nodal invasion and M1 metastasis have a worse prognosis. Multivariate Cox regression analysis showed that survival was independent on indicators of worse prognosis (HR 1, 95 CI 1.015-2.19, p=0.017).

As a result: The patients with extensive stage, N2 nodal invasion and M1 metastasis were found to related with shorter survival. Sarcomatous histology were found as an independent worse prognostic factor in MPM.

P1256
Malignant pleural mesothelioma stage III and IV: retrospective analysis of ten years in a central hospital
Claudia Aze, Jose Sanches, Ligia Fernandes, Filipa Cruz e Costa, Fernando Barata. Pulmonology Department, Centro Hospitalar Universitário de Coimbra, CHC, Coimbra, Portugal

Introduction: Pleural mesothelioma (PM) is the most frequent malignant primary tumor of pleura. The incidence in Western Europe is still rising due to the prolonged latency of the disease.

Aims: Determine demographic, epidemiological, histological and therapeutical aspects of malignant PM in stage III and IV. Evaluate survival rates.

Methods: The study was conducted in an European central hospital covering approximately 475.000 inhabitants. We performed retrospective analysis of cases diagnosed in our department over a period of 10 years. Survival analysis was performed using Kaplan Meier method and Cox regression.

Results: We diagnosed 32 cases in stages III/IV (91.5% of total), 84.4% men, median age 61.0 ± 10.2 years, 50% of cases with current smoking, and 20% of cases exposure to tobacco. Exposure to asbestos was reported in 56.5% and had occurred, on average, 41.4±10.8 years before. Approximately 50% of exposures were associated with building construction and 24% with car mechanic. In 87.5% the diagnosis was obtained with video-assisted thoracic surgery. Histology was epithelioid in 84%. All patients received chemotherapy: 53.1% carboplatin+gemcitabine, 37.5% pemetrexed+cisplatin and 9.4% cisplatin+gemcitabine. Hematological toxicity occurred in 18.8% and non haematological toxicity in 12.5% (grade 3/4). Prophylactic local radiotherapy was performed in 75%. Median survival was 51.6±9.4 weeks. There was no statistically significant difference according to chemotherapy regimen.

Conclusion: Malignant PM must be considered, particularly in men involved in mechanics, even with unrecognized or remote exposure to asbestos. In our series no difference was seen combining platinum analogs with gemcitabine or pemetrexed.

P1257
Pleural atypical mesothelial hyperplasia: An early stage of pleural malignant mesothelioma?
Thomas Vandenomontene, Sophie Laroumagne, Olivier Bylicki, Sophie Guissano, Hervé Dutau, Philippe Astoul. 1 Department of Thoracic Oncology, Pleural Diseases, and Interventional Pulmonology, Hôpital Nord, Marseille, France; 2Department of Pathology, Hôpital Nord, Marseille, France

Mesothelioma is a neoplastic process most often secondary to asbestos exposure. Atypical mesothelial hyperplasia (AMH) is thought to be a benign process in reaction to various processes, including infectious pleurisy and recurring transudative pleural effusion. However, it is unknown if there might be a link between AMH and malignant pleural mesothelioma (MPM).

Herein, we present the case of a 69 year-old patient with documented asbestos exposure in whom MPM was diagnosed four months after a first diagnosis of AMH. Thoracoscopy showed inflammation of the posterior parietal pleura and white lymphangitis of the anterior pleura, without nodules or other suspicious lesion. Biopsies taken from the anterior pleura showed AMH.

Two months later, the patient returned with a recurring right sided effusion. CT-scan revealed a subcarinal lymph node measuring 15x8mm and a pleural effusion with partial atelectasis of the right lower and middle lobes.

The thoracoscopy was performed, four months after the initial one. The pleura was dramatically changed, with numerous nodules and neoplastic lymphangitis. Multiple biopsies were performed on the diaphragmatic and posterior pleural surface to investigate the causal relation with asbestos. Whether mesothelioma evolves from atypical hyperplasia, as epithelioid-derived cancer of other origins, remains to be elucidated.

Conclusion: Diagnosis of MPM relies on pleural biopsy specimens. Thoracoscopy is particularly useful in guiding pleural biopsies and in symptomatic improvement if pleurodesis is performed.

P1258
Role of medical thoracoscopy in diagnosis of recurrent undiagnosed pleural effusion
Ramadan Bakr, Ibrahim Elmhallewia, Osama Mansour, Ahmad Ali, Samy El-Dahdouh. Chest Department, Menoufia University, Shebin Elkom, Menoufiya, Egypt

Background: The urge for the resurgence of thoracoscopic techniques came essentially from the depressive situation of chronic exudates not diagnosed in 20-40% of cases after using the ordinary diagnostic methods.

Methods: This study comprised 20 cases with exudative pleural effusion, all of them were subjected to full history taking, clinical examination, laboratory investigations, radiological examination (chest x-ray and CT), abdominal US, chest US if needed, tuberculin test, sputum for AFB, ABG and ECG. For all patients, pleural tapping and biochemical, cytological, bacteriological and immunological examinations for the pleural aspirates, as well as blind Abrams needle pleural biopsy and histopathological examination were done. The etiologic diagnosis of pleural effusion was not settled after all these investigations, and thus, medical thoracoscopy, under local anesthesia, was carried out for each patient.

Results: The mean age of patients was 57.6 years. The diagnosis was achieved in 85% of cases, while 15% of cases diagnosed as non specific pleuritis. The range of biopsies were 65% malignant (mesothelioma, 35% metastatic adenocarcinoma, 5% of either lymphoma or thymoma), and 35% of cases were non malignant, 15% undiagnosed, 10% TB, 5% of either erythema or RA). 20% of cases had complication in the form of 10% malposition of the intercostal tube and 5% of either hemotoma or infection at the site of tube entry.

Conclusion: Medical thoracoscopy, under local anesthesia and conscious sedation, is an effective procedure for diagnosing the underlying etiology of recurrent pleural effusion of unknown etiology, with minimal complications.

P1259
Study of thoracoscopic pleural biopsies for nondiagnostic pleural effusion
Yulin Kim, Sun Young Kyung, Sang Pyo Lee, Sung Hwan Jeong, Shion Myung Kang, Sang Min Lee, Jeong-Woong Park. Division of Pulmonology and Critical Care Medicine, Department of Internal Medicine, Gachon University Gil Hospital, Incheon, Korea

Background: We performed thoracentesis and pleural biopsy by cope needle to find cause of exudative pleural effusion. Usually about 20% of them can’t find cause. We study thoracoscopic biopsy for nondiagnostic pleural effusions.

Method: We enrolled patients from April 2004 to May 2010. We included patients with nondiagnostic pleural effusion through stumput study, thoracentesis, washing microbiologic study and cytology by bronchoscopy. Twenty-six patients were performed thoracoscopic pleural biopsy.

Result: Twenty-four patients were identified. Their mean age was 60.5±15.3years, and 16(66.7%) of the patients were men. Four patients weren’t performed thoracentesis. Characteristics of pleural effusion were lymphomatous (9/75%), poly-dominent(2;10%), eosinophil dominant (1/5%) and unknown(2/10%). Final diagnosis of patients with undiagnostic pleural effusion were malignant effusion (n=14, 58.3%), Tb pleurisy(n=3, 12.5%), chronic inflammation and fibrosis(n=5, 20.8%) and hemorrhagic effusion and cosinophilic effusion (n=2, 8.3%). The most common cause of malignant effusion was secondary not primary lung cancer. Metastatic effusion were 5 patients (35.7%). Malignant mesothelioma were 3patients (21.4%). adenocarcinoma of unknown origin were 2patients (14.3%). Primary lung cancer were 4patients (25.8%).

Conclusion: Fifteen patients(58.3%) of nondiagnostic effusion were diagnosed malignant effusion. In These 15 patients, secondary malignant effusion were 10 patients(74.3%). In Conclusion, we consider thoracoscopic biopsy and systemic examination to identified nodiagnostic pleural effusion.

P1260
Medical thoracoscopy experience: 3 years on
Burhan Khan, Hamid Aminy Raouf, Majid Mustafig. Department of Respiratory Medicine, Darent Valley Hospital, Dartford, Kent, United Kingdom

Aim: To describe the qualitative and quantitative experience and outcomes at 3 years of medical thoracoscopy (MT) in a DGH.

Methods: Retrospective case series review of all consecutive adult patients under- going MT.

Results: To date, 39 MT’s have been done between Sept ’09 and Sept’11. Median age 71 years (range:28.6-87 years); 28 (72%) male. Median age of patients with malignancy 70(range:48.3-87 years), 15 male (65%). MT was non-diagnostic in 3 cases (7.7%) with one confirmed as metastatic carcinoma on CTGBx. 9/10 MPM were pleurodesed; 8(89%) successful All 13 non-MPM were pleurodesed; 9(70%)
successful. Overall pleurodesis success rate was 77.3%. Excluding the two patients who died within 30 days, pleurodesis success rate is 85% (17/20) for all malignant pleural effusion.

Conclusions: Success rates are reported in literature 82.1% - 95% in patients having a single procedure and one pleurodesis only, similar to ours but for the 2 patients aged 72 and 76 years who died; having significant co-morbidities and confirmed metastatic carcinomas with poor pre-op performance status of 3.

MT was well tolerated in our cohort of patients who had median age of 70, and success rates varied dependent on pathology; better in MPM than carcinoma. Qualitatively, the most significant result was the duration of pleural fluid recurrence free days that patients achieved, thus mitigating symptoms and avoiding further or repeated invasive pleural interventions.

P1261

Results of treatment of the metastatic pleural effusion

Goran Kondov1, Zoran Spirtovski1, Risto Colanceski2, Saso Jovev1, Biserka Caeva2, Borislav Kondov2. 1Thoracic Surgery, University Clinic for Thoracic and Vascular Surgery, Skopje, Macedonia, The Former Yugoslav Republic of; 2Pulmonology, University Clinic for Pulmonology, Skopje, Macedonia, The Former Yugoslav Republic of

Metastatic pleural effusion is big health, social and personal problem. Diagnosis of patients is 1 to 60 months which is according underlying disease, stage of the disease, treatment response, characteristics of the patients and their reserve.

We analyze 60 patients with confirmed malignant pleural effusion: 28 patients with breast cancer, 14 with lung cancer, 8 with mesothelioma, 5 with gastric carcinoma, and 5 with other malignant lesions. Mean age were 56 years.

At this 60 patients we have done 194 procedures. We analyze effects of thoracocentesis only (60), placing pleurocurt (37), placing of thoracic drain (54), VATS with talk pudrage (13) and thoracoscopic drain and thoracic drainage with slurry talk pleurodesis (14). Recurrence of pleural effusion, febrile condition, appearing of the empyema problems with heart, dispnea, life treating conditions were followed at all patients.

Results: Recurrence of pleural effusion were detected at 71.2%, where the best results were with use of VATS with talk pudrage (53.8%), than is thoracic drainage with slurry talk pleurodesis with success rate of 50%. With only placing of drain success rate was 29.6% or with pleurocurt placing 27%. With thoracocentesis only, no one has had success.

Unwanted conditions were detected the most frequently at thoracic drainage with slurry talk pleurodesis where were detected 14.3% heart problems, 35.7% dispnea and respiratory symptoms, 35.7% febrile conditions with septic conditions. Conclusion: VATS with talk pudrage give the best results with control of the malignant pleural effusion, but need hospitalization and general anesthesia procedure, procedure which was not recommended for many patients which is in bad general conditions.
Iodopovidone is an effective, safe, cheap, easily available alternative to other agents used via thoracoscopy. The combination of low-dose doxycycline with low-dose talc appears to be a safe and rational approach to pleurodesis with reasonable side-effects.

Methods: In a prospective study, 20 consecutive patients with recurrent and biopsy-proven malignant effusions and 4 patients with recurrent pneumothorax were included. All pleurodesis was performed with talc plus doxycycline as the sclerosing agent. Doses of doxycycline (250 mg) and talc (2.5 grame) were half the "usual" doses. The sclerosing agents were administered via tube thoracostomy. Post-pleurodesis postero-anterior (PA) radiographs were obtained after tube removal and 30 days following the procedure. Successful therapy was defined as a complete absence or minor re-accumulation of pleural effusion one month after pleurodesis.

Results: Twenty-four cases were identified (8 women, 16 men, Mean age was 65.2 years). No immediate perioperative complications were noted. Chest tube drainage averaged 4.3±2.5 days. Length of stay after the procedure 4.8±3.2 days. Eight patients (33%) reported persistence or worsening dyspnea in the immediate postoperative period. Only one developed respiratory distress; no any parenchymal changes on chest radiography and no required ventilatory support. Other immediate postoperative period events included chest pain in 10 patients (42%) and fever in 28% patients. Twenty patients (83%) had successful pleurodesis and 4 (17%) failed.

Conclusions: The combination of low-dose doxycycline with low-dose talc appears to be a safe and rational approach to pleurodesis with reasonable side-effects.

P1265
Combination therapy with intrapleural doxycycline and talc in reduced doses for pleurodesis
Khaled Hassaan, Pulmonary Medicine, Zagazig University Hospital, Zagazig, Egypt

Background: We hypothesized that combining doxycycline and talc in half the usual doses would be synergistic in inducing pleurodesis.

Objective: The aim of the study was to evaluate safety and efficacy of low-dose doxycycline combined with low-dose talc for pleurodesis.

Methods: In a prospective study, 20 consecutive patients with recurrent and biopsy-proven malignant effusions and 4 patients with recurrent pneumothorax were included. All pleurodesis was performed with talc plus doxycycline as the sclerosing agent. Doses of doxycycline (250 mg) and talc (2.5 grame) were half the "usual" doses. The sclerosing agents were administered via tube thoracostomy. Post-pleurodesis postero-anterior (PA) radiographs were obtained after tube removal and 30 days following the procedure. Successful therapy was defined as a complete absence or minor re-accumulation of pleural effusion one month after pleurodesis.

Results: Twenty-four cases were identified (8 women, 16 men, Mean age was 65.2 years). No immediate perioperative complications were noted. Chest tube drainage averaged 4.3±2.5 days. Length of stay after the procedure 4.8±3.2 days. Eight patients (33%) reported persistence or worsening dyspnea in the immediate postoperative period. Only one developed respiratory distress; no any parenchymal changes on chest radiography and no required ventilatory support. Other immediate postoperative period events included chest pain in 10 patients (42%) and fever in 28% patients. Twenty patients (83%) had successful pleurodesis and 4 (17%) failed.

Conclusions: The combination of low-dose doxycycline with low-dose talc appears to be a safe and rational approach to pleurodesis with reasonable side-effects.

P1266
Iodopovidone: An effective agent pleurodesis used through chest tube
Kotti Amini, Daghileh Hafagou, Snam Houda, Saad Soumaya, Kahloul Olfa, Tritar Fatma, Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia Pneumology C, Abderrahmane Mami Hospital, Ariana, Tunisia

Background: Most variety of pleural irritants have been used for pleurodesis, the ideal agent should produce pleurodesis effectively, safely, and in shortest possible time.

Objective: Compare efficacy and safety of iodopovidone used through chest tube to other agents used via thoracoscopy.

Patients and methods: Fifty six patients (35 men and 21 women) with malignant pleural effusion (n=40) or pneumothorax (n=10) aged from 5 to 76 years, were distributed into 2 groups:

– G1: 40 patients treated with injecting iodopovidone 3 successively days (20 ml iodopovidone + 30 ml saline solution) via chest tube.
– G2: 16 patients had pleurodesis through thoracoscopic using talc.

Results: Time to pleurodesis was similar in 2 groups (8±3 vs 6±2 days). As the mean length of hospitalization (31.3±12 vs 27±4.15 days) and mean length of drainage (6±1 days vs 10.6±8.1 days), there is no statistically difference in the 2 groups. A complete response with no recurrence was similar in 2 groups obtained in 44 (78.5%) of cases. After instillation of the sclerosing agent, intense cough and dyspnea were noted only during G1 (n= 3), and 2 patients had systemic hypotension and intense pleuritic pain. Local complications were observed in 10 cases (18%) with no statistically difference in 2 groups: pneumothorax (n=7) and empyema (n=3). Chest pain evaluated with visual scale measurement after a removed tube was similar in 2 groups. As the mean length of follow-up, there is no statistically difference (5±2.9 and 6.3±1.8 months).

Conclusion: Iodopovidone is an effective, safe, cheap, easily available alternative to achieve chemical pleurodesis in cases of recurrent, incapacitating effusions regardless of etiology.

P1267
Pleural effusions in lung cancer
Milic Medenica, Redrep Kraja, Mirus Medenica. Bronchology, Hospital for Lung Diseases “Brezovik”, Niksic, Montenegro, Serbia Bronchology, Hospital for Lung Diseases "Brezovik", Niksic, Montenegro, Serbia Student at School of Medicine, University of St Andrews, United Kingdom

The most common cause of malignant effusions in males is lung cancer. Malignant effusions are the result of spread of lung cancer to pleura or dissemination of metastatic tumour to one of the pleural surfaces. Paramalignant effusions are the result of lung cancer, but not a result of spread of malignant diseases to pleura.

Methods: The study group comprised of patients in territory of Montenegro, in time period from 01.01.2008 to 31.07.2011. All patients with pleural effusions had their pleural liquid cytologically tested, and histological processing of samples of pleural tissue obtained by blind needle biopsy (66 patients) or VATS (8 patients) was done. Descriptive statistical method and retrospective study were used.

Results: Total number of newly diagnosed cases of lung cancer was 585 (squamous cell ca - 361 (62%), SCLC- 139 (23.5%) adenoca 85– (14.5%). Paramalignant effusion was diagnosed in 33 patients (5.64%). Paramalignant effusion was found in 17 patients with squamous cell ca (4.7%), in 9 patients with SCLC (6.5%) and in 3 patients with adenoca (3.6%). No statistical significance was found when correlating frequency of paramalignant effusion to histological type of lung cancer (p<0.05). Malignant effusion was diagnosed in 55 patients. Malignant effusion was the most common in pts suffering from adenoca (found in 26 patients – 30.6%, p<0.01), while malignant effusions were found in 13 pts with squamous cell ca (3.6%), and in SCLC in 9 patients (6.5%).

Discussion: No statistical significance was found when trying to correlate frequency of paramalignant effusion in different histological types of lung cancer. In the group of patients with malignant effusion adenoca is the most common causal factor of spread of malignant disease to pleura.

Bronchoscopic revealed an almost complete obstruction of the left main stem bronchus with extensive infiltration of the mucosa by tumorous tissue. The EBUS-TBNA biopsies demonstrated the suspect of a neoplasm of hematologic origin. The patient was transferred to a referral center for hemat-o-ncology and underwent a bone marrow biopsy. It could be diagnosed an acute myeloid leukemia. The mediastinal mass and bronchial infiltration corresponded to a chloroma (myeloid sarcoma) as a rare and severe initial manifestation of the disease.

Chloroma is an extramedullary, solid tumor which occurs in association with myelodysplastic or leukemic disorders. It affects 3-8% of patients with acute myeloid leukemia and can present as the initial manifestation of hematologic malignancy. The anatomic distribution includes bone, nerve, lymph node, and skin, but may involve a variety of soft tissues. Pulmonary and mediastinal involvement is rare. Just one case has yet been reported in literature with an identical pattern of airway infiltration.

P1269
Ectopic heterotopic mediastinal thyroid tissue mimicking lung cancer
Kalliopi Athanasiosi1, Maria-Styliana Kolokotroni 1, Iliana Samiotis 1, Despina Violidaki 1, Konstantina Sotiriou 1, Dimitra Rondogiani 2, Ion Bellenis 2, 1Thoracic Surgery, General Hospital “Evangelismos”, Athens, Greece; 2Pathology, General Hospital “Evangelismos”, Athens, Greece; 3Anaesthesiology, General Hospital “Evangelismos”, Athens, Greece

Objective: Ectopic intrathoracic thyroid tissue is a very rare presentation of a mediastinal mass, comprising 1% of mediastinal tumors and can be distinguished from restenormal goiter or secondary intrathoracic goiter from the fact that the former receives its blood supply from mediastinal vessels rather than the neck and is not connected to the cervical thyroid. We present a series of 9 patients with heterotopic mediastinal thyroid mimicking lung cancer.

Material: Nine patients, 5 male and 4 female ranging in age between 56 and 79 years were admitted at our hospital. All patients but two were asymptomatic. Chest radiography revealed a mass in the superior middle or posterior mediastinum, in 2 cases with tracheal deviation. CT scan revealed a mass and further investigation took place with MRI. Preoperative staging was negative for metastatic disease in all cases and ultrasonography, scintgram and I131 uptake precluded the possible existence of thyroid tissue. Thyroid function tests were also normal.

Results: All patients were led to surgery and were submitted either to lateral mini-thoracotomy (n=5), or cervical incision (n=3) or thoracoscopry (n=1). In all cases there was an encapsulated mass with blood supply from intrathoracic vessels.
and histopathology revealed thyroid. The postoperative course was uneventful and no recurrence was observed in a follow up of 2 months to 4 years.

**Conclusion:** Although malignant transformation in heterotopic thyroid tissue is extremely rare, these masses should be resected in order to put the diagnosis and to avoid later complications such as progressive enlargement, hemorrhage within the mass causing respiratory failure, and compression of vital mediastinal organs.

**P1270**
Endobronchial ultrasound transbronchial needle aspiration at Aberdeen Royal Infirmary: How are we doing?

David Miller, Pratheega Mahendra, Valerie Bruce, Keith Kerr, Mary McKean, Mahendran Chetty, Graeme Currie.

Aberdeen Royal Infirmary, Aberdeen, United Kingdom; Department of Pathology, Aberdeen Royal Infirmary, Aberdeen, United Kingdom

**Background:** Endobronchial ultrasound transbronchial needle aspiration (EBUS-TBNA) is a more convenient alternative to mediastinoscopy for sampling mediastinal lymph nodes. We describe the demographics, results, and diagnostic sensitivity of EBUS-TBNA in the 1st 100 procedures performed.

**Methods:** Since the service began in 2010, patient age, gender, length of procedure, sedative doses, numbers of passes for each node and results were recorded and retrospectively analysed.

**Results:** Of 100 patients, 66 were male with mean age 62 years (range 22-88). Mean procedure duration was 16 minutes, and median doses of midazolam and fentanyl were 4mg and 100mcg respectively. 142 lymph nodes were sampled with median number of passes of 4 per node. Lymphoid material was obtained from 126 (86%) of all nodes sampled. A pathological abnormality was found in 73 patients: NSCLC (n=34), SCLC (n=20), granulomatous inflammation (n=14), possible lymphoma (n=1) and metastatic neck (n=1), urological (n=2) and breast cancer (n=1). In the remaining 27 patients, no lymph node was sampled in 10 and lymph node was sampled in 17 cases with no abnormality noted; of the latter, 9 were true negatives. The diagnostic yield that trainees should achieve before becoming independent bronchoscopists.

**Conclusion:** Locally our experienced bronchoscopists are exceeding the 80% diagnostic yield in cases of a definite tumour. Using the lower limit for success, we suggest that 95% of trainee bronchoscopists should be achieving a minimum diagnostic yield of 75%. More data is needed in order to obtain more robust statistical data which can be developed into realistic benchmarks and assessment tools to measure trainee competency.

**P1271**
Ideal volume sampling in the diagnosis of malignant pleural effusions

Vasile Anastasakos, Mpsirtsztogou Danai, Zetros Athanasios, Mpampoulos Stavros, Marketos Charalambous, Georgios Politis. Respiratory Unit, Agos Savvas Oncological Hospital, Athens, Greece

**Introduction:** Management of pleural effusion is based on established guidelines deriving from scientific committees and experts on pleural diseases all over the world. Nevertheless true consensus on volume sampling in malignant pleural effusions has not yet been achieved. Only few publications have been published over the past 10 years. Further studies should take place in order to clarify this essential point in the management of malignant pleural effusions.

**Hypothesis:** 20 to 40 ml of pleural fluid could improve cytology yield in high risk malignancy patients.

**Methods and materials:** Patients with at least medium sized pleural effusion and high risk for malignancy are enrolled. Pleural fluid is extracted as follows:

1. 10cc of pleural fluid sent for cell typing and ALB, PFT, LDH, CHOL, TG analysis
2. 20cc of pleural fluid extracted and placed as sample A
3. 30cc of pleural fluid extracted and placed as sample B
4. 150cc of pleural fluid should be extracted and placed as sample C

Samples A, B and C are sent for cytology.

Cytology results include the following:

1. Positivity or negativity for malignancy
2. Malignant cells numerosity (rare, infrequent, frequent, dense)
3. First data in our research strongly support our hypothesis and we feel that with our sample growing we will be able to show that a larger quantity of pleural fluid will not improve results (whilst will affect costs and laboratory man hours), but 20 to 40 ml could play a role in diagnosis and should be the target quantity. We hope our study will help to decrease time to diagnosis, reduce cost (less paracentesis, less adverse effects, less hospitalization time) and provide material for evidence based guideline development in the future.

**Conclusion:** Practising doctors tend to develop their own rational examination routine which can be improved by adding items of high precision (e.g. crico-sternal...
The impact of hands-on respiratory management for physicians in clinical practice and its future perspective
Kazuki Hasegawa1, Ryoma Tanaka1, Norihito Kaneko2, 1Pulmonary Department, Kameda Medical Center, Kamogawa, Chiba, Japan; 2Pulmonary & Critical Care Medicine, LDS Hospital, Salt Lake City, UT, United States; 3Master of Health Professions Education, Maastricht University, Maastricht, Netherlands

Introduction: To respond to the demands of systemic mechanical ventilation management education, the Respiratory Management Hands-on Workshop for Physicians in-training (RMWP) began in November of 2010 as an extracurricular program, followed by the Brush-up workshop for supervisory doctors in July of 2011.

Objectives: To evaluate the impacts and the value of RMWP on clinical practice and to establish a future direction, we conducted a pre/post-test, a questionnaire on the contents, and a post-survey of the workshop attendees via the Web.

Methods: The pre/post-test and the anonymous questionnaire were conducted during the workshops. As for the post-survey, the e-mail with questions regarding workshop was sent in September 2011 to the attendees of the workshop and the first day brush-up workshop for advisory doctors.

Results: The attendees’ knowledge base requiring for respiratory management was not correlated with experiences of mechanical ventilation. In regard to the post-survey, a total of the 55% (61 out of 111) answered. There are two remarkable findings. Firstly, the number of physicians using Assist-Control mode increased, whereas SIMV mode decreased. Secondly, the lecture of Graphic monitoring & Lung mechanics, although the lecture had been marked as less useful than others in the questionnaire taken right after the workshop, was marked as the most useful lecture in their practice.

Conclusions: The results of post-survey indicated the potential to change physicians’ behavior in respiratory management. RMWP should provide both lectures and practice sessions with expert eyes to overcome the physicians’ misunderstandings and lack of the whole picture.
Patients’ knowledge and prejudices about chronic obstructive pulmonary disease

Lipumila Nagomni-Obadovic, 1,2 Draga Peus1, 2 Internal Medicine, School of Medicine University of Belgrade, Serbia; 3 Teaching Hospital of Lung Diseases, Clinical Centre of Serbia, Belgrade, Serbia

Background: Proper patients’ (Pts) knowledge on a chronic disease is an important issue in successful disease management.

Aim: To estimate Pts’ knowledge and prejudices about chronic obstructive pulmonary disease (COPD).

Methods: Observational, questionnaire based study included 68 pts (mean age 63 yr, M/F=41/27) treated for COPD at University hospital in Belgrade, Serbia, from June to December 2011. Pts completed the 9-item questionnaire voluntarily and anonymously.

Results: A total of 50 (73.5%) pts underestimated recommended respiratory rehabilitation and have not used it; 28 (41.2%) pts prefer teophyllin compared to the other therapy; 41 (60.2%) pts have not get vaccinated against influenza to reduce exacerbation of the disease; 33 (48.5%) pts used more frequently short-acting β2 agonists instead advised therapy scheme; 29 (42.6%) pts had correct technique of using inhalation therapy; 22 (32.4%) pts overreact in using antibiotics during exacerbation; 53 (77.9%) Pts do not seek help for symptoms of depression in COPD; 20 (29.1%) pts cut down therapy themselves; 36 (52.9%) Pts are active smokers and one third of them do not recognize tobacco smoking as risk factor for pulmonary disease.

Conclusion: COPD Pts’ knowledge about the disease should be improved to achieve their better adherence to treatment, quality of life and more successful disease management.

Pleural procedures – Are junior doctors struggling to gain experience?

Manish Gautam, Diana Lees, Josheel Naveed, Chris Warburton, Lisa Davies.

Respiratory Medicine, Aintree Chest Centre, Liverpool, United Kingdom

Introduction: BTS guidelines and UK training curricula highlight the importance of gaining experience in pleural procedures. By the end of core medical training (CMT), trainees are required to demonstrate competency in pleural aspiration and Seldinger chest drain insertion.

Aim: To investigate the self-reported competency of junior doctors in performing pleural procedures

Method: On the spot’ questionnaires were randomly distributed to 64 doctors training in a large university teaching hospital. Participants graded their level of confidence in performing a variety of pleural procedures and possible reasons for lack of experience.

Results: Response rate was 91%; 7 Speciality trainees (ST3-7), 17CMTs, 12 Foundation Year 2 (FY2) and 1 FY1 trainees. 36% reported independent ability to perform pleural tap, 31% aspiration, 21% chest drain insertion, 22% pleurodesis, 45% removal and 34% flushing of chest drains. All STs reported competence, but, 76% of trainees felt they were struggling to gain sufficient practical experience. Those with respiratory experience were more likely to report competence (p=0.001) although only 1/3 could insert a chest drain independently. Top reasons for ‘struggling’ were increasing use of ultrasound (US) (33%), followed by perceived lack of senior encouragement (17%).

Conclusion: Our data suggest that the majority of trainee physicians do not feel competent to undertake pleural procedures independently. With increasing use of US for pleural procedures, trainees are having difficulty gaining experience. For CMTs, UK curricula now state mandatory competency in chest drain insertion for pneumothorax only, but training programmes must ensure adequate exposure to important pleural procedures.

Beyond PROs – Using narrative techniques to understand the real life of patients with COPD

Mohammad Al Ubaydli1, Mike Baldwin1, Anne Marie Cunningham2, Alexander Mackay3, David Snowden, Wisaa Wedracha3, 4 Centre for Health Informatics & Multiprofessional Education, University College London, United Kingdom; 3 Forham Research Centre, Novartis, Horsham, United Kingdom; 2 Medical School, University College London, United Kingdom; 4 School of Medicine, Cardiff University, Cardiff, United Kingdom

Background: The experience of living with COPD is complex and emotional [1,2]. Knowledge of illness experience is different from biological disease [3]. Traditional COPD questionnaires were based around patient-reported outcomes, but did not have enough focus on patient-reported information about the illness [4]. Narrative capture technique [5] could offer new insights. It has been applied outside of health care in anthropology, defence and development contexts. Unlike structured PROs it accepts the patient giving information as a story, a narrative. And in narrative capture technique, the person telling the story is also the person explaining its meaning.

Method: Asking patients daily to enter stories, and to indicate the meaning of each of these stories through labeling.

Conclusion: This narrative technique may be a feasible one for understanding how COPD fits into the patient’s overall life.

Impact of a structured educational program for nursing staff on chest drain care

Raman Ahmed, Rehan Naseer, Allison Scott, Matthew Callister. Respiratory Medicine, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: At the 2011 ERS congress we presented findings from a survey of nursing staff regarding chest drain knowledge, care and management in our tertiary care centre. Worryingly we found only 17% felt they had adequate training in chest drain care. We present our intervention and subsequent feedback.

Intervention: Unlike doctors in the UK, nursing staff usually do not have a structured training program. We developed an interactive self- directed workshop on chest drain knowledge and management, based on the adult learning principles of Andragogy. The instructional design theories used to help learning included constructivism and the use of cognitivism and behaviouralist design which allowed efficient construction and transfer of knowledge. Nursing staff based on respiratory wards were asked to complete the workbook and a self assessment at the end. They also attended a workshop which included 30mins of lectures followed by 30mins of group discussion. Structured forms were used to collect feedback.

Feedback: 24 feedback forms were analysed. 96% ‘agreed’ or ‘strongly agreed’.
1. The workbook was relevant to their current role.
2. The activities and tasks helped to improve their understanding of the topic
3. The training provided them with new knowledge on chest drain management.
4. Completion of the training improved their confidence in dealing with chest drains.

Subjectively we felt patient care and safety improved on the wards.

Conclusion: Formal training sessions of nursing staff on chest drain care has proved very popular and productive for nursing staff and we recommend other hospitals should consider developing similar sessions to improve the standard of care.

A pleural information programme: For patients and training

Burhan Khan, Hamid Amnay Raouf. Department of Respiratory, Medicine, Darent Valley Hospital, Dartford, Kent, United Kingdom

Background: Pleural effusions usually signify advanced disease, increased symptom load and limited life expectancy when malignant. They need prompt effective management, safely and with least possible inconvenience and discomfort. Patient choice is key and informed consent is crucial because of possible risks related to the invasive pleural intervention.

Aim: To develop an interactive tool for healthcare professionals to illustrate and explain the various pleural modalities to patients and trainees.
PI283
Survey of bronchoscope disinfection practices by chest physicians attending IP CME in Navi Mumbai, Maharashtra
H S Sandeep, Arvind Kate, Prarthit Chauhuri, Prashant Chhajed. Department of Pulmonology, Fortis-Hiranandani Hospital, Vashi, Navi Mumbai, Maharashtra, India

Aim: To study various methods used for disinfecting bronchoscope by delegates attending a CME on Interventional Pulmonology.

Methods: A 23 question survey was divided into sub groups like location of bronchoscopy suite, disinfecting techniques, bronchoscope care and sedation practices. The survey was distributed to participants from Western India in a CME on Interventional Pulmonology.

Results: 31 out of 40 participants completed the questionnaire. One was excluded as it was incomplete. 8 questionnaires were completed by medical director of bronchoscopy suite, 18 by chest physicians and 5 by the fellows.

Conclusion: Increased awareness and education is required for bronchoscope disinfection techniques and adherence to guidelines.

PI284
Online self-management in patients with COPD or asthma: With or without the healthcare provider?
Johannes In’t Veen1, Bianka Mennema2, Esther van Noort3. 1Pulmonology, St Franciscus Gasthuis, Rotterdam, Netherlands; 2Pulmonology, Havenziekenhuis, Rotterdam, Netherlands; 3Connect, Curavista BV, Geert Groeneweg, Netherlands

Introduction: Self-management plays a key role in integrated care strategies for chronic diseases. Curavista Health is an online patient self-management platform for severe chronic diseases, including asthma and COPD. MyCOPDOnline & Myasthmaonline which consists of 3 basic-elements: 1. Health status; 2. Self-management; 3. eConsult. We incorporated the program into our daily hospital routine for outpatients. Patients however also can participate without health care provider, as open access program.

Aim: The aim of the study was to retrospectively analyze the adherence to the program of patients with or without health care provider.

Results: The content of the program was identical in both groups. Age and gender were comparable. In the group without coaching (n=831), 68% used the program once, 18% twice and 14% three times or more. In the group with coaching (n=95), 33% used the program once, 17% twice and 50% three times or more (p<0.001).

Discussion: Self-management suggests that patients manage themselves and the role of the professional is limited. In contrast, these data suggest that participants make better use of eHealth programmes when supported by healthcare professionals. Therefore eHealth should be embedded into regular care. It might imply not only a role change for patients to achieve self management, but also for the health care professional in transition from ‘medication manager’ to coach.

PI285
The general practitioners knowledge and educational programs efficiency in antibiotic use
Roman Bontsevitch1, Ruslan Bontsevitch2. 1Internal Medicine, St. Iouasof Belgorod Regional Clinical Hospital, Belgorod, Russian Federation; 2IT and Optimization Department, AXOR ltd, Dnipropetrovsk, Ukraine

Aim: To study and compare the level of general practitioners (GPs) knowledge in questions covered problems of rational antibiotic (AB) use in pulmonology in different regions. To estimate the importance of rational AB use educational and control programs (ECP).

Methods: During 2006-2012 ECP were developed and carried out among 58 GPs in Dnipropetrovsk’s region (DN), 35 – in Lрабатунгardi (LA) and 31 – in Belgorod (BE). Special questionnaire included 10 complex tasks with a set of questions has been created to estimate an initial and final levels of medical staff awareness (LMSA). The knowledge of AB groups, dosage, frequency and indications of usage, combinations, timing of therapy, cancellation and replace of AB was assessed.

Results: After GPs completed questionnaire at the first time, the level of correct answers (LCA) has totalled 48.6%, in DN – 51.6%, LA – 39.8% (p<0.05, BE – 53.1%. Taking into account the results of received data there have been developed and carried out special ECP Comparative exercise was repeated year later. Summary LCA was statistically (p<0.05) increased to 62.5% (in DN – 62.7%, LA – 60.1%, BE – 64.9%) without statistically differences between regions. The validity of AB prescribing, quality of treatment was statistically increasing, and on the opposite, quantity of GPs mistakes was statistically decreasing (p<0.05).

The most difficult questions were the following: rationale combinations, empirical therapy, pneumonia therapy and MO sensitivity.

Conclusions: There is a necessity to carry out the rationale AB use ECP among GPs to increase LSMA and quality of treatment, and to decrease mistakes. Therefore, the most difficult questions are to be studied more deeply.

PI286
Tele-education in asthma management. What are the benefits?
Olga Vakhno1, Vitaly Kupaev2, Dmitry Nagarkin3. 1Pulmonology, Samara Regional Clinical Hospital, Samara, Russian Federation; 2General Practice, Samara State Medical University, Samara, Russian Federation; 3Allergology and Immunology, Samara Regional Clinical Hospital, Samara, Russian Federation

The aim was to research two approaches of asthma education and to find the most effective one.

98 mild asthmatic patients have been involved randomly so far (age 41.0±15.2 yrs). We study 3 groups according to the type of chosen education: 1st group have passed the ordinary asthma education (were educated by physician) (n=22), 2nd-have passed tele-education asthma program (n=36), 3rd-didn’t have any advantage (n=30).

Criteria to objectify the effectiveness were: asthma control assessed by ACT and ACQ, life quality level, lung function, Cooperation Index (CI), the cost of intervention, self-management, knowledge control test results.

The majority of patients initially had partly controlled asthma (43.9%) and current working social status (60.6%). Finally we have detected that patients of the 1st and 2nd groups have obtained significantly higher control level, higher life quality values, decrease in taking reliever medications in comparison with the 3rd group (p<0.05). The higher Cooperation Index was observed in the 1st group (Mean=67.0%, p<0.05). Cost of ordinary asthma education, performed by physician (the 1st group) was 20.1 € and tele-education (the 2nd group) –10.7 €. There were significant correlations in the 2nd group between results of asthma control (ACT™ and ACQ scores) and knowledge control test results (rACQ=0.77, p<0.05 and rACQ=0.68, p<0.05). ACT and ACQ results were significantly lower in the 3rd group (MeanACQ=16.3 pts, MeanACT= 1.8, p<0.05).

</tr>
</tbody>
</table>

*For those who answered yes to the above question.
Conclusion: So, each of the approaches to asthma education leads to higher asthma control. Besides this, tele-education has shown more cost-effectiveness. This instrument is required to be available to each patient.

P1288
Semantic pattern analysis of patient perceptions using automated co-occurrence information mapping
Mark Rolfe1, Jo Powell-Bright1, Daniel Dodd2, Research Evaluation Unit, Oxford, United Kingdom; 2The Thoughtware Group, Byron Bay, NSW, Australia

Background: The majority of patients with chronic diseases seek additional information from the internet following medical consultations. Text analytics is a widely recognized, validated system for modelling the structure and information content of text. Here we describe a unique method for identifying and analysing linguistic information from the internet to provide quantitative, unprompted insights into patients’ sentiments about their conditions.

Methods: Boolean- and thesaurus-based, machine-learning software is used to conduct an iterative nonlinear search of the web for all relevant texts containing broad keywords related to a given chronic disease. Texts are then analysed by Leximancer (v4.0), a text-mining tool that identifies themes and concepts from large bodies of text using a statistics-based algorithm.

Results: This innovative approach ensures that a comprehensive disease-specific dataset is captured from the web. Leximancer automatically identifies commonly occurring concepts (weighted combinations of words that co-occur within the text). They were presented visually as maps, showing the strength of the relationship between different concepts (relative frequency and inter-connectedness) to facilitate semantic classification. Positive and negative sentiments about specific aspects of the disease and its management can be identified and selected for statistical analysis, demonstrating the validity of this technique.

Conclusion: The internet is a data-rich source of patient-to-patient and patient-to-healthcare professional communications. The sentiment analysis method described can facilitate broader understanding of patient perceptions of their disease and its management.

P1289
Home telemonitoring of CPAP: A feasibility study
Jean Louis Fraysse1, Nathalie Delavillemarque2, Bernad Gasparutto2, Ludvine Leseux1, Paul Leophonte1, Alain Didier1, 1Prestataire de Santé à Domicile, 2SADIR, Larrey, France; 3Prestataire de Santé à Domicile, Aliseo, Orvault, France; 4Prestataire de Santé à Domicile, ADR Assistance, Isneauville, France

Background: The most commonly used treatment for sleep apnea syndrome (SAS) is the application of constant positive airway pressure (CPAP) during sleep. Compliance is an essential element of CPAP efficiency. Compliance is dependent on the quality of the coverage care and on the information of the patients. With the telemedicine emergence, telemonitoring of the CPAP makes its appearance in France.

Methods: This study is observational and multi centers. The main aim of this study was to evaluate the feasibility of CPAP telemonitoring in SAS patients (n=90). During the installation of equipment, patients receive the instruction to connect the CPAP SD card to a connecting box named twitoo, every week during 2 months. The data transmission is made towards the study coordinator, the home care provider named SADIR, by the way of a telemedicine platform, located in Toulouse, France. Actual numbers and frequency of remote-monitoring box connexions are quantified.

Results: 92% of patients (n=62) connected SD card to twitoo at least once. We expected a maximum of 8 connections with a frequency of one connection every 7.6 days. We observed a mean of 6.2 connections during the 2 months, with a frequency of one connection every 7.6 days.

Conclusion: This study demonstrated good adhesion of the patients to this new tool of data transmission, by telemonitoring, of their CPAP treatment. Its efficacy on treatment compliance has to be evaluated in a larger group using a randomized procedure.

P1290
Parental educational intervention for asthma in children: A randomized controlled trial
Anita Dodos1, Joanne Hardman1, Caroline Hardman2, Claire Jambor1, 1University of Sydney, School of Nursing and Midwifery, Sydney, Australia; 2Macquarie University, Sydney, Australia

Introduction: Byron Bay, NSW, Australia

Objective: To investigate how important parent’s level of general education was for the success of organized Asthma Educational Intervention (AEI) program. We assessed parents’ knowledge of asthma by questionnaire before, during and after the AEI. Success of the AEI was determined using the control group and the intervention group. The AEI group was divided into low level of education (parents with low education) and high level of education (parents with high education) groups. Parents: with low (≤ 12 years) and high (> 12 years) levels of education. This study is observational and multi centers. The main aim of this study was to evaluate the feasibility of CPAP telemonitoring in SAS patients (n=90). During the installation of equipment, patients receive the instruction to connect the CPAP SD card to a connecting box named twitoo, every week during 2 months. The data transmission is made towards the study coordinator, the home care provider named SADIR, by the way of a telemedicine platform, located in Toulouse, France. Actual numbers and frequency of remote-monitoring box connexions are quantified.

Results: 92% of patients (n=62) connected SD card to twitoo at least once. We expected a maximum of 8 connections with a frequency of one connection every 7.6 days. We observed a mean of 6.2 connections during the 2 months, with a frequency of one connection every 7.6 days.

Conclusion: This study demonstrated good adhesion of the patients to this new tool of data transmission, by telemonitoring, of their CPAP treatment. Its efficacy on treatment compliance has to be evaluated in a larger group using a randomized procedure.

P1291
Cost-utility analysis of indacaterol – A once-daily maintenance bronchodilator for patients with COPD
Yumi Asukai1, Jiatiti Ananthapavlan1, Bill Malcolm1, Ann Radwan1, Ian Keyzer2, 1Health Economics and Outcomes Research, IMS Health, London, United Kingdom; 2Scientific Operations, Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom; 3Clinical Development & Medical Affairs, Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom; 4Health Economics and Outcomes Research, Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom

Introduction: COPD is a chronic incurable disease; however, there are effective treatments available. In the UK, long-acting bronchodilators are first-line treatments for COPD patients requiring maintenance therapy, and there are several options available. Aims: To establish from the UK NHS perspective, the cost-effectiveness (CE) profile of indacaterol, the first once-daily LABA, compared to tiotropium and salmeterol, in patients with moderate to severe COPD.

Methods: A Markov model was developed with four health states describing the GOLD severity stages. From each of the states, patients could experience a severe or non severe exacerbation, move to a different COPD state, remain in the current state or die. Transition probabilities were based on data from the indaceterol clinical trials. Cost and resource use data was taken from UK based sources, published literature and expert opinion. Sensitivity analyses (SA) were also conducted.

122. Looking at the cost effectiveness of asthma and COPD treatment by novel drugs and improved management

P1292
A UK based cost-utility analysis of indacaterol – A once-daily maintenance bronchodilator for patients with COPD
Yumi Asukai1, Jiatiti Ananthapavlan1, Bill Malcolm1, Ann Radwan1, Ian Keyzer2, 1Health Economics and Outcomes Research, IMS Health, London, United Kingdom; 2Scientific Operations, Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom; 3Clinical Development & Medical Affairs, Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom; 4Health Economics and Outcomes Research, Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom

Introduction: COPD is a chronic incurable disease; however, there are effective treatments available. In the UK, long-acting bronchodilators are first-line treatments for COPD patients requiring maintenance therapy, and there are several options available. Aims: To establish from the UK NHS perspective, the cost-effectiveness (CE) profile of indacaterol, the first once-daily LABA, compared to tiotropium and salmeterol, in patients with moderate to severe COPD.

Methods: A Markov model was developed with four health states describing the GOLD severity stages. From each of the states, patients could experience a severe or non severe exacerbation, move to a different COPD state, remain in the current state or die. Transition probabilities were based on data from the indaceterol clinical trials. Cost and resource use data was taken from UK based sources, published literature and expert opinion. Sensitivity analyses (SA) were also conducted.
Results: Indacaterol dominates both tiotropium and salmeterol over a 3-year time horizon with a cost saving of €137 and €289 respectively. The one-way SA indicated that the time horizon and the mortality rate associated with very severe COPD had the largest impact on the results. The probabilistic SA showed that over 75% and 90% of the iterations when compared to salmeterol and tiotropium respectively produced dominant results for indacaterol.

Conclusion: The CE analyses demonstrate that indacaterol dominates both tiotropium and salmeterol and is likely to remain cost-effective under a range of assumptions.

P1293
The drug costs associated with COPD prescription medicine in Denmark
Peter Lønberg1, Marie Jakobsen2, Niels Aaker3, Jens Dollerup4, Peter Bo Poulsen5
1Department of Public Health, Section of Social Medicine, University of Copenhagen, Denmark; 2Department of Labour and Health, COW AS, Lyngby, Denmark; 3Medical & Access, Pfizer Denmark, Ballerup, Denmark

Background: Spirometric studies of the general population estimate that 430,000 Danes have chronic obstructive lung disease (COPD). COPD is mainly caused by smoking with smoking cessation being considered the most important intervention to prevent disease progression. Cost-of-illness of COPD in Denmark is significant. However, the use of prescription medicine for COPD has not been analysed for the Danish population.

Aim and objective: Analyse the societal costs associated with prescription medicine for the treatment of COPD in Denmark.

Methods: The study was designed as a nation-wide retrospective register study of the drug costs (ATC group R03) associated from COPD from 2001-2010. Data were retrieved from the Prescription Database and the National Patient Register. The population included individuals (40+ years) having had at least one prescription of medications (R03) with an indication code indicating COPD. Patients dying were included up to time of death. A societal perspective included both public reimbursement costs and co-payment. Costs were calculated in fixed 2010-prices using a Laypeyres price index (average treatment cost per DDD and DDD amount sold).

Results: In the period 2001-2010, 292,646 individuals (40+ years) have had at least one prescription of R03 medication. Among these, 124,020 with a COPD diagnosis had been hospitalized, whereas 46,218 have not. The annual average drug cost (R03) was DKK 8,017 per patient (Euro 1,069) with a total average cost per year of 680 million DKK (91 million Euros).

Conclusions: The annual costs of prescription medicine for COPD in Denmark are significant. For comparison smoking cessation treatment costs, i.e. the primary intervention towards COPD, are much lower.

P1294
Varenicline is a cost-effective pharmacotherapy in smoking cessation of nicotine dependent patients with mild to moderate COPD
Heikki Ekroos1, Jarmo Hahl2, Kaisa Tippurainen3, Kari Linden4, Miika Linna5, Maarit Saarinen6, Aino Pikkarainen7, Heikki Soininen8, Maria Saarinen9, Kari Manninen10, Pasi Savela11
1 of 239s

Background: Smoking causes significant burden to health care systems and societies and is the most common cause of COPD, one of the leading causes of death globally. Smoking accelerates progression of the disease, yet many people continue to smoke after COPD diagnosis.

Objective: To study the cost-effectiveness (CE) of varenicline combined with physician advice as a smoking cessation compared to physician advice alone in smokers with mild to moderate COPD from a Finnish health care payer perspective.

Methods: A Markov cohort health state transition structure was used to model the lifetime transitions of a smoker cohort through COPD stages I-IV, lung cancer and death. Data from pivotal safety and efficacy study of varenicline for smoking cessation were used with Finnish morbidity, mortality, smoking and health care resource consumption registry data and results from local quality of life studies.

Results: In the base case analysis incremental CE ratio (ICER) of varenicline is €1,1000/Quality Adjusted Life Year (QALY) gained or €1,000/Year Life gained in lifetime analysis. A frequently referred ICER threshold of € 4000/QALY gained is achieved before 11 years. Both univariate and probabilistic sensitivity analysis (PSA) confirm the robustness of these results; in PSA the probability of varenicline being cost-effective is 100% at a willingness to pay (WTP) level of €4000/QALY gained in lifetime horizon, and exceeds 50% at WTP level of €3000/QALY gained after 10 years.

Conclusions: The study suggests that varenicline combined with physician advice is cost-effective compared to physician advice alone in smoking cessation of Finnish patients with mild to moderate COPD.

P1295
The potential cost-effectiveness of glycopyrronium bromide, a novel LAMA muscle antagonist (LAMA). It will provide a potential alternative therapy option for the maintenance treatment of moderate-to-severe COPD.

Objective: To estimate resource utilization and economic impact of switching uncontrolled asthma and exacerbating COPD patients on monotherapy to fixed dose combination treatment in Germany
Sadik Ardic1, Maria Jakobsen2, Niels Anker2, Jens Dollerup3, Peter Bo Poulsen4
1Ankara University, Ankara, Turkey; 2Clinic of Chest Diseases, Yedikule Chest Research Hospital, Ankara, Turkey; 3Medical Department, Pfizer Oy, Helsinki, Finland; 4HEMA institute/Department of Industrial Engineering and Management, Aalto University and National Institute for Health and Welfare, Helsinki, Finland

Aim and objective: The potential cost-effectiveness of glycopyrronium bromide, a novel LAMA therapy, was evaluated in the Swedish market, given different pricing scenarios.

Methods: An economic evaluation was conducted based on the use of a Markov model to evaluate the cost-effectiveness of glycopyrronium with varying thresholds of cost-effectiveness. The main clinical inputs were the improvement in lung function and the rate ratio of exacerbation. These were obtained from the phase III clinical trial data comparing glycopyrronium with tiotropium and placebo. Drug acquisition costs in Sweden for the comparators were estimated from the Swedish Formulary (PSS). Costs of maintenance therapy and exacerbation treatment were obtained from published Swedish studies.

Results: When evaluated over a three year time horizon, glycopyrronium is cost-effective (at 500,000 SEK (USD 75,188) per QALY) compared to tiotropium, up to a public price of SEK18.15 (USD 2.73) using a payer perspective and SEK18.49 (USD 2.78) using a societal perspective.

Conclusion: Results of the economic analyses show that once-daily glycopyr- nonium is a cost-effective treatment alternative to tiotropium under a number of different pricing assumptions.
TL (3595 Euro) for asthma and 10798 TL (4629 Euro) for COPD. LABA+ICS combination (1132 TL, 485 Euro) was the highest drug-related cost. Poor control and increased severity of both asthma and COPD caused higher hospital cost and higher total direct cost (for p < 0.001).

Conclusions: The study revealed that based on the significant relation to direct costs, strategies to enable better disease control and to reduce severity of the disease in asthma and COPD must be considered in healthcare policies to limit economic burden.

P1298
Cost-effectiveness of early assisted discharge for COPD exacerbations in the Netherlands
Lucas Goossens1, Cecile Utens1, Frank Smeenk3, Onno van Schayck2, Maureen Rutgers-van Molken1 1 Institute for Medical Technology Assessment, Erasmus University, Rotterdam, Netherlands; 2CAPHRI, Maastricht University, Maastricht, Netherlands; 3 Pulmonary Disease, Catharina Hospital, Eindhoven, Netherlands.

Background: Hospital admissions for exacerbations of chronic obstructive pulmonary disease (COPD) are the main cost drivers of the disease. An alternative is treating suitable patients at home. This study reports on the cost-effectiveness of the GO AHEAD trial in the Netherlands.

Methods: Patients (n=139) were randomized to seven days of inpatient hospital treatment (HOSP), or to three inpatient hospital days and home treatment by community nurses for four days (EAD). Nursing and physician activities were analysed in detail in order to estimate costs for inpatient days. Healthcare resource use, absenteeism, and informal care were recorded in cost diaries. Calculations were performed from a healthcare perspective and a societal perspective, including costs outside healthcare.

Results: Seven days after admission, mean change from baseline Clinical COPD Questionnaire (CCQ) score was better for HOSP, but not statistically significantly: -0.5% (95% CI: -0.04; 0.61). EAD saved costs. The difference was significant from a healthcare perspective: -244 (95% CI: -315; -168). Societal: -65 (95% CI: -152; 25) After three months follow-up, differences in effectiveness had disappeared. The difference in quality-adjusted life years (QALYs) was 0.0054 (CI: -0.021; 0.0095). EAD saved costs from a healthcare perspective, but not significantly: -168 (95% CI: -1253; 922). From a societal perspective, total costs increased, due to higher informal costs: €908 (CI: -553; 2296).

Conclusions: No clear evidence was found to conclude that either treatment was more effective or less costly.

P1299
Inpatient hospital care or hospital-at-home for COPD exacerbations: A discrete choice experiment
Lucas Goossens1, Cecile Utens1, Frank Smeenk3, Bas Donkers4, Onno van Schayck2, Maureen Rutgers-van Molken1 1 Institute for Medical Technology Assessment, Erasmus University, Rotterdam, Netherlands; 2 Pulmonary Disease, Catharina Hospital, Eindhoven, Netherlands; 3 Erasmus School of Economics, Erasmus University, Rotterdam, Netherlands.

Objective: Quantifying patient preferences for different aspects of hospital-at-home care in the Netherlands for patients with COPD.

Methods: In a discrete-choice experiment, respondents were asked to make multiple choices between hospital treatment as usual (7 days) and two combinations of hospital admission (3 days) followed by treatment at home. The latter was described by attributes: training of homecare nurses (general/pulmonary), number of different nurses involved, number of daily visits, co-payments, readmission risk, contact in case of worsening disease (GP/hospital), and informal caregiver burden.

Hospital treatment was constant. Respondents were COPD patients in an RCT where focused effort can improve care and outcomes: finding out, living with the condition, when things go wrong and towards the end of life.

Results: 202 questionnaires were returned. 25% of patients and caregivers opted for hospital treatment regardless of the description of the hospital-at-home program, 46% never chose the hospital. The best models contained four latent classes, defined by different preferences for the hospital and for the caregiver burden. Preferences for other attributes were shared by all classes. Except for the number of visits, all attributes had a significant effect on choices in the expected direction.

Conclusion: Considerable proportions of patients and caregivers have a preference for either admission or hospital-at-home, irrespective of the characteristics of the hospital-at-home program. Financial burden and informal caregiver burden weighed most on the choice between hospital-at-home options. The number of daily visits did not play a role.

P1300
Health care claims analysis to quantify the burden of moderate-to-severe asthma
James Zazzali1, Eunice Chang2, Michael Broder1, 1Medical Affairs, Genentech, Inc, South San Francisco, CA, United States; 2Health Economics and Outcomes Research, Partnership for Health Analytic Research, LLC, Beverly Hills, CA, United States

Objectives: To describe the economic burden and health services use among moderate to severe asthma patients.

Methods: Retrospective cross-sectional cohort analysis using health insurance claims. Study period was 01/07/2006 through 30/06/2007. It included patients aged ≥12 who had an asthma diagnosis and used medium to high dose ICS/LABA with or without oral steroids and/or omalizumab (US National Heart Lung and Blood Institute [NHLBI] Steps 4-6) and who did not have chronic obstructive pulmonary disease (COPD).

Results: Conclusions: The economic burden of health care on patients with moderate-to-severe asthma is quite high and increases with disease severity. Although health care utilization by asthma patients has decreased in recent years, patients with severe asthma still spend significantly more time and money on health care than those with more manageable symptoms. Medications that better target both asthma symptoms and the underlying disease process should reduce these costs.

P1301
Managing COPD as a long term condition: Reducing variation and improving quality of care
Catherine Blackaby1, Phil Duncan, Alex Porter, Lung Programme, NHS Improvement, Leicester, United Kingdom

Introduction: COPD costs the UK healthcare system an estimated £1112m pa with national data indicating significant unwarranted variation in quality of care, recorded prevalence and hospital admission. Experience across a national improvement programme has identified four stages of any long-term condition where focused effort can improve care and outcomes: finding out, living with the condition, when things go wrong and towards the end of life.

Aim: To identify what information and approaches can help primary care teams in England use capacity differently to improve care and outcomes for patients living with COPD.

Method: Two practices, two clinical commissioning groups and one specialist respiratory team tested approaches to improve delivery of long term care for COPD patients. Evaluation of the patient pathway and current use of primary and secondary care resources identified priority areas. Clinical teams then tested how information, consultations and organisation of work could be adapted to improve healthcare resource use and patient-reported outcomes.

Results: Understanding current resource use and comparative performance demonstrated potential for more proactive use of capacity in areas such as education, self care and medicines management. The first two sites who spent increased time proactively with patients reported improvement in self management of exacerbations and medicines management.

Conclusion: Focusing effort on a small number of sites, regularly using comparative data and providing practical support can facilitate change and demonstrate how capacity may be used differently to improve quality of care for people living with COPD.

Improving adult asthma care in England: Emerging learning from a programme of national improvement projects
Hannah Wall, Phil Duncan, Alex Porter. Lung, NHS Improvement, Leicester, Leicestershire, United Kingdom

Introduction: Asthma is a long-term respiratory condition affecting up to 5.9% of the England population. There have been between 1000 and 1200 deaths a year since 2000 with almost 40% of these under 75 years old. Asthma is responsible for large numbers of emergency attendances to Emergency Departments and emergency admissions.

Aims: To use service improvement approaches to define the patient pathway in order to improve the patients experience and outcomes of care – and reduce overall variation.

Method: Seven improvement projects from primary and secondary care used improvement methodologies to analyse the existing patient pathway, implement service redesign and assess the impact for patients with asthma in relation to: diagnosis and medicines optimisation, chronic disease management and acute care. Primary care data was used to identify cohorts of patients eligible for diagnosis and review and secondary data was used to demonstrate areas of duplication and gaps in service provision.

Results: Implementation of principles such as: primary care register reviews, self-management support, medicines optimisation, standardised care in acute settings and primary care follow up on discharge have demonstrated cost savings and increased productivity in a number of improvement projects. Project data on reduction in admissions and Emergency Department attendances demonstrates improved outcomes. Patient feedback highlights a positive experience of redesigned services.

Conclusion: There is variation in the delivery and quality of asthma services in England. Systematic improvement approaches reduces variation and increases productivity as well as delivering a positive experience of care.

Pl303
Efficacy and safety of applying the British Thoracic Society (BTS) criteria to determine appropriateness of follow up in general respiratory clinics
Satinder Dalay, Vikan Panammyo, Shiva Bikmall, Alces M. Turner, Rahul Mulherker. Department of Respiratory Medicine & Physiology, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

Introduction: Respiratory physicians are under increasing pressure in England to discharge patients with chronic illnesses to primary care. The BTS statement on criteria for specialist referral, admission, discharge and follow-up for adults with respiratory disease (Thorax 2008; 63(Suppl I):i1–i16.) remains the only available basis for this dialogue.

Aim: To assess the impact of implementing BTS criteria for discharge on follow-up to new ratio (“new-to-follow up” ratio) in a general respiratory clinic (efficacy) and to assess readmission rates of those discharged as a measure of appropriateness of discharge.

Methods: Retrospective analysis of “new-to-follow up” ratios of one pilot general respiratory clinic in a large teaching hospital covered over a 2 week period in July 2010; repeat analysis undertaken (Oct-Dec 2010) after a BTS statement-guided clinical reform was implemented (Jul-Dec 2010) with a management plan in the clinic letter. Unscheduled hospital admission in 6 months following the date of the clinic discharge were compared with preceding 6 months.

Results: Number of Follow-up-to-new ratio pre-reform was 5.0 (144/29); post-reform improved to 0.86 (111/129); clinic waiting time fell from 13 to 5 weeks. There was a significant drop in all-cause and respiratory-related admission rates for those who were reviewed and discharged.

Conclusion: Patient-focussed, multidisciplinary approach to long-term respiratory conditions allows accurate diagnosis and appropriate discharge planning to take place using the BTS criteria.

Pl304
Economic analysis of costs associated with a respiratory intensive care unit (RICU) in a tertiary care teaching hospital in northern India
Kumari Shweta1, Sachin Kumar2, Anil Kumar Gupta2, Surinder Kumar Jindal2, Ashok Kumar2,1.1Hospital Administration, All India Institute of Medical Sciences, New Delhi, Delhi, India; 2Pulmonary Medicine, Institute of Liver & Biliary Sciences, New Delhi, Delhi, India; 3Hospital Administration, Post Graduate Institute of Medical Education & Research, Chandigarh, India; 4Pulmonary Medicine, Post Graduate Institute of Medical Education & Research, Chandigarh, India

Background: There is paucity of cost analytical studies from resource constrained developing countries defining the costs of intensive care.

Objective: Economic analysis of costs associated with RICU.

Methods: Prospective cost analysis study conducted in 74 patients admitted in the RICU from Dec 2008 to Feb 2009. Costs segregated into fixed and variable cost. Correlation of the costs to the length of stay, mechanical ventilation and therapeutic intervention scoring system-28 (TISS-28) also done.

Results: The total cost per day was U.S. $ 222.

Cost of RICU care (per patient per day)

<table>
<thead>
<tr>
<th>Total cost</th>
<th>INR 10,364 (U.S. $222)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total fixed cost</td>
<td>INR 4,478 (U.S. $104.43)</td>
</tr>
<tr>
<td>Total variable cost</td>
<td>INR 5,886 (U.S. $137.74)</td>

<tr>
<td>Total cost for ventilated patient</td>
<td>INR 6,585 (U.S. $140.98)</td>
</tr>
<tr>
<td>Total cost for ventilated patient</td>
<td>INR 12,429 (U.S. $286.09)</td>
</tr>
</tbody>
</table>

53.6% of the total cost was borne by the patients. The mean daily drug cost represented 69.8% of the variable and personnel salary constituted 86% of fixed cost. The TISS-28 score per nurse was significantly higher in non-survivors (69.2) than in survivors (30.6) and strongly correlated with the total cost (r = 0.91).

Conclusions: Great disparity exists in economic terms in the intensive care in the western and developing world. Although, considerably less expensive, intensive care is expensive relative to the cost of living in India. The cost block methodology provides a framework for estimation of costs; is useful in future planning of resource allocation within the financial constraints and allows comparisons between ICUs internationally in an economical model of evidence based care.

P1305
Verbal abuse and other violence types against doctors in chest diseases polyclinic
Sumeet Beri, Fatih Alasan, Peri Arback, Chest Diseases, Duzce University Faculty of Medicine, Duzce, Turkey

Aim: There are a few studies focused on unexpected patient-doctor relationship such as verbal abuse and the other types of violence.

Materials and methods: Two hundred thirty one patients (134 male, 97 female) who accepted filling out the forms and admitted to Chest Diseases Polyclinic between September and December 2011, were included in the study.

Results: The mean age of the patients was 53.6±16.7 (15-85) years. The mean duration for anamnesis was 10.1±4.2 minutes. Forty five patients used verbal abuse or other types of violence (6.1%). Mostly, patients used violence by themselves (78.6%). Seven patients ridiculed (50%), two patients abused (14.3%), two patients threatened (14.3%) and three patients tried to enter free of turn (21.4%). Negative interaction mostly occurred in examination room (63.4%) and before the beginning of anamnesis (64.3%). The mean duration from the anamnesis to the final diagnosis was 41.7±75.2 minutes (min:0-max:180). The mean duration rates of verbal abusers to university hospital (27.9±24.6, Median=25) were significantly higher than the others (8.7±12.7, p=0.007, Median=5). The mean number of households of verbal abusers (2.8±2.0, Median=2) was significantly lower than the others (3.8±1.7, p=0.041, Median=4).

Conclusion: Verbal abuse is the most seen form of the negative relationships between patient and doctor. Making realistic changes in referral system can satisfy the expectations of patients. The positive relationship rights are necessary not only for patients but also for doctors.

146. Prognosis and outcome of respiratory infections

1360
Dynamic changes of serum sTREM-1 and its gene polymorphisms associated with sepsis prognosis
Longoxiang Su1,2, Lixin Xie1,2, Zhaoyou Jiang1,2, Xin Zhang1,2, Dan Feng1,2,
1Department of Respiratory Medicine, Hainan Branch of Chinese PLA General Hospital, Sanya, Hainan, China; 2Department of Respiratory Medicine, Chinese PLA General Hospital, Beijing, China

Introduction: More and more studies have confirmed that sepsis is an acquired generic disease.

Objectives: To explore how sepsis prognosis is associated with the dynamic changes of serum sTREM-1, as well as with gene polymorphisms.

Methods: 80 subjects were selected from inpatients in the RICU, SICU and EICU. 80 healthy volunteers acted as control. To detect the dynamic changes of serum sTREM-1 over a 14-day observation, ELISA was performed. Four exons of TREM-1 gene were sequenced on ABI3730.

Results: The nonsurvivors’sTREM-1 levels remain significantly higher than the survivors’ over period of 14 days(<0.01). The curves show that the nonsurvivors
register higher sTREM-1 levels at the initial stage, which steadily go up with the passage of time. In contrast, the survivors’ sTREM-1 levels are on the decline all the time. Three TREM-1 SNPs (rs14472509, rs2234237 and rs2234246) are detected from four exons. In three inherited models, rs2234237 is clearly related to sepsis prognosis ($P<0.05$). The log-rank test shows that patients with the rs2234237 genetic variant stand a greater probability of a 28-day death ($P<0.05$). However, no relationship is spotted between TREM-1 gene polymorphism and the dynamic concentrations of serum sTREM-1. Logistic regression analysis shows that sTREM-1-APECH II score, and TREM-1 rs2234237 genetic variation are risk factors affecting the prognosis.

Conclusions: Dynamic changes in serum sTREM-1 may be more accurate and valuable for sepsis monitoring and for dynamic assessments of prognosis. It is proved that TREM-1 rs2234237 polymorphism is associated with high 28-day mortality among sepsis patients, constituting a risk factor affecting prognosis.

1361 Vitamin D level predicts clinical outcome in community-acquired pneumonia
Hilde Remmelts1,2,3, Ewout van de Garde4,5, Sabine Meurant4, Evelyn Peck5,6, Jean Danoiseaux5, Jan Grutters7, Douwe Biesma1,11, Willem Jan Bos1, Ger Rijkers1,10,11, 1Department of Internal Medicine, St. Antonius Hospital, Nieuwegein, Netherlands; 2Department of Internal Medicine and Infectious Diseases, University Medical Centre, Utrecht, Netherlands; 3Department of Internal Medicine, Gelderse Valles Hospital, Ede, Netherlands; 4Department of Clinical Pharmacy, St. Antonius Hospital, Nieuwegein, Netherlands; 5Division of Pharmacoeconomics and Clinical Pharmacology, Utrecht University, Utrecht, Netherlands; 6School for Mental Health and Neuroscience, Maastricht University Medical Centre, Maastricht, Netherlands; 7Department of Internal Medicine, Division of Clinical and Experimental Immunology, Maastricht University Medical Centre, Maastricht, Netherlands; 8Academic MS Centre Limburg, Orbis Medical Centre, Sittard, Netherlands; 9Laboratory for Clinical Immunology, Maastricht University Medical Centre, Maastricht, Netherlands; 10Department of Pulmonology, St. Antonius Hospital, Nieuwegein, Netherlands; 11Department of Internal Medicine, University Medical Centre, Utrecht, Netherlands; 12Department of Sciences, Roosevelt Academy, Middelburg, Netherlands; 13Department of Medical Microbiology and Immunology, St. Antonius Hospital, Nieuwegein, Netherlands

Rationale: Vitamin D plays a role in host defense against infection. Vitamin D deficiency is common. The prognostic value of vitamin D in pneumonia is unknown.

Objective: To examine the impact of vitamin D status on outcome in community-acquired pneumonia (CAP).

Methods: Subanalysis of a prospective study in 272 adults presenting to the emergency department with CAP. 25-hydroxyvitamin D, leukocytes, C-reactive protein, total cortisol, the Pneumonia Severity Index (PSI) score and the CURB-65 score were measured. Intensive care unit (ICU) admission during hospitalization and 30-day mortality were assessed.

Results: 143/272 patients (52%) were vitamin D deficient ($\leq 50$ nmol/L), of which 65 patients were severe deficient ($\leq 30$ nmol/L). Severe vitamin D deficiency was associated with an increased risk of ICU admission and 30-day mortality. Vitamin D was an independent predictor of 30-day mortality (area under the curve (AUC) 0.75, 95% confidence interval (CI) 0.63-0.87). When combined with the PSI score, the prognostic accuracy was superior to that of the PSI score alone (AUC 0.85, 95% CI 0.75-0.96 vs. AUC 0.78, 95% CI 0.64-0.91). The association between severe vitamin D deficiency and the combined endpoint mortality/ICU admission persisted after thorough adjustment for confounding, adding to a possible causal relationship.

Conclusion: The vitamin D level is an independent predictor of 30-day mortality, and adds prognostic value to the PSI score.

1362 Obesity is associated with improved outcome in community-acquired pneumonia
Anika Singanayagam1, Aran Singanayagam2, Adam Hill3, James D. Chalmers3, 1Department of Infection and Immunity, The Royal London Hospital, London, United Kingdom; 2Department of Respiratory Medicine, Imperial College, London, United Kingdom; 3MRC Centre for Inflammation Research, University of Edinburgh, United Kingdom

Background: Obesity was shown to be an independent risk factor for adverse outcome from 2009 pandemic H1N1 influenza. There is a relative paucity of information regarding whether this link applies to other pulmonary infections. We aimed to investigate whether body mass index (BMI) correlates with outcome in community-acquired pneumonia (CAP).

Methods: We performed a prospective observational study of consecutive patients presenting to hospital with a primary diagnosis of CAP between January 2005 and December 2009. BMI measured on admission was used to classify patients into 2 groups: obese (BMI $\geq$30) and non-obese (BMI <30). Outcomes of interest were 30-day mortality and need for mechanical ventilation or vasopressor support (MV/VS). Multivariable logistic regression was used to compare outcomes in these patients to non-obese patients, adjusting for admission severity of illness (CURB65 criteria), diabetes mellitus, COPD and prior statin use.

Results: 1079 patients were included in the study with 21% classified as obese. Mean age was 62.5 years. There was no difference in admission severity (mean CURB65 score 1.44 vs 1.39) or immediate requirement for MV/VS between obese and non-obese groups. Despite this, obese patients had lower 30-day mortality compared with non-obese patients (6.7% vs 10.5%, p=0.3). After multivariable adjustment for confounders, obesity remained significantly associated with reduced 30-day mortality (OR=0.54, 95% CI 0.30-0.97, p=0.04).

Conclusions: In our prospective study, obesity was shown to exert a protective effect on mortality from CAP. The mechanism of this effect is unclear. Further correlation from clinical and scientific studies is warranted.
Cigarette smoke extract (CSE) alters the secretion profile of the Pseudomonas aeruginosa strain PA14

Nasreen S, Richard Waite, Joe Aduse-Opoku, Jonathan Gregg. Academic Unit of Paediatrics, QMUL, London, United Kingdom Centre of Infectious Disease, QMUL, London, United Kingdom Centre of Infectious Disease, QMUL, London, United Kingdom

Background: In North America, a major cause of morbidity and mortality is due to chronic obstructive pulmonary disease (COPD), an emerging epidemic that requires a better understanding of the pathobiology of the disease. The single most important factor in the development of COPD is cigarette smoke, where the mechanisms and pathogenesis of the disease remain unclear. The airways of COPD patients are colonized with potential pathogens, including Pseudomonas aeruginosa (Ps). However, the effect of cigarette smoke on the cellular physiology of Ps is not known. Since Ps utilizes a variety of secreted virulence factors during infection, we sought to assess whether CSE affects protein secretion in the Ps strain PA14.

Methods: An overnight growth of Ps strain PA14 (Ps) was inoculated into cell culture media 1) only 2) Ps +0.1% CSE 3) Ps+0.5% CSE and 4) Ps+1% CSE and harvested (OD 0.8). The cultures were then filter sterilised and the proteins precipitated by acetone; culture secreted proteins were then determined by SDS-PAGE.

Results: CSE increased the production of low molecular weight proteins in a dose dependent manner by the virulent Ps strain PA14 when stimulated with 0.1, 0.5 and 1% CSE as observed on an acrylamide gel.

Conclusion: We have shown that CSE causes a significant physiological response in PA14 by up-regulating the production of its secreted proteins. Enhanced production of these proteins can potentially cause severe damage to the upper and lower airways of smokers which can therefore influence the development of progressive COPD.

1365 Obesity and outcomes in patients hospitalized for pneumonia

Sharif Khabah, T. D. Eirich, R. S. Padwal, A. M. Malhotra, J. K. Minhas-Sandhu, T. F. Marrie, S. R. Majumdar. Department of Medicine, University of Alberta, Edmonton, AB, Canada

Background: Obesity is a risk factor for acquiring pneumonia, but studies also suggest it is associated with better pneumonia-related outcomes. We examined the impact of obesity on short-term mortality in patients hospitalized with pneumonia.

Methods: For 2-years clinical data were prospectively collected on all consecutive adults admitted with pneumonia to 6 hospitals in Edmonton, Alberta, Canada. We identified 907 patients who also had body mass index (BMI, kg/m²) collected. Patients were categorized as underweight (BMI<18.5), overweight (18.5 to 25), overweight (25 to 30), and obese (>30).

Results: Overall, 65% were <65 years, 52% were female and 15% reported recent weight loss. 84 (9%) were underweight, 358 (39%) normal, 228 (25%) overweight, and 108 (12%) obese. Two-thirds had severe pneumonia (63% PSI class IV/V) and 79 (9%) patients died. In-hospital mortality was greatest among the underweight (12 [14%] vs normal 36 [10%]) vs overweight (21 [9%] vs obese (10 [4%], p<0.001 for trend). Compared with normal weight, obese patients had lower rates of in-hospital mortality (4% vs 10%, unadjusted odds ratio (OR) 0.39, 95%CI 0.19-0.81) that remained significant in multivariable analyses adjusted for age, sex, comorbidities, and clinical-radiographic severity of pneumonia (adjusted OR 0.44, 95%CI 0.21-0.94, p=0.035). However, these effects were not observed with normal weight, neither underweight (adjusted p=0.47) nor overweight (adjusted p=0.64) were associated with mortality.

Conclusion: In patients hospitalized with pneumonia, obesity was independently associated with lower short-term mortality, while neither underweight nor overweight were. This suggests a protective influence for BMIs in the range of 18.5 to 25.

Bacterial prevalence and load during COPD exacerbation and recovery

Davinder Garcha1, Anant Patel1, Alex Mackay1, Tim McHugh2, Gavin Donaldson1, Jadwiga Wedzicha1.

Background: Acute respiratory infections (ARI) share features with common, non-infectious complications after lung transplantation (LTx) making accurate and rapid diagnosis crucial for the management of LTx recipients.

Objectives: To evaluate the performance of a novel multiplex-PCR assay in addition to routine evaluation.

Methods: In this ongoing prospective cohort study, LTx-outpatients with any new symptom of ARI were screened for 24 respiratory viruses (RV) and atypical bacteria by a multiplex-PCR assay performed on throat swabs. Routine evaluation included PCR for 14 RV on throat washes and lower respiratory tract (LRT) sampling (BAL for quantitative microbiology, direct immunofluorescence, viral culture, PCR, and tranbronchial biopsy), if indicated.

Results: Between Sept. 2011 and Feb. 2012, among 104 episodes from 95 LTx recipients, 30 RV were detected in 29 patients (31%): 9 rhino-, 7 parainfluenza, 6 metapneumovirus-, 4 corona-, 3 adenovirus, 2 RSV, 2 CMV, and 3 viral coinfections. The most common bacterial pathogen wasPs strain PA14 (12/104 episodes) compared to 26% (23/90) with routine evaluation (p=0.20, p=0.03), including additional 4 RV. RV were more frequently detected in LRT than in URT samples (24% vs 14%; p=0.10, p=0.40). Agreement between both PCR assays in URT specimens was moderate (RV detected in 7 of 21 throat washes; k=0.45, p=0.011). Definite clinical diagnoses were suspected (28 subjects) and proven viral infection (26%), BOS (23%), AR (11%), bacterial infection (9), obstructive airway complication (4), pneumonia (3), and CMV infection (1).

Conclusions: In LTx recipients, virological methodology and sampling are complementary, with LRT specimens resulting in higher diagnostic yield.

147. Asthma: from childhood environment to adult phenotypes

1368 Feasibility of measurements of fraction of exhaled nitric oxide (FENO) in a large population based study (ADONIX)

Kristina Waa1, Lars Modig1, Kjell Toren1, Anna-Carin Olin1. 1Occupational and Environmental Medicine, Sahlgrenska University Hospital, Göteborg, Sweden; 2Occupational and Environmental Medicine, Umeå University, Umeå, Sweden

FENO is used in epidemiological studies as a non-invasive marker of airway inflammation in COPD and asthma. However, no studies has systematically evaluated the feasibility of this method in a large population-based study. We studied the possibility of implementing FENO measurements in the ADONIX study. FENO measurements were performed at baseline and annually thereafter in all ADONIX participants. The feasibility of the measurements was assessed by measuring the number of participants responding to the invitation, the distribution of the FENO values was evaluated, and the area under the curve was calculated for each participant.
inflammation. Some patients do not manage to fulfill the measurement criteria. The objective was to examine if there are any differences between subjects that do and do not manage to perform a correct FENO measurement, mainly relating to respiratory disease and differences in lung function. The Adonix-cohort comprises a general population sample of 6,296 subjects (52% women), aged 25 to 75 years. They have all been examined with FENO (NIOX, Aerocrine, Sweden), lung function questionnaires and blood samples. To fulfill the measurement criteria for FENO the subjects had to exhale to a 50 mL±10% (mean level 45-55 mL/s and allowed instant flow 40-50 mL/s) during the last 3 seconds of the expiration. In total 14,625 children (50% female) aged 8 years from 5 European birth cohorts (MAS, BAMSE, PIAMA, LISA, and GINI) were included in the statistical analyses. A total of 217 subjects (3.4%, 67% women) were unable to perform a correct test. These subjects were characterized by significantly lower lung function; FVC 3.6 vs 4.2 L (p=0.001) and FEV1 2.8 vs 3.3 L (p=0.001), but also lower predicted lung function: FVCpred 105 vs 109% and FEV1pred 98.3 vs 103.4%. In addition, we found a statistically significant over representation of subjects with asthma (13.1 vs 8.8%) in the group that did not manage to perform the test.

Conclusions: Although adolescence levels in classrooms are relatively low, long-term exposure seems to be a risk factor for respiratory health of schoolchildren.

Manuela C. Wehrens1, Ana Maria B. Menezes1, Ludovica A. Silva1, 

Maternal obesity and inhaled corticosteroid use in childhood

Methods: To assess whether indoor toluene may affect respiratory health in schoolchildren of five European countries (HESE study)

Results: in 628 children (mean age 10yrs) of five European countries: Sweden, Norway, Denmark, France, and blood samples. To fulfill the measurement criteria for FENO the subjects had to exhale to a 50 mL±10% (mean level 45-55 mL/s and allowed instant flow 40-50 mL/s) during the last 3 seconds of the expiration (OR 4.37, 95%CI 2.19-9.75 per 1 μg/m³ increment) and wheeze (OR 3.24, 1.25-8.45). These associations were significant after further accounting for the fixed effect of the classroom.

Conclusion: Although toluene levels in classrooms are relatively low, long-term exposure seems to be a risk factor for respiratory health of schoolchildren.

L372 IgE-associated phenotypes in 8-year old children. Cluster analysis of European birth cohorts

Marta Benet1, Jean Bousquet2, Josep M. Amo1, Joachim Heimrich1, Tomasz Król1, Heenette A. Silva3, Fernando C. Wehrmeister, 

Judith García-Aymerich1, on behalf of the McDALL Consortium. 

Objective: to examine if there are any differences between subjects that do and do not manage to perform a correct FENO measurement, mainly relating to respiratory disease and differences in lung function. The Adonix-cohort comprises a general population sample of 6,296 subjects (52% women), aged 25 to 75 years. They have all been examined with FENO (NIOX, Aerocrine, Sweden), lung function questionnaires and blood samples. To fulfill the measurement criteria for FENO the subjects had to exhale to a 50 mL±10% (mean level 45-55 mL/s and allowed instant flow 40-50 mL/s) during the last 3 seconds of the expiration. In total 14,625 children (50% female) aged 8 years from 5 European birth cohorts (MAS, BAMSE, PIAMA, LISA, and GINI) were included in the statistical analyses. A total of 217 subjects (3.4%, 67% women) were unable to perform a correct test. These subjects were characterized by significantly lower lung function; FVC 3.6 vs 4.2 L (p=0.001) and FEV1 2.8 vs 3.3 L (p=0.001), but also lower predicted lung function: FVCpred 105 vs 109% and FEV1pred 98.3 vs 103.4%. In addition, we found a statistically significant over representation of subjects with asthma (13.1 vs 8.8%) in the group that did not manage to perform the test.

Conclusions: Although adolescence levels in classrooms are relatively low, long-term exposure seems to be a risk factor for respiratory health of schoolchildren.
was different between groups (see Table): 5% vs 54% for ever asthma, 6% vs 54% for ever allergic rhinitis, and 26% vs 69% for ever eczema, in Groups 1 and 2, respectively. Specific IgE positivity was observed in 28% and 64% of children, respectively. Thus, Group 1 could correspond to healthy children from the general population, while Group 2 puts together children with different allergic diseases. These data suggest that allergic diseases could be better described as one single entity rather than as independent, solely organ-related diseases.

1373 Temporal stability of asthma phenotypes identified by a clustering approach: An ECRHS-SAPALDIA-EGEA study

Valérie Simon1, Anne Boucher1, Ivan Curcic3.4, Xavier Basagagna6,7,8, Hans Haugen2, Josep Maria Anto3,7,8, Jean Bousquet1,2,3, Pierre Olivier Brandqvist4,5,6,7, Joachim Heinrich1,2, Christa Janson1, Nino Künzli2, Roberto de Marco4, Thierry Rouchal4, Simon Francis Thomsen4,5.

Background: The temporal stability over time of asthma phenotypes identified using clustering methods has never been addressed.

Aims: To assess whether repeated Latent Class Analysis (LCA) applied in asthma a decade apart leads to the identification of comparable phenotypes, and to characterize the transition between them.

Methods: The LCA was applied twice, 10 years apart, on data from 2399 asthmatic children in 3 epidemiological surveys using standardized protocols: ECRHS (European Community Respiratory Health Survey, n=1450), SAPALDIA (Swiss cohort study on air pollution and lung disease, n=589) and EGEA (Epidemiological study on Genetics and Environmental Asthma, n=506). 14 variables giving personal characteristics, asthma symptoms, treatment, age of asthma onset, allergic characteristics, lung function and bronchial hyperresponsiveness were considered at both time points.

Results: A model with four latent classes was selected at each time point (prevalence between 14%-36%, mean posterior probability 84%). Two of them were predominantly composed of subjects with active asthma, mainly differing by allergic status and age at onset. Two others were predominantly composed of subjects with inactive-mild asthma, mainly differentiated by allergic status. Most of the population (60%) was assigned to the same asthma phenotype at both time points, although stability varied between phenotypes from 47% for “active adult-onset asthma” to 68% for “inactive-mild non-allergic asthma”).

Conclusion: Asthma phenotypes identified by a clustering approach 10 years apart were comparable. Further analyses will be conducted using Latent transition analysis.

1374 Serum eosinophilic cationic protein (ECP) in adult monozygotic and dizygotic twins

Simon Francis Thomsen1, Asger Sverrild2, Sophie van der Sluis3, Kirsten Ohan Kyrk5, Vibeke Backer2.1, Department of Dermato-Allergology, Gentofte Hospital, Copenhagen, Denmark; 2Department of Respiratory Medicine, Bispebjerg Hospital, Copenhagen, Denmark; 3Department of Functional Genomics & Department of Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands; 4Institute of Regional Health Services Research & Odense Patient Data Explorative Network, University of Southern Denmark, Odense, Denmark.

Aim: To assess whether repeated Latent Class Analysis (LCA) applied in asthma a decade apart leads to the identification of comparable phenotypes, and to characterize the transition between them.

Methods: The LCA was applied twice, 10 years apart, on data from 2399 asthmatic children in 3 epidemiological surveys using standardized protocols: ECRHS (European Community Respiratory Health Survey, n=1450), SAPALDIA (Swiss cohort study on air pollution and lung disease, n=589) and EGEA (Epidemiological study on Genetics and Environmental Asthma, n=506). 14 variables giving personal characteristics, asthma symptoms, treatment, age of asthma onset, allergic characteristics, lung function and bronchial hyperresponsiveness were considered at both time points.

Results: A model with four latent classes was selected at each time point (prevalence between 14%-36%, mean posterior probability 84%). Two of them were predominantly composed of subjects with active asthma, mainly differing by allergic status and age at onset. Two others were predominantly composed of subjects with inactive-mild asthma, mainly differentiated by allergic status. Most of the population (60%) was assigned to the same asthma phenotype at both time points, although stability varied between phenotypes from 47% for “active adult-onset asthma” to 68% for “inactive-mild non-allergic asthma”).

Conclusion: Asthma phenotypes identified by a clustering approach 10 years apart were comparable. Further analyses will be conducted using Latent transition analysis.

1375 Gender differences in bronchial responsiveness: A population-based cohort

Jordi Sunyer1,2,3, Dominique Courbon4,5, Chantal Raherisson4, Deborah Jarvis4, Peter Burney1, Bénédicte Leynaert2,3,4,5. ECRHS, INSERM unit 700, Paris, France; 3ISPED U897, Université Bordeaux Segalen, Bordeaux, France; 4National Heart and Lung Institute, Imperial College London, London, United Kingdom; 5Centre d’Investigation Clinique, Hôpital Bichat, Paris, France.

Background: Incidence of adult asthma, particularly non-allergic asthma, is higher in women but underlying mechanisms remain unclear. Cross-sectional studies have shown that bronchial hyper-responsiveness (BHR) is more frequent in women but gender differences in the onset and prognosis of BHR have been little studied.

Methods: Gender differences in BHR were studied in men and women without asthma or asthma-like symptoms participating in the European Community Respiratory Health Survey (baseline 1991-93; n=7521, age 20-44 years). BHR was defined as a 20% decrease in FEV1 for a methacholine dose ≥ 1 mg.

Results: At baseline, BHR was more frequent in women (12.6%) than in men (6.0%) (adjusted odds-ratio (OR): 2.33 95%CI 1.82-2.98). In subjects without BHR at baseline, BHR at follow-up (1998-2000) was observed in 8.2% (139/1649) women and 4.1% (76/1834) men (adjusted OR 2.74; 95%CI 1.92-3.91). Gender difference in BHR onset was significant in never-smokers, smokers and non-atopic subjects but was not observed in atopic subjects. In subjects with BHR at baseline, no gender difference in BHR persistence and prognosis of BHR as regards asthma was observed: in 172 women and 105 men with BHR at baseline, respectively 54.6% vs 48.6% still had BHR at follow-up (p=0.33); 20.4% vs. 23.8% had developed asthma-like symptoms (p=0.50), and 12.8% vs. 15.2% had asthma-like symptoms and BHR (p=0.56). BHR was a significant predictor for asthma development in both sexes.

Conclusions: This study suggests that female sex is a risk factor for the development of BHR during adult life. Further research on the influence of sex-specific factors on BHR is needed to understand the mechanisms underlying the development of asthma in men and women.

148. Tobacco cessation and tobacco cessation services

1376 Genetic factors on quitting habits and smoking characteristics: A twin study

Kinga Karlinger1, Andrea Agnes Molnar1, Zsolt Garami4, Viktor Berczi1, Ildiko Horvath2.1, Department of Radiology and Oncotherapy, Semmelweis University, Budapest, Hungary; 2Department of Palmonology, Semmelweis University, Budapest, Hungary; 3Research Group for Inflammation Biology and Immunogenetics, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary; 4DeBakery Heart and Vascular Center, The Methodist Hospital, Houston, TX, United States.

Introduction: It is well known that quitting has a genetic background; however, no detailed information is available in this field. Our aim was to investigate different quitting and smoking characteristics of monozygotic (MZ) and dizygotic (DZ) twins in order to investigate the genetic contribution.

Methods: Smoking 72 twin pairs (65 Hungarian and 7 American, 44 MZ and 28 DZ; mean age 44±17 years; standard deviation/SD) filled in a questionnaire concerning smoking and quitting habits. The prevalence of concordant answers was calculated from the answers of 9 MZ and 3 DZ twin pairs whose both members quit smoking. Significantly higher rate of concordant answers in MZ twins compared to DZ twins suggested a genetic influence.

Results: No significant difference was observed in the concordant answers concerning quitting attempts and duration of quitting period in MZ versus DZ twins (63% vs. 70%; 2.9±4.0 versus 1.9±1.5 years, p=0.05). Similarly, no significant difference was found in concordant answers regarding the history of quitting, mean difference in first cigarette smoking after wake-up, self-reported tobacco dependence, and certain smoking characteristics (what part of the cigarette is smoked, depth of imbibing the smoke, frequency of taking sniffs; and the frequency of thoughts concerning quitting smoking, harmful effects of smoking on other persons or him/herself, harmful operation of tobacco factories, cost of smoking) in MZ versus DZ twin pairs (p=0.05 for all characteristics).
Conclusions: In conclusion, this small twin study indicates no genetic influence on certain quitting habits, thoughts and smoking characteristics. A larger study sample is warranted.

1377 A pilot study of the acceptability of snus and nicotine pouch in smoking cessation
Julian Crane1, Brent Caldwell2, Vicki Ward2, Angela Thie2
1Medicine, University of Newcastle, Newcastle upon Tyne, UK; 2Respiratory Medicine, Wellington Hospital, Wellington, New Zealand

New Zealand is aiming to become entirely smokefree by 2025. This goal is endorsed by the Ministry of Health and widely by the tobacco control community. To achieve this goal will require a number of new initiatives both in policy and smoking cessation. We have recently commenced a small pilot study to examine the acceptability of snus (aoral tobacco) and a nicotine pouch (Zonnic) amongst hospitalised smokers who have previously tried and failed to quit with NRT. 100 hospitalised smokers who wished to quit were enrolled and have been followed for at least 3 months. Smokers were given 1 week to try both products and then chose one to use for three months in a further quit attempt.

During the first weeks’ trial the nicotine pouch was more satisfying (using the CES) than snus median score 4.0 (IQR 2-5), 4 (IQR 3-5) p=0.05 and more enjoyable 4.0 (IQR 3-5), 3.0 (IQR 1-4) p<0.01, respectively. During the 2 weeks prior to quitting 50 subjects chose to use the nicotine pouch, 25 chose snus and 25 chose to use neither, except occasionally.

At 3 months, of the 16 who used snus regularly 5 were quit (31%) and a further 3 had smoked less than 2 cigarettes in the last 7 days. Of the 24 who used the nicotine pouch 4 were quit (16.6%) and a further 2 subjects had smoked less than 2 cigarettes.

Amongst smokers with no history of oral tobacco use, the nicotine pouch appears more satisfying and enjoyable and is chosen twice as often as snus, but may be less effective for cessation. Alternatively, those who choose snus may be better able to quit than those who choose znic. A full RCT will be required to confirm these findings.

(This study was funded entirely by the New Zealand Ministry of Health).

1378 Quitting smoking with Champix: Parallel, randomised clinical trial of efficacy for the first time in Iran
Gholamreza Heydari1, Saeid FallahiTafati1, 2Tobacco Control Research Center, National Research Institute of TB & Lung Diseases, Tehran, Islamic Republic of Iran; 3National Research Institute of TB & Lung Diseases, Tehran, Islamic Republic of Iran

Introduction: Smoking cessation programs were first introduced in Iran in 1997 by the National Research Institute of Tuberculosis and Lung Diseases and up to now, various nicotine replacement therapies have been prescribed. The aim of this study was to evaluate effectiveness of Varenicline for tobacco cessation in this country and compare it with other measures.

Materials and methods: This was a randomized parallel clinical study during 2009-2010.

Participants were divided into three parallel groups randomly. The first group received brief counseling on cessation. The second group received nicotine patches 15 mg/daily for 8 weeks and the third group was prescribed Varenicline one 0.5 mg pill daily for the first 3 days, followed by 0.5 mg twice a day for 4 days and subsequently 1 mg twice daily for 8 weeks.

Results: The study had 272 participants including 160 men (58.8%). Ninety one people were in the first group, 92 individuals in the second and 89 in the third group. At the end of the first month, 128 people from total (47.1%) succeeded in quitting; this included 17 individuals (18.7%) in the first group, 60 (65.2%) in the second group and 51 (57.3%) in the third group (P<0.001). Follow up at 6 month and a year showed 111 people of total (40.8%) and 58 individual (21.3%) remained smoke free which included 12 (13.2%) and 6 (6.6%) in the first group, 47 (51.1%) and 23 (25%) in the second group and 52 (58.4%) and 29(32.6%) in the third group respectively (P=0.000).

Conclusion: Drug treatment can improve success in quitting several fold. Success with Varenicline is slightly better from nicotine replacement treatment.

1379 Smokers’ characteristics, pharmacological treatment and their association with weight gain during smoking cessation
Melaine Fidelix, Suzana Tanni, Livia Baldini, Andre Bertani, Liana Coelho, Fabiana Kuipers Tanni, Mirella Alves de Araujo, Ana Carolina Taffoni, Rosana V. de Souza, Carmen V. de Souza, Maria conceição dos Santos, Milena Machado, Gabriela Pinto, Cristiane Miranda, brazil

Smoking cessation is responsible for many deaths. However, the adherence to the treatment is difficult by several factors.

Aim: Investigate if the weight gain during smoking cessation is associated with smokers characteristics or smoking cessation treatment strategies.

Methods: 148 smokers (female=65.5%, age=50.2±11.6y) were evaluated at baseline and after one year during a smoking cessation program. At baseline, all patients were analyzed by general date, anthropometric measurements, motivation stage, nicotine dependence, Hospital Anxiety and Depression Scale (HADS) and pharmacological treatment for smoking cessation. After one year of treatment, the patients were reevaluated for smoking cessation, weight changes. Weight gain above 3.0 kg was considered significant. We used T test, Chi2 and multiple logistic regression.

Results: Among 148 smokers, 81.8% received at least one pharmacological treat ment and 20.2% used bupropion. After one year, 34.4% of patients (60.78% female, age: 51.5±11.3y) were abstinent and they gained more weight [5 (2-10) kg, p<0.001] than patients who continued smoking [0 (0-4) kg]. Only 17.6% of abstinent patients, used bupropion. Among smokers, 41.9% gained weight over 3.0 kg, however we did not find associations of weight gain with HADS scores, intensity of nicotine dependence, motivational status. The multiple logistic regression showed that current smoker had lower chance of weight gain after one year [OR=0.18 (95%CI=0.08-0.40)].

Conclusion: Ours results confirms previous findings of weight gain after smoking cessation and did not identify association between weight gain and any patient characteristics or treatment strategy.

1380 Effectiveness of smoking cessation advice following admission to hospital
Nicola Hunt, Laura Watkins, Oliver McConnell, Sam Westall, Catriona Holden, James Young-Jameson, Marta Barbosa, Striram Chandramouli
Respiratory Medicine, Macclesfield District General Hospital, Macclesfield, United Kingdom

Introduction: Hospitalization offers patients a good opportunity to quit smoking especially when they are admitted with a respiratory illness. The Department of Health (DoH) recommends that all inpatient smokers should be offered support by a smoking cessation officer(SCO).

Aims: • Evaluate if smoking cessation advice is offered to patients admitted with a respiratory illness • Identify a relationship between abstinence and types of smoking cessation aids used

Methods: Prospective follow up of 100 patients in respiratory clinic following hospital admission with a respiratory condition between December 2010 and October 2011. Baseline demographics and data on smoking habits and advice were collected. Chi squared test was used to assess statistical significance.

Results: Median (range) age of patients was 62 years (22 – 97). 52 were male. Of 100 patients 85 were offered cessation advice. 51 (60%) were seen by SCO. At follow up (1 to 3 months post discharge) 36 patients were abstinent. Age, gender or degree of tobacco consumption pre-admission did not influence likelihood of cessation.

SCO review was associated with abstinence (p=0.02). The most effective methods of cessation were willpower (P=0.001) and use of nicotine replacement therapy (NRT, p=0.000).

Conclusions: The majority of patients admitted with an acute respiratory illness were offered cessation advice as recommended by DoH. SCO counselling and NRT are powerful tools and affect success rates. Surprisingly, most quitters in our study did not use additional aids and used hospitalisation alone as an impetus to give up smoking.

1381 Learning platform for smoking cessation project: From beginning to date
Ahşe Gökçek Dilektaşi1, Oğuz Kökçen2, Sule Akcay2, Erica Kunt Uzaslan3, 4Medicine, University of Newcastle, Newcastle upon Tyne, UK; 5Respiratory Medicine, Uludag University Faculty of Medicine, Bursa, Turkey; 6Department of Pulmonary Diseases, Dokuz Eylül University Faculty of Medicine, İzmir, Turkey; 7Department of Pulmonary Diseases, Başkent University Faculty of Medicine, Ankara, Turkey; 8Sakarya School of Health, Sakarya School of Health, Sakarya, Turkey; 9Department of Pulmonary Diseases, Adnan Menderes University Faculty of Medicine, Aydın, Turkey; 10Department of Pulmonary Diseases, İnönü University Faculty of Medicine, Malatya, Turkey; 11Department of Pulmonary Diseases, Mersin University Faculty of Medicine, Mersin, Turkey; 12Department of Pulmonary Diseases, Karadeniz Technical University Faculty of Medicine, Trabzon, Turkey; 13Department of Pulmonary Diseases, Atatürk University Faculty of Medicine, Erzurum, Turkey; 14Department of Pulmonary Diseases, Yeditepe Pulmonary Diseases and Surgery Training and Research Hospital, Istanbul, Turkey; 15Department of Pulmonary Diseases, Atatürk Pulmonary Diseases and Surgery Training and Research Hospital, Ankara, Turkey

Background: Although 35% of the adults in Turkey are current smokers, the number of trained physicians and smoking cessation (SC) clinics are not enough to meet the demand.

Aim: This national project aimed to create the necessary infrastructure for providing SC therapy all-around the country and to train physicians in this topic. This project was run by Turkish Thoracic Society Tobacco Working Group and supported by a grant from Pfizer Foundation.

Methods: For this purpose, an organization network including field training...
Tobacco cessation clinics in Europe: Data from eSCCAN project
Agnès Deleuze, Joseph Osman, Bertrand Dautzenberg, Association, OFT (Office Français de Prévénion du Tabagisme), Paris, France

The eSCCAN project aims to federate smoking cessation clinics in Europe to share and improve practices.

Method: Identification of eSCCAN experts in 26 of the 27 European countries has allowed to organize meetings and internet communication to reach a consensus among the smoking cessation clinics in Europe and to specify their number.

Results: The current estimate is that there is about 2500 tobacco cessation clinics in Europe. A minority of them are centres of counselling to stop smoking without the possibility of prescription; a higher number is made of doctors' offices or pharmacies. The vast majority consists of tobacco cessation clinics with several health professionals and all facilities for smoking cessation.

Examples of good and bad practices have been described on many topics such as rendez-vous delays, that must be less than 3 weeks for a first appointment. Some definitions have met consensus as the definition of healing, and in particular the period which defines a successful cessation. While waiting to close the debate, the recommendation is to record the cessation at 3, 6, and 12 months, with a particular focus at 6 months.

A code and a self-audit in many languages are available on the website for a first evaluation of the activity of the consultations that will enable future improvement.

Conclusions: The project provides real rapprochement eSCCAN knowledge to practices for smoking cessation in Europe that support in each country in Europe less than 10% of smokers, but disseminate knowledge and contribute to the assessment for teaching and research.

Use of radial endobronchial ultrasound for diagnosing peripheral lung lesions – A tertiary centre experience
Adrian Chim, Ananthan Devanand, Mariko Koh. Department of Respiratory and Critical Care Medicine, Singapore General Hospital, Singapore, Singapore

Introduction: Small peripheral lung lesions continue to pose a diagnostic dilemma for pulmonologists. Flexible bronchoscopy with fluoroscopy has a limited diagnostic sensitivity (31-56%) for such lesions. Radial endobronchial ultrasound (EBUS) is a relatively new technique that has been used to improve yield, although diagnostic performance has been reported to vary considerably. We describe the characteristics of patients who underwent radial EBUS and outcomes in our centre.

Methods: Retrospective review was performed for 123 patients from Singapore General Hospital with peripheral lung lesions who underwent bronchoscope evaluation with radial EBUS guidance from August 2008 to December 2011.

Results: Median patient age was 64 years. Overall diagnostic yield was 68.3% with no difference for malignant (68.5%) or non-malignant (68%) lesions (p=0.954).

Year-on-year diagnostic yield generally improved with increasing experience: in 2008, yield was 42.9% as compared to 2011 (80%). Data for ultrasound probe location was available for 93 patients. Yield was higher if the probe was within the lesion (78.3%) than when the probe was adjacent to the lesion (40%) (p=0.001). Data for lesion size was available for 118 patients. 40 patients had lesions less than 20mm diameter. Diagnostic yield of such lesions (75.3%) was higher than for larger lesions (64.1%), although this did not reach statistical significance (p=0.169).

Conclusion: Radial EBUS is useful for evaluating peripheral lesions of less than 20mm diameter. Training and experience is important to improve diagnostic yield. We recommend that the ultrasound probe be positioned within the lesion before attempting bronchoscopic biopsy.

Optical coherence tomography for increasing the diagnostic yield of TBNA
Melissa Suter1, Lida Hariri2, Alex Chie1, Khay Tan1, Guillermo Teamey3, Colleen Channick1, Michael Lantos1, Muri Mino-Kenudson2, Brett Bouma3.

1Pulmonary and Critical Care Unit, Harvard Medical School and Massachusetts General Hospital, Boston, MA, United States; 2Pathology Department, Harvard Medical School and Massachusetts General Hospital, Boston, MA, United States; 3Wellman Center for Photomedicine, Harvard Medical School and Massachusetts General Hospital, Boston, MA, United States; 4Thoracic Surgery Division, Harvard Medical School and Massachusetts General Hospital, Boston, MA, United States

Introduction: Bronchial biopsy techniques of peripheral nodules are associated with poor diagnostic yields. Optical coherence tomography (OCT) can be used to assess tissue microstructure in vivo, however is typically restricted to airway or pleural-based approaches. The aim of this study was to develop a transbronchial OCT catheter, and to investigate the potential of OCT to differentiate nodules from parenchyma with the goal of increasing the TBNA diagnostic yield of peripheral nodules.

Methods: We developed a narrow diameter OCT catheter compatible with standard 21-gauge TBNA needles. Safety and feasibility was demonstrated in 3 swine, in vivo. To determine the accuracy of OCT for differentiating nodules from surrounding parenchyma, OCT was conducted in 35 surgically resected tissue specimens. 2 OCT experts, 2 pathologists, and 2 pulmonologists interpreted the OCT data offline.

Results: Successful imaging was conducted in all swine. Image criteria for differentiating parenchyma from nodule included signal void spaces corresponding to alveoli, and linear regularly spaced specular reflections representing collapsed alveoli. Nodules were found to have a generalized homogeneous appearance. Blinded readers diagnosed the OCT images as nodule or parenchyma with an average accuracy of 95.6%.

Conclusions: We have developed the first transbronchial OCT catheter that is compatible with standard 21-gauge TBNA needles, and have demonstrated that OCT can accurately differentiate nodules from surrounding parenchyma. We anticipate that transbronchial OCT may be useful in increasing the diagnostic yield of TBNA by confirming the needle placement within the target nodule prior to biopsy.
1386 Qualitative and economical analysis of transbronchial lung biopsy with the cryoprobe
Beatriz Amat1, Sandra Sapia2, Maria Fernanda Sanchez3, Jose Manuel Leon1, Ana Camarasa1, Juan Manuel Cörcoles1, Juan Jose Egea4, Maria Ródenas1, Silvia Cores5, Servicio de Neumología, 1Servicio de Anatomía Patológica, 2Servicio de Radiología, 3Servicio de Anestesia, Hospital Vinalopó, Elche (Alicante), Spain

Objective: To analyze the histological quality of transbronchial lung cytobiopsy in patients with interstitial or malignant lung diseases in which a previous transbronchial lung biopsy (TBB) with conventional forces was not diagnostic. A second objective was to analyze the cost of TBB with the flexible cryoprobe compared with surgical lung biopsy.

Patients and methods: From 01.02.2011 until 31.01.2012, 19 TBB with the flexible cryoprobe were performed. Afterwards, we analyze the cost of a TBB with the flexible cryoprobe compared with surgical lung biopsy.

Results: We obtained representative material in 18/19 (95%) patients. Cytobiopsies total specimen area was 20-60 mm² compared to TBB with forces which was done in 13 patients did not show crush artifact in any case. In 15/19 (79%) patients we obtained a definitive diagnosis: 2 malignant tumors and 13 benign disease: 6 usual interstitial pneumonia, 1 nonspecific interstitial pneumonia, 1 desquamative interstitial pneumonia, 1 idiopathic pulmonary fibrosis, 1 follicular bronchiolitis, 1 solitary nodules, 1 respiratory bronchiolitis and 1 organizing pneumonia. In 3 patients we found some pathological findings but a definitive diagnosis was not achieved. The cost of TBB with cryoprobe was $351 € against the cost of surgical lung biopsy which was $1,189 €.

Conclusions: Transbronchial cryobiopsies are larger than TBB with conventional forces with a preserved sample because of the absence of crush artifact. Moreover, cryobiopsies were cheaper than surgical lung biopsy. Hence, transbronchial cryobiopsies could be considered as a prior step or a potentially replacing tool for the open lung biopsy.

1387 Trans-parenchymal nodule access (TPNA) – Real-time image-guided approach to pulmonary nodules
Felix J.F. Heth1, Gerard A. Silvestri2, Thomas Keast3, Lav Rav3, Jason Gibbs3, Henky Wibowo2, Kun-Chang Yu1, Daniel H. Sterman4, 1Pneumology and Critical Care, Thoraxlink, University of Heidelberg, Germany; 2Pneumology, Medical University of South Carolina, Charleston, SC, United States; 3Engineering, Broncus Technologies, Inc., Mountain View, United States; 4Section of Interventional Pulmonology and Thoracic Oncology Pulmonology, University of Pennsylvania Medical Center, Philadelphia, United States

Background: Currently, pulmonary nodules (PN) are accessed by Transbronchial Needle Aspiration (TTNA) or Transbronchial Needle Aspiration (TBNA). There is a clinical need for improvement of bronchoscopic access to small (<10mm) intraparenchymal PNs such that the high yield of TTNA and the safety of TBNA is a clinical need for improvement of bronchoscopic access to small (<10mm) intraparenchymal PNs in the upper and lower lobes. CT scans were acquired and plans were generated to prescribe a needle-free, straight-line path from a central airway location directly to the target using an image guidance system (LungPoint®). Access through the open lung biopsy was initiated with a TBNA needle followed by balloon dilation and sheath insertion. Advancement of the sheath was guided by overlaying CT-defined targets and tunnels onto the live fluoroscopy images using the system. The sheath enabled target sampling with 2.0mm biopsy forceps through the lumen.

Results: In 10 canines, 31 targets averaging 34mm (21mm – 50mm) from the airway wall and 7.5mm (0.1mm – 21mm) from the pleura, were accessed via TPNA and sampled. Sampling results indicated a yield of 90.4% with no pneumothoraces and minimal bleeding (<2ml).

Conclusions: These canine studies demonstrate that TPNA has the potential to achieve the high yield of TTNA with the low complication profile associated with TBNA.

1388 Combination of CT-guided core biopsy with rapid-on-site-evaluation of imprint cytology enables time and cost savings in diagnosis of peripheral lung tumors
Henky Wibowo2, Kun-Chang Yu1, Daniel H. Sterman4, 1Pneumology and Critical Care, Thoraxlink, University of Heidelberg, Germany; 2Pneumology, Medical University of South Carolina, Charleston, SC, United States; 3Engineering, Broncus Technologies, Inc., Mountain View, United States; 4Section of Interventional Pulmonology and Thoracic Oncology Pulmonology, University of Pennsylvania Medical Center, Philadelphia, United States

Background: To perform a biopsy of a peripheral lung nodule is technically more challenging than biopsy of a central lesion. In peripheral lesions, a CT-guided core biopsy was performed after a probable diagnosis was reached by the CT examination. A rapid-on-site-evaluation of imprint cytology was performed on the biopsy sample. The additional imprint cytology was calculated with another 21,07 Euro. The reduced time to diagnosis allowed for cost savings of 890 Euro.

Conclusion: The combination of CT-guided core biopsy and imprint cytology enables a fast and very reliable tumor diagnosis and can save costs in the diagnostic work up of patients with peripheral lung nodules.

1389 Prospective international trial of endobronchial implantation of electromagnetic fiducials for real-time tracking of lung tumors during radiotherapy (RT)
Chris Boltig, Daniel Nader, Felix Herth, Alexander Chen, Gerald Paris, Frank Zimmermann, Daniela Gompelmann, Michael Payne, Parag Parikh, Michael Tamm. Medicine, Faculty of Health Sciences, Tygerberg, Cape Town, South Africa; Pulmonology, Medicine, Talca, United States; Pneumologie, Thoraxlink, Heidelberg, Germany; Medical Centre to Louis, United States; Pulmonology, University Hospital, Basel, Switzerland

Introduction: Technologic advance in RT delivery has resulted in dramatic improvement in lung cancer tumor control, but respiratory motion of these tumors still complicates RT. We present our results implanting novel anchored electromagnetic transponders (Varian Medical, Palo Alto, CA) which provide real-time localization and tracking of tumor position during RT.

Methods: 31 patients (pts) underwent thoracic bronchoscopic implantation of 3 transponders (93 total) in small airways in or near the tumor under fluoroscopy ± CT. By using electromagnetic navigation or EBUS, Transponder positions were determined from serial CTs to assess positional stability. Localization and tracking of transponders and tumor was performed using the Calypso System during RT.

Results: There were 14 males/17 females, ages 43-79 (med. 63), with 10/31 tumors in the LUL and 21 in the RUL. There were no complications, no unique skills or tools were required for implantation, and satisfaction with the procedure was high. 29 pts had no significant problems associated with the transponder or procedure. One pt with an apical pleural-based tumor developed a pneumothorax, resolving overnight after chest tube placement. Migration of 1 transponder at appx 1 wk was attributed to implantation in a larger airway; pt was asymptomatic.

Conclusion: Implantation of electromagnetic anchored transponders is feasible and safe. This technology should enable highly accurate delivery of radiotherapy.

150. Physiological monitoring during sleep and in neuromuscular disease in children

1390 Assessment of diaphragm thickness variations by ultrasoundography in patients with Duchenne muscular dystrophy (DMD)
Mariana Laviola1,2, Rita Prioli1,3, Marianna Romei2, Grazia D’Angelico2, Andrea Aliverti2,3, Dipartimento di Biogengetica, Politecnico di Milano, Milano, Italy; 2IRCCS E. Medea, La Nostra Famiglia, Bosisio Parini, Italy

Variations of diaphragm thickness (DT) during different respiratory maneuvers can be measured by B-mode ultrasonography (US). In order to verify if this parameter provides useful insights for functional assessment in DMD, we measured DT by a 7.5 MHz US linear probe in the 9th or 10th right intercostal space in 39 DMD patients (age 16±3.4 yrs. FVC 53±24.8%pred) in supine position (rest-expiration during quiet breathing; QB) and maximal inspiratory pressure (MIP) at residual volume. The contribution of the abdominal compartment to tidal volume (Vabd%) was assessed by optoelectronic plethysmography during QB and an inspiratory capacity (IC) maneuver.

Patients were subdivided into 3 groups according to age (G1: n=11, age<14; G2: n=13, 14<age<18; G3: n=15, age>18 yrs). MIP was significantly higher in G2 compared to both G1 and G3 (figure, left). The variation of DT during the MIP maneuver, expressed as % change of DT at rest, was significantly greater in G3.
compared to G1. Patients belonging to G3 group were also characterized by lower Vab% during subjects volume variations of AB led RCP (negative phase shifts, figure 1) independently on age. A similar behavior was found in G1 DMD patients, but not in older subjects (G2, G3 and G4) where RCP was the leading component (<p<0.05).

In conclusion, in DMD patients lying supine the action of the inspiratory rib cage muscles progressively increases with age relative to the diaphragm. Accurate monitoring of TAA during spontaneous breathing is a valid indicator of diaphragm function progress in DMD.

**1392**

Which are the most informative parameters to follow the respiratory decline in Duchenne muscular dystrophy? Sonia Khirn1, Adriana Ramirez2, Guillaume Aubertin1, Michèle Bouli6, Chrystelle Chemouny3, Veronique Forin1, Brigitte Fauroux1, 5 INSERM UMR S-038, AP-HP, Hôpital Armand Trousseau, Paris, France; 1ADEC Assistance, ADEC Assistance, Saintes, France; 1Pediatric Pulmonology Department, AP-HP; Hôpital Armand Trousseau, Paris, France; 4Respiratory Physiology Department, AP-HP; Hôpital Armand Trousseau, Paris, France; 6Pediatric Rehabilitation Department, AP-HP; Hôpital Armand Trousseau, Paris, France

Rationale: Duchenne muscular dystrophy causes progressive respiratory muscle weakness. Few information is available on the natural evolution of respiratory parameters in both Duchenne muscular dystrophy.

Objectives: In order to identify respiratory parameters associated with the earliest decline, lung function, blood gases, respiratory mechanics, and respiratory muscle strength were measured in 48 boys with Duchenne muscular dystrophy (mean age 12.7±3.4 years, range 7.6–19 years), over a period of 10 years.

Main results: Only four parameters showed an important decline with age. Gastroc pressure during cough was below normal in all patients with a mean 5.7±3.8 cmH2O decline per year. Sniff nasal inspiratory pressure tended to increase between the age of 10 years followed by a rapid decline (mean decrease 4.8±4.9 cmH2O or 5.2±4.4% predicted per year). Absolute forced vital capacity values peaked around 13-14 years of age and remained mainly over 1 liter but predicted values showed a mean 4.1±6.4% decline per year. Diaphragmatic tension time index increased above normal after the age of 14 years old with a mean increase of 0.2±0.04 year per year.

Conclusion: Repeated gastric pressure during cough, sniff nasal inspiratory pressure, and forced vital capacity measurements provide simple tools to assess the progression of respiratory muscle weakness in young boys with Duchenne muscular dystrophy. Endurance indexes decline at a later age. These indexes may help to monitor treatment effects.

**1393**

Inefficient cough in Duchenne muscular dystrophy (DMD)

Antonella LoManno1, Marianna Romei2, Grazià D'Angelo1, Andrea Aliverti1, 1Department of Biostegnecia, Policlinico di Milano, Milano, Italy; 2IRCCS E. Medea, La Nostra Famiglia, Bossio Parini, Italy

In DMD, impaired cough secondary to muscle weakness leads to serious respiratory complications, namely atelectasis, ineffective airway clearance, pneumonia and tracheal intubations. In order to study which factors influence and determine inefficient cough in DMD we studied 36 DMD patients and 15 healthy controls (C; age: 16.3±5.4 yrs). Peak cough flow (PFC) was measured at the mouth while rib cage (RC), abdominal (AB) and total chest wall (CW) volume variations were measured by opto-electronic plethysmography during quiet breathing and maximal cough (supine position). PFC was <160 L/min in 15 patients (inefficient cough, age:17.6±5.4 yrs, FVC 33.7±20% predicted) and >270 L/min in 9 (efficient cough, age:16.1±4.3 yrs, FVC 70.8±34% predicted). Tidal volume (Vt) was similar in L, E and C. In L, RC, AB and CW inspired volumes preceding cough were significantly lower than controls and inspired AB volume was lower than E (panel A). Thoraco-abdominal asynchrony during cough, quantified by labored breathing index (LBI), and percentage abdominal contribution to VT (%ΔVAB) were respectively higher and lower in I group (panel B and C).

In conclusion, in DMD inefficient cough is characterized by impaired inspiration, thoraco-abdominal asynchrony and lower abdominal contribution to volume variations due to diaphragmatic weakness. %ΔVAB, that does not require patient’s collaboration, seems to be a good predictor of inefficient cough.

**1394**

Adiposity but not severity of obstructive sleep-disordered breathing correlates with morning plasma TNF-α levels in Greek children

Vasiliki Theodogi1,2, Vasiliki Varlami3, Georgia Malakasiot1, Irene Tsilioni1, Konstantinos Chaidas1, Emmanouel Alexopoulos1, Athanasios Kaditis4, Konstantinos Georgoulis1, 1Sleep Disorders Laboratory, Larissa University Hospital, Larissa, Greece; 2First Department of Pediatrics, Pediatric Pulmonology Unit, University of Athens School of Medicine and Aghia Sophia Children’s Hospital, Athens, Greece

Background: Sleep-disordered breathing (SDB) has been associated with increased frequency of excessive daytime sleepiness (EDS). In adults, increased TNF-α plasma levels probably mediate this association, but conflicting results have been reported in children. We hypothesized that: i) the higher the severity of SDB in childhood, the higher the frequency of EDS and morning TNF-α plasma levels; ii) subjects with high TNF-α levels are more likely to have EDS.

Methods: Children without and with snoring underwent polysomnography, EDS and plasma levels measurements. The 3 groups did not differ regarding TNF-α

In conclusion, SDB in children is associated with increased plasma TNF-α levels, mainly in those who have severe SDB and consequently high EDS.
levels (0.63 ± 0.2 vs. 0.65 ± 0.2 vs. 0.57 ± 0.13 pg/mL; p < 0.05). TNF-α levels were associated significantly with body mass index z-score (p < 0.05), but not atH or SpO2 nadir (p > 0.05). Subjects with high TNF-α levels (> 0.57 pg/mL; i.e. median in controls) were not elevated risk for EDS compared to those with low levels. (OR [95% CI] adjusted for obesity: 1.9 [0.6-6.4]).

Conclusions: Increasing severity of SDB is related to increasing frequency of EDS but not with elevated TNF-α plasma concentrations which are positively correlated with the degree of adiposity. Children with high TNF-α levels are not at increased risk for EDS.

1395
Low morning serum cortisol levels in children with adenotonsillar hypertrophy and obstructive sleep apnea
Georgia Malakasioti1, Vasiliki Varlami1, Vasiliki Theologi1, Konstantinos Chaidas1, Nikolaos Liakos2, Konstantinos Georgoulisian1, Athanasios Kaditis1, 2Sleep Disorders Laboratory, Larissa University Hospital, Larissa, Greece; 3Biochemistry, Larissa University Hospital, Larissa, Greece; 4First Department of Pediatrics, Pediatric Pulmonology Unit, University of Athens School of Medicine and Agia Sophia Children's Hospital, Athens, Greece

Adenoidal and tonsillar tissue in children with obstructive sleep apnea (OSA) has enhanced expression of glucocorticoid receptors (Goldbart 2005). Although this finding suggests a favorable profile for topical steroid therapy in children with OSA, its pathogenic role in adenotonsillar hypertrophy is unknown. It is possible that overexpression of glucocorticoid receptors in pharyngeal lymphoid tissue reflects low endogenous cortisol levels. We hypothesized that children with OSA and tonsillar hypertrophy have lower morning serum cortisol levels compared to healthy control subjects.

Methods: Consecutive children with snoring and participating without snoring underwent polysomnography, grading of tonsillar size and measurement of morning serum cortisol.

Results: Children with moderate-to-severe OSA (n=17; 6.1 ± 2.2 yo; AHI 14.7 ± 10.6 episodes/h) had significantly lower morning serum cortisol levels than subjects with mild OSA (n=14; 6.8 ± 2.3 yo; AHI 2.6 ± 1.2 episodes/h) or control participants without snoring (n=14; 6.5 ± 2.5 yo; AHI 0.7 ± 0.2 episodes/h): 16.4 ± 8.7 vs. 23.3 ± 4.2 or 22.3 ± 5.3 mcg/dL; p < 0.05. In contrast, children with moderate-to-severe OSA (n=13; 5.1 ± 1.1 yo; AHI 11.1 ± 5.6 episodes/h) had similar cortisol levels relative to subjects with mild OSA (n=13; 6.8 ± 2.4 yo; AHI 2.4 ± 1.2 episodes/h) or control participants without snoring: 25.6 ± 8.1 or 20.2 ± 1.1 or 22.3 ± 5.3 mcg/dL; p = 0.05.

Conclusions: Low morning serum cortisol in children with OSA and tonsillar hypertrophy might be responsible for the enhanced expression of glucocorticoid levels in pharyngeal lymphoid tissue.

1396
Sleep disordered breathing in children with trisomy 21 and pulmonary hypertension
Jonathan Wong1, 2, Janette Reyes3, Indra Narang1, 4, 5Division of Respiratory Medicine, Hospital for Sick Children, Toronto, ON, Canada; 2Division of Neonatology, Hospital for Sick Children, Toronto, ON, Canada; 3Division of Cardiology, Hospital for Sick Children, Toronto, ON, Canada

Introduction: Children with trisomy 21 (T21) have a significantly high prevalence of sleep disordered breathing (SDB), specifically obstructive sleep apnea (OSA). Children with T21 are also at risk for pulmonary arterial hypertension (PAH). It is unclear if PAH per se confers additional risk for OSA in this population.

Aim: To compare the prevalence of SDB in T21 children with PAH and without PAH and with controls.

Methods: This was a retrospective study where PSG data on all non-obese children at the Hospital for Sick Children, Toronto with T21 and/or PAH referred over a 3 year period, were reviewed and compared with PSG data in age-matched controls. The main outcome measure was the obstructive apnea-hypopnea index (OAHl).

Results: PSG of 33 children aged 0.2 – 8 years with a BMI < 25 kg/m2 were reviewed and compared in 4 groups; 1) controls (n=8), 2) children with PAH (n=9), 3) children with T21 (n=10), and 4) children with both T21 and PAH (n=6). In children with both T21 and PAH, there was a significantly higher OAHl (p=0.01) and a trend for lower oxygen saturations and a higher nCO2 when compared with the other groups (see figures below).

Conclusions: Children with both T21 and PAH are at increased risk of severe OSA. All children with T21 who are known to have PAH should undergo sleep surveillance with PSG. Future research may be directed towards understanding the interaction of T21 and PAH predisposing to OSA.

Reliability of EGFR mutations detection in NSCLC brain metastases by two different allele-specific PCR methods
Michal Skronski1, Pawel Krawczyk2, Kamila Wojas-Krawczyk2, Bozena Jarosz3, Tomasz Kucharczyk2, Paulina Jagus1, Marek Sawicki1, Barbara Wilczyńska1, Tomasz Trojanowski1, Janusz Milanski2, 3

Reliable detection of EGFR mutations in lung cancer metastases requires highly sensitive and robust molecular method. Our aim was to assess effectiveness of two highly sensitive PCR methods in detection of EGFR activating mutations in FFPE samples of brain metastases from 142 NSCLC patients. Isolated DNA was analyzed for EGFR exon 19 deletions and exon 21 L858R mutations by real-time PCR PNA-LNA PCR clamp and allele-specific PCR (ASP-PCR). If discrepant, results were re-evaluated by TaqMan genotyping. Direct sequencing analyses are ongoing. All samples were successfully analyzed. In 37 samples (26%) DNA was of low quality and PCR pre-amplification was performed prior to PNA-LNA PCR clamp analysis. In total 11 out of 142 samples (8%) proved positive for EGFR activating mutations. 6 samples (55% of detected) were positive for exon 19 deletions (n=3) and L858R substitution (n=3) as assessed by both PNA-LNA PCR clamp and ASP-PCR. ASP-PCR, but not PNA-LNA PCR clamp, detected 3 further L858R mutations, whereas 1 L858R substitution and 1 rare A859T mutation were detected by PNA-LNA PCR clamp only. None of discrepant L858R substitutions were confirmed by TaqMan genotyping. A different approach to molecular diagnostics represented by two highly sensitive methods employed in our study might be responsible for observed discrepancies.

1398
The role of the regulated retrotransposon transcriptome in asthma
N. Miglino, M. Roth, Michael Tamm, P. Borger. Department Biomedicine, University Hospital, Basel, Switzerland

Rationale: Genetic studies identified over 200 asthma susceptibility genes that associate with the asthmatic pathology. In the light of the novel functions for mobile DNA elements, we propose that complex diseases, such as asthma, may result from transposed and transposable elements (TEs) which integrate in asthma susceptibility genes or in their regulatory elements.

Objectives: To investigate whether TEs may cause asthma. Therefore, we performed (i) in-silico analysis of TEs in selected asthma susceptibility genes which could potentially function as transcription modulators; (ii) establish CAGE libraries (open analysis of gene expression) using human lung tissue of asthma patients and of healthy controls; and (iii) analyze the transcriptome of the lung tissue CAGE libraries.

Methods: The gene sequence of twelve asthma susceptibility genes (DPF10, CFYF2, HLA-G, GPR5, SFRSS, PIF11, ADAM33, PDCD1, CHI3L1, ORML1, PDE4D, DNN1B) were analyzed in silico for the presence of TEs. In addition, we analyzed the 100 000 5’-upstream bp region in order to localize TEs that may potentially act as alternative promoters/enhancers.

Results: In silico analysis showed that the TE content in the 12 analyzed gene

Linda Ekerling1, Serena O’Neill1, Sara Hansson2, Carolina Shibh0n3, Jan Lovatt4, Bo Lundback5, Krystof Research Centre, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2Proteomics Core Facility, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 3Division of Respiratory Medicine, Hanover Medical School, Hanover, Germany; 4Division of Pulmonary Diseases, Philipps University, Marburg, Germany; 5Institute for Pathology, Hanover Medical School, Hanover, Germany; 6University of Giessen Lung Center, University Hospital, Giessen, Germany; 7Division of Thoracic Surgery, Medical University of Vienna, Austria; 8Department of Theoretical Bioinformatics, German Cancer Research Center DKFZ, Heidelberg, Germany; 9Department of Internal Medicine V, Pathomorphology, Allergology, Respiratory and Environmental Medicine, Saarland University, Homburg/Saar, Germany; 10Institute of Molecular Pathology, Hanover Medical School, Hanover, Germany

Chronic obstructive pulmonary disease (COPD) is influenced by environmental and genetic factors. An important fraction of COPD cases harbor a major genetic determinant, inherited ZZ (Glu342Lys)- α1-antiproteinase deficiency (AATD). Severe, ZZ AATD is associated with a predisposition to early onset, rapidly progressive COPD where emphysema is a major component. We hypothesized that gene expression pattern differs in end-stage COPD with and without AATD. Tissues from explanted lungs of end-stage AATD-related (ZZ, n=3) were treated with α1-antiproteinase augmentation therapy and “normal” (MM, n=3) COPD were used for microarray gene expression analysis. A total of 162 genes were found to be differentially expressed (p-value ≤ 0.05 and |FC| ≥ 2) between MM and ZZ COPD patients. Of these, 134 genes were up-regulated and 28 were down-regulated. When compared to healthy individuals, a subgroup of genes, zinc finger protein 165, snail homolog 1 (Drosophila), and Krüppel-like transcription factors (KLFs) were found to be up-regulated in ZZ COPD patients only.

1400 Regulation of microRNA-mRNA target pairs in a model of bronchopulmonary dysplasia

Christopher Collarg1, William Carey2, Jie Dong2, Y.S. Prakash3, Dennis Wigle4, 1Division of General Thoracic Surgery, Mayo Clinic, Rochester, MN, United States; 2Department of Anesthesia, Mayo Clinic, Rochester, MN, United States; 3Department of Respiratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China; 4Department of Respiratory Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan, China

Background: Bronchopulmonary dysplasia (BPD) is a chronic lung disease of premature neonates characterized by arrested pulmonary alveolar development. Objective: Because microRNA (miRNAs) may regulate the translation of messenger RNAs (mRNAs), we used a computational approach to identify miRNA targets that may be involved in BPD. Methods: Neonatal mice were exposed to 80% oxygen (O2) or room air (RA) for either 14 or 29 days. Lung histology was assessed using standard techniques. Comprehensive miRNA and mRNA profiling was performed using lung tissue from each group. Potential direct miRNA targets of these miRNAs were systematically predicted through miRNA-mRNA correlations and computational mapping in miRBase. Functional significance was investigated using Gene Ontology (GO) term enrichment analysis for miRNA regulatory networks using the DAVID and MetaCore databases.

Results: At both 14 and 29 days, the lungs of O2 mice displayed histological changes consistent with BPD. Between the two time points we identified 2,714 miRNAs and 66 mRNAs that were dynamically regulated by O2 exposure. All but one of the miRNAs were up-regulated. We identified 581 dynamically regulated, direct miRNA targets of these miRNAs by computational mapping in miRBase. Gene ontology enrichment and pathway analysis revealed that hyperoxia modulated genes involved in a variety of lung developmental processes, including cell cycle, cell adhesion, inflammation and angiogenesis. Conclusion: A murine model of BPD is characterized by altered expression of Wnt/β-catenin signaling may be involved in airway inflammation and fibrosis. Overexpression of Wnt antagonists may contribute to this process, implicating potential therapeutic targets for the treatment of COPD.

1403 ADAM33 protein found in bronchial brushings and biopsies is increased in bronchial carcinomas

Romauna Mikes1, Bernd Lamprecht1, Allison-Lynn Andrews2, Stephen T. Holgate3, Donna E. Davies4, Michael Studnicka4, Hans Michael Hatch2, 1Department of Pulmonary Medicine, Paracelsus Medical University, Salzburg, Austria; 2Roger Brook laboratory, Clinical & Experimental Sciences, Faculty of Medicine, University of Southampton, Southampton General Hospital, United Kingdom

Background: The asthma and COPD susceptibility gene, ADAM33, is selectively expressed in mesenchymal cells and the activity of soluble ADAM33 has been linked to angiogenesis and airway remodeling. Aims: We hypothesized that ADAM33 mRNA & protein are differentially expressed in bronchial biopsies from healthy airways and bronchial carcinomas. Methods: Paired primary human bronchial fibroblasts (n=4) from healthy and tumor tissue were grown +/- TGFβ2 to induce myofibroblast differentiation. Fibroblasts,
bronchial biopsies (n=12) and brushings (n=12) were analysed for ADAM33 expression using quantitative RT-PCR and western blotting. Immunohistochemistry for ADAM33 was performed on bronchial biopsies.

**Results:**

TGFS-α caused induction of α-SMA and suppression of ADAM33 mRNA expression in normal and tumor fibroblasts. ADAM33 mRNA expression tended to be decreased in tumor biopsies whereas ADAM33 protein expression was significantly increased (bands of 45 and 75 kDa). In bronchial brushings ADAM33 mRNA was not detectable. However, there was a single band at ~75kDa for ADAM33 and also specific staining for ADAM33 in the epithelium of bronchial biopsies.

**Conclusions:** Similar to cells from healthy and asthmatic volunteers TGFS-α suppressed expression of ADAM33 mRNA in normal and tumor fibroblasts. ADAM33 protein was increased in bronchial tumor biopsies suggesting potential roles in tumorigenesis and growth. The presence of ADAM33 protein in bronchial brushings and biopsies in the absence of ADAM33 mRNA expression in brushings suggests that the mesenchyme is the source for ADAM33 protein in the epithelium.

* R.M. was supported by ERS short-term research training fellowship in 2010/2011 in Southampton, UK.

### Independent validation of prognostic value of 22 microRNAs (miRs) in stage I-II lung adenocarcinoma (AC)

**Claudia Jafari**, Margot Skrzypski, Krysztof Goryca, Amelia Szymonowska-Narloch, Ewa Jassem, Piotr Czapiński, Wojciech Biernat, Ryszard Pawłowski, Witold Ryzman, Jakub Jacewicz, *Oncology and Radiotherapy, Medical University of Gdańsk, Pomorskie, Poland; 2Department of Oncological Genetics, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Mazowieckie, Poland; 3Laboratory of Bioinformatics and Systems Biology, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Mazowieckie, Poland; 4Allergology and Pulmonology, Medical University of Gdańsk, Pomorskie, Poland; 5Pathology, Medical University of Gdańsk, Pomorskie, Poland; 6Forensic Medicine, Medical University of Gdańsk, Pomorskie, Poland; 7Thoracic Surgery, Medical University of Gdańsk, Pomorskie, Poland

**Background:** About 50% of NSCLC patients (pts) will develop distant metastases following pulmonary resection. Currently, apart from clinical stage at diagnosis, there are no reliable factors to select the high risk pts for adjuvant chemotherapy. We previously demonstrated prognostic value of 22 miRs in frozen tissue samples of early stage SqCLC, and the feasibility of their expression assessment in formalin fixed paraffin embedded (FFPE) samples (Skrzypski et al. J Clin Oncol 2010; 28:15s). In this study, we validated the prognostic value of these miRs in an independent cohort of early AC pts.

**Methods:** FFPE tumor samples were obtained from 82 stage I-II AC pts who underwent radical pulmonary resection, 44% of whom developed distant metastases. Median follow-up of pts who did not develop metastases was 5.53 years (range, 3.01-8.9 years). miRs were isolated from tumor tissue with RecoverAll kit (Ambion). Expression of 22 miRs previously found to be related to the risk of metastases was analyzed by RT-PCR assay (Appliedbiosystems). Raw data were normalized vs. the expression of U6. Individual miRs were correlated with distant metastases-free survival (MFS).

**Results:** MiR-22**2** (p=0.0003) and miR-222 (p=0.002) were significantly related to MFS. Using the median of the miR-222 expression as a cut-off value, the median MFS was 2.12 years in the high risk group, and not reached in the low risk group (HR=1.95). Using the median of the miR-222 expression as a cut-off value, the median MFS was 2.56 years in the high risk group, and not reached in the low risk group (HR=1.78). **Conclusions:** MiR-222 and miR-222 are strong predictors of distant relapse in operable early AC.

**152.** Microbiological advances in the diagnosis of tuberculosis

**P1405**

### Comparison of molecular and immunological methods for a rapid diagnosis of smear-negative tuberculosis

**Claudia Jafari**, Sabine Ruesch-Gerdes, Martin Ernst, Elvira Richter, Barbara Kalidost, Christoph Lange, *Clinical Infectious Diseases, Research Center, Borstel, Germany; National Reference Center for Mycobacteria, Research Center, Borstel, Germany; Immunecell-Analytics, Research Center, Borstel, Germany

**Background:** A rapid diagnosis or exclusion of pulmonary tuberculosis (pTB) in pTB suspects with negative acid-fast-bacilli (AFB) sputum smears is at times still challenging in clinical practice.

**Methods:** We compared in retrospect results of Xpert MTB/Rif (single sputum or BAL specimen) nucleic acid amplification with a Mycobacterium tuberculosis-specific bronchoalveolar-lavage (BAL) Elispot in suspects of pTB with negative AFB sputum smears at a TB referral center in Germany.

**Results:** In 96 suspects of pTB with negative AFB sputum smears admitted from 04/2010-10/2011 in our clinic, pTB was confirmed by culture in 10 cases and clinically suspected in 9 cases. Sensitivity, specificity, positive and negative likelihood ratio were 60%, 97%, 30, 0.41 for culture confirmed cases and 42.1%, 97%, 21, 0.59 for all TB patients for the Xpert MTB/Rif and 89%, 62.6%, 2.1, 0.32 for culture confirmed cases and 89.4%, 62.6%, 2.4, 0.17 for all TB patients for the M. tuberculosis specific BAL-Elispot. BAL-Elispot identified 10 out of 11 patients with pTB (including 3 out of 4 with culture confirmed TB) with a negative Xpert MTB/Rif test.

**Conclusion:** A positive result of a Xpert MTB/Rif test on a sputum or BAL specimen has a very high likelihood for the diagnosis of active TB, however the sensitivity is insufficient to rule out pTB with a negative result. BAL-Elispot identifies the majority of TB cases in suspects of pTB with negative AFB sputum smears and negative Xpert MTB/Rif test but the specificity of the BAL-Elispot is suboptimal for a confirmed diagnosis.

**P1406**

### Diagnostic role of micro-MGIT culture of BAL samples in sputum smear-negative pulmonary tuberculosis

**Jasleen Rana**, Gursh Sidhuwan, Debasish Biswas, *Pulmonary Medicine, Himalayan Institute of Medical Sciences, Dehradun, Uttarakhand, India

**Microbiology, Himalayan Institute of Medical Sciences, Dehradun, Uttarakhand, India**

**Introduction:** In view of the diagnostic difficulties associated with sputum- negative pulmonary TB (PTB), we aimed at exploring if bronchoalveolar lavage (BAL) samples can be subjected to near-microscopy and molecular-mycobacterial culture (by Mycobacterial Growth Indicator Tube method) to achieve improved diagnosis of this condition.

**Methods:** Patients presenting with clinico-radiological features suggestive of pulmonary tuberculosis and whose sputum smears were negative for acid-fast bacilli (AFB) or who could not expectorate sputum were prospectively enrolled in this study. BAL samples collected from them were subjected to smear-microscopy for AFB and micro-mGHT culture. BAL samples were also inoculated on Lowenstein- Jensen (LJ) slants.

**Results:** A total of 105 patients (74 males) were recruited in the study, with a mean (±SD) age of 51 (± 15) years. The diagnosis of PTB was made in 52 patients on the basis of clinico- radiological presentation, with or without microbiological confirmation. Thirty- four patients (65.4%) had microbiologically confirmed PTB. Of them, AFB was detected in 12 BAL samples, while culture- positivity was noted in 24 and 27 patients by the LJ and MGIT methods respectively. Inter- test agreement between the LJ and MGIT methods was found to be significant (κ= 0.66; p<0.001). However, the mean time to positivity was significantly lower for the MGIT method than for the LJ method (p<0.001).

**Conclusion:** Examination of BAL samples by smear-microscopy and micro-MGIT culture can, therefore, provide a rapid and definitive diagnosis of PTB in sputum-negative patients.

**P1407**

### Effective variable-number tandem repeats loci for discrimination of Mycobacterium tuberculosis isolated from Korea

**Young Ki Park**, Hee Yoon Kang, Ji Hye Lee, Sa Rang Kim, Research and Development, Korean Institute of Tuberculosis, Ongyo Chungbuk, Korea

**Introduction:** The variable-number tandem repeats (VNTR) typing is a promising method to discriminate M. tuberculosis isolates in molecular epidemiology.

**Objectives:** The purpose of this study was to evaluate already known VNTR loci and to select best combination of VNTR loci set for discrimination Korean TB strains.

**Methods:** The 307 clinical isolates collected from throughout Korea were genotyped using IS6110 RFLP, and analyzed the number of VNTR copies for the 32 VNTR loci including Supply-15, Supply-24 and JATA-15 (except QUB-18; MIRU-02, -04, -10, -16, -20, -23, -24, -26, -27, -31, -39, -40, ETR-A, -B, -C, QUB-11a, -11b, -15, -26, Mubh-04, -21, VNTR-3322, -3336, -3360, -4120, -4156. And then, allelic diversity (h) and the Hunter-Gaston discriminatory index (HGDI) were calculated to evaluate discriminatory power of locus and combination of VNTR loci.

**Results:** As a results of analysis of the 32 VNTR loci, we found that 12 loci (MIRU-26, -31, QUB-11a, -11b, -26, Mubh-04, -21, VNTR-3322, -3336, -3820, -4120, -4156) showed high discrimination power (each h values of them was over 0.6). This new 12-locus combination for Korea TB strains was designated as a KT-12. The discriminatory index (HGDI) of IS6110 RFLP and VNTRs of Supply-15, Supply-24, JATA-15, and KT-12 was 0.9992, 0.9980, 0.9987, 0.9992 and 0.9997 respectively. Also the percentage of clustered cases was 16.6%(51/307), 21.8%(67/307), 16.9%(52/307), 14.3%(44/307), 6.8%(21/307) respectively.

**Conclusions:** The newly proposed VNTR typing system, KT-12 loci can be effective tool for M. tuberculosis genotyping in Korea where the Beijing strains are predominant.
P1408 Evaluation of real time polymerase chain reaction, adenosine deaminase and interferon gamma in tubercular pleural effusions
Charanjit Kaur 1, Balakrishnan Menon 1, Pulmonary Medicine, Vallabhibhai Patel Chest Institute, University of Delhi, New Delhi, India; 2Biochemistry, Vardaman Mahavir Medical College & Safdarjang Hospital, New Delhi, India

Introduction: Pleural effusions are a common manifestation of tuberculosis. Real Time Polymerase Chain Reaction (RT-PCR), Adenosine Deaminase (ADA) and Interferon gamma release assay (INF) provide faster results than Ziehl Neelson (ZN) staining and Culture on LJ medium. RT-PCR is superior to conventional PCR in sensitivity, specificity with lower contamination and reduction in time to result.

Aims and Objectives: To evaluate the sensitivity of RT-PCR. ADA and INF in cases of pleural effusions due to tuberculosis.

Methods: RT-PCR was performed in 168 patients of tubercular pleural effusions. All patients had positive Mantoux test with high protein and lymphocyte percentage.

RT-PCR was performed by detecting amplification reaction for the insert element IS6110 of the Mycobacterium tuberculosis complex (Biostub-QT, Biostools Labs, Spain) using a real-time centrifugal amplification system (Rotor-Gene 3000, Corbett Research, Australia). ADA was estimated by enzymatic method (BQ Kits, San Diego, USA) and INF was measured using Quantiferon TR Gold kit from Cellstest Ltd, USA on Automated ELISA Reader (TECAN, Miltenyzer).

Results: RT-PCR was positive in 154 of the 168 cases of tubercular pleural effusions (Sensitivity 91.67%). ADA showed high positivity in 162 of 168 cases (sensitivity 96.42%). INF showed sensitivity of 69.64% (positive in 117 of 168 cases).

The sensitivity of ZN staining in tubercular pleural effusion was 13.10%, Culture for AFB by LJ medium was 31.55% and BACTEC was 57.14%.

Conclusion: Real time PCR provides rapid diagnosis of tubercular pleural effusions. The diagnostic efficiency could be increased by combining RT-PCR with ADA.

P1409 Rapid detection of Mycobacterium tuberculosis from clinical specimens using a new target
Davood Darban Sarakhtil1, Mohammad Mehdi Feizabadi2, Abbas Ali Imani Fooladi1, Mohammad Javad Nasiri1, 1Department of Microbiology and Immunology, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran; 2Department of Microbiology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran

Introduction: Auramine O fluorescent stain was found to be more sensitive than Ziehl Neelsen stain and weakly acid fast bacteria (e.g: Nocardia species). The aim of this study was to develop a new sensitive and specific method for detection of M. tuberculosis. The aim of this study was to develop a new sensitive and specific PCR method for detection of M. tuberculosis directly from respiratory specimens.

Methods: The identification of M. tuberculosis isolates was confirmed using standard biochemical tests. Primer 3 plus software was used to design primers from CYP141. The expected size of the amplicon was 173 bp. We collected spuata from 247 suspected patients of different cities of Iran.

Results: With the exception of M. tuberculosis complex, no amplification was obtained with DNA from other mycobacteria, potentially pathogenic bacteria in the respiratory tract and human cells. These results give evidence that CYP141 can be used as a target for direct detection of M. tuberculosis from respiratory specimens.

Discussion: We obtained positive results with a trace amount of template DNA, as little as 1pg. Rv3121 or CYP141 exists in all M. tuberculosis isolates used in this study. The high overall specificity (97.8%) and sensitivity (85.7%) of this target (MOTT) and weakly acid fast bacteria (e.g: Nocardia species). The aim of this study was to modify the time of decolorization by 0.5% acid alcohol in order to increase the specificity without affecting the sensitivity of the stain. Smears were prepared from 25 bacterial cultures classified into 4 different groups. Group A comprises Mycobacterium tuberculosis complex, group B comprises 15 Mycobacteria other than tuberculosis (MOTT), group C comprises Nocardia farcinica and group D comprises one Gram positive and one Gram negative bacteria. All smears were stained with Auramine O fluorescence stain (IML-Red, Germany). 6 smears from each bacterial isolates were decolorized by 0.5% acid alcohol for (1, 2, 3, 4, 5, 10 m) to each smear separately, then all smears were counterstained with K permanganate for 1 m. All group (B) bacterial isolates were stained 100% fluorescence after 5 minutes decolorization time but the fluorescence of group (B) isolates were reduced to 73.3% after 5 minutes decolorization time and to 53.3% after 10 minutes. Group (C) showed weak fluorescence after 1 and 2 minutes which completely decolorized after 3 minutes. In conclusion, Mycobacterium tuberculosis complex was resistant to decolorization with 0.5% acid alcohol for 10 minutes while some MOTT were decolorized when using the same time.

P1411 Detection of fluoroquinolone resistance associated mutations in Mycobacterium tuberculosis by use of sequencing and TaqMan probes
Veronika Slizen1, Aksana Zalutskaya1, Larisa Surkova1
1Immunomorphological Investigations, National Scientific and Clinical Center for Pulmonology and Tuberculosis, Minsk, Belarus; 2Microbiology, Immunology, Virology, Belarusian State Medical University, Minsk, Belarus

Introduction: Mutations conferring resistance of MTT to fluoroquinolones occur in two short discrete segments of gyrA and gyrB genes. The aim of the amino acids at positions 88, 90 and 94 in gyrA plays a crucial role in the acquired resistance to fluoroquinolones. The aim of investigations is to evaluate the method of real time PCR with dual TaqMan probes for rapid detection of MTT resistance to fluoroquinolones.

Methods: Resistance to ofloxacin of MTT was determined by reference technique. gyrA and gyrB genes were amplified and autosequenced. The real-time PCR with dual TaqMan probes was developed to detect mutations in triplets 90, 94 of the gyrA gene.

Results: The gyrA codons 90, 91, 94 were reported to be the most frequently mutated codons worldwide, the same tendency was registered in Belarus: point mutations were predominately localized at codons 90 and 94 and rarer - 91. Mutations occurred at codon 90 resulted in Ala→Val replacements, at triplet 94 Asp→Gly or Asp→Asn, at codon 91 - Ser→Pro. The designed dual TaqMan probes for real-time PCR allowed detecting mutations in triplets 90, 94 of gyrA gene. Samples with mutations were characterized by above-threshold florescence on JOE-channel and subthreshold florescence on FAM-channel, while samples without mutations displayed above-threshold florescence on FAM-channel and subthreshold florescence on JOE-channel. The results obtained by real-time PCR with dual TaqMan probes showed high level of coincidence with sequencing data (94%).

Conclusion: The dominant mutations in 90, 94 triplets gyrA can be rapidly and effectively detected by PCR with dual-probe TaqMan probes.

P1412 Resazurin microtitre assay (REMA) plate – A simple, rapid and inexpensive method for detection of drug resistance in Mycobacterium tuberculosis Sudharrth Kunte, Alaka Karmarkar, Sujata Dharmashale, Swapnara Hatolkar
Department of Microbiology, B. J. Medical College, Pune, Maharashtra, India

Introduction: The sensitivity of REMA for the respective drugs was found to be 94.4%, 93.75%, 93.3% and 66.6%. The specificity of REMA for the respective drug was found to be 100%, 100%, 45.5% and 35.3%. The cost of REMA Plate method came out to be half of that required for Proportion Method.

Conclusions: REMA can be considered as one of the most rapid and inexpensive method to find out drug resistance to INH and RIF and can be of great advantage in the diagnosis of MDR-TB. ETM and STR, two drugs known to be difficult to test showed a low specificity.

Evaluation of real time polymerase chain reaction in tubercular mediastinal lymphadenopathy

Balasubramanian Thirumalai 1, Charanjit Kaur 1. 1Pulmonary Medicine, Vallabhbhai Patel Chest Institute, University of Delhi, New Delhi, India; 2Biochemistry, Vardhman Mahavir Medical College & Safdarjung Hospital, New Delhi, India

**Introduction:** Mediastinal lymphadenopathy is a common manifestation of tuberculosis. Several other conditions such as Sarcoïdosis and lung cancers also cause mediastinal lymphadenopathy. Radiology alone does not provide a diagnosis of TB in such cases. Conventional methods such as culture on L3 medium give results after several weeks while ZN stain for AFB has low sensitivity. We studied the sensitivity of Real Time Polymerase Chain Reaction (RT-PCR) on samples obtained by Trans Bronchial Needle Aspiration (TBNA) through fiberoptic bronchoscopy.

**Aims and Objectives:** To evaluate the sensitivity of RT-PCR in cases of mediastinal lymphadenopathy due to tuberculosis.

**Methods:** RT-PCR was performed in 39 consecutive patients of mediastinal lymphadenopathy who underwent fiberoptic bronchoscopy and TBNA of the mediastinal nodes. Final diagnosis of all patients was based on Histopathology, ZN staining and BACTEC culture for AFB.

RT-PCR was performed by detecting amplification reaction for the insert element IS6110 of the Mycobacterium tuberculosis complex (Biotub QT, Biotools Labs, Spain) using a real-time centrifugal amplification system (Rotor-Gene 3000, Corbett Research, Australia).

**Results:** Of the 39 cases of mediastinal lymphadenopathy, 21 were due to tuberculosis. In 11 cases the cause was Sarcoïdosis and 7 cases were due to malignancy. RT-PCR was positive in 19 of the 21 cases of tuberculosis ( Sensitivity 90.48%). There was 1 false positive RT-PCR in a case of lung malignancy. The Specificity of RT-PCR in tuberculosis was 94.74%

**Conclusion:** Real time PCR is valuable in the diagnosis of mediastinal lymphadenopathy due to tuberculosis with a sensitivity of 90.48% and specificity of 94.74%.

**Xpert MTB/RIF assay for rapid detection of Mycobacterium tuberculosis and rifampicin resistance**

Debavrat Bhattacharyya 1, A. Agarwal 2, M.S. Barthwal 1, C.D.S. Katoch 1.

1Respiratory Medicine, Military Hospital (Cardio Thoracic Centre), Pune, Maharashtra, India; 2Microbiology, Military Hospital (Cardio Thoracic Centre), Pune, Maharashtra, India

**Introduction:** Xpert MTB/RIF is a novel molecular diagnostic point of care test for rapid detection of MTB and its susceptibility to rifampicin (RIF).

**Objective:** This study was performed to evaluate the performance of Xpert MTB/RIF assay in detection of MTB and resistance to rifampicin from sputum specimens taking positive culture for MTB and phenotypic resistance to rifampicin as reference standards.

**Materials and methods:** 126 consecutive patients of pulmonary tuberculosis presenting to the hospital from December 2010 to January 2012 were enrolled for the study. Their sputum samples were subjected to concentrated ZN microscopy, culture on solid (LI) and liquid (MGIT) media. All positive cultures were identified as MTB complex using SD-TB Ag MPT 64 Rapid immunochromatographic test and indescriminating susceptibility testing performed by MGIT SIRE.

**Result:** Of the 126 cases included in the study, 83 were smear-positive and 43 were smear-negative. Of patients with culture positive samples, 20 of 126 (15.9%) were found to have multdrug resistance on indirect drug susceptibility testing with MGIT SIRE. With positive culture as the reference standard, MTB/RIF assay when done detected 98.7% of smear positive cases and 72.1% of smear negative cases. The test correctly identified all 20 of rifampicin resistant culture isolates and 105 of 106 rifampicin susceptible isolates for a sensitivity, specificity, positive predictive value and negative predictive value of 100%, 99%, 95.2% and 100% respectively.

**Conclusion:** Xpert MTB/RIF assay is a reliable technique for rapid detection of Mycobacterium tuberculosis and Rifampicin resistance from pulmonary specimens.

**The prevalence of pyrazinamide resistance in multidrug resistant tuberculosis cases in the Netherlands**

Sami Simoes 1, Jakko van Ingen 2, Martin Boeree 1, Dick Van Soolingen 2.

1Respiratory Medicine, Radboud University Medical Centre, Nijmegen, Netherlands; 2Medical Microbiology, Radboud University Medical Centre, Nijmegen, Netherlands

**Introduction:** Pyrazinamide is very important in the treatment of multidrug resistant tuberculosis (MDR TB). Unfortunately, studies on the prevalence of pyrazinamide resistance in MDR TB cases are scarce and mainly come from non-European countries.

**Aims and objectives:** Our aim was to determine the prevalence of pyrazinamide resistance in MDR TB cases from the Netherlands.

**Methods:** We retrospectively analyzed pyrazinamide resistance in all MDR TB cases from the Netherlands found in 2007-2011. Drug susceptibility testing was performed using the Mycobacterial Growth Indicator Tube (MGIT) method. Also in every resistant isolate the pncA gene was sequenced. Resistance was determined using a diagnostic algorithm described recently by our group incorporating both methods (Simons, S.O., et al. JCM 2012: 50:428-34).

**Results:** 61 cases of multidrug resistant tuberculosis were seen in the Netherlands from 2007-2011. Pyrazinamide resistance testing was possible in 59 cases. In 17 MDR TB cases pyrazinamide resistance was observed (29%). 16 out of these 17 cases carried a nonsynonymous mutation in the pncA gene.

**Conclusions:** Our data suggest that among MDR TB cases in the Netherlands pyrazinamide resistance is around 29%. Strategies are required to determine the optimal diagnostic algorithm in this population.

**Comparative analysis of detection of Mycobacterium tuberculosis and rifampicin resistance determination through microbiological and molecular methods for pulmonary tuberculosis patients with presence or absence of sputum**

Maria Alvarez Figueroa 1,2, Ekaterina Dolgova 1,2, Maria Gordukova 1,2, Dmytry Belov 1,2.

1Department of Health, Moscow SUNDAY, SEPTEMBER 2ND 2012 254s 2Epidemiology Federal Service for Surveillance on Consumers Rights Protection and Human Well-Being, Moscow, Russia; 2Center for TB Morphological Studies, Tuberculosis Clinical Hospital No. 7, Moscow, Russian Federation

**Introduction:** The majority of studies on diagnostics of pulmonary tuberculosis (PTB) used only sputum that appears at later stages of disease and don’t use bronchoalveolar lavage (BAL) fluid obtained by bronchoscopy. At the same time these patients are epidemiologically dangerous even at the early stages of disease. The aim of our study was to compare the possibilities of microbiological and molecular genetics methods for Mycobacterium tuberculosis (MTB) detection and rifampicin resistance identification (RIF-R) in new cases of PTB through sputum or BAL fluid examination. We conducted a double-blind randomized retrospective investigation. The aetiology of PTB has been proven by receiving the culture growth or histological examination of lung tissue with Ziehl-Neelsen staining. A total of 134 specimens (32 sputum and 102 BAL fluid) from 133 patients gave positive results by Real-Time PCR (kit “AmpliSencMTB-FL”) and by sequencing of rpoB gene (kit “AmpliSencMTB-RIF-seq”). We received growing of MTB culture in only 23 sputum and 56 (54.9%) BAL fluid compared to the molecular genetics investigations. We found RIF-R in 12 (38.7%) sputum and 37 (36.3%) BAL fluid by all methods. In addition to the culture method we managed to detect RIF-R in 15 sputum and 25 BAL fluid samples (plus one insignificant mutation). Due to the higher sensitivity of molecular genetics methods we not only found out MTB in proven cases of PTB more likely than culture method, but also higher level of RIF-R that did not demonstrate a difference between patients with presence or absence of sputum.

**P1417**

**Assessment of molecular assays for detection of MDR Mycobacterium tuberculosis resistant to second-line injectable drugs**

Marina Gikas 1, Ludmila Krylova, Moscow Department of Health, Moscow Scientific and Clinical Anti-tuberculosis Center, Moscow, Russian Federation

With the emergence of MDR-TB and XDR-TB rapid and accurate second-line drug susceptibility testing became essential. The [GenoType® MTBDRsl] (Hain Lifescience, Germany) gives the possibility to identify mutations in the rrs, gyrA and embB genes. The aim of the present study was to assess the sensitivity of this molecular assay for the identification of M. tuberculosis resistant to second-line injectable drugs (SLIDs), as, to our knowledge, detection of rrs mutations is not sufficient for this purpose. 40 MDR M. tuberculosis strains, also resistant to SLIDs, were chosen from our culture collection. 20 SLIDs-resistant strains were adopted as control. Three DNA targets were investigated: the rrs gene, the embB promoter region and the embA gene. The [GenoType®] was used to detect rrs mutations and SSCP and sequencing were performed for all three genes. All kanamycin and capreomycin-resistant cultures carried an A1404G substitution in the rrs gene and were detected with all the molecular assays, but one of the strains also had an embB mutation. 8 kanamycin-resistant strains carried various embA mutations, the most common being the C141T substitution, and thus could not be identified with the [GenoType®]. No mutations were found in the embA gene. One of the SLIDs-susceptible strains carried a C12T mutation. Therefore 20% of M. tuberculosis strains resistant to kanamycin could not be detected with the [GenoType®]. Mutations in the embB promoter region are found in kanamycin-resistant M. tuberculosis strains at high rates and should be included in molecular assays for detection of SLIDs resistance.

**P1418**

**Modern molecular direct tests for rapid identification and drug susceptibility testing of Mycobacterium tuberculosis**

Ksenia Gilka, Elena Nosova, Maria Krasnova, Department of Health, Moscow Scientific and Clinical Anti-tuberculosis Center, Moscow, Russian Federation

Molecular tests are widely used for detection of M. tuberculosis (MTB) in clinical samples in laboratories around the world. At present, there are molecular tests allowing to perform MTB detection and DST to antituberculosis drugs simultaneously.
We performed a comparative analysis of three molecular tests: GeneXpert MTB/RIF (Cepheid, USA), GenoType MTBDRplus (Hain LifeScience, Germany) and TB-Biochip MDR (LLC "BIOCHIP", Russia).

All in all 151 sputum samples were investigated. 32 of them were smear- and culture-positive, and 19 of them were smear-negative but culture-positive. Co-occurrence of the results of MTB detection by molecular tests with the culture test in Racine, USA and in Becton Dickinson, USA were 92.8%, 78.4% and 49.02% respectively. For GeneXpert MTB/RIF, TB-Biochip MDR and MTBDRplus respectively. For the smear-negative and growth-positive sputum samples results coincided in 80.9% and 52.4% of cases for GeneXpert MTB/RIF and TB-Biochip MDR respectively. Results of molecular and bacteriologic DST to rifampicin (RIF) (isoniazid (BIN)) coincided in 100%, 97.4% and 100% of cases for GeneXpert MTB/RIF, "TB-Biochip MDR" and MTBDRplus respectively. Our data show, that GeneXpert MTB/RIF is the fastest real-time test with the highest sensitivity, but we can get the information about MTB sensitivity only to RIF. As to TB-Biochip MDR and MTBDRplus tests, they are also simple, reliable and establishing of DST to RIF and INH, but the sensitivity of MTBDRplus is not enough to analyze smear-negative samples.

P1419

Population-based study of fluoroquinolone-resistance in clinical isolates of Mycobacterium tuberculosis in Novosibirsk Oblast, Russian Federation

Yana Batyrshina, Tatyana Ponomareva, Pavel Filimonov, Microbiology, Novosibirsk TB Research Institute, Novosibirsk, Russian Federation

Background: Fluoroquinolones (FQ) are used for treatment of many bacterial infections frequently. These drugs are being used for treatment of MDR-TB in Novosibirsk Oblast (NO) since 2003.

Aims: To evaluate prevalence of primary drug resistance of M. tuberculosis to FQ in NO. To estimate contribution of common prescription of FQ treatment of non-TB infections to resistance selection in mycobacterial population.

Methods: Minimal inhibitory concentrations (MIC) of ofloxacin (OFL) were determined for 344 isolates of M. tuberculosis from 344 patients with newly diagnosed TB. This selection consisted from 165 isolates obtained in 2000-2002 and 179 in 2006-2010. DST was conducted on all isolates and based on results they were divided additionally in to the following groups - 141 fully susceptible to first-line anti-tuberculosis drugs isolates, 83 MDR isolates and 120 resistant other than MDR.

Results: An increase in MIC of OFL (6,0-32,0 mcg/ml) was detected in the MDR-group (7,2%, 95%CI:3,4-14,9) exclusively and only among isolates obtained in 2006-2010 (3,4%, 95%CI:1,5-7,1). FQs have not been prescribed to 6 patients with FQ-resistant MTB (MIC of OFL > 40 mcg/ml) within the period prior to establishing of TB diagnosis. 3 of them had had a contact with an MDR-TB patient. The calculated prevalence of primary FQ-resistance of M. tuberculosis in NO was 6,4%, 95%CI:2,9-13,2 (result of the sampling of 94 isolates obtained in 2006-2010).

Conclusions: These findings indicate that emerging FQ-resistance in MBT strains in NO is the result of treatment of patients with MDR-TB rather than from FQ prescriptions to general population for non-TB infections.

Substantial time reduction in diagnosis of Mycobacterium tuberculosis rifampicin and isoniazid resistance by the application of a DNA strip hybridization assay in clinical samples

Panagiota Ioannidou1, Dimitrios Pavlopoules1, Simona Karahezova1, Ioanna Marinou1, Euthemia Konstantinidou1, Marina Panagi1, Anastasios Skouroglou1, Georgios Dionellis2, Nikolaos Koulouris2, Anas Skouroglou1, Georgios Dionellis2, Nikolaos Koulouris2, Ioanna Marinou1, Euthemia Konstantinidou1, Marina Panagi1, University, Minsk, Belarus; 2Microbiology, Immunology, Virology, Belarusian State Medical University, Minsk, Belarus

The MTBDRplus (Hain LifeScience, Nehren, Germany) is a molecular assay detecting mutations involved in M. tuberculosis rifampicin (RMP) and isoniazid (INH) resistance, approved for application on culture isolates and smear-positive (AFB+) specimens. We evaluated its performance as a routine diagnostic assay directly on clinical specimens.

Methods: Consecutive AFB+ and selected AFB− specimens, from high risk patients for drug resistance, were assayed. The results were compared to conventional drug susceptibility testing (DST). For time reduction estimation we counted the days elapsed before patient’s first positive culture was available.

Results: 475 specimens were analyzed. Interpretable MTBDRplus results were obtained for 331/400 (82.7%) AFB+, 33/70 (47) AFB− and 1/5 (20%) microscopically suspicious specimens. We identified 13 MDR, 28 INH resistant, 2 RMP resistant, and 2 rpo polypharmaceuticals. Disagreement between DST and MTBDRplus mainly involved strains with inhA mutations (68) conflicting resis- tance to low INH concentrations2. The sensitivity, specificity, PPV and NPV values for RMP and INH resistance detection were 100%, 99%, 96%, 92%, 8%, 100% and 86, 6%, 96, 94% respectively. Substantial reduction in drug susceptibility diagnosis was recorded (14±6±2 days).

Conclusions: The MTBDRplus assay was informative for the great majority of AFB+ cases, highly accurate for screening RMP and INH resistance and its application achieved considerable reduction in diagnostic delay.

P1421

Dual TaqMan probes for the detection of rifampicin resistance in Mycobacterium tuberculosis

Vera M. Slizien1,2, Larissa Surkova1.

1Immuno-morphological Investigations, National Scientific and Clinical Center for Pulmonology and Tuberculosis, Minsk, Belarus; 2Microbiology, Immunology, Virology, Belarusian State Medical University, Minsk, Belarus

Mutations (SNP) at codons 526, 531 of rpo gene of MTB are considered to be biomarkers of resistance to rifampicin (RIF). The aim of the study was to develop 96-well plate qPCR platform with dual TaqMan probes for the prediction of RMP resistance in MTB.

Methods: A total number of 122 DNA extracts from MTB cultures were studied. SNPs in 516, 526, 531 codons of rpo gene were detected by autosequencing and qPCR with dual TaqMan probes (labeled with FAM and JOE for identification of wild and mutated codons correspondingly).

Results: We present a 96-well PCR plate method for identification of SNPs in rpo gene of MTB. Each 96-well PCR plate is organized as follows: 1) 12 DNA extracts can be investigated collectively; 2) four wells are used for each DNA extract to identify MTB and mutations in 516, 526, 531 codons; 3) one set of controls per 6 DNA extracts is provided including positive, negative (with and without mutations), and no-template controls for each control tested. The entire assay includes the following steps: 1) filling wells with DNA-extracts and PCR reaction mixtures using repeater pipette; 2) amplification and data bioanalysis including: a) detection of fluorescence threshold using method of negatives with 20% tolerance; b) allele discrimination analysis based on detection of differences in JOE and FAM fluorescence. The results obtained with this real time PCR design agreed well with DNA sequencing data. Out of 122 DNA extracts (488 reactions) 8 samples were false negative (7%) versus sequencing data. This 96-well PCR plates uses 48 DNA extracts of 20 DNA reactions in 6 lines, and represents an adequate method for the specific and rapid detection of RMP resistance in MTB cultures.

P1422

Line probe assay (LPA) based rapid detection of multiple drug resistant (MDR) mycobacterium tuberculosis (MTB)

T.S. Tzogulshvili1,2, Rupali Hire1, Swati Shrotri1, Yuji Kondo1,3, Pulmonary Medicine, Jatulinic, Mumbai, Maharashtra, India; 2tuberculosis, Xpert DNA Research, Mumbai, Maharashtra, India; 3tuberculosis, Blotron Healthcare, Mumbai, Maharashtra, India

Objective: Rapid confirmation of diagnosis of MTB and MDR-MTB in clinical samples by Line probe assays based on Reverse DNA hybridization(RDH)

Methods: RDH is useful for detection of mutations related to drug resistance in Mycobacterium tuberculosis. The sample size of 50 AFB staining positive sputum samples was taken. Of these 30% were cases known to be MDR cases as detected from culture tests and 79% were fresh smear positive cases on treatment for TB. The Line probe assays were developed to cover common drug resistant mutations with rifampicin, INH, and aminoglycosides. The genes probed were rpoB, katG, gyrA, gyrB, rrs, eis, the MTB complex and NTN. The end point was detected was by avidin biotin labeled nested PCR products from patient samples.

Results: All the 50 smear positive samples were detected as MTB or NTN positive by the LPA assay. All the known MDR cases showed drug resistance related mutations in the LPA. About 30% had mutations in the gyrA gene and all were observed in clinically known MDR cases; 46% of mutations were seen in the rpo gene and 56% in the katG region. The efficacy of the line probe when related to culture tests was greater than 90%.

Conclusion: The LPA assay relates well with both MTB mycobacterial presence and Drug resistance.

References:

Cigarette smoke upregulates IL-8/CXCL8 expression by augmenting mRNA stability via p38 MAPK-induced MK2 phosphorylation which was accompanied by the phosphorylation of MAPK-activated kinase 2 (MK2), a known downstream substrate of the p38 MAPK. In both BHSMC and human alveolar macrophages, pharmacological inhibition of p38 MAPK only acutely accelerated the decay of IL-8 mRNA levels upon stimulation with CSE or acrolein and subsequent blockade of mRNA neo-synthesis with actinomycin D. Conversely, pharmacological inhibition of extracellular-signal-regulated kinase 1/2 (ERK1/2) signalling did not affect mRNA stability but inhibited both CSE- and acrolein-induced steady-state levels of IL-8 mRNA, suggesting a transcriptional effect. In sum, p38 MAPK/MK2 signalling appear to be an important post-transcriptional mechanism underlying CSE-induced IL-8 mRNA upregulation.

Cigarette smoke is the most important risk factor for the development of Chronic Obstructive Pulmonary Disease (COPD). A large body of evidence exists indicating that cigarette smoke is able to activate the Epidermal Growth Factor Receptor. We have previously established that aconitase cigarette smoke extract (CSE) stimulates CXCL8 and VEGF release from normal human lung fibroblasts (NHFL) and airways smooth muscle cells (ASM) and that these effects are mediated by the α,β-unsaturated aldehydes contained in the CSE such as acrolein. Here we examined the effect of pharmacological inhibition of EGFR on CXCL8 and VEGF release induced by CSE and acrolein. We found that the EGFR inhibitors AG1478, gefitinib and PD153035 inhibit CSE- and acrolein-induced CXCL8 release in both NHFL and ASM, but do not affect neither TNFα-induced CXCL8 release nor CSE-induced VEGF release. We have previously shown that CSE-evoked CXCL8 and VEGF release was accompanied by a rapid p38 MAPK phosphorylation mimicking by acrolein. Because p38 MAPK phosphorylation is one of the possible downstream pathways activated by EGFR, we examined the effects of EGFR inhibitors on p38 MAPK phosphorylation. We observed that all three EGFR inhibitors failed in modifying p38 MAPK phosphorylation evoked by CSE. In sum, pharmacological inhibition of EGFR suggests that EGFR is involved in CXCL8 release through a p38 MAPK independent mechanism. Given the pivotal role of CXCL8 and VEGF as neutrophils chemoattractant and angiogenic factor respectively, this study sheds light on the different mechanisms through which cigarette smoke can orchestrate inflammation and vascular remodeling in the lung.

Cigarette smoke (CS) as a major source for oxidative stress in the lungs, is the main cause of chronic obstructive pulmonary disease (COPD). Patients suffering from COPD are more susceptible to viral infections resulting in acute exacerbations. Viral infections induce expression of immunoproteasomes (IP) via IFNγ-signaling. This specialized form of proteasome is destined to improve antigen presentation and the control of viral infections. The role of IP in viral lung infections is unknown. Expression levels of IP-subunits LMP2 and LMP7 were evaluated in wildtype (wt) as well as LMP2+ and LMP7+ deficient mice in whole lung homogenates. Of note, we observed pronounced expression of IP-subunits in wt lungs compared to other organs. Immunohistochemical analysis of lung sections revealed that IP positive staining was observed in cells adjacent to airways, but also in alveolar regions. To study regulation of IP in vivo, we analyzed expression of IP in different lung cell lines. IFNγ induced pronounced expression of IP in both lung epithelial and fibroblasts cells, as detected by qRT-PCR and western blotting. In COPD patients and in PBT-cells from HC subjects stimulated with CSE. CSE causes the release of chemokines but reduces IgE/antigen-induced degranulation and cytokine release. Interestingly, CSE was found in CSE. Both CSE and acrolein induced p38 mitogen-activated protein kinase (MAPK) phosphorylation -induced CXCL8 release through a p38 MAPK independent mechanism. Given the pivotal role of CXCL8 and VEGF as neutrophils chemoattractant and angiogenic factor respectively, this study sheds light on the different mechanisms through which cigarette smoke can orchestrate inflammation and vascular remodeling in the lung. Chronic obstructive pulmonary disease (COPD) is a multicomponent disease characterized by emphysema and/or chronic bronchitis. COPD is mostly associated with cigarette smoking. Many inflammatory cells are present in the airways of patients with COPD. Cigarette smoke contains over 4,700 chemical compounds, including free radicals and LPS (a Toll Like Receptor 4 agonist) at concentrations which may contribute to the pathogenesis of diseases like COPD. Toll-like recep-
P1428 Role of interferon-γ in tumor necrosis factor-α-mediated increase of lung microvascular endothelial cells

Yoshio Nakajima1, Yutaka Nakamura, Naomi Suzuki, Yu Utsumi, Nobuhiro Sasaki, Kohei Yamachika. Division of Pulmonary Medicine, Allergy, and Rheumatology, Iwate Medical University School of Medicine, Morioka, Japan

Background: Chronic obstructive pulmonary disease (COPD) is an inflammatory lung disease in which tumor necrosis factor-α (TNF-α) and interferon-γ (IFN-γ) are respectively and have been suggested to play pathogenic roles. The effect of these agents on angiogenesis in the lung tissues of COPD is unknown.

Objective: To examine the effects of these mediators on lung endothelial cells (ECs).

Methods: NR2f knockout mice were exposed to cigarette smoke (CS) for 4 weeks, and the down-regulated genes referring to vascularity in the whole lung were identified by microarray analysis. To confirm the protein levels, which were indicated in the microarray data, cell lines, namely human umbilical vein microvascular endothelial cells (HUVECs) and human microvascular endothelial cells (HMECs) were used. The protein levels of TNF-α and IFN-γ were performed, thereafter ECs were submitted to an examination of protein levels expression using immunoblotting or immunocytochemistry.

Results: Microarray analysis data have shown that the mRNA expression of angiogenin-like protein 1 (AmotL1) decreased in response to CS when compared to no exposure to CS. TNF-α enhanced vascular endothelial cell growth factor (VEGF) production by cultured lung fibroblasts, however, vascularity was decreased when treated with IFN-γ. In addition, IFN-γ induced tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) receptors on ECs and attenuated the expression of AmotL1 localized to endothelial cell-cell junctions.

Conclusions: These results suggest that IFN-γ acts as anti-angiogenesis by regulating the expression of TRAIL receptors and AmotL1 on ECs, which were induced by the enhanced VEGF production by TNF-α-stimulated lung fibroblasts.

P1429 Second hand smoke exposure impairs CD39 expression and function in the lung

Adileh Kletrater1, Jonas Saly1, Jean Sævings2, Martin Zamora3, Laima Taraseviciene-Stewart1

1. Medicine, University of Colorado, Aurora, CO, United States; 2. Microbiology, Infectious Diseases and Immunology, University of Quebec, QC, Canada

Chronic second hand smoke (SHS) exposure is the main risk factor for non-smokers to develop chronic obstructive pulmonary disease COPD. The mechanisms behind the chronic inflammation and lung destruction are not completely understood.

In response to injury vascular and blood cells release ATP that is implicated in regulating immune responses. In the present report, we have shown that chronic SHS exposure induced a down-regulation of CD39 expression in the whole lung tissue on mRNA and protein levels. Moreover, CD39 expression was decreased in the lungs from COPD patients. In addition, CD39 expression in the whole lung tissue on mRNA and protein levels. Moreover, CD39 expression was decreased in the lungs from COPD patients. Cigarette smoke extract in vitro almost abolished CD39 and CD73 expression in the alveolar macrophages and vascular endothelial cells. Second hand smoke exposure impairs ectonucleotidase expression in the lungs and leads to accumulation of extracellular ATP that confers increased proinflammatory responses leading to the development of emphysema.

P1430 Chronic obstructive pulmonary disease (COPD) is one of the most prevalent, and among smokers with COPD. CD98 was measured on AM using flow cytometry. We showed that SHS exposure downregulated CD98 expression on AMs of healthy smokers and COPD patients.

Methods: Sprague Dawley rats were exposed to SHS in a smoking chamber (total particulate matter levels 115 mg/m³). The expression levels of CD39 and CD73 in the alveolar macrophages and vascular endothelial cells. Second hand smoke exposure impairs ectonucleotidase expression in the lungs and leads to accumulation of extracellular ATP that confers increased proinflammatory responses leading to the development of emphysema.

P1431 Lectins improve efferocytosis via changes to cytoskeletal remodeling: Relevance to COPD

Violet Mukaro1, Johan Byland2, Jessica Ahern1, Mark Holmes1, Greg Hodge3, Paul Reynolds1, Sandra Hodge4, 1. Thoracic Medicine, Royal Adelaide Hospital, Adelaide, Australia; 2. Sahlgrenska Academy, University of Gothenburg, Sweden

Objective: To examine the effects of these mediators on lung endothelial cells (ECs).

Methods: NR2f knockout mice were exposed to cigarette smoke (CS) for 4 weeks, and the down-regulated genes referring to vascularity in the whole lung were identified by microarray analysis. To confirm the protein levels, which were indicated in the microarray data, cell lines, namely human umbilical vein microvascular endothelial cells (HUVECs) and human microvascular endothelial cells (HMECs) were used. The protein levels of TNF-α and IFN-γ were performed, thereafter ECs were submitted to an examination of protein levels expression using immunoblotting or immunocytochemistry.

Results: Microarray analysis data have shown that the mRNA expression of angiogenin-like protein 1 (AmotL1) decreased in response to CS when compared to no exposure to CS. TNF-α enhanced vascular endothelial cell growth factor (VEGF) production by cultured lung fibroblasts, however, vascularity was decreased when treated with IFN-γ. In addition, IFN-γ induced tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) receptors on ECs and attenuated the expression of AmotL1 localized to endothelial cell-cell junctions.

Conclusions: These results suggest that IFN-γ acts as anti-angiogenesis by regulating the expression of TRAIL receptors and AmotL1 on ECs, which were induced by the enhanced VEGF production by TNF-α-stimulated lung fibroblasts.

Second hand smoke exposure impairs CD39 expression and function in the lung

P1432 Enhanced cytotoxic function of NK and NKT-like cells associated with decreased CD94 (Kp43) in the airway in COPD

Greg Hodge1,2, Violet Mukaro1,2, Mark Holmes1,2, Paul Reynolds1,2, Sandra Hodge4, 1. Thoracic Medicine, Royal Adelaide Hospital, Adelaide, Australia; 2. Lung Research, Hanson Institute, Adelaide, Australia

NK and NKT-like cells represent a small but important proportion of effector lymphocytes that we have previously shown to be a major source of pro-inflammatory cytokines and granymes. We hypothesized that NK and NKT-like cells would be increased in the airway in COPD and that this would be accompanied by a reduction in expression of the inhibitory receptor CD94 (Kp43) and increased expression of the cytotoxic potential by production of granymes A and B and using a cytotoxicity assay. In blood from COPD subjects, there were no significant changes in NK or NKT-like cell numbers or expression of granyme A or cytotoxic potential vs controls. There was however, increased expression of granyme B and decreased expression of CD94 by both cell types vs controls.

In the airway in COPD, NK and NKT-like numbers were increased, associated with increased NK cytotoxicity, increased expression of granyme B and decreased expression of the inhibitory receptor CD94. Treatment strategies that target NK and NKT-like cells, their cytotoxicity and production of inflammatory mediators in the airway may improve COPD morbidity.

P1433 The role of IL-17 and lymphoid follicles in the pathogenesis of COPD

Koshika Yadava1, 2, Aurelien Trompette1, 2, Anke Sichelstiel1, 2, Laurent Nicod1, 2, Benjamin Marsland1, 2, Laboratoire de Pneumologie, CHUV, Lausanne, Switzerland; 3. Faculty of Biology and Medicine, UNIL, Lausanne, Switzerland

Chronic Obstructive Pulmonary Disease (COPD) is one of the most prevalent respiratory diseases in the world. There is no definitive treatment to arrest the progressive loss of lung function characteristic of COPD, partly due to a lack of understanding of the underlying cellular pathological mechanisms. In individuals with severe COPD, there is an accumulation of adaptive immune cells as well as an increase in the frequency of lymphoid follicles in the lung; however, the role of lymphoid follicles in driving the disease and the factors that promote their formation are largely unknown. In addition, individuals with COPD exhibit elevated levels of IL-17, a cytokine that is associated with autoimmunity and was recently shown to promote lymphoid neogenesis. We have modeled different...
severities of COPD by incremental instillation of LPS and elastase in mice. We observed an increase in the levels of IL-17A following repeated challenges, which coincided with the progressive drop in lung function as well as the appearance of lymphoid follicles. IL-17A production was in part triggered by the engagement of Toll Like Receptor 3 implicating a role for an endogenous danger signal in COPD. Neutralization of IL-17A at specific times after the initiation of disease ameliorated the impaired function and affected B Cell lineage and pro-angiogen Activations. Our data indicates that IL-17A is involved in COPD progression by induction of lymphoid follicles and regulation of both innate and adaptive immunity.

Rationale: Although adaptive immune responses are critical for combating distant airway infections in COPD, the structural basis for alveolar antigen uptake has remained poorly investigated. This study investigates the interface between alveolar lumen and the adaptive immune system at different severities of COPD.

Methods: Lung resections (n=31) from mild (GOLD I), moderate-severe (GOLD II-III), and very severe (GOLD IV) COPD patients were used to study detailed histological assessment of components of the adaptive immune system in distal lung. Never-smokers and non-COPD smokers served as controls (n=15).

Results: COPD patients showed increased numbers and size of lymphoid aggregates compared to controls and in non-smokers. Immunohistochemistry for common lymphoid markers showed, increased numbers of B cells, T cells and macrophages. These aggregates were mainly composed of B cells (98%) with a minor contribution of T cells (2%) and macrophages (2%). However, the total epithelial TLR7-immunoreactivity was upregulated in COPD patients in comparison to controls and non-smokers.

Conclusions: Whether the altered expression reflects a natural adaption to the increased pathogen burden in advanced COPD or is part of a dysfunctional immune-regulation in COPD remains to be determined.

P1435 Diverse and altered distribution patterns of TLR5 and TLR7 in the distal lung of COPD patients

Methods: GOLD I (n=6), GOLD II-III (n=13), GOLD IV patients (n=8), and controls (n=15) were enrolled in this study. Immunohistochemical staining was used to identify TLR5 and TLR7 positive cells.

Results: TLR5 immunoreactivity was identified in sub-epithelial glands, airway smooth muscle, CD68+ macrophages, CD138+ plasma cells, CD208+ type II pneumocytes and the small airway epithelium. In control subjects and mild COPD (GOLD I) TLR5 was expressed in the alveolar and small airway epithelium and the alveolar lumen. In moderate-severe (GOLD II-III) and severe COPD (GOLD IV) alveolar and small airway wall matrix components were stained with a hyaluronan binding protein. All stainings were corrected for total surface area and data expressed as mean % of stained area.

Conclusions: These results indicate that remodeling in the alveolar and SA wall in COPD show marked similarities and both relate to FEV1.

P1436 Metabolomic fingerprinting in the identification of biomarkers in COPD patients

Methods: Metabolomic fingerprinting is able to achieve the identification of novel biomarkers the comprehensive characterization of the entire metabolome of a disease. The main objective is to use it to understand the pathological basis underlying COPD and its relationship to the severity and phenotypic characteristics.

Results: Observational case-control study involving COPD patients and controls without COPD or cardiovascular history. COPD patients were grouped in chronic bronchitis and emphysema, and at different stages of GOLD. Different platforms are required to capture all metabolites in one sample of plasma and separation techniques such as gas chromatography coupled to mass spectrometry (GC-MS).

Conclusions: Using metabolomic fingerprinting in plasma we could identify markers and differentiate phenotypes and early stages in COPD.

P1437 Comparable matrix alterations in the alveolar and small airway wall of COPD patient lungs

Results: Using metabolomic fingerprinting in plasma we could identify markers and differentiate phenotypes and early stages in COPD.

Conclusions: Using metabolomic fingerprinting in plasma we could identify markers and differentiate phenotypes and early stages in COPD.

P1438 Corticosteroid insensitivity in airway smooth muscle cells of severe asthma and COPD: Modulation by IFN-γ

Methods: Aper-nuclear expression in the small airway epithelium irrespective of the study group. However, the total epithelial TLR7-immunoreactivity was upregulated in GOLD IV patients compared to never smokers (p=0.009). TLR7 expression was also detected in S100B+ nerve cells, CD68+ macrophages, B- and T-lymphocytes, and CD56+ NK cells.

Conclusion: Both epithelial TLR5 and TLR7 are upregulated in advanced COPD. Whether the altered expression reflects a natural adaption to the increased pathogen burden in advanced COPD or is part of a dysfunctional immune-regulation in COPD remains to be determined.
Conclusions: ASCMs of SA, smokers and COPD display CS insensitivity. IFN-γ impairs the suppressive effect of Dex on CXCL8 in the healthy and asthmatics but improves it in smokers and COPD, suggesting differential mechanisms underlying CS insensitivity in SA and smokers/COPD.

P1439
Inhaled corticosteroids (ICS) attenuates epithelial mesenchymal transition (EMT) in COPD: A key to understanding long term benefits?
Sukhwinder Singh Sohal1, Amir Sofiani1, Dario Reid1,2, Chris Ward1,2
Steven Westen1, Hans Konrad Muller1, Richard Wood-Baker1, Eugene Haydn Walters1,1 NHMRC Centre for Research Excellence in Chronic Respiratory Disease, University of Tasmania, Hobart, TAS, Australia; 2Iron Metabolism Laboratory, Queensland Institute of Medical Research, Brisbane, QLD, Australia; 3Respiratory Medicine, Institute of Cellular Medicine, Newcastle upon Tyne, Newcastle, United Kingdom

Introduction: We recently published that EMT is an active process in COPD airways. Our knowledge about the effects of ICS on this process in COPD is very limited.

Objective: To assess the effects ofICS on EMT in endobronchial biopsies (ebb) from COPD patients.

Methods: A double-blinded, randomized, placebo-controlled study assessed the effects of inhaled fluticasone propionate (FP, 500μg twice daily) on EMT in 34 COPD patients. Ebb were assessed for EMT related reticolar basement membrane (Rbm) fragmentation and immunostained for the EMT signatures S100A4 (a fibroblast epitope), matrix-metalloproteinase-9 (MMP-9) and epithelial activation marker, epidermal growth factor receptor (EGFR).

Results:

Comparison at baseline and after treatment (FP, n=23 and placebo, n=11)
Markers Before (FP) After (FP) Before (Placebo) After (Placebo)
% Rbm fragmentation 19.1 (0.2-42.8) % 2.6 (0.88-6.6) 24.0 (6.6-100) 26.9 (2.5-48.5)
S100A4 positive cells in Rbm per mm Rbm 25.8 (2.455-3.9) 12.3 (0.6-24.9) 19.8 (2.931.6) 17.4 (0.3-35.5)
S100A4 positive cells in Rbm per mm of Rbm 44.4 (15.3-92.6) 20.8 (2.6-60.7) 23.1 (14.82.9) 29.3 (3.6-48.1)
MMP-9 positive cells in Rbm clefts per mm of Rbm 0.6 (0.0-22.4) 1.1 (0.0-4) 1.3 (0.27)
EGFR % ciliated

Data expressed as medians and ranges. *No significant difference at baseline. **Significant difference after treatment with FP (p<0.03).

Conclusions: This is the first study to report that ICS have potent anti-EMT effects in COPD. This may be a mechanistic link between ICS treatment and long term reduction in smoking-related lung cancer seen in COPD.

P1441
One size does not fit all – Impact of the one liter tidal volume breathing protocol on indices from nitrogen multiple-breath washout in children
Sophie Yammine, Florence Singer, Philipp Latzin. Department of Paediatric Pneumology, University Children’s Hospital of Bern, Switzerland

Background: Nitrogen multiple-breath washout (N2MBW) is a useful tidal breathing lung function test to assess ventilation inhomogeneity (Vi), e.g. in Cystic Fibrosis (CF) patients. One liter tidal volume (VT) breathing protocols are regarded to improve comparability of results between subjects breathing at different VT and are widely used in adults. The impact of protocols using fixed VT on results in children is unknown. We assessed whether breathing at fixed VT impacts N2MBW indices in school-aged children.

Methods: Ten children with CF and 16 healthy children performed six N2MBW tests using a validated setup (Exhalyzer D, Eco Medics, Switzerland). Children performed three baseline N2MBW at free tidal breathing and three N2MBW at increased VT with a target of one liter using an incentive. Outcomes were size and variability of lung clearance index (LCI), functional residual capacity (FRC), Scdol and Sacin.

Results: All 26 children achieved six N2MBW. Mean (SD) VT at free tidal breathing was 0.5 (0.1) L, at fixed VT 1.2 (0.2) L. Comparing free tidal breathing with the one liter VT N2MBW, LCI increased on average (95% CD 2.3 (0.6-3.9) in CF children and 1.4 (0.5-2.3) in healthy children. LCI increased by more than one LCI unit in 9 out of 10 CF children and in 14 out of 16 healthy children. FRC decreased, Scdol and Sacin increased significantly. Variability within tests and between subjects increased for all MBW outcomes.

Conclusion: Fixed tidal breathing protocols impact N2MBW indices as shown for the one liter VT protocol in school-aged children. Underlying physiological mechanisms and applicability in adult patients require further study.

Epithelial cell regulation of immunity in cystic fibrosis
Jane Falconer1, Malcolm Brodlie1, Sonya Cornall1, Anthony de Souza2, James Lordan3, Paul Corris1, Catharina Hilbers1, Chris Ward1
1Institute of Cellular Medicine, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 2Institute of Transplantation, Freeman Hospital, Newcastle upon Tyne, United Kingdom

Introduction: Despite clinical importance, the adaptive immune system in cystic fibrosis (CF) lung disease has been sparsely studied.

Methods: We isolated CF primary human bronchial epithelial cells (PBEC) and assessed their modulation of monocyte-derived dendritic cell (moDC) function and downstream T cell activation, hypothesising that epithelial cells skew immunity to favour chronic infection and lung damage in CF. Healthy monocytes were cultured with the conditioned medium from 6 steady-state CF patient PBEC during moDC differentiation with IL-4 and GM-CSF.

Results: Compared to control moDC, epithelial cell conditioned moDC were tolerogenic and macrophage-like (CD1a, [darr] CD86, [darr] CD14 and [darr] CD1a), reducing low T cell proliferation and interferon-γ production in an allogeneic mixed lymphocyte reaction (MLR) with T cells from healthy donors.

Conclusion: This study is the first to report that CF epithelial cells modulate moDC function and favour chronic infection and lung damage in CF. We provide evidence that the lung epithelium may be a key regulator of the adaptive immune system in CF.

Connexin 37 and Connexin 43 genotypes in correlation to cytokines in induced sputum and blood in cystic fibrosis (CF)
Olad Eickmeyer1, Michael Ludwig1, Felix Schreiner1, Louisa van den Boom1, Michael J. Lentze1, Doris Nguempol1, Ralf Schubert1, Stefan Zielen1, Sabina Schmitt-Grohe1,1 Algemene Pediatrie, Zentrum fuer Kinderheilkunde des Universitaetsklinikum, Bonn, Germany; 2Pneumology, Allergy and Cystic Fibrosis, Children’s Hospital, Goethe University, Frankfurt, Germany; 3Clinical Chemistry and Clinical Pharmacology, University of Bonn, Germany

Background: We have provided evidence in previous studies that cytokines (IL-8, TNF alpha, LBP) measured in whole blood correlate well with lung function in delta 508 homozygous patients. GAP junction proteins (connexins) might be of importance for the influx of blood cells into the lung. Our aim was to assess the relationship between connexin genotypes, cytokines (IL-8, TNF-alpha and LBP) in induced sputum and blood and lung disease.

Methods: 24 patients homozygous for delta F 508 (median age 20.5 y, m/f 14/10, BMI 20.35 kg/m2, Stbowman score 75, FEV1 (%R) 83%) were examined. Sequence analysis was performed for GAP junction protein α1 (GJA1/Connexin 43) and gap junction protein α4 (GJA4/connexin 37). Cytokines were assessed in blood and induced sputum (IS) by chemiluminescence (DPC Biermann, Bad Homburg, Germany).

Results: Here we present the first preliminary data: For 18 patients cytokine and gap junction protein analysis was performed for GAP junction protein α1 (GJA1/Connexin 43) and gap junction protein α4 (GJA4/connexin 37). Cytokines were assessed in blood and induced sputum (IS) 154. Cystic fibrosis (adults and children): new basic and clinical physiology research

Figure 1. Steady state moDC phenotype and function altered by PBEC derived soluble factors

259s
lymphocyte reaction (MLR). Stimulation of PBEC or direct stimulation of mDC with clinically isolated Burkholderia cepacia whole cell lysate gave a mature, highly stimulatory mDC phenotype while Pseudomonas aeruginosa induced poor maturation and a less potent T cell response.

Conclusion: CF epithelial cells secrete factors which contribute to immune tolerance. CF pathogens may have a variable ability to overcome this regulation and induce an immune response which may favour chronic infection by Pseudomonas aeruginosa.

P1443 Proteases from anaerobic bacteria cleave naturally occurring innate antiproteases in cystic fibrosis

Michelle Murray, David Bergin, Noel Gerald McElvaney. Department of Medicine, Royal College of Surgeons of Ireland, Education and Research Centre, Dublin 9, Ireland

Introduction: Cystic fibrosis (CF) results in chronic bacterial pulmonary infection leading to an irreversable decline in lung function and ultimately respiratory failure. There is evidence now that CF infection is polymicrobial and that anaerobic bacteria which are not usually detected by routine culture are responsible for at least in part for pathogenic infection (1).

Aims: We aim to study if proteases from P. melaninogenica, the most common anaerobic bacteria found in the CF lung (2), cleave the host innate human antiproteases namely, alpha one antitrypsin (AAT), secretory leukocyte protease inhibitor (SLPI) and elafin.

Method: P. melaninogenica is grown and incubated at 37°C in Luria Bertani Broth (LB) broth, and Basal Anaerobic Media (BAM) broth under strict anaerobic conditions in an anaerobic recumbent. Recombinant SLPI, Elafin and native AAT were included for selected time points with supernatant and cleavage products visualised by SDS-PAGE electrophoresis and Western Blotting analysis using specific antibodies raised against these antiproteases.

Results: P. melaninogenica produces proteases on Day 4.5,6 of incubation and they have distinct cleavage patterns and these cleavage products cleave naturally occurring antiproteases.

P1444 Pseudomonas aeruginosa counteracts the host defense functions of MIG/CXCL9

Sandra Jovic 1, Thomas von Kanel 2, André Schaller 1, Richard Kraemer 2, Women's and Children's Hospital, Singapore, Singapore; 2Infection, Immunity and Inflammation, University of Leicester, United Kingdom; 3Cardiothoracic Transplantation, Portus Institute, Unit of Child Health, Great Ormond Street Hospital for Children, London, United Kingdom

Introduction: Cystic fibrosis (CF) is caused by a defect in the cystic fibrosis transmembrane conductance regulator (CFTR) gene. A number of studies have been performed to investigate whether CFTR dysfunction in CF is primarily a result of the genetic defect or due to chronic bacterial infection and inflammation.

Aim: The aim of this study was to provide support for intrinsic alterations in CF. Specifically to determine whether accumulation of CFTR within the endoplasmic reticulum (ER) of circulating neutrophils from patients with CF leads to ER stress responses including the release of ER calcium (Ca2+) stores. This study focused on the ER-resident chaperone, GRP78 and ATF6, a transcription factor that coordinates the unfolded protein response (UPR).

Methods: Neutrophils were purified from whole blood and the cytosols were analysed using Western blotting for ER stress markers ATF6 and GRP78. Intraacellular Ca2+ was determined using a fluorometric assay.

Results: Western blots revealed that markers of ER stress, GRP78 and cleaved ATF6, were increased in neutrophil cytosols of patients with CF homogygous for the AF508 mutation, when compared to healthy controls (n=8 for both groups). In addition, densitometric analysis of immunobands confirmed significant up-regulation of both GRP78 and active ATF6 in CF neutrophils compared to control cells (p<0.05). Intraacellular Ca2+ was increased in the CF neutrophils compared to healthy controls.

Conclusions: Our data demonstrates for the first time activation of the UPR in vivo in neutrophils isolated from individuals with CF, which may in part explain the exaggerated inflammatory response of these cells.

P1447 Cytokine and chemokine release in response to Pseudomonas aeruginosa (PA), by bronchial epithelium of the native airway and transplanted lung of paediatric cystic fibrosis (CF) lung transplant recipients

Brian Thomas 1, P.P.E. Freestone 2, Paul Aurore 1, Helen Spencer 1, Rob A. Hirst 2, G. Williams 3,4, Chris O’Callaghan 2,3,1 1Pulmonary Respiratory Medicine, KK Women’s and Children’s Hospital, Singapore, Singapore; 2Infection, Immunity and Inflammation, University of Leicester, United Kingdom; 3Cardiothoracic Transplantation, Portus Institute, Unit of Child Health, Great Ormond Street Hospital for Children, London, United Kingdom

Introduction: Infection and inflammation are implicated in the pathophysiology of Bronchiolitis Obliterans Syndrome (BOS), the major cause of mortality following lung transplantation. It is unclear if the cytokine and chemokine release by Cystic Fibrosis (CF) airway epithelium in response to pathogens differs from that of the transplanted lung.

Aims: We hypothesised that there is no difference in the cytokine and chemokine release in response to Pseudomonas aeruginosa (PA), by the epithelium of the native CF airway and the transplanted lung.

Methods: 5 children who had lung transplantations for CF (Great Ormond Street Hospital for Children, London, UK), were studied. Bronchoscopic brushings from above and below the airway anastomosis were cultured to differentiated ciliated epithelium in an air-liquid interface (ALI). The epithelium was exposed to late exponential cultures of PA (105 CFU per ml). The culture supernatants were harvested at baseline and 5 hours post PA exposure. The cytokines and chemokines in the culture supernatants were measured using a multiplex ELISA based protein array (SECTOR Imager 6000, MSD).

Results: There were no differences in baseline levels of cytokines and chemokines. 5 hours after exposure to PA, the release of chemokines - CCL2, CCL5, CCL13, CXCL8 and the cytokines - IL1β, IL13 and TNFα, by the native CF epithelium was significantly higher (p<0.01) compared to that from the transplanted lung.

Conclusion: The differential cytokine and chemokine release in response to pathogens may be contributory to the exaggerated inflammatory response of the CF epithelium.
P1448
Ciliary function of the nasal and bronchial epithelium in children with cystic fibrosis

Bijn Thomas 1, Paul Aurora 1, Helen Spencer 1, Andrew Rutman 2, Rob A. Hirst 2,

Chris O’Callaghan 2, 3, 4. Paediatric Respiratory Medicine, KK Women’s and

Children’s Hospital, Singapore, Singapore; 2Infection, Immunity and Inflammation, University of Leicester, United Kingdom; 3Cardiothoracic Transplantation, Portex Unit, Institute of Child Health, Great Ormond Street Hospital for Children, London, United Kingdom

Background: Normal ciliary function is essential in pulmonary defence. It is unclear if there is any difference in ciliary function between the nasal and the bronchial epithelium, in children with Cystic Fibrosis (CF).

Aims: Our aim was to determine if there is any difference in ciliary function between the nasal and the bronchial epithelium, in children with CF.

Methods: 9 children with CF (2 males, median [IQ] age: 14.1 [12.8-15.7] years, median [IQ] duration post transplant: 12 [9-15.5] months), who had lung transplant at the GOS Hospital for Children (London, UK) were studied. Nasal brushings and bronchoscopic bronchial brushings from the lower airway above the anastomosis were studied using digital high speed video camera to determine the ciliary beat frequency (CBF) and beat pattern, as described previously. (Thomas B. et al. Eur Respir J. 2009;34:401-4).

Results: There was no significant difference in CBF or beat pattern between the epithelium of the nose and the lower airway above the anastomosis. Sputum IgG and IgA antibody concentrations remained under the detection limit of the assay in most samples, and were significantly increased above the detection limit of the assay in all subjects, and were significantly increased in Pa+ as compared to Pa- patients. As expected serum IgA levels were elevated in Pa+ as compared to Pa- patients.

Discussion: There was no significant difference in CBF or beat pattern between the nasal and the bronchial epithelium in paediatric CF lung transplant recipients. Supported by an unconditional grant by Gilead Sciences, Inc and the Sophia fund: 'steun door Zeevaart.'

P1449
Detection of antibodies against Pseudomonas aeruginosa in the sputum of cystic fibrosis patients: A pilot study

Krisztina Kelemen, Eszter Csizsér, Imre Bartta, Balázs Antus. Pulmonologie, National Korányi Institute for TB and Pulmonology, Budapest, Hungary

Chronic Pseudomonas aeruginosa (Pa) infection plays a pivotal role in disease progression in patients with cystic fibrosis (CF). The aim of this cross-sectional study was to test whether anti-Pa antibodies can be detected in the sputum using common serological methods.

During routineambulatory visits blood and spontaneously expectorated sputum samples were obtained from 29 adult CF patients (11 chronicallyinfected with Pa [Pa+]. 10 non-infected [Pa-] and 8 intermittently infected [Pa+/-]). Anti-Pa antibodies (IgA and IgG) in serum and in sputum supernatant were measured with ELISA originally developed for measuring anti-Pa antibodies in serum (Genesisc Diagnostics). Data are presented as means ± SEM.

As expected serum IgA levels were elevated in Pa+ as compared to Pa- patients (20.3±9.5 vs. 6.0±1.5 pg/ml, respectively, p<0.05). Sputum IgA levels were above the detection limit of the assay in all subjects, and were significantly increased in Pa+ compared to Pa- patients (20.6±5.6 vs. 8.5±1.1 pg/ml, respectively, p<0.05).

In Pa+- patients sputum IgA levels were similar to that of Pa- patients (p>0.05). In all subjects serum and sputum IgA levels showed a close correlation (r=0.525, p<0.01). The sensitivity and the specificity of the assay in sputum were 70% and 72%, respectively, as compared to 44% and 90% in serum. Sputum IgG antibody concentrations remained under the detection limit of the assay in most cases. In conclusion, sputum anti-Pa IgA antibody levels are elevated in patients with chronic Pa infection. The sensitivity of the assay is even greater in sputum than in serum raising the possibility that sputum could be maternally of choice for the early detection of Pa.

P1450
Tracking disease progression in cystic fibrosis using bronchiectasis, trapped air and quality of life

Leonie Tepper 1, 2, Elisabeth Utem 3, Daan Caudri 1, Alexandra Quittner 4,

Biju Thomas 1, Paul Aurora 1, Helen Spencer 1, Andrew Rutman 2, Rob A. Hirst 2,

Chris O’Callaghan 2, 3, 4. Paediatric Respiratory Medicine, KK Women’s and

Children’s Hospital, Singapore, Singapore; 2Infection, Immunity and Inflammation, University of Leicester, United Kingdom; 3Cardiothoracic Transplantation, Portex Unit, Institute of Child Health, Great Ormond Street Hospital for Children, London, United Kingdom

Background: Progression of cystic fibrosis (CF) is characterized by bronchiectasis (BE) and trapped air (TA) on CT. We hypothesize that progression of BE, and TA results in a lower Health Related Quality of Life (HRQoL), assessed by the Cystic Fibrosis Questionnaire-Revised (CFQ-R).

Objective: To evaluate associations between changes in BE, TA, and CFQ-R over time.

Methods: Cohort study (July 2007-January 2012). Clinical stable CF patients, with two routine bi-annual chest CTs, and CFQ-Rs. CT scans were anonymous and randomly scored, using CF-CT BE and TA scores. Scores are expressed as % of maximum score. CFQ-R was completed by children (aged 6-13 years) and adolescents (aged ≥ 14 years). Score-range 0-100, higher scores indicate better HRQoL. For changes in CF-CT BE, TA score, CFQ-R respiratory-symptoms domain scores, their correlations, and to test the hypothesis we used Student’s paired t-test, Spearman’s correlation coefficient, and linear regression model, adjusted for age and gender.

Results: CF patients (n=40): mean age T1 11.9 years, T2 13.8 years. In two years there was a significant increase in CF-CT BE scores (p<0.03) and CF-CT TA scores (p<0.03), but not in CFQ-R scores. At T1, CFQ-R BE scores (p<0.01, r=0.49) and CF-CT TA scores (p=0.05, r=0.34) correlate with CFQ-R scores. At T2, similar correlations were found: CF-CT BE (p<0.01, r=0.41), CF-CT TA (p=0.02, r=0.37). Change in CF-CT BE and TA scores did not correlate to change in CFQ-R scores.

Conclusion: BE and TA correlates to HRQoL. Modest progression of BE and TA did not result in impairment of HRQoL.

P1451
Lung clearance index (LCI) and hyperinflation in children with cystic fibrosis (CF)

Koh Al-Khathlan 1, 2, Erol Gaugill 1, Caroline Beardsmore 1, Infection, Immunity and Inflammation, Leicester University, Leicester, United Kingdom; 2Respiratory Care, Dammam University, Dammam, Saudi Arabia

Introduction: LCI is used to detect early CF lung disease.1, 2, 3 However, there are few data relating changes in LCI to lung volumes, and extent of hyperinflation, in children with CF. Therefore, we aimed to look at the association between LCI (derived from multiple-breath nitrogen washout (MBNW) and two indices of hyperinflation (i) residual volume/total lung capacity (RV/TLC), and (ii) the difference between FRC determined by plethysmography (FRCp) and MBNW (FRCMBNW). Methods: Children with CF completed MBNW and plethysmography as part of their annual review. All tests were performed, analysed and reported according to ATS/ERS recommendations. The difference between FRCp and FRCMBNW was expressed as a % of FRCp, and called FRCdiff. Results were examined using Spearman’s rank correlation coefficient.

Results: 37 children with CF (aged 5-17) completed lung function tests. A significant correlation was found between LCI and RV/TLC (r=0.516, p=0.001) (Figure), and between LCI and FRCdiff (r=0.433, p=0.011).

Discussion: The adoption of LCI as an ideal marker for early lung disease requires that it should correspond to established markers of abnormalities in lung function.4 Our findings showed comparable decline in LCI and indices of hyperinflation in children with CF.

Short term effects of chest physiotherapy in children with cystic fibrosis assessed by a new lung function test
Chiara Abbas, Florian Singer, Carmen Casaulta, Philipp Latzin. Pediatrics, University Hospital, Bern, Switzerland

Background: No lung function test exists that is able to assess short-term effects of physiotherapeutic treatment (PT) in children with Cystic Fibrosis (CF). We recently developed a tidal single-breath washout (SBW) using two tracer gases to measure ventilation inhomogeneity (VI).

Aims: We assessed whether this new SBW test is able to measure short-term effects of PT and inhalation.

Methods: Children with CF (n=25) between 6 and 16 years performed lung function assessments prior to and after inhalation and PT. Assessments consisted of a double tracer gas SBW (DTG-SBW) and spirometry. DTG contained sulfur hexafluoride (SF6) and helium (He), and was induced during tidal breathing. A side-stream ultrasonic flowmeter measured molar mass. DTG-SBW outcome was percentage of expired volume where expired molar mass equals inspired molar mass, reflecting inspired ratio of SF6 and He (IPDTG).

Results: After intervention IPDTG decreased from 65.6±25.8% to 59.7%±(±25.4) resulting in a mean difference of -7.3% (95%CI -12.9 to -1.8) and MEF25.75 increased from 1.41 L/s to 1.62 L/s resulting in a mean difference of 0.19 L/s (95%CI 0.02 to 0.37). In a post-hoc subgroup analysis we found that the DTG-SBW is more suited to detect changes in VI in patients with mild CF lung disease (n=14, FEV1 z-score <−2), whereas spirometry indexes increased only in patients with moderate CF lung function (n=11, FEV1 z-score <−2).

Conclusion: The DTG-SBW seems to be a promising test to detect short-term effects of physiotherapy and inhalation.

P1453

Peripulmonary airflow and severity of CF lung disease – A cross-sectional study from childhood to late middle age
Fatma Al Jassim1, Anders Lindblad2, Per Gustafsson1. 1Paediatric Pulmonology and Allergy, Q204, Astrid Lindgren Children’s Hospital. Karolinska University Hospital, Stockholm, Sweden; 2Pediatrics, Central Hospital Skövde, Skövde, Sweden; 3CF Centre, Queen Silvia Children’s Hospital, Gothenburg, Sweden

Background: Ventilation inhomogeneity (VI) measured by multiple-breathe washout (MBW) is a characteristic feature of cystic fibrosis (CF) and correlates more closely than spirometry with HRCT structural lung damage (Thorax 2008;63:129). MBW provides both global indices of VI such as the lung clearance index (LCI) and specific indices of VI arising in the conductive (Scond) and the acinar (Sacin) part of the conducting airways. DTG-SBW outcome was percentage of expired volume where expired molar mass equals inspired molar mass, reflecting inspired ratio of SF6 and He (IPDTG).

Methods: The LCI, Scond and Sacin were measured by SF6 MBW in 71 CF subjects aged 7.1-55.4 yrs (median 17.4) with FEV1 % pred (median 86). Data are given as z-scores (Respiration 2009;78:339). It is unknown how Sccond and Sacin reflect overall lung disease severity over a wide age range.

Results: The LCI, Scond and Sacin were measured by SF6 MBW in 71 CF subjects aged 7.1-55.4 yrs (median 17.4) with FEV1 % pred (median 86). Data are given as z-scores (Respiration 2009;78:339). It is unknown how Sccond and Sacin reflect overall lung disease severity over a wide age range.

Conclusions: These cross-sectional findings suggest that LCI is more useful than Scond in monitoring CF lung disease. Scond may, however, be used as an early marker of lung involvement.

Cystic fibrosis pulmonary function in adult patients with cystic fibrosis
Daniela Savì1, Mattia IntermuO2, Giuseppe Cimmì1, Elena Angeli2, Serena Quattrocchi1, Patrizia Troiani1, Salvatore Cucchiara1, Paolo Palange2.
1Regional Cystic Fibrosis Centre - Pediatrics Department, Sapienza - University of Rome, Italy; 2Department of Public Health and Infectious Diseases, Sapienza - University of Rome, Italy

Introduction: Habitual physical activity has important clinical implications in Cystic Fibrosis (CF) and has therapeutic effects on sputum clearance, respiratory muscle strength and quality of life. While recent studies have shown that aerobic fitness is related to survival, that physically active CF patients have higher physical performance and lower metabolic rate at rest, the role of physical activity in improving muscle strength in terms of oxidative capacity.

Methods: Eleven stable CF patients (mean SD age 32 (9) yrs; FEV1 2.7 (0.8) L; IC 8.0 (0.9) L), were studied at rest, during symptom-limited incremental exercise test (CPET) and during 6MWT. We assessed daily physical activity using both SW (SenseWear, SW) that subjects wore for 4 consecutive days from waking until going to bed including weekends, and the Habitual Activity Estimation Scale Questionnaire (HAESQ).

Results: There was no difference between the weekdays and weekends recordings in any activity variable. We found no agreement in physical activity measured by SW vs HAESQ. By contrast, we found a close relationship between SW step count and VO2peak (r2=0.60; p<0.001) and SW energy expenditure vs VO2peak (r2=0.78; p<0.005) at CPET. Distance at 6MWT was not correlated to any physical activity variables, either at SW or HAESQ.

Conclusions: Adults CF patients have similar habitual physical activity levels at weekdays and weekends. Activity levels measured by the subjective methods and by the objective monitoring, i.e., SW vs HAESQ, seems to provide different information on the level of daily physical activity. Physical activity is related to degree of airflow obstruction and to the maximum exercise capacity.

P1454

Prolonged oxygen kinetics during submaximal cardiopulmonary exercise testing (CPET) in adult patients with cystic fibrosis (CF) and their relationship with indices of oxidative capacity
Elmi Armeniakou1, Alphonse Jeanneret-Grosjean2, Annie Landuyt1, Guyolane Lebeuf2, Celine Bergeron2. 1Regional Cystic Fibrosis Centre - Pediatrics Department, Sapienza - University of Rome, Italy; 2Department of Pulmonary and Critical Care Medicine, National and Kapodistrian University, Athens, Greece

Background: Patients with cystic fibrosis demonstrate reduced exercise capacity. As the submaximal exercise testing overcomes many of the limitations of maximal exercise testing, indices of submaximal exercise capacity like time constant (t-on) of oxygen uptake (VO2peak) and the slope of recovery after maximal CPET as it is expressed by the ratio of oxygen consumption to time (VO2/t slope)

Results: The main finding is that t-on in control group is significantly lower (29.3±5.38 s) than t-on in CF group (42.5±6.15 s, p<0.05). Moreover, a statistically significant negative correlation is found between t-on and indices of oxidative capacity of maximal CPET such as: VO2peak (r=-0.53, p=0.049), AT % (r=-0.645, p=0.013) and VO2/t slope (r=−0.576, p=0.031).

Conclusion: Oxygen kinetics of submaximal CPET in adult patients with cystic fibrosis are prolonged and they are correlated with indices of oxidative capacity during maximal CPET.

P1456

Acute exercise in cystic fibrosis patients increases neuropsychological pulmonary inflammation
Michael Laskine1, Stanislaw Ptaszynski2, Claude Pouirt3.
1Alphonse Jeanneret-Grosjean1,2, Annie Landuyt1, Guyolane Lebeuf2, Celine Bergeron2. 1Regional Cystic Fibrosis Centre - Pediatrics Department, Sapienza - University of Rome, Italy; 2Department of Pulmonary and Critical Care Medicine, National and Kapodistrian University, Athens, Greece

Background: Neuropsychological inflammation mainly from recurrent bacterial infection characterizes cystic fibrosis (CF) Airways. Repeated inflammatory insults may lead to progressive lung function decline. Acute exercise is reported to trigger a systemic inflammatory response, but inflammation pattern has been poorly studied.

Methods: 12 subjects with mild to moderate stable CF (FEV1<50% of p.v.) underwent a constant load exercise test at 80% of their maximal load. Sputum and blood were sampled before and 1 hour after exercise and analysed for differential leukocyte counts.

Results: 6 females and 6 males completed the study with a mean FEV1 of 72.2% and a mean exercise time of 4.6 minutes. No desaturation was reported. Table 1 summarizes the differential leukocytes counts in blood and sputum. Exercise Arises a 2.2 fold increase in airway neutrophils (p=0.019) and 1.4 fold increase in blood neutrophils (p=0.01)

Conclusion: We demonstrate that acute exercise increases the peripheral and airway inflammation.

Conclusion: We demonstrate that acute exercise increases the peripheral and airway inflammation.
way inflammation in stable CF subjects. This burst of neutrophils might have a dual role in which it might improve local defense against infections and participate in airway destruction through release of elastase and other mediators. The modulation of this inflammatory response by exercise training has to be explored.

P1457 Heart rate variability response to submaximal exercise in children with cystic fibrosis

Vanessa Ressegui, Rêncio Florêncio, Silvia Briliante, Ilíza Lima, Fernando Lavezzo, Guilherme Pregonez. Physical Therapy Department, Federal University of Rio Grande do Norte, Natal, RN, Brazil

Background: Rehabilitation or physical activity can improve chronic respiratory disease as a Cystic Fibrosis. Nevertheless, because autonomic dysfunction is common in CF, heart control may be affected in response to exercise.

Objective: To assess the cardiac autonomic control using heart rate variability (HRV) analysis before and after a six-minute walking test (6MWOT).

Methods: We studied lung function at baseline and HRV before and after 6MWOT in children’s with CF and matched healthy control group.

Results: Thirty children in the CF group (6 male) mean age: 12±2.7 years, with obstructive disease (FEV1/FVC: 0.83±0.11, FEV1: 71.4±2.11%pred) and 12 healthy children (6 male), mean age 11.4±2.4 years, with normal lung function (FEV1/FVC: 0.93±0.12, FEV1: 91.6±17.4%pred) were evaluated. Baseline HRV was different between CF and CG in LFnu: 53.18±15.01 vs. 32.79±7.91, p = 0.0003; HFnu: 25.4±1.84 vs. 53.19±9.36, p = 0.0018; HFnu: 47.3±1.48 vs. 68.34±6.87, p = 0.0009; and LF/HF: 1.25±0.72 vs. 0.49±0.18, p < 0.0066. After the 6MWOT was observed significant differences between groups for LF(Fnu/2): 846.69 vs.754.81 vs. 345.58±197.18, p=0.027, LFhu: 35.44±8.06 vs. 25.88±6.20, p=0.0024; LFnu: 34.2±16.27 vs. 34.9±8.71, p=0.0000; HFnu: 27.42±17.73 vs. 48.13±33, p=0.0003; HFnu: 40.45±15.8 v. 65.59±8.18, p<0.0003; and LF/HF: 1.94±1.7 vs. 0.53±0.21, p=0.0001.

Conclusion: Children with CF had higher sympathetic drive at baseline and after a submaximal exercise test compared to the CG, suggesting a sympatho-vagal dysfunction.

155. The best posters on quality of life and coping styles in COPD

P1458 TELEMOLD project: A telemonitoring system that combines oximetry and physical activity quantification to improve long term oxygen therapy

Carina Gassain1, Inês Faria1, Manuela Zamb1, Isabel Matias1, Rui César da Neves1, Patma Rodrigues1, Cristina Barbaru1. 1Servicio de Pneumologia II, Hospital Pulido Valente - CHLN, Lisboa, Portugal; 2Software Development, CAST, Lisboa, Portugal

Background: Standard assessment to long term oxygen therapy (LTOT) prescription involves periodic clinical tests (arterial blood gas, 6-min walk test and nocturnal oximetry) carried out in several hospital visits. However, there is some evidence that oxygen demand during daily activities may not be correctly estimated by such tests, when compared to continuous ambulatory oximetry.

Aim: To evaluate the clinical usefulness of a home telemonitoring system in LTOT optimization.

Methods: Thirty five respiratory failure patients (29 with LTOT, 6 under evaluation for LTOT) followed in an University Hospital were real-time monitored with an oximeter sensor (Nonin Avan 4000 system) and an accelerometer (BioPlux motion). Signals were sent via Bluetooth to a mobile phone and then via 3G or GPRS to a server. Continuous and secure access to data through an Internet site was established.

Results: Each patient was monitored in average 7.6±4.5 (range 2-19) days, in a total of 83.0±66.9 (4.8-228.8) hours. Percentage of valid records was in average 65.4±24.1% (0-100%). Percentages of rest, activity and sleep records per patient were, in average, 28.4±21.3%, 65±5.5% and 59.3±24.6%, respectively. Significative desaturation during rest, activity and sleep was found on 2, 26 and 9 patients, respectively. Patient’s user-friendliness was fairly good (75.8% reported it as easy/very easy).

Conclusion: Our study suggests that a telemonitoring system combining oximetry and physical activity evaluation may improve LTOT through a more adequate oxygen flow prescription, namely during daily activities. This project was funded with a grant by Fundação Vodafone Portugal.

P1459 Quality of life in patients receiving home oxygen therapy (HOT) for chronic respiratory diseases (CRD)

Peter Firth1, Ruth Sladek1, Tina Jones1, Mary Luszcz1, Debra Rowett2, Paul Cafferella2, Tanya Elling2, Paddy Phillips3. 1Faculty of Health Sciences, Flinders University, Bedford Park, SA, Australia; 2Respiratory Medicine, Repatriation General Hospital, Daw Park, SA, Australia

Introduction: Health related quality of life (HRQOL) is impaired in chronic obstructive pulmonary disease (COPD). Less is known about impacts of HOT on health status in patients with CRDs. We hypothesized that health status would be impaired independent of underlying respiratory disease, and physical and mental health status would be lower than population norms.

Methods: Patients receiving HOT from 3 hospitals in South Australia completed Australian Karnovsky Performance Scale (AKPS), Short Form 36 (SF36) and Chronic Respiratory Questionnaire (CRQ). Scores were compared to population norms. Correlations were made with Sperman (skewed) or Pearson (normal distributions). Differences in scores between CRD types were evaluated by Student T-test.

Results: Data were available from 197 patients (mean age=74±4; SD=9 yrs; 62% male; 155 (78.6%) with COPD, 32 (16.2%) pulmonary fibrosis (PF), and 10 (6.2%) other CRDs). No differences in HRQOL were seen between COPD and IPF. SF36 emotional dimensions were similar to population norms. Physical health dimensions were substantially lower than population norms. Patients’ AKPS performance was on average “requiring occasional assistance” (64.8; SD=12.1). CRQ dyspnoea (3.4; 1-6) and fatigue (3.29; 1-7) scores indicated moderate impairment; emotional function (4.4; 1-5) and mastery (4.4; 1-5) were not impaired. CRQ domains (except emotional function) were highly correlated with AKPS and SF36 dimensions (p<0.001).

Conclusions: Patients receiving HOT for respiratory diseases had severe physical disability, which correlated closely with dyspnoea and fatigue, but their mental and emotional status were similar to population norms.

P1460 Influence of patient activation and health literacy on quality of life among patients with COPD

David Coulta1, Bradford Jackson2, Karan Singh2, Seong Jee Bae3. 1Internal Medicine, University of Texas HSC-Tyler, TX, United States; 2Biostatistics, University of North Texas HSC, Fort Worth, TX, United States

Background: While many factors contribute to the health status of patients with COPD little attention has been given to the influence of patient activation (PA) and health literacy (HL).

Objectives: The purpose of this analysis was to examine the influence of PA and HL on quality of life (QOL) among a sample of patients with COPD.

Methods: This was a cross-sectional analysis of baseline data from patients with COPD eligible for pulmonary rehabilitation enrolled in a self-management clinical trial. PA was measured using two questions: confidence on when to seek medical care (ACT1) and frequency of taking a list of medications to doctor visits (ACT2). HL was measured using three questions: confidence in filling out forms, frequency of help needed to read hospital materials, or problems learning about medical condition. QOL was measured using generic (SF-12) and disease-specific (Chronic Respiratory Questionnaire [CRQ]) instruments.

Results: Of 218 patients the majority reported being confident/very confident when to seek medical care (ACT1=79.8%) and taking a list of medicines (ACT2=68.1%). The association between levels of PA and QOL was examined separately using linear regression: ACT1 was directly and significantly associated with CRQ, and SF-12 physical and mental composite scores. In contrast ACT2 was only significantly, but inversely associated with CRQ. There was no association between levels of HL and any measures of QOL.

Conclusion: These results suggest that a component of patient activation (ACT1) is associated with improved QOL and may offer a specific target for intervention to enhance activation and outcomes.

Funding: National Institutes of Health-NHLII R18 HL092955.
symptoms, 8 showed mild depression, and 6 moderate depression. None showed severe depression. Mean PCS and MCS were 46.4 (±10.4) and 47.5 (±9.6) respectively. PCS and MCS values lower respect to mean value of Italian general population were found in 22 and 17 subjects, respectively. A negative relationship was found between BDI-II and PCS (p=0.02). BDI-II was linearly correlated to BODE (r=0.0001) but not to GOLD stage. MCS was inversely correlated to BODE (p=0.02), but not to GOLD Stage. MCS was not related to BODE and to GOLD Stage. Among individual components of BODE, only MRC was a good and direct predictor for depression (p=.007), and an inverse predictor for both MCS (p=.007) and PCS (p=.0002). In conclusion, a greater dyspnea perception, regardless of disease severity, is associated with higher depression score and poorer QoL.

P1462
Self-efficacy and quality of life in COPD patients
Marinella Sommaruga 1, Paola Gremigni 2, Vincenzo Zagà 1, Claudia Gotti 1, Linda Ratzi 1, Piercarluele Santun 1, 1Psychology Unit, Maegarsi Foundation, Care and Research Institute, Milano, Italy; 2Department of Psychology, University of Bologna, Bologna, Italy; 3Pneumonology Unit, City of Bologna Health Unit, Bologna, Italy; 4Pulmonary Rehabilitation, Università degli Studi di Milano, Maegarsi Foundation, Care and Research Institute, Milano, Italy

Background and purpose: Chronic obstructive pulmonary disease (COPD) is a complex chronic multi-component disease. Understanding the mechanisms of health related quality of life (HRQL) impairment should help identifying targets of pulmonary rehabilitation (PR). Research has shown positive correlations between self-efficacy and outcome in patients with COPD (Kojic MK. Int J Nurs Practice 2011; 17:1-8, Arnold R et al. Behav Med, 2005 31:107-15). This study sought to evaluate the relative role of self-efficacy and socio-demographic variables in the prediction of HRQL in COPD patients.

Methods: A total of 103 COPD patients (60% males, mean aged 70±14 years) presented dyspnea perception, regardless of disease severity, is associated with higher depression score and poorer QoL.

Results: Stepwise multiple regression analysis revealed that age and self-efficacy were correlated with HRQL (R²=0.27). These findings suggest that the HRQL is negatively correlated with age (b =0.30) and positively correlated with self-efficacy (b =0.36), independent of gender, level of education, and marital status. Conclusions: In a chronic diseases such as COPD, it is important to work in improving confidence in the patient’s ability to follow a self-care regimen by increasing self-efficacy, especially in older patients, as it may positively affect quality of life. Therefore, clinicians should include careful assessment of self-efficacy in their routine evaluation of patients before entering a pulmonary rehabilitation program.

P1463
Validation of CAT as an independent assessment tool in pulmonary rehabilitation (PR) for chronic obstructive pulmonary disease (COPD)
Shakila Devi Perumal 1, 2, Cormac McGuire 1, Mary Francis O’Driscoll 1, Timothy J. McDonnell 1, 3, 4, Department of Physiotherapy, St. Michael’s Hospital, Dun Laoghaire, Dublin, Ireland; 2Department of Respiratory Medicine, St. Michael’s Hospital, Dun Laoghaire, Dublin, Ireland

The benefits of PR in COPD are well recognised but the practical assessment of patients undergoing PR can be complex. The COPD assessment test (CAT) is a recently introduced simple, validated 8-item questionnaire designed to assess the impact of COPD symptoms on quality of life (QOL). We hypothesized that CAT could be used as a screening tool and outcome measure to assess QOL in COPD. 60 patients with COPD enrolled in 8 weeks outpatient PR between January 2011 and October 2011 were studied. Patients completed CAT score, chronic respiratory disease questionnaire (CRQD), hospital anxiety and depression (HAD) at baseline and at 8 weeks. Functional status (6 min walk test (6MWT) and incremental shuttle walk test (ISWT)), dyspnoea (MRCD) and body mass index (BMI) were measured.

52 COPD patients completed the 8 weeks PR and data were available for 37 patients with mean (SD) age 67.8 (9.2) yrs and FEV1 49.6 (20.7) % predicted. There was a significant difference in 6MWT (47.03m), ISWT (47.84m), MRCD (3.03 points), CRQD (-3.02 points), Anxiety (1.5 points), depression (0.69points) and CAT (3.63 points) post PR. CAT correlated closely with CRQD at baseline and following PR whereas there was good correlation only with ISWT, anxiety and depression post PR.

CAT is an independent, simple and highly responsive outcome measure that can also be utilized for screening patients with COPD for PR.

P1464
Developing a patient reported experience measure for COPD
Michaela Roberts 1, Sharon Andrews 2, Susan Wallis 3, Matthew Hudson 4, Robyn Hudson 1, 5, 1Institute for Health Sciences Education, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, United Kingdom; 2Department of Acute Care, Anglia Ruskin University, Chelmsford, United Kingdom; 3Department of Primary and Public Health, Anglia Ruskin University, Chelmsford, United Kingdom; 4Acute COPD Early Response Service, Homerton University Hospital NHS Foundation Trust, London, United Kingdom; 5North East London, North Central London & Essex (NCLES), Health Innovation Education Cluster (HEIC), London, United Kingdom

Introduction: The patient experience and patient outcomes are metrics for quality improvements in healthcare. There is now available patient reported experience measure (PREM) for COPD.

Study Aim
The aim of the study is to create a valid and reliable PREM for patients with COPD.

Methods: Sixty four people with COPD across the community of North East London, North Central London and Essex and 19 with recent hospital experience were interviewed to capture their patient journey with COPD. Analysis of the interview data was by a two layer approach: content and then by affective (emotive or felt) responses.

Results: Eighteen different affective responses were described by patients and were grouped as positive, negative or ambivalent. Positive responses included: hope, gratitude, comfort/reassured, acceptance, optimism, altruism, happy and respect. Negative responses included scared, anxiety, fear, frustration, worry, feeling depressed, denial and embarrassment: ‘selfmotivation’ and control were contextual and could be either positive or negative. The community patient groups’ experience centred around five categories identified in the content analysis: ‘journey to Diagnosis’; ‘Smoking’; ‘Usual Care’; ‘Exacerbation (flare-up)’ and ‘My Everyday Life’. The hospital patient experience was categorised as: ‘Going to Hospital’; ‘On Arrival to Hospital’; ‘On the Ward’; ‘Discharge from hospital’ and ‘Follow-up care’. Items on patients’ affective responses were generated from the categories to develop a PREM-COPD scale.

Conclusion: Completion of the testing of the PREM-COPD will result in a valid and reliable instrument to be used to measure self-defined important patient experiences when using healthcare services.
